PREFACE

This is the **One Hundred Twenty-Eight** Issue of Current Awareness Bulletin started by Delhi Technological University, Central Library. The aim of the bulletin is to compile, preserve and disseminate information published by the faculty, students and alumni for mutual benefits. The bulletin also aims to propagate the intellectual contribution of Delhi Technological University (DTU) as a whole to the academia.

The bulletin contains information resources available in the internet in the form of articles, reports, presentations published in international journals, websites, etc. by the faculty and students of DTU. The publications of faculty and student which are not covered in this bulletin may be because of the reason that the full text either was not accessible or could not be searched by the search engine used by the library for this purpose.

The learned faculty and students are requested to provide their uncovered publications to the library either through email or in CD, etc. to make the bulletin more comprehensive.

This issue contains the information published during **August, 2023**. The arrangement of the contents is alphabetical. The full text of the article which is either subscribed by the university or available in the web is provided in this bulletin.

Central Library

CONTENTS

1. A 3.3kW Modified LLC Resonant Converter for Grid-Tied EV System Under Wide Voltage Range, ***7.Monish Ansari***, ***6.Gaurav Yadav*** & ***3.Mukhtiar Singh***, Electrical, DTU

2. A Compact Wideband SRR-Based C-Shaped Antenna for 5G New Radio Band n258, ***6.Suresh Angadi***, Thennarasan Sabapathy, ***3.N.S. Raghava***, Muzammil Jusoh, Hamsakutty Vettikalladi, Ali M. Almuhlafi and Mohamed Himdi, ECE, DTU

3. A Cross-Domain Semi-Supervised Zero-Shot Learning Model for the Classification of Hyperspectral Images, ***6.Pallavi Ranjan*** and Gautam Gupta, DTU

4. A Fast & efficient Noise-resistant Recommender System using Semantic Ontology and User Networks, ***8.Ayush Tanwar***, ***3.Vinod Kumar***, ***8.Chitraksh Grover*** and ***8.Arhan Relan***, CSE, DTU

5. A New Cosmological Model: Exploring the Evolution of the Universe and Unveiling Super-Accelerated Expansion, ***7.Himanshu Chaudhary***, Dhruv Arora, Ujjal Debnath, G.Mustafa and S. K. Maurya, Mathematics, DTU

6. A novel cobalt(II) acetate complex bearing lutidine ligand: a promising electrocatalyst for oxygen evolution reaction, Deepika Tanwar, Priya Jain, ***6.Deepali Ahluwalia***, Athul Sudheendranath, Sajesh P. Thomas, Pravin P. Ingole and Umesh Kumar, Applied Chemistry, DTU

7. A Review on Community Detection Approach for Recommender Systems, ***7.Akansha Mittal*** and ***3.Anurag Goel***, CSE, DTU

8. A Review on Recent Encoder-Decoder Architectures for Drivable Region Detection and Segmentation, ***6.Dhruv Sharma***, ***3.S. Indu*** and ***3.N. Jayanthi***, Electronics, DTU

9. A single–Port to Dual-Port Reconfigurable 7T SRAM Bit Cell for High Speed, Power Saving and Low Voltage Application, ***6.Bhawna Rawat*** and ***3.Poornima Mittal***, Electronics, DTU

10. A Statistical Analysis Model of Wind Power Generation Forecasting for the Western Region of India, Sulagna M., Piyush H., ***7.1.Vineet S***. and Pankaj R, Electrical, DTU

11. A SURVEY PAPER ON INTELLIGENT INTRUSION DETECTION SYSTEM BASED ON DEEP LEARNING APPROACH, ***7.Prateek Shrivastava*** and ***3.Rajesh Kumar Yadav***, CSE, DTU

12. Adsorption of anionic dye from aqueous environment using surface-engineered Zn/Cu hydroxy double salt-based material: mechanistic, equilibrium and kinetic studies, ***6.Bhamini Pandey***, ***3.Poonam Singh*** and ***3.Vinod Kumar***, A Chemistry, DTU

13. Advanced Intelligent approach for state of charge estimation of lithium-ion battery, ***6.Deepak Kumar***, ***3.M. Rizwan***, & ***3.Amrish K. Panwar***, Electrical & A Physics, DTU

14. Advancement in steam reforming of methanol to produce hydrogen: A review, ***6.Ravindra Kumar*** and ***3.Anil Kumar***, Mechanical and Environment, DTU

15. Aerodynamic Study of Various Tall Building Under Wind Load, ***8.Payal Devi***, ***8.Abhishek Prakash Paswan***, ***8.Hemant Gautam***, ***8.Rahul Kumar Meena*** and ***3.Ritu Raj***, Civil, DTU

16. An Overview on Integration of Artificial Intelligence Tools to Predict the Nature of Chronic Obstructive Pulmonary Disease, ***6.Sourabh Sharma*** and ***3.Yasha Hasija***, Biotechnology, DTU

17. Apple Leaves Disease Detection Using Multilayer Convolutional Neural Network, ***7.Saradindu Das*** and ***3.Abhilasha Sharma***, Software Engineering, DTU

18. Application of Feedforward Neural Network in Portfolio Optimization and Geometric Brownian Motion in Stock Price Prediction, ***8.Anirudh Kumar Aheer***, ***8.Ashish Kumar Pradhan*** and ***3.Dr. R Srivastava***, Applied Mathematics, DTU

19. Assessment of Spatiotemporal Variations in Water Quality of the Urban River Reach, Yamuna, Delhi, ***6.Nibedita Verma***, ***3.Geeta Singh*** and ***6.Naved Ahsan***, Environmental, DTU

20. Attention-free based dual-encoder mechanism for Aspect-based Multimodal Sentiment Recognition, ***8.Pankaj Gupta***, ***8.Ananya Pandey***, ***8.Ajeet Kumar*** and ***3.Dinesh Kumar Vishwakarma***, Applied Physics and IT, DTU

21. Blockchain-Enabled Healthcare Records Management: A Survey of Implementation Strategies, ***7.Divya Kuntal*** and ***3.Dinesh Kumar Vishwakarma***, IT, DTU

22. Capacitor Trapped Current Fed ZCS-ZVS Push Pull DC-DC converter for renewable energy conversion, ***7.Dhananjay Yadav*** and ***3.Vishal Verma***, Electrical, DTU

23. Compact BERT-Based Multi-Models for Efficient Fake News Detection, ***8.Vineet Rana***, ***8.Vyom Garg***, ***8.Yatharth Mago*** and ***3.Dr. Aruna Bhat***, CSE, DTU

24. Comparative Analysis Of Machine Learning Models For Fake News Classification, ***8.Archit Gupta***, ***8.Arnav Batla***, ***8.Chaitanya Kumar*** and ***3.Dr. Goonjan Jain***, Applied Mathematics, DTU

25. Comparative Analysis of ResNet and DenseNet for Differential Cryptanalysis of SPECK 32/64 Lightweight Block Cipher, ***8.Ayan Sajwan*** and Girish Mishra, Physics, DTU

26. Comparison of Fuzzy-C-Means Method with KMeans Algorithm and Self Organizing Maps using Image Quantization, ***8.Rishabh Chauhan***, ***3.Rajan Yadav*** and ***8.Rajesh Kumar Gupta***, Applied Mathematics, DTU

27. Constraints on the Parameters of Modified Chaplygin-Jacobi and Modified Chaplygin-Abel Gases in f(T) Gravity Model, ***7.Himanshu Chaudhary***, Ujjal Debnath, Tanusree Roy, Sayani Maity and G.Mustafa, Applied Mathematics, DTU

28. Credit Card Fraud Detection using Neural Embeddings and Radial Basis Network with a novel hybrid fruitfly-fireworks algorithm, ***3.Indu Singh***, ***8.Nilesh Aditya***, ***8.Pranjal Srivastava***, Shivanshu Mittal, Taruvar Mittal and ***8.Noel Vaibhav Surin***, CSE, DTU

29. Cyberbullying Detection using Deep Learning Models in Bengali Language, ***3.Rohit Beniwal***, ***8.Shivam jha***, ***8.Smarth Mehta*** and ***8.Riyan dhiman***, CSE, DTU

30. Deep learning algorithms for person re-identifcation: sate-of-the-art and research challenges, ***8.Ankit Yadav*** and ***3.Dinesh Kumar Vishwakarma***, IT, DTU

31. Deep Learning-based Binary Classification for Spam Detection in SMS Data: Addressing Imbalanced Data with Sampling Techniques, ***3.Dr. Manoj Sethi***, ***8.Naman Tyagi***, ***8.Parmeet Singh Kalsi*** and ***8.Parupalli Atchuta Rao***, CSE, DTU

32. Design and Control of a 2kW Electric Vehicle Charger, ***7.Sushant Chaturvedi*** and ***3.Alka Singh***, Electrical, DTU

33. Design of advanced intrusion detection systems based on hybrid machine learning techniques in hierarchically wireless sensor networks, ***6.Gebrekiros Gebreyesus Gebremariam***, ***3.J. Panda*** and ***3.S. Indu***, Electronics, DTU

34. Design and Analysis of 4*4-Bit Vedic Multiplier with 32nm CNFET Technology, ***8.Ritik Gupta***, ***8.Rohit Ghughtyal***, ***8.Sai Prateek Mahapatra*** and ***3.Sonal Singh***, Electronics, DTU

35. Detection and Classification of Diabetic and Hypertensive Retinopathy Using CNN & Autoencoder, ***8.Amardeep Singh Kapoor***, ***8.Akshat Jain*** and ***3.Dinesh Kumar Vishwakarma***, IT, DTU

36. Development and assessment of carboxymethyl tamarind kernel gum-based pH-responsive hydrogel for release of diclofenac sodium, ***6.Priyanka Meena***, ***3.Poonam Singh*** and ***3.Sudhir G. Warkar***, Applied Chemistry, DTU

37. Development of flood susceptibility map using a GIS-based AHP approach: a novel case study on Idukki district, India, ***6.Zohaib Ahmed Khan*** and ***3.Bharat Jhamnani***, Civil, DTU

38. Elucidating the molecular mechanism of ultrasound-enhanced lipase-catalyzed biodiesel synthesis: a computational study, Karan Kumar1 · Pallavi Patro, Unnati Raut, ***6.Varsha Yadav***, Lepakshi Barbora and Vijayanand S. Moholkar, Biotechnology, DTU

39. Empirical validation of feature selection techniques for cross-project defect prediction, ***3.Ruchika Malhotra*** and ***3.Shweta Meena***, Software, DTU

40. Energy matrices and life cycle conversion analysis of N-identical hybrid double slope solar distiller unit using Al2O3 nanoparticle, Dharamveer Singh, Ashok Kumar Yadav, ***3.Anil Kumar*** and ***3.Samsher***, Mechanical, DTU

41. Energy transfer induced colour tunable photoluminescence performance of thermally stable Sm3+/Eu3+ co-doped Ba3MoTiO8 phosphors for white LED applications, ***7.Pooja Rohilla*** and ***3.A. S. Rao***, Applied Physics, DTU

42. Enhanced solar cell efficiency: copper zinc tin sulfde absorber thickness and defect density analysis, K. C. Devendra, Deb Kumar Shah, ***8.Subhash Kumar***, Nawraj Bhattarai, Dipak Raj Adhikari, Khim B. Khattri, M. Shaheer Akhtar, Ahmad Umar, Ahmed A. Ibrahim, Mohsen A. M. Alhamami, Sotirios Baskoutas and O.-Bong Yang, Electrical, DTU

43. Ensemble Transfer Learning for Distinguishing Cognitively Normal and Mild Cognitive Impairment Patients Using MRI, ***8.Pratham Grover***, Kunal Chaturvedi, Xing Zi, Amit Saxena, Tony Jan and Mukesh Prasad, Biotechnology, DTU

44. Environmental sustainability analysis of biofuels: a critical review of LCA studies, ***6.Kulvendra Patel*** and ***3.S. K. Singh***, Environmental, DTU

45. Evaluating Metaheuristic Algorithms and Neural Networks for PID Tuning, ***8.Abhigyan Adarsh***, ***8.Amal Chawla***, ***8.Anirudh Singh*** and ***3.Bharat Bhushan***, Electrical, DTU

46. Evaluating the impact of wind effects on tall buildings with various plan shapes, ***6.Indrajeet Singh***, ***6.Abhishek Prakash Paswan***, ***6.Chitrakshi***, ***3.Ritu Raj***, ***3.S. Anbu kumar*** and ***8.1.Rahul Kumar Meena***, Civil, DTU

47. Evaluation of Various Beams Using Computational Tools , Bhagya Jayant, ***8.1.Rahul Kumar Meena***, ***8.Aastha Singh***, ***8.Agyeya Mishra***, ***8.Navneet Dalal***, ***8.Rajvir Singh***, ***3.Shailendra Kumar*** and ***3.Ritu Raj***, Civil, DTU

48. Exploring the Efficacy of Deep Learning Models for Multiclass Toxic Comment Classification in Social Media Using Natural Language Processing, ***3.Prashant Giridhar Shambharkar***, ***8.Hastej Singh***, ***8.Harshit Raj Raghav*** and ***8.Hilansh Verma***, CSE, DTU

49. Exploring the Impacts of HDPE Microplastics on Growth and Physiological Behavior of Brassica juncea (Mustard Plant), ***6.Megha Bansal***, ***3.Deenan Santhiya*** and ***3.Jai Gopal Sharma***, Biotechnology and Chemistry, DTU

50. Exploring Tidal Force Effects and Shadow Constraints for Schwarzschild-like Black Hole in Starobinsky-Bel-Robinson Gravity, Dhruv Arora, Niyaz Uddin Molla, ***7.Himanshu Chaudhary***, Ujjal Debnath, Farruh Atamurotov and G .Mustafa, Applied Mathematics, DTU

51. Facial Image Pre-processing for Enhanced Ethnicity Classification, ***8.Keshav Goel***, ***8.Hitesh Dhiman***, ***8.Himanshu Yadav*** and ***3.Shailender Kumar***, CSE, DTU

52. Failure investigations of last stage lowpressure steam turbine blade, ***6.Nitin Sehra*** and ***3.Sushla Rani***, Mechanical, DTU

53. FPGA-Based Acceleration of a Neural Network for Symbol Classification with Hardware-Optimised Multiplier Implementation, ***8.Lakshay Chandna***, ***8.Megha Sharma***, ***8.Kushik Agarwal***, ***3.Anup Kumar Mandpura*** and ***3.Himanshu Singh***, Electrical, DTU

54. Graphene oxide/Mn3O4 Nanocomposites for Advanced Electrochemical Biosensor for Fumonisin B1 Detection, ***6.Sandeep Sarpal***, Avinash Kumar Singh, Hema Bhardwaj, ***3.Nitin Kumar Puri*** and Pratima R. Solanki, Applied Physics, DTU

55. Hindi Hit Songs Prediction Using Machine Learning Algorithms, ***3.Rohit Beniwal***, ***8.Satvik Batra***, ***8.Shivank Gupta*** and ***8.Shashi Shekhar***, CSE, DTU

56. Histone Deacetylase 6 as A Putative Target in Alzheimer's Disease Therapeutics, ***6.Shubham Kumar Shrivastav*** and ***3.Pravir Kumar***, Biotechnology, DTU

57. Huntington's Disease Biomarker Discovery: A Computational Approach, ***6.Jasmeer Singh Kalra*** and ***3.Pravir Kumar***, Biotechnology, DTU

58. Hybrid reversible watermarking algorithm using histogram shifting and pairwise prediction error expansion, ***3.Lavi Tanwar*** and ***3.Jeebananda Panda***, ECE, DTU

59. Hydrostatic Pressure Efect on the Thermodynamic Properties of Quantum Wire Under a Crossed Electromagnetic Field, ***8.Pranay Khosla***, ***8.Sakshi Arora***, ***8.Yash Gupta***, ***8.Priyanka*** and ***3.Rinku Sharma***, Applied Physics, DTU

60. Impact of Wind Effects on High-rise Buildings Having Varying Cross Sections, ***8.Devesh Kasana***, ***8.Dhawal Tayal***, ***8.Dhruv Choudhary***, ***3.S. Anbukumar***, ***3.Ritu Raj*** and ***8.Rahul Kumar Meena***, Civil, DTU

61. Implementation of a Deepfake Detection System using Convolutional Neural Networks and Adversarial Training, ***8.Sahithi Bommareddy***, ***8.Tanya Samyal*** and ***3.Sonika Dahiya***, Software Engineering, DTU

62. Investigating the Impact of Visual Attention Models in Face Forgery Detection, ***8.Ankit Yadav*** and ***3.Dinesh Kumar Vishwakarma***, IT, DTU

63. Isolated DC-DC Converter with Synchronous Rectification for Electric Vehicle Battery Charging, ***7.Awanish Akash*** and ***3.Mini Sreejeth***, Electrical, DTU

64. Legitimate and spam SMS classifcation employing novel Ensemble feature selection algorithm, ***3.Shailender Kumar*** and ***6.Shweta Gupta***, CSE, DTU

65. Link Prediction in Social Network using Gradient Boosting, ***8.Sanket Barman*** and ***8.Sanyam Srivastava***, CSE, DTU

66. Low Supply QFGMOS CCCII with Low-pass and High-pass Filter Applications, ***8.Ujjval Gupta***, ***8.Subrut Shanker Yagnik***, ***8.Vaibhav Gangian*** and ***3.Anupama***, Electrical, DTU

67. Luminescence Studies on Dy3+ Doped Calcium Aluminum Borosilicate (CABS) Glasses for White Light Emission and Applications in w-LEDs, Ravita, Aman Prasad, ***6.Pooja Rohilla***, ***6.Rajat Bajaj***, ***6.Anu***, Rajesh Punia and ***3.Allam Srinivasa Rao***, Applied Physics, DTU

68. Mapping the Field of Research on Entrepreneurial Success: A Bibliometric Study and Future Research Agenda, Varda Sardana and ***6.Shubham Singhania***, USME, DTU

69. Modeling and simulation of material removal characteristics in magnetorheological shear thickening polishing, Zhen Ma, Yebing Tian, Cheng Qian, ***6.Shadab Ahmad***, Zenghua Fan and Zhiguang Sun, Production, DTU

70. Modified Decoupled Sense Amplifier with Improved Sensing Speed for Low-Voltage Diferential SRAM, ***6.AYUSH***, ***3.POORNIMA MITTAL*** & ***3.RAJESH ROHILLA***, DTU

71. Multilabel News Category Classification using Machine Learning, ***8.Roshan Kumar Shah***, ***8.Sahil Kumar*** and ***8.Shashank***, CSE, DTU

72. Multimodal Sarcasm Detection (MSD) in Videos using Deep Learning Models, ***6.Ananya Pandey*** and ***3.Dinesh Kumar Vishwakarma***, IT, DTU

73. Natural Ester Oil-Based High Permittivity CaCu3Ti4O12 (CCTO) Nanofluids an Eco-friendly Insulating Medium for Power Transformer, Arun Ram Prasath R T, Sankar Narayan Mahato, Nirmal Kumar Roy, Thomas Paramanandam, Mubeen Akhtar Ansari and ***7.1.Joges Chandra Biswas***, Electrical, DTU

74. Natural Language Processing based Automatic Making of Use Case Diagram, ***3.Prof. Shailender Kumar***, ***8.Aryaman, Aryan*** and ***8.Divyank Yadav***, CSE, DTU

75. Network Trafc Analysis in Software-Defned Networking Using RYU Controller, ***8.Shanu Bhardwaj*** and ***3.Ashish Girdhar***, CSE, DTU

76. Nonlinear Regression Analysis of Rut Profile Data for Optimal Data Storage and Efficient Terrain Condition Analysis, ***6.Manoj Kumar Kalra***, ***3.Ashutosh Trivedi***, and Sanjay Kumar Shukla, Civil, DTU

77. Novel Enzymatic Biosensor Utilizing a MoS2/MoO3 Nanohybrid for the Electrochemical Detection of Xanthine in Fish Meat, Prateek Sharma, ***6.Deeksha Thakur*** and ***3.Devendra Kumar***, Applied Chemistry, DTU

78. Object tracking via a Novel Parametric Decisions based RGB-Thermal Fusion, Satbir Singh, Arun Khosla and ***3.Rajiv Kapoor***, Electronics, DTU

79. Observational constraints on teleparallel effective equation of state, S. H. Shekh, ***7.H. Chaudhary***, A. Bouali and A. Dixit, Applied Mathematics, DTU

80. Offensive Hinglish Text Classification Using Longformer, Bigbird & HingMBert, ***8.Yakshit Bansal***, ***8.Sumit Samdarshi***, ***6.Sushant Kumar*** and ***3.Dinesh Kumar Vishwakarma***, IT, DTU

81. ON A CLASS OF CERTAIN NON-UNIVALENT FUNCTIONS, ***3.S. SIVAPRASAD KUMAR*** AND ***8.POOJA YADAV***, APPLIED MATHEMATICS, DTU

82. Optimal design of renewable energy based hybrid system considering weather forecasting using machine learning techniques, ***6.Bandana Sharma***, ***3.M. Rizwan*** and P. Anand, Electrical, DTU

83. Optimal Shade Dispersion Strategy for Enhanced PV Power Extraction Under PSCs, ***6.Ranjeet Singh***, ***3.Vinod Kumar Yadav*** and ***3.Madhusudan Singh***, Electrical, DTU

84. Optimal threshold selection for segmentation of Chest X-Ray images using opposition-based swarm-inspired algorithm for diagnosis of pneumonia, ***6.Tejna Khosla*** and ***3.Om Prakash Verma***, CSE and Electronics, DTU

85. Parametric Optimization of FSWed Dissimilar Composite Joints of AA7075 and AA6061 Using RSM, ***3.R. S. Mishra*** and ***6.Sumit Jain***, Mechanical, DTU

86. Partially Omnidirectional and Circularly Polarized MIMO Antenna covering sub-6 GHz Band for 5G Fast Plan, Monika Kaushik, ***7.1.Jasdeep K. Dhanoa*** and Mukesh K. Khandelwal, Electronics, DTU

87. Performance Enhancement of a PMSM Drive using ANFISHCC for Electric Vehicles, ***6.Brijendra Sangar***, ***3.Madhusudan Singh*** & ***3.Mini Sreejeth***, Electrical, DTU

88. Physics Based Numerical Model of a Nanoscale Dielectric Modulated Step Graded Germanium Source Biotube FET Sensor: Modelling and Simulation, Amit Das, ***3.Sonam Rewari***, Binod Kumar Kanaujia, S.S. Deswal and R.S. Gupta, ECE, DTU

89. Potential of Green Energy: Current Status in Indian Subcontinent, ***7.1.Nikita Jaiswal***, Ashish Vishwakarma and Kshama Shukla, Civil, DTU

90. Potential of Rhodosporidium toruloides for Fatty Acids Production Using Lignocellulose Biomass, ***8.Sushant Sunder***, ***7.Anshul Gupta***, Rashmi Kataria and Rohit Ruhal, Biotechnology, DTU

91. Power Quality Enhancement using Adaptive Notch Filter in Grid Distribution System, ***8.Chirag Singh***, ***8.Gautam Kumar***, ***8.Himanshu Kumar*** and ***3.Ankita Arora***, Electrical, DTU

92. Reversible Data Hiding scheme for color images based on skewed histograms and cross-channel correlation, ***8.Priyansh Bhatnagar***, ***8.Prateek Tomar***, ***8.Rishabh Naagar*** and ***3.Rajeev Kumar***, CSE, DTU

93. Role of Oxidative Stress and Genetic Polymorphism of Matrix Metalloproteinase-2 and Tissue Inhibitor of Metalloproteinase-2 in COPD, ***6.Poonam Sangwan***, Huma Quasimi, ***3.Jai Gopal Sharma***, Mohammad Anwar Habib and Mohammad Iqbal Alam, Biotechnology, DTU

94. Sarcasm Detection on News Headline Dataset Using Language Models, ***3.Abhilasha Sharma***, ***8.Abhi Uday Pandey*** and ***8.Apoorv Gupta***, Software Engineering, DTU

95. SDL-Net: A combined CNN & RNN Human Activity Recognition model, ***8.Dhruv Gupta***, ***8.Ananya Komal Singh***, ***8.Naman Gupta*** and ***3.Dinesh Kumar Vishwakarma***, IT, DTU

96. Semantic Consistency for Assuring Reliability of Large Language Models, ***8.Harsh Raj***, Vipul Gupta, Domenic Rosati and Subhabrata Majumdar, IT, DTU

97. Sign Language to Text Conversion using Hand Gesture Recognition, ***8.Tanya Kemkar***, ***8.Vasudha Rai*** and ***3.Dr. Bindu Verma***, IT, DTU

98. Small-Signal Modeling of GaN-BTG MOSFET for Wireless Applications, ***3.M. M. Tripathi*** and ***6.Ajay Kumar***, Electrical, DTU

99. Solar Power Prediction Based on Recurrent Neural Networks Using LSTM and Dense Layer With ReLU Activation Function, ***8.Deepanshu Gupta*** and ***3.Vanjari Venkata Ramana***, Electrical, DTU

100. SPV-wind-BES-based islanded electrical supply system for remote applications with power quality enhancement, ***6.Sombir Kundu***, ***3.Madhusudan Singh*** and Ashutosh K. Giri, Electrical, DTU

101. Television as a Tool of Memory and Identity in Khaled Hosseini's Novels, ***8.Priya Meena*** and ***3.Rajiv Ranjan Dwivedi***, DTU

102. The efectiveness of research and development tax incentives in India: a quasi-experimental approach, ***3.Aakanksha Kaushik***, USME, DTU

103. Third Order Quadrature Oscillator with Arbitrary Phase Shift Generation and Amplitude Modulation Using MDXCCCTA, Garima Shukla and ***3.1.Sajal K. Paul***, Electronics, DTU

104. Towards Accurate Stress Classification: Combining Advanced Feature Selection and Deep Learning, ***8.Lovish Arya***, ***8.Harshal Chowdhary***, ***8.Ishita Agrawal*** and ***3.Indu Sreedevi***, Electronics, DTU

105. Tuning A PID Controller using Metaheuristic Algorithms, ***3.Mini Sreejeth***, ***8.Rishant Kumar***, ***8.Nishant Tripathi*** and ***8.Prateek Garg***, Electrical, DTU

106. Unbalanced Half-bridge Split Capacitor Power Decoupling with Multi-Order Frequency Control for 800V On-board Battery Charger, Tuyen D. Nguyen, Long H. B. Nguyen, Dong Tran, ***7.1.Ravi Nath Tripathi*** and Hai N. Tran, Electrical, DTU

107. Using Dielectric Rods to Reconfigure Combline Filters in Center Frequency and Bandwidth, ***7.1.ABHISHEK SHARMA***, SANTIAGO COGOLLOS, VICENTE E. BORIA, AND MARCO GUGLIELMI, Electronics, DTU

108. VDTA-C based voltage mode Tow-Thomas Biquad filter, ***7.Puneet Pandey***, ***3.Dr. Bhavnesh Jaint*** and ***6.Dr.Garima Mann***, Electrical, DTU

109. Water surface profle prediction in non-prismatic compound channel using support vector machine (SVM), ***7.Vijay Kaushik*** and ***3.Munendra Kumar***, Civil, DTU

2023 3rd International Conference on Intelligent Technologies (CONIT) | 979-8-3503-3860-7/23/$31.00 ©2023 IEEE | DOI: 10.1109/CONIT59222.2023.10205690

***Abstract*—This study describes the design of a single-phase, two-stage, On-Board charger (OBC) for light loads that may function in the Grid to Vehicle (G2V) operation mode. The first stage AC-DC converter of EV (Electric Vehicle) charger plays a very important role in supporting the grid power factor unity and the H-bridge inverter is regulated for this purpose using a Second Order Generalised Integrator (SOGI) control approach, which exhibits a stable steady state as well as excellent dynamic behaviour. To maintain the international electrotechnical Commission (IEC)-61000-3-2 standard for the power quality PQ of the grid throughout operations. Additionally, the design's performance has been verified in the presence of Sag and Swell grid voltage and diverse operating conditions. The second stage is the Modified LLC converter is used for DC-DC conversion, this converter is capable of achieving Zero Voltage Switching (ZVS) for all switches. The modified LLC converter uses fewer switches than a conventional LLC converter, which greatly reduces reverse power and turn-off losses while also allowing for significantly higher Voltage conversion. A Proportional Integral controller is implemented to control the DC-DC converter's switches. Using a PWM controller with a steady battery current, the charging current and voltage of the battery are tracked and controlled. For the 3.3kW system ratings, an extensive simulation analysis is performed. To examine the grid's reactivity, an inductive load additionally has been attached to the grid.**

Keywords—EV (Electric Vehicle), Second Order Generalized Integrator, Modified LLC Converter, Active Power Factor Correction (APFC), Phase Locked Loop (PLL).

I. INTRODUCTION

An amazing technology that has always moulded and influenced human culture and propelled social advancement for ages is the electric car [1]. The automobile has been an immensely significant vehicle throughout a large portion of the world [2]. Electric transportation the requirement for practically every form of public conveyance and around 50% of all private for-hire transit to have electric cars by 2030 makes vehicular technology an increasingly prominent field [3]. Therefore, increasing the viability and demand for these e-cars, particularly plug-in hybrid e-cars (PHEVs) and hybrid electric cars (HEVs). The construction of onboard charging infrastructures for EVs is necessary to reduce reliance on such cars. To extend the amount of time and miles that a vehicle may be driven off of a battery pack, plug-in electric vehicles (PEVs) need to overcome the problem of distance anxiety.

The (APFC) stage, which can be powered by mono-phase, ternary-phase, or each source of power, is often built into EV chargers. This stage is followed by several stacks of isolated DC-DC converters that operate via identical input-output dc connections [4]. For several reasons including its larger density of power and a threefold faster charging than a single-phase system, a three-phase system is typically favored. Numerous AC-DC power converter configurations have been suggested in the literature [5] for the APFC stage development. The three-phase voltage source converter (VSC) has the most potential for the APFC stage because of its higher power density, higher efficiency, ability to manage bidirectional power flow, and ease of control adoption.

Moving on to the FEC controller, its major goal is to keep the grid current within the boundaries of the IEC *61000-3-2* standard while keeping an uninterrupted DC-link voltage. In G2V mode, it is also primarily to maintain the source's unity power factor and the grid current's THD below 5% following IEEE standards. The performance of EV chargers is negatively impacted by several grid uncertainties (sag, swell, and harmonics) in the supply. Added to that, the PLL's preciseness in estimating the synchronizing phase degrades under non-ideal (distorted and abnormal) grid voltage circumstances. Under both ideal and non-ideal grid voltage circumstances, SRF and PQ theory are equally beneficial, as suggested in [6]. However, for the PLL to function well under problematic grid voltage circumstances. A substantial advancement in estimating synchronization reference phases is required. A positive sequence extractor-based EPLL [8] and an SSI-PLL [7] are proposed in the published work in this area. The three-phase system's three-phase multiplication procedure and complicated trigonometric calculations are introduced by using EPLL. In [9], a novel strategy known as the SOGI algorithm for synchronization reference phase estimation is put forward. Although the SOGI's transient performance at different frequencies causes significant phase shifts. As a result, [9] proposes a SOGI-FLL based on frequency locking rather than traditional phase locking. FLL does, however, make the controller more complicated and diminish the steady-state margin when added to SOGI.

For high DC-DC power conversion the LLC resonating and Dual Active Bridge (DAB) converters are most suitable choices. Due to the fact that both converters offer inherent soft-switching capabilities and deliver effective energy conversion [10], [11]. In order to increase overall system effectiveness and dependability, Paper [12] describes a bidirectional EV charger using the SOGI technique. PLL could be employed in the control loop to enhance system performance. In [13], a two-way OBC technology has been presented in which G2V, V2G, and V2L operations are studied. To preserve the integrity of the electricity in grids

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:20:03 UTC from IEEE Xplore. Restrictions apply.

while using the G2V mode of functioning the charging of the EV's batteries needs to be managed.

The LLC converter is a good topological arrangement for the isolated dc-dc conversion stage, as seen in Fig. (1), due to its soft-switching properties for every one of the power components from 0 to full load spectrum [14], [15]. A synchronous rectifier (SR) is typically utilized to identify the current zero-crossing point or sense the device diminished voltage to accomplish a high efficiency of conversion. In unidirectional power applications, LLC converters often utilize these SR approaches. fortunately, when it is employed in bidirectional power applications, the SR has to switch among the two-side bridges following the power direction because of the asymmetry of the topology and gain characteristics. The approach to management will become more complicated as a result of sensing both the power direction and the shifting control logic.

An On-Board PEV charger is suggested in the present investigation with additional characteristics to increase power quality. A shunt compensator is used for crucial current removal using the SOGI approach input to the H-Bridge Inverter. At the DC-DC converter side, the high conversion gain is achieved with a lesser number of switches in comparison to Dual Active Bridge (DAB) converter, additionally, all switches achieved ZVS under the proposed modulation technique. The battery is being charged for different referenced current, and safety and reliability is maintained with the help of the proposed isolated converter. The suggested system features a G2V approach to functioning harmonic elimination and supply-side power factor enhancement. Power batteries made of lithium-ion with a modified LLC DC-DC converter. In addition, the charger works better in ideal and non-ideal conditions. Furthermore, the modified LLC-grade interactive charger also performs well in voltage sag and swell conditions. The hysteresis current controller has the advantage of less complexity and better performance than the other current controller. During the distorted grid voltage condition, the SOGI-based voltage filter out the distortion from the voltage, therefore, is not similar to the measured grade voltage during the distorted grid voltage condition. In the aforementioned piece, a single-phase OBC EV charger concept for extreme voltage and enormous energy charging applications is presented in its entirety.

II. SYSTEM CONFIGURATION

The architecture utilized for EV chargers is depicted in Fig. (1). The system consists of two conversion stages, the initial of which is an AC-DC conversion stage and the other of which is a DC-DC conversion stage. With the suggested controlled arrangement, the first stage AC-DC converter functions as a regulated rectifier. The second stage is a modified LLC converter with six MOSFET switches with ZVS characteristics. The Lithium Ion battery is charged after the second stage with Constant Current (CC) charging.

III. CONTROLLER DESIGN

A. Second-Order Generalized Integrator Method: [SOGI]

The SOGI block's goal, as previously mentioned, is to provide two in-phase, in-quadratic signals to the mains voltage. The percentage of errors is k times increased whenever the supply is first compared to the in-phase signal. This parameter has a substantial impact on the overall efficacy of SOGI. This block adapts the system to shifting frequencies by using the ω` created by the 2nd half of the configuration.

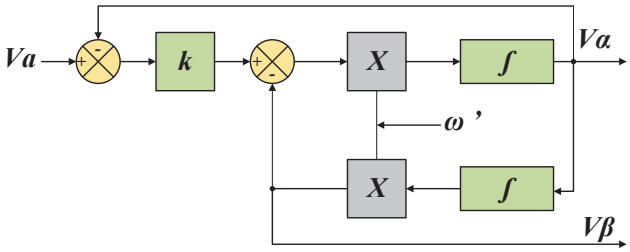

Fig. 3. Representation of SOGI controller.

The aforementioned block can eliminate the 100Hz and 120Hz frequency components from the detected sample. The frequency spectrum arrangement of SOGI is as outlined below:

$$SOGI = \frac{\omega s}{\omega^2 + s^2} \tag{1}$$

ω is the resonance frequency, commonly referred to as the basic angular frequency. For voltages α and β, the closed-loop conversion function is presented in (2) and (3), below:

$$H_\alpha(s) = \frac{v_\alpha(s)}{v(s)} = \frac{k\omega s}{s^2 + k\omega s + \omega^2} \tag{2}$$

$$H_\beta(s) = \frac{v_\beta(s)}{v(s)} = \frac{k\omega^2}{s^2 + k\omega s + \omega^2} \tag{3}$$

$H_\alpha(s)$ is a 2nd-order BPF with no phase shift, while $H_\beta(s)$ is a 2nd-order low-frequency filter with gain equal to 1 and 90° phase departure at 314 rad/s.

By using a SOGI filter, the basic aspect of the load current is removed. The SOGI block processes the supplied signal (I_{load}), which results in the equal-phase and quadrature-phase signals I_α and I_β respectively, being produced at the output. Thus, it is possible to determine the basic current (I_f) using

$$I_f = \sqrt{I_f{}^2 + I_\beta{}^2} \tag{4}$$

In order to determine the switching loss in the shunt compensator using the V_{dc_ref}*, the V_{dc} is traversed through an LPF. Using the inaccuracy of the dc link voltage as input, a PI controller computes the switching loss (I_{loss}) of the recommended system. A steady 400V DC connection voltage is sustained. The formula is described below:

$$I_{loss}(k) = [(k_p + k_i / s)(V_{dc_ref}{}^*(k) - V_{dc}(k))] \tag{5}$$

where k_p and k_i are the PI controller's gain coefficients. Equation (6)'s DC link loss component and fundamental load current component are added to get the total reference current magnitude (I_{tot}).

$$I_{tot} = I_{loss} + I_f \tag{6}$$

Now, the following equation is used to produce the unit template (u_a).

$$u_a = \frac{v_\alpha}{\sqrt{v_\alpha{}^2 + v_\beta{}^2}} \tag{7}$$

Multiplying the total reference current by the unit template yields the reference current.

$$I_{ref} = I_{tot} * u_a \tag{8}$$

Finally, gating pulses are produced for GSC's IGBT switches (insulated gate bipolar transistors) using a hysteresis current controller (HCC). In Fig. (2), the full control system is shown.

B. Modified LLC Converter

The equivalent model of the Bidirectional LLC converter is shown in Fig. (4). V_{in} is the total input voltage, while the output voltage is V_0. The resonant tank is composed of the resonant inductor L_r, two split capacitors C_1 and C_2, and two clamping diodes D_1 and D_2. The magnetizing inductor L_m of the isolated transformer has a turn ratio of n.

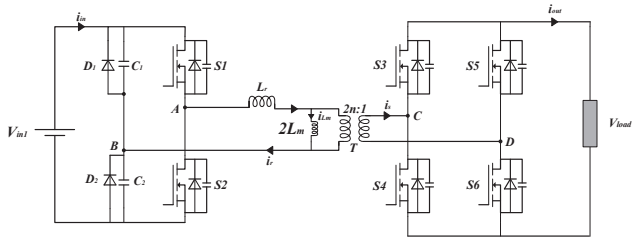

Fig. 4. Equivalent Bidirectional LLC resonant converter.

The energy stored in the junction capacitor must be smaller than that of the magnetizing inductor L_r in order to meet the ZVS requirements from the research.

$$\frac{1}{2} L_m i_{Lm_peak}^2 \geq \frac{1}{2}(C_{S3} + C_{S4} + C_{S5} + C_{S6}) V_0^2 . \tag{9}$$

where C_{S3}, C_{S4}, C_{S5}, and C_{S6} are the junction capacitors for the individual switches

where T_{dead} is dead time and is described below:

$$T_{dead} = \frac{1}{2 f_s} - \frac{1}{2 f_r} . \tag{10}$$

The range of L_m can be identified and expressed as follow, the range of the magnetizing inductance is,

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:20:03 UTC from IEEE Xplore. Restrictions apply.

$$L_m \le \sqrt{\frac{n^2 V_0^2 L_r}{32 C_{S1} f_s V_{in1}}}. \quad (11)$$

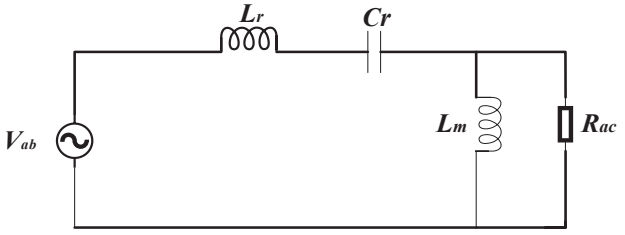

Fig. 5. Equivalent model of the LLC converter.

$$R_{ac} = \frac{8n^2 R_0}{\pi^2}. \quad (12)$$

The real load of the converter is R_0, and the resonating frequency is f_r.

$$f_r = \frac{1}{2\pi\sqrt{L_r C_r}}. \quad (13)$$

LLC converter Gain is described below:

$$M = \frac{f^2(m-1)}{\sqrt{(m.f^2-1)^2 + f^2(f^2-1)^2.(m-1)^2.Q^2}} \quad (14)$$

where

$$f = \frac{f_s}{f_r}. \quad (15)$$

$$Q = \frac{\sqrt{L_r / C_r}}{R_{ac}}. \quad (16)$$

$$m = \frac{L_r + L_m}{L_r}. \quad (17)$$

$$f_r = \frac{1}{2\pi\sqrt{L_r C_r}}. \quad (18)$$

Transformer turns ratio

The transformer turns ratio for this converter is described as:

$$n = \frac{V_{in}}{8V_0}. \quad (19)$$

Design of Resonant Tank

$$C_1 = \frac{P_{\max}}{2 f_s V_{in1}^2}. \quad (20)$$

where P_{max} is the maximum output power that each LLC converter is capable of producing. Additionally, L_r can be computed using,

$$Lr = \frac{1}{8\pi^2 C_1 f_s^2}. \quad (21)$$

C. PI Controller For DC-DC Converter

To determine an error signal, the reference current from the battery (I_{bref}) and the actual battery current (I_{bat}) are juxtaposed. The error signal is input into the PI controller, as shown in Fig. (1), and the PI controller's output is routed into the PWM block, which produces the electric throb for the isolated LLC converter. The Ziegler-Nichols frequency response technique is used to adjust the PI controller. The use of this technique requires a closed-loop PID controller. To acquire anticipated process features such as it is necessary to drive the controller to its stability boundaries. When there is a lesser dead time, this approach performs smoothly.

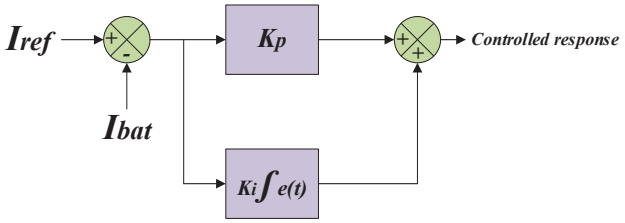

Fig. 6. PI controller for DC-DC converter stage.

IV. Simulation Results

By modeling under different operating circumstances, the efficacy of the proposed battery charger is verified. Additionally, the input to the battery charger is regarded to be an AC power source with 230 V RMS voltage and 50 Hz frequency. The designed charger's responsiveness is confirmed while variable grid voltage operations are obtained for three separate situations, taking into account the various operating circumstances. Fig. (7) shows the normal operation of the grid, Fig. (9) shows a non-ideal grid in which harmonics are introduced known as weak grid operation and Fig. (11) shows the 10% sag & swell in the grid voltage which is also a non-ideal case. The total behaviour of all three cases is shown and changes is seen in power factor, battery current, and SoC. The THD is calculated for every case and a comparison is done.

Particularly noteworthy are the simulation findings during the G2V operation under rated conditions shown in Figs. (7),(9),(11), and THD responses in Figs. (8),(10),(12). The waveforms of in-phase grid voltage, V_g, and grid current, I_g, illustrated in Fig. (7), indicate unity-power-factor (UPF) charging. Furthermore, the stabilized DC link voltage, V_{dc}, validates the VSC's efficacy. Additionally, I_{bat}'s controlled charging current demonstrates that the created charger efficiently controls the charging activity. Also, the battery current ripples adhere to the pertinent international standard. Fig. (8) also shows the fast Fourier-transform (FFT) evaluation of the grid current. The total harmonics distortion (THD) of grid current is indicated as 1.61% here. As a result,

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:20:03 UTC from IEEE Xplore. Restrictions apply.

the designed charger's G2V functioning adheres to the power quality requirement, and the battery is being charged.

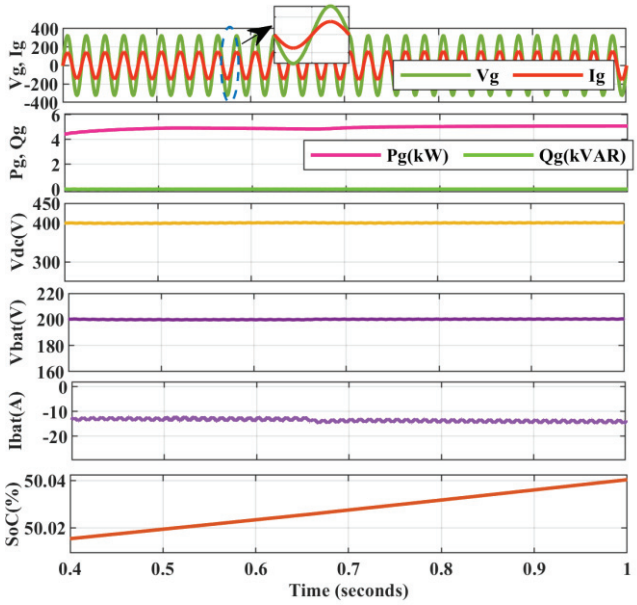

Fig. 7. Steady state performance under normal operating condition.

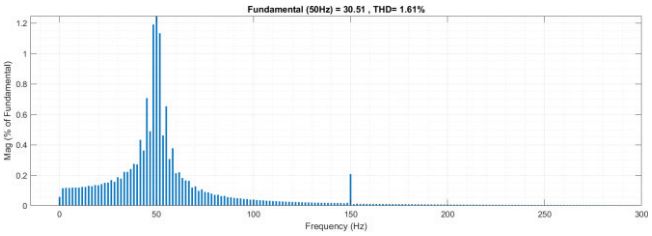

Fig. 8. THD under normal operating condition.

Fig. (9) depicts the system's weak grid operation, in which odd-ordered harmonics are added to grid voltage to test the system's robustness. As illustrated in Fig. (9), odd-ordered harmonics such as the 5^{th}, 7^{th}, 11^{th}, and 13^{th} distort

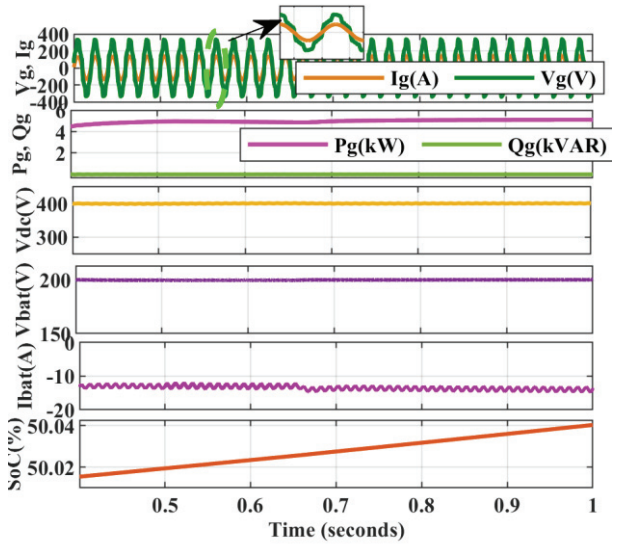

Fig. 9. Steady state performance when harmonics are injected (weak grid operating condition).

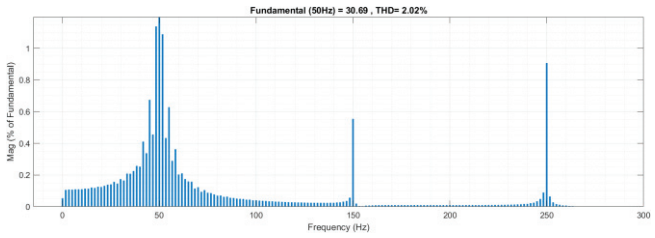

Fig. 10. THD under weak grid operation.

the grid voltage, but an input filter with SOGI control is far more efficient, attempting to align grid current with grid voltage to preserve power factor. V_{dc} and the battery charging current are both constant during this procedure. The predicted THD for this operation is 2.02%, which is likewise following the IEC requirement for grid current, as shown in Fig. (10).

Fig. (11) depicts the sag and swell of grid voltage under non-ideal conditions. During this operation, 10% of grid voltage is reduced between 0.5s and 0.6s, and 10% of grid voltage is increased between 0.7s and 0.8s, demonstrating the system's durability as V_{dc} is maintained constant throughout the operation, battery charging current is also kept constant.

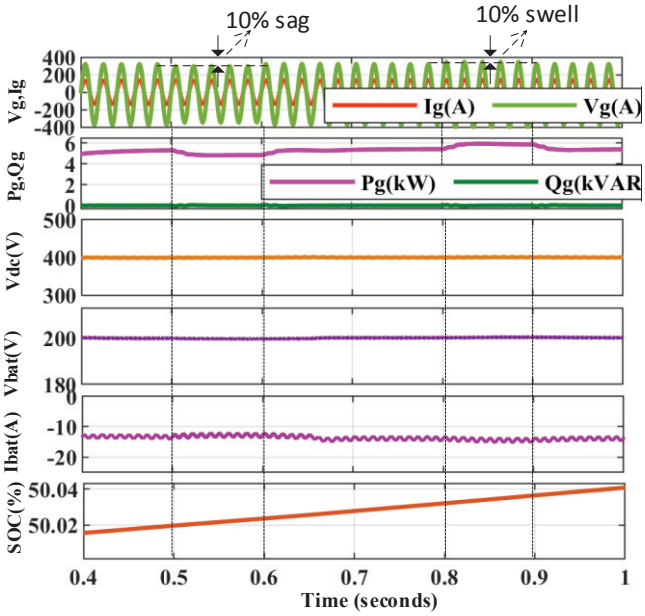

Fig. 11. Steady state performance when sag and swell in grid voltage.

Notably, THD adheres to the IEC norm for grid current quality, which is *1.87%* in this situation, as seen in Fig. (12).

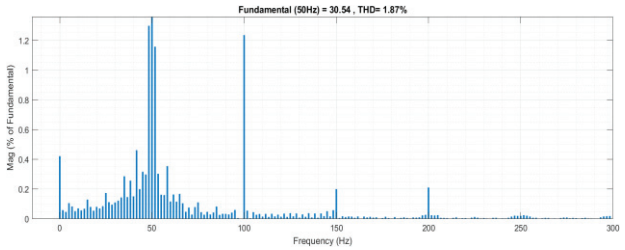

Fig. 12. THD under sag-swell voltage variation.

The resonating behaviour of the regulated MOSFET switches is seen in Fig. (13). To boost system efficiency with significantly reduced losses in the DC-DC conversion stage, all switches achieve ZVS at all conditions during G2V operating mode. All of the switches dissipate close to zero

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:20:03 UTC from IEEE Xplore. Restrictions apply.

power for the Modified LLC converter, which justifies the need for isolated converters in the system nicely.

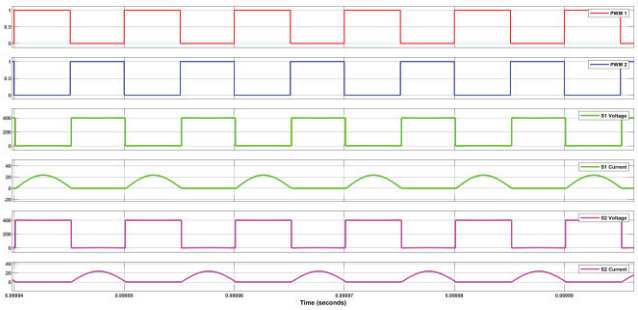

Fig. 13. Resonating nature of switches showing voltage and current with respect to the PWM.

V. CONCLUSION

This study investigates a two-stage On-Board charging system for different practical approaches. Two converters are introduced with a controlled scheme separately. AC-DC converter is controlled through a SOGI controller whereas a modified DC-DC converter is controlled through a PI controller and optimum results are obtained for diverse conditions. The functionality of the suggested technique is demonstrated by Matlab/Simulink results. Grid to Vehicle charging mode is designed for onboard EV chargers. At a frequency switching of 100 kHz, the onboard charger's planned system architecture was realized. The final findings demonstrate that the specified power efficiency is greater than 96%, the PF is over 99%, and the THD of grid current is less than 2% for the three separate situations described above. To demonstrate the reliability and efficiency of the SOGI controller for AC-DC converters and the PI controller for modified DC-DC converters, simulation studies are performed as well under steady state and dynamic conditions. For large voltage, large power EV charging applications, the LLC single phase On-Board charger offers inexpensive pricing, minimal electromagnetic interference, excellent dependability, compactness, and highly effective development. To assure converter performance within a wide voltage range for EV charging applications, a modified LLC converter's resonant behaviour is discovered inside the operational region using a second-order generalized integrated approach. Future experimental testing will be conducted to obtain a more precise picture of the overall effectiveness of your suggested system. For the DC-DC converter, a more durable and effective controller will be used to stabilize the dynamic behaviour of the battery side.

Abstract: This paper proposes a compact wideband split ring resonator (SRR) based C-shaped antenna for 5G new radio (NR) band n258 millimeter wave (mm-Wave). The proposed antenna covers a wideband frequency range from 24.1 GHz to 28.3 GHz with a reflection coefficient below -10 dB. Stubs are used at each C-shaped element for impedance matching of the antenna. The proposed antenna comprises SRRs with stubs to increase the bandwidth and gain simultaneously for better performance in mm-Wave applications. A simple SRR structure is modeled to function as a reactive impedance surface with inductive property for frequencies less than 30.2 GHz. The proposed antenna realizes an impedance bandwidth of 16.1% and covers a wideband of 4.2 GHz (24.1 GHz -28.3 GHz). The use of stubs and SRR has improved the performance of the proposed antenna at mm-Wave frequencies. Specifically, the deployment of the SRR is able to produce an improved gain for the overall direction of the antenna. The simulation and measured results agree well and maintain a 7.49 dBi gain with a bandwidth of 4.2 GHz. An average efficiency of 90% can be attained in the operating range of the antenna. The designed antenna is applicable for 5G NR Band n258.

Keywords: SRR; millimeter wave; 5G; wide-band antenna

1. Introduction

The viability of 5G networks extends the facility of spectrum utilization, network flexibility, and multi-connectivity in the sphere of wireless technology. The development of 5G increases the high data rate and improves the occupancy of bandwidth in many communication devices, allowing higher mobile users per unit area [1]. In 5G millimeter wave technology, various approaches have been taken to enhance bandwidth, improve antenna gain, and achieve miniaturization. These approaches could help invent future innovations that meet millimeter wireless standards and play a key role in the communication medium.

To realize a wide bandwidth in millimeter wave frequencies, a defected ground approach [2] was used in antenna design. A new wideband array antenna was considered for mm-Wave applications intended for high data rates in wireless communications [3]. In other related work, inverted L-slots were placed at radiating elements to improve the bandwidth of an individual feed and match the impedance parameter of the antenna for millimeter wave applications in 5G mobile

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 11 August 2023 doi:10.20944/preprints202308.0963.v1

applications [4]. An electromagnetic band gap (EBG) ground was positioned side by side in the antenna array for better matching and improved radiating properties of the antenna, making it acceptable for enabling mobile terminals in 5G communication [5]. Slots can be added to improve the bandwidth in mm-Wave frequencies and reduce the effective area in the radiating patch [6]. An EBG-based substrate-integrated waveguide (SIW) antenna has been shown and proven to operate in mm-Wave applications [7].

Apart from bandwidth enhancement, gain improvement is also considered one of the key achievements in 5G antenna designs. The split ring resonator (SRR) has been introduced in antenna design to improve gain in 5G wireless technology that operates at the low band (600-850 MHz), mid-band (3.4-3.6 GHz), and higher band in millimeter wave (mm-Wave) frequencies of (24-28) GHz, as reported in [8-9]. Array antennas have also been used for mm-Wave 5G smartphones to improve gain in the antenna design, as reported in [10]. In addition, dielectric resonator antennas (DRA) have been used to improve gain and bandwidth for mm-Wave applications, as reported in [11-12]. In the view of wireless communication under 5G technology, a dual E-shaped patch antenna generated a multiband with stubs inserted between the elements and enhanced the wideband property into ultra-wideband, which has shown better results in terms of gain, as reported in [13,14]. Furthermore, meta-surface based approach has also been used in 5G antennas to improve gain, as reported in [15].

In addition to bandwidth and gain enhancement, the design of 5G antennas is also considered in terms of miniaturization. A basic square-shaped patch loaded with a slot was proposed in [16] to achieve miniaturization. An optimized low-profile antenna is designed using an artificial magnetic conductor reflector, maintaining low cross-polarization and increasing gain and bandwidth with antenna efficiency [17]. A miniaturized mm-Wave antenna has also been designed for a multiple-input multiple-output 5G antenna that operates with beam scanning ability [18]. Nevertheless, all reported works still lack in achieving a compact antenna that operates at mm-Wave 5G new radio (NR) band and attains high gain for an omnidirectional radiation pattern.

In this work, a C-shaped patch antenna was modeled with simple split ring resonators (SRR) to improve the quasi-omnidirectional radiation pattern over a wideband for 5G mm-Wave applications. Rectangular stubs were used preceding every portion of the C-shaped patch to eliminate the dual band and enable the wideband property of the antenna. In general, monopole microstrip patch antennas face limitations such as narrow bandwidth [19] and low gain [20]. To overcome these limitations, careful analyses were carried out, and the proposed design was optimized and investigated at each phase to finally develop the antenna with wide-band, omnidirectional pattern, and high gain characteristics. A compact wideband antenna was proposed in frequency range 2 (FR2) 5G NR band n258. The impedance bandwidth of 16.1% is achieved, covering two bands centered at 25.2 GHz and 27.7 GHz frequencies.

2. Antenna Design and Analysis

The geometry of the compact wideband SRR-based antenna for 5G mm-Wave application is presented in **Error! Reference source not found.**. The designed wideband antenna was printed on a Rogers RT/duroid 5880 substrate with a relative permittivity of 2.2, and a dielectric loss tangent of 0.0009. The overall dimension of the antenna is covered by the length L_s, width W_s, and substrate height of 1.6 mm. S_L and S_W are the length and width of the stub. **Error! Reference source not found.** shows the complete dimensions of the proposed antenna. The dimensions of the ground plane G_p are placed at the lowermost sheet of the antenna to enable omni-directional radiation pattern characteristics. At each element in the array, the rectangular stubs are used prior to the C-shaped structure to reduce the losses and widen the bandwidth of the antenna as shown in the parametric analysis. Then, an SRR is used to improve the radiation pattern characteristic of the antenna. Finally, 4 elements of C-shaped radiating element SRR could be developed as shown in Figure 1.

[1] All Dimensions are in mm.

2.1. SRR unit cell design

Figure 2 (a) shows the SRR unit cell design along with its reflection phase result. A simple 7 mm x 7 mm square-shaped SRR unit cell was adopted with a ring width of 1 mm. The slit width between the ring is C_4. The boundaries of the SRR unit cell were covered by a perfect electric conductor (PEC) and perfect magnetic conductor (PMC) perpendicular to the incident electric (E) and magnetic (H) fields. This SRR was subjected to transverse electromagnetic waves (TEM) coming from the +z direction. As shown in Figure 2(b), the SRR acts as an inductor below the center frequency at 30.2 GHz which can help to store the magnetic energy that could compensate for the electrical energy [21]. This reflection phase characteristic of the SRR is expected to enhance the radiation characteristics of the antenna within the operating range from 24.2 to 28.3 GHz.

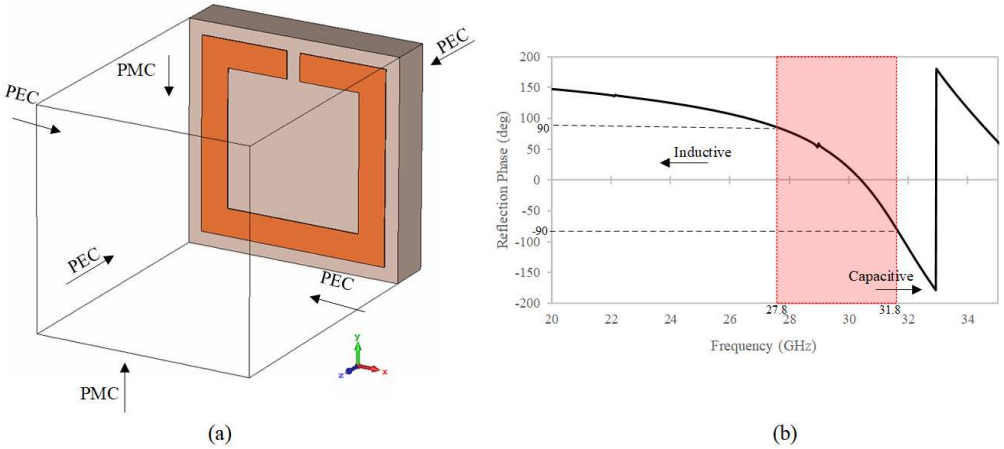

Figure 2. The SRR design: (a) unit cell (b) Reflection phase result.

2.2. Equivalent circuit model of the SRR-based C-Shaped antenna

The equivalent circuit for the compact wideband SRR-based antenna is shown in Figure 3. Here the circuit is established based on resistor (*R*), inductor (*L*), and capacitor (*C*), and the equivalent circuit is considered only for one element in the array from the feed line. Z_c is the characteristic impedance and R_f is the loss present in the feed line. The equivalent circuit model is adopted based on [22] and modified according to the dimension of the proposed antenna in this work. The inductor L_1 and Capacitor C_1 are represented [22] as microstrip lines in the equivalent circuit.

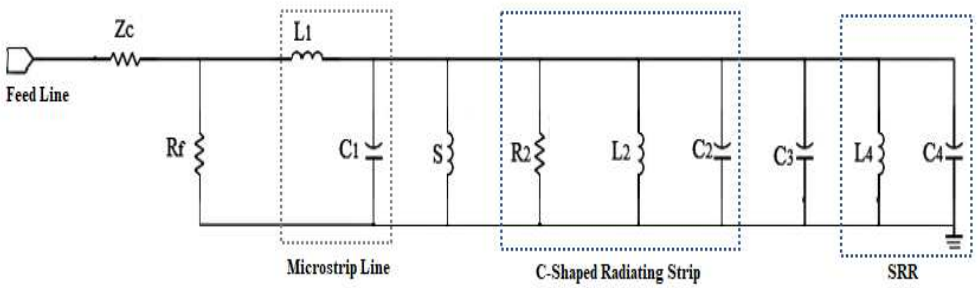

Figure 3. Equivalent Circuit Model for a single element in the proposed antenna.

The mathematical expression for L_1 and C_1 are represented as follows.

$$L_1 = 100H\left(4\sqrt{\frac{D}{H} - 4.21}\right)nH \tag{1}$$

$$C_1 = D\left\{(9.5E_r + 1.25)\frac{D}{H} + 5.2E_r + 7\right\}pF \tag{2}$$

where *D* and *H* represent the width of the feedline and height of the substrate respectively and E_r is the relative permittivity. In the equivalent circuit model, *S* represents a stub placed for impedance matching and for widening the bandwidth. The width (W_{stub}) and length (L_{stub}) of the stub [13] are expressed in equations (3) and (4) respectively.

$$L_{stub} = \frac{1}{f_r}\sqrt{\frac{c}{\frac{E_r + 1}{2}}} \tag{3}$$

$$W_{stub} = S_w + D \tag{4}$$

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 11 August 2023 doi:10.20944/preprints202308.0963.v1

where c is the speed of the light and f_r is the resonant frequency. Based on the C_5 and C_6 dimensions as shown in Figure 1, the effective length (L_{eff1}) and width (W_{eff1}) of the C-Shaped radiating strip for one element can be calculated as follows,

$$L_{eff1} = C_5 + C_6 \tag{5}$$

$$W_{eff1} = C_7 \tag{6}$$

The expression for the capacitor (C_2), resistor (R_2), and inductor (L_2) of the equivalent circuit can be expressed in equations 7, 8, and 9.

$$C_2 = \frac{L_{eff1} W_{eff1} E_{eff}}{2H} \cos^2 \frac{\pi \left(L_{p3} + G_p \right)}{L_{eff1}} \tag{7}$$

$$R_2 = \frac{Q}{\left(2\pi f_r\right)^2 C_2} \tag{8}$$

$$L_2 = \frac{1}{\left(2\pi f_r\right)^2 C_2} \tag{9}$$

where the quality factor, Q can be expressed as,

$$Q = \frac{c\sqrt{E_{eff}}}{4 f_r} \tag{10}$$

In the equivalent circuit model, L_4 is the inductance and C_4 is the capacitance for the square split ring resonator. For a square split ring resonator, the resonant frequency f_{srr} is expressed as

$$f_{srr} = \frac{1}{2\pi} \sqrt{\frac{1}{L_4 + C_4}} \tag{11}$$

where C_4 is the total equivalent capacitance of the SRR,

$$C_4 = \frac{L_4 \sqrt{E_{eff}}}{c Z_c} + \frac{E_O N H}{2 L_4} \tag{12}$$

where Z_C is the characteristic impedance and L_4 is the total equivalent inductance of the SRR. The L_4 can be expressed as follows,

$$L_4 = 0.0002 L_{eff1} \left(2.303 \log_{10} \frac{4 L_{eff1}}{c} - \gamma \right) \mu H \tag{13}$$

where γ = 2.853 for a wire loop of the square geometry and the L_{eff1} can be calculated based on the total length of the SRR as,

$$L_{eff1} = s_1 + s_2 + s_3 \tag{14}$$

3. Results and Discussion

The simulation was carried out using the HFSS EM modeling tool. The proposed antenna was fabricated and tested using the Vector Network Analyzer of R & S ZND 40. The S-parameter and peak gain results were observed in each simulation stage to observe the effect of the sub-matching and the SRR.

3.1. The Design Evolution of The Proposed Antenna

The evolution process of the proposed antenna is shown in **Error! Reference source not found.Error! Reference source not found.**. The reflection coefficient response for each stage is shown

Preprints (www.preprints.org) | NOT PEER-REVIEWED | Posted: 11 August 2023 doi:10.20944/preprints202308.0963.v1

in Figure 4. of the proposed SRR-based antenna. Antenna 1 with diameter D = 2mm resonates with two resonant frequencies at 25.4 and 27.8 with S_{11} of -24.07 and -14.71 and covers a bandwidth in each band at 1.2 and 0.9 with a gain of 9.22. The addition of two stubs in antenna 2 increases the bandwidth of the antenna and resonates at two frequencies with an increase in S_{11} of -36.05 at 25.5 and -16.06 at 27.8 with a bandwidth of 1 GHz and 1.1 GHz. In antenna 3, the stubs were placed before each element of the antenna and it covers the wider bandwidth of 4.1 GHz and resonates at two frequencies of 25.1 and 27.8 GHz with a reflection coefficient of -16.6 and -15.29, and attains a peak gain of 7.1 dB. The proposed Array Antenna resonates at 25.2 and 27.7 with S11 of -18.43 and -16.11 with an increased peak gain of 7.49 dB as shown in Figure 5(b). The results from the design evaluation are summarized in **Error! Reference source not found.** 3.

Figure 5. Simulation results of SRR-based C-Shaped Antenna: (a) Response of S11 Vs Frequency; (b) Response of Peak Gain Vs Frequency.

The use of SRR to improve the overall gain of the antenna may not be clearly observed through this 2D radiation pattern result, because it does not show the radiation pattern characteristic for the overall beam coverage. Therefore, in what follows, the 3D radiation pattern of the antenna is investigated.

3.2. D Radiation Pattern Analysis

In this design, the SRR mainly helps to improve the antenna gain for most of the directions, and thus attains an omnidirectional radiation pattern. From Table 2. It can be seen that the antenna's reflection coefficient remains the same for Antenna 3 and the proposed antenna. This explains that the wide-band property was obtained mainly from the use of stubs. The 2D radiation patterns shown in Table 2 are also almost similar for both Antenna 3 and the proposed antenna, just that a slight improvement can be obtained in terms of the peak gain. To further observe the advantage of the SRR, the 3D radiation pattern results are compared. Figure 6 and Figure 7 show the radiation pattern results for

Antenna 3 and the proposed antenna, respectively. The results also compared two operating frequencies, 25.1 GHz and 27.8 GHz. Compared with Antenna 3, the proposed antenna manages to radiate with more gain for a wide range of angles. Hence, it shows that the high gain is not limited to certain directions/angles but covers most of the directions with the use of the SRR. The results were also further validated with the observation of the total efficiency and the peak gain proposed antenna and the antenna without SRR. It can be seen from Figure 8 that the antenna efficiency reaches 99% with better gain in the operating range of the antenna.

3.3. The Fabricated Antenna and The Measurement Results

The measurement and simulation results of S_{11} against frequency are shown in Figure 9 (a). The top view and rear view of the fabricated Antenna are shown in Figure 9 (b). The measurement was made in the laboratory using a Vector network analyzer (R & S ZND 40). After measuring the proposed wideband antenna resonates at 25.2GHz and 27. 7 GHz in the mm-Wave band (24.1 GHz - 28.3 GHz) below -10 dB. Figure 9. Fabrication and Measurement Results of the proposed antenna: (a) Simulation and Measurement results of the Proposed Antenna; (b) Fabrication of the proposed antenna; (c) Measurement Set-up; (d) VNA Measured Results.

shows the comparison of simulated and measured results relevant to the impedance bandwidth. The impedance bandwidth of simulated results is 16.1(%) and 13.40(%) is for measured results. This slight mismatch could be due to the soldering effect of the SMA port on the transmission line.

Table 5 presents the comparison of the proposed antenna with similarly proposed works for mm-Wave operating frequencies. In terms of dimension, the proposed antenna has a comparable size to most of the works. Only works [23] and [24] have smaller sizes compared with the proposed antenna. In terms of bandwidth and gain the proposed antenna have better results compared with most of the existing works reported in the literature. Specifically, the use of SRR cannot be compared with the existing works as the 3D radiation patterns are not revealed. Therefore, the advantage of the SRR was comprehensively analyzed and discussed.

4. Conclusion

This paper proposed a C-shaped SRR-based 5G mm-Wave antenna, which is a significant contribution to the field of wireless communication. The antenna's stub matching technique improves its bandwidth, while the SRR enhances its radiation characteristics. This study modeled a simple SRR to have inductive properties for frequencies below 30.2 GHz, which enables the antenna to have better radiation characteristics at its operating range. The proposed antenna operates with a wide band that resonates at 25.2 GHz and 27.7 GHz frequencies, with an impressive impedance bandwidth of 4.02 (24.1-28.3 GHz) and a reflection coefficient of -18.431 dB and -16.113 dB, respectively. The proposed compact wideband array antenna has an acceptable peak gain of 7.49 dBi with the use of SRR. These results outperform most of the existing works reported in the literature in terms of bandwidth and gain. Furthermore, the proposed antenna is applicable for use in 5G NR Band n258 FR2 (mm-Wave) at the 5G spectrum. The comprehensive analyses and discussions of the SRR's advantages in this paper demonstrate its potential to improve the antenna's radiation properties and bandwidth. Overall, the proposed C-shaped SRR-based 5G mm-Wave antenna is a promising candidate for future wireless communication systems and can contribute to the development of 5G technology.

RESEARCH ARTICLE

A Cross-Domain Semi-Supervised Zero-Shot Learning Model for the Classification of Hyperspectral Images

Pallavi Ranjan[1] · Gautam Gupta[2]

Received: 17 February 2023 / Accepted: 14 June 2023
© Indian Society of Remote Sensing 2023

Abstract
The cost of obtaining spectral information has dropped significantly due to the remarkable progress in hyperspectral imagery. However, annotating the hyperspectral samples remains a labour-intensive and time-consuming behaviour. Given the challenge of labelling annotations, most conventional hyperspectral classifiers are tested and trained to use a solitary hyperspectral image cube, resulting in two challenges. Firstly, the existing classification models give reasonably close to perfect accuracy, but they are hard to extrapolate to other datasets. Second, hyperspectral datasets are not typically collected in the same scene; different data sets will contain distinct spectral bands. To address these concerns, a new framework for hyperspectral image stratification is proposed in this paper that requires training and analysing separately throughout heterogeneous hyperspectral datasets. Even though annotating hyperspectral data are beneficial, it has received very little attention from the hyperspectral community. The proposed zero-shot learning-based novel model maps the features between training and testing datasets by proposing a convolutional and word embedding model. The feature mapping module associates the training and testing set leading to classification. Experiments on benchmark hyperspectral datasets including Indian Pines (IP), Pavia University (PU), Kennedy Space Center (KSC) validate the performance of proposed cross-domain model.

Keywords Hyperspectral classification · Zero-shot learning · Cross-domain · Deep learning

Introduction

A hyperspectral image (HSI) is a three-dimensional cuboid with an improved spectral resolution than traditional remote sensing imagery. Amongst other areas, HSI classification is one of the prominent domains in hyperspectral data observation. It refers to classifying each pixel of an image based on spectral and spatial properties. The rich spatial and spectral data inside an HSI improve the interpretation potentiality of remote sensing imagery, attracting interest and use in environmental monitoring, medical, defence, military, and precision agriculture, to name a few (Li et al., 2019; Lv & Wang, 2020).

Due to the rich data in HSI, substantial work has been developed to leverage existing spatial and spectral information (Paoletti et al., 2018) effectively. Because trying to label hyperspectral data is time-consuming and expensive, the current hyperspectral realm lacks a sized directory such as ImageNet (Deng et al., 2009). Furthermore, a small percentage of datasets have labelled pixels, whereas conventional supervised models rely on extensive labelled training data for good classification performance (Wu & Prasad, 2018). This challenge of insufficient labelled samples jeopardises the development of supervised and semi-supervised algorithms (Pan et al., 2021). Moreover, datasets like Indian Pines (IP) and Salinas (SA) (Pan et al., 2021) characterize themselves in terms of spatial distribution and land cover. Trained models generalise poorly to unseen datasets resulting in a poor classification performance (Lampert et al., 2009; Pan et al., 2021; Wu & Prasad, 2018).

To address the above-mentioned limitations, we present a new framework for HSI classification that can perform

Published online: 31 July 2023

cross-domain classification. The training set for the proposed novel model will be disjoint from the testing set. Evaluation of an entirely new dataset would result in unseen and unknown categories of data. Hence, the critical challenge is establishing associations between seen and unknown data, that is, disjoint training and testing sets. Hyperspectral data labels are arbitrarily defined using natural science-known facts. Label semantic representations can be viewed as a type of high-level feature. Inspired by recent advances in zero-shot learning (Biswas & Annadani, 2018; Lampert et al., 2014; Pan et al., 2021; Socher et al., 2013), we create word embeddings to bridge the gap between seen and unseen categories. The feature mapping in the embedding space is used to obtain the relationships between trained categories in the training set and unseen categories in the testing set. As a result, the salient points of this study are:

1. This study proposes a cross-domain classifier, which differs from the homogeneous idea of training and testing on the same datasets. The newly proposed novel HSI classifier categorises datasets captured using different sensors.
2. The proposed classification framework builds a novel model trained using similarity mapping between extracted features and generated word embeddings. The features are extracted using a convolutional neural network (CNN), and word embeddings are generated using long short-term memory (LSTM)-based module. The pre-trained model is tested on a dataset with unseen classes.
3. The trained model was tested against three benchmark hyperspectral datasets to validate its performance.

Table 1 summarises a list of related cross-domain models based on zero-shot learning and summarises their performance.

Methodology

The proposed model consists of two phases. First, a pre-trained feature mapping module $f_m(.)$ is built using the visual features $f(V)$ and word embeddings $g(E)$ present in the training dataset. In the second phase, the testing dataset is passed through a pre-trained feature-mapped module $f_m(.)$ to assess the similarity , between training data τ_r and testing τ_ε data and predict a label b_j^{te}. All experiments were run using 12 GB RAM on the TensorFlow framework, and GPU was 1×Tesla K80 compute 3.7 2496 CUDA cores 12 GB GDDR5 VRAM. The optimized learning rate was 0.00001, and the AdaDelta optimizer ran for 60 epochs.

Feature Mapping Model

The training HSI data are embedded into hyperspectral visual features using an HSI classification model (Firat et al., 2022). The significant spectral and spatial features contained in HSI cubes were retrieved using the three dimensional CNN (3D-CNN) and ResNet model to tackle the problem of vanishing gradients. Mei et al. (2019) combined an attention network with CNN to focus on the discriminative features, eventually dealing with the problem of the complexity of HSI data. Multiple other models are available that deal with HSI classification (Dang et al., 2023; Ranjan & Girdhar, 2022). CNN has excellent potential in automatically learning the features. However, it only captures the spatial features and disregards the essential spectral features contained in HSI (Guo et al., 2022). Moreover, the accuracy decreases with an increase in the number of layers (Zhong et al., 2017). Therefore, to extract the visual features, this study uses the residual network introduced by Socher et al. (2013), which has shown excellent performance for classifying HSI by mitigating the declining accuracy phenomenon (Zhong et al., 2017). The main feature of ResNet is layer skipping, which effectively alleviates the gradient descent problem by reusing previous layers activations until the subsequent layer learns its weights (Alotaibi & Alotaibi, 2020; Xue et al., 2021). The residual network can be described by Eq. (1) where A_i is the output of ith unit, W_i denotes the parameters of residual structure. The nonlinear layers as shown in Fig. 1, the nonlinear layers stacked together build the function $F(A_i, W_i)$ instead of mapping desired A_{i+1} directly. Deep residual networks are easier to optimize then CNNs, have more representative capacities and provide higher classification accuracy considering the deeper layers involved (Zhong et al., 2017). This model was optimized using adaptive moment optimization and sparse categorical cross entropy, trained for 60 epochs and batch size 16 with verbose set to true. Figure 1 depicts the process.

$$A_{i+1} = \max\{0, A_i + F(A_i, W_i)\} \quad \text{(Zhong etal. 2017)} \qquad (1)$$

Word Embedding Model

The word embeddings were generated to connect the training and testing set that are disjoint sets. Various methods exist in the literature that establishes relationships

Table 1 Current trends in literature including proposed models and their performance

References	Model	Hardware	Datasets used and OA				Findings	Limitations

between categories using semantic information like attributes (Biswas & Annadani, 2018). Other methods that use high-level attributes to discover the semantic relationships are presented by Lampert et al., (2009, 2014). A study by Akata et al. (2016) embeds classes using the attribute vector space. The parameters of this component are found on a training dataset of labelled samples to ensure that the proper classes score higher than the erroneous ones in a given image. Wang et al. (2016) mapped the image and text description into a common vector space and computed similarity using cosine distance. Unlike CNN models, the LSTM focuses on assessing the temporal structure beginning with words or characters (Reed et al., 2016). This is an LSTM-based model that generates text vectors. Given a text description of w words $T = \{t_1, t_2, t_3 \ldots t_w\}$, the proposed LSTM-based model models the long-term dependencies using two types of states, including a cell state defined as c and a hidden state defined as h. The existing inputs x_t and previous state inputs (c_{t-1}, h_{t-1}) are combined for a specific time step to compute the current state. Three gates control the message passing during the integration, including a forget gate f_t, an input gate i_t, and an output gate o_t.

The proposed Conv1D-LSTM embedding model works using vector-based similarity representation, allowing greater capacity to characterise global alignments between images and sentences. The text data containing the description of classes, as shown in Table 1 were collected from Graña et al. (2021). The collected data were pre-processed using lemmatization, removing stop words, contraction mapping, and tokenization technique, and the word embeddings were generated and fed into the embedding layer. The input is a textual description of the label, and the output is a vector describing the sequence. This vector is then compared to a new label vector to determine which label is most likely to be similar to the image. The proposed embedding Conv1D-LSTM model, depicted in Fig. 2, employs an embedding layer followed by Conv1D and max-pooling, which is then fed into an LSTM and flattening layer to classify the word embeddings and produces vector output. This was optimized using adaptive moment optimization and sparse categorical

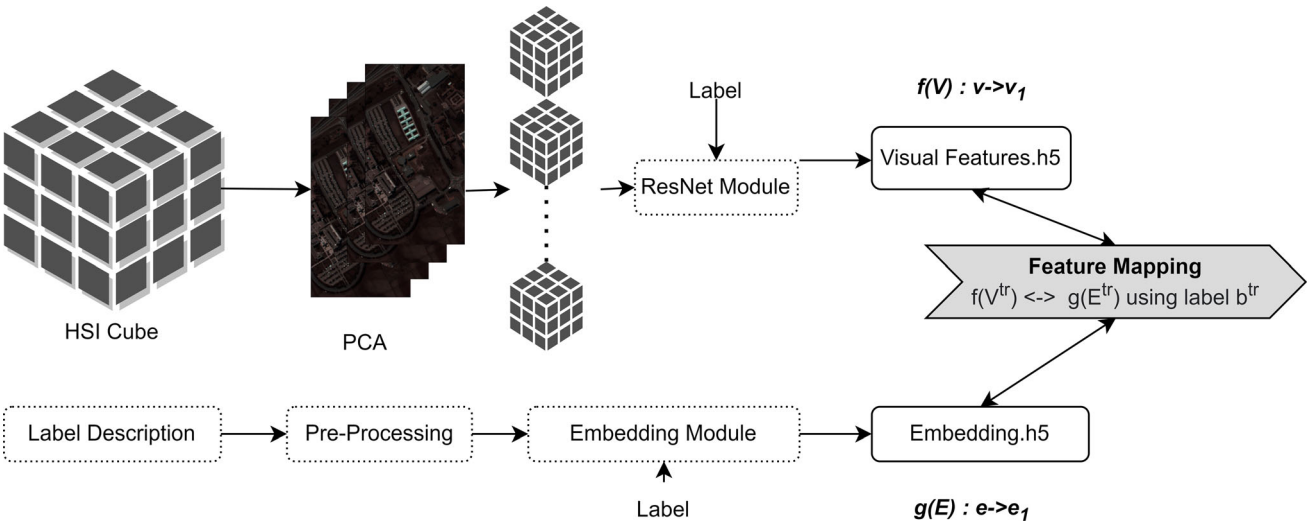

Fig. 1 Building a feature mapping model in Python 3.9 using TensorFlow framework

entropy, trained for 60 epochs in a batch size of 16 with verbose set to true. Figure 1 depicts the process briefly, and Fig. 2 depicts the layers involved in the embedding model.

Layout Similarity Mapping

The way features are mapped with semantic embeddings differs in different zero-shot learning-based networks. Various models discover projection mapping from visual to semantic space (Lampert et al., 2014; Socher et al., 2013), whereas others learn projections from semantic to visual space (Shigeto et al., 2015). This study (Pan et al., 2021) proposed a method for hyperspectral data that maps label embeddings to the visual feature space and learns correspondence between semantic visual embeddings in the visual space. It is done to ameliorate the hubness issue typically found in nearest neighbour searches for high-dimensional information (Radovanovic et al. n.d.). The proposed work maps visual features with word embeddings using a standard label y^{tr}. Figure 3 shows how the similarity is mapped. Table 2 shows the description of labels.

Testing the Pre-trained Model

The proposed work maps visual features with word embeddings using a standard label y^{tr}. The testing data were reduced to hundred bands by selecting discriminative bands using principal component analysis and eventually fed into a pre-trained feature mapping module. The pre-

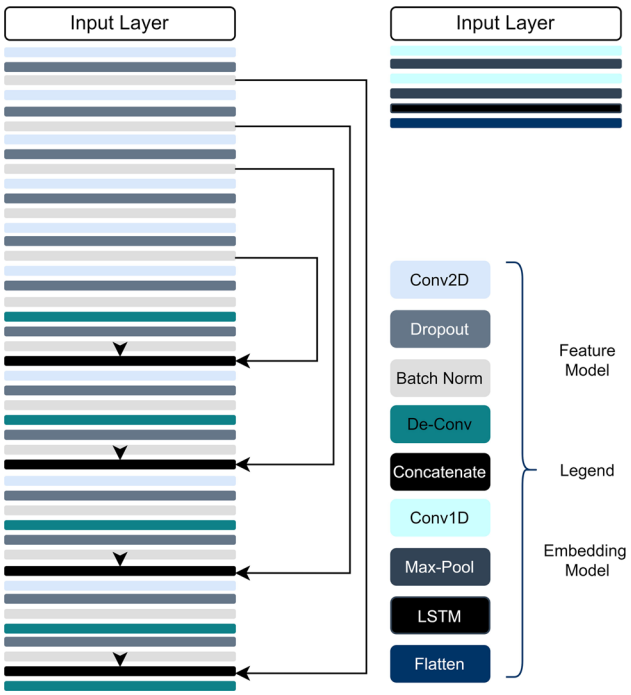

Fig. 2 Layers involved in feature model and embedding model

Table 2 Descriptions of categories

Asphalt	Sticky; black; extremely viscous liquid petroleum in semi-solid form; used as a binder in road construction; used for sealing flat roofs
Meadows	An open habitat; is a field with grasses, herbs, and other non-woody plants for vegetation. Demonstrates animal courtship insects that nest, gather food, and pollinate; meadows that are agricultural, transitional, or perennial
Gravel	Fragments of rock; crushed stone; fine, medium, or coarse; used for road construction, construction fill, and a variety of other minor purposes; distributed as river deposits, river flood plains, and glacial deposits
Painted metal sheets	A type of metal; used in metalworking; thin sheets used as foil or leaf, and thick pieces used as a plate or structural steel; other metals like aluminium, copper, nickel, silver, and gold can be used as metal sheets too

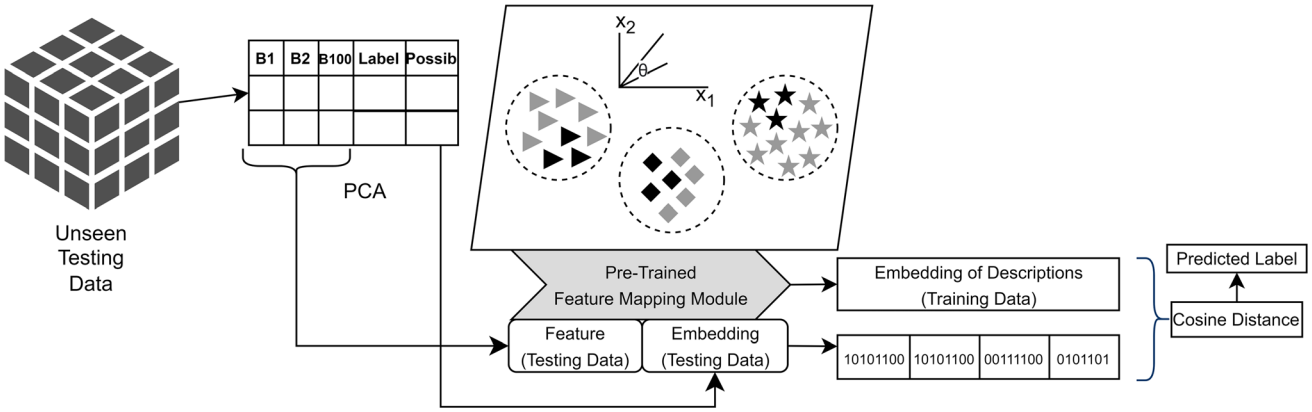

Fig. 4 Testing the model

trained feature mapping is transmitted to the visual elements of test samples and word embeddings of the testing categories. A metric learning method assigns the most appropriate category. The proposed model uses cosine similarity computed using a similarity vector between different training and testing datasets. The cosine or Euclidean distance is used in most previous methods to represent the similarities of two feature vectors that can record the relevance of the testing point with all the training points. The metric was top-K classification accuracy, and the results were top-4 accuracy. Before dividing the total number of classes, the average of correct predictions was calculated for each class. The accuracy of multiclass classification was calculated by evaluating the given test image on text descriptions from all classes, sorting the final prediction score in increasing order and selecting the top accuracy, algorithm 2 for reference. For $k = 4$, the top-k accuracy is written in Eq. (2), where m_c is the number of correct predictions of top-k rank in c. Figure 4 describes the process.

$$\text{accuracy}_{\text{topk}} = \frac{1}{||\tau_\varepsilon||}\sum_{i=1}^{||\tau_\varepsilon||}\frac{m_c}{\left\{b_j^{\text{te}}\right\}} \tag{2}$$

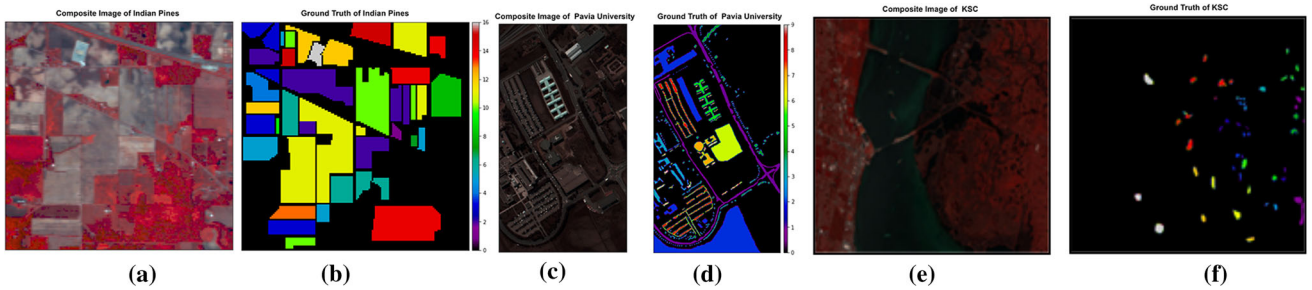

Fig. 5 **a** Composite image of Indian Pines **b** ground truth of Indian Pines **c** composite image of Pavia University **d** ground truth of Pavia University **e** composite image of Kenedy space centre **f** ground truth of Kennedy space centre

Algorithm 1 : The proposed model

Input :

Seen Training Images $\tau_r = \{a_i^{tr}, b_i^{tr}\}$ for *i=1 to n* in τ_r

Unseen Testing Images $\tau_\varepsilon = \{a_j^{te}\}$ for *j=1 to m* in τ_ε

$\mathbb{Z}\tau_r$ and $\mathbb{Z}\tau_\varepsilon$ Classes belonging to seen and unseen data

Output :

Predicting labels $\{b_j^{te}\}$ from unseen testing data for *j=1 to m* in τ_ε

Step 1. Finding visual features using Feature Modelling $f(V): v \Longrightarrow v_1$

Step 2. Find word embeddings using Embedding Modelling $g(E): e \Longrightarrow e_1$

Step 3. **for** $\forall \{a_i^{tr}, b_i^{tr}\}$, find feature mapping $f_m(.): f(V^{\tau_r}) \Leftrightarrow g(E^{\tau_r})$

$f_m(.): v_1 \longrightarrow e_1$ on τ_r with label b_i^{tr}

$f_m(.): e_1 \longrightarrow v_1$ on τ_r with label b_i^{tr}

end

Step 4. Similarity Prediction

for $\forall a_j^{te} \in \tau_\varepsilon$ Repeat below steps

Get the $f(a_j^{te}) \in v_1$ and $g(e_j^{te}) \in e_1$

Using the pre-trained $f_m(.)$, get the embedding

Using cosine similarity $cos(.)$, Find the final label b_j^{te}

end

Algorithm 2 : Sorting the prediction score

```
for i=1 to n-1
        j=1
        do while j>0 and A[j]<A[j-1]
        T = A[j]
        A[j] = A[j-1]
        A[j-1] = T
        j = j-1
        end
end
```

Experimental Settings

In order to test the performance of the proposed model, three datasets were chosen, including Pavia University (PU), Indian Pines (IP), and Kennedy Space Centre (KSC) (Graña et al., 2021). The composite and ground truth image of these datasets are shown in Fig. 5. Table 3 shows the properties of these datasets, including the sensor using which these were captured. The bands collected by the sensor is specific to the sensor type due to difference in wavelength and spectral resolution. The experimental dataset was consistent by selecting hundred discriminative bands from the dataset. We have taken three datasets for experimental purposes and divided them into two groups. For group 1, we trained the model using PU and IP and KSC, whereas Group 2 was trained using IP and tested using PU and KSC. In T_r T_e, T_r denotes the dataset on which the model was trained, and T_e denotes the testing set on which results were obtained. Figure 6 shows the sample distribution for each dataset.

Datasets

Results

Figure 7 shows the spectra for the IP dataset. This presents the interclass and intraclass distance between different categories of IP for particular bands. Figure 8 shows the PCA projection of IP classes over PU classes. The coloured dots represent the PU classes, and the black dots represent the IP classes. Some classes are hard to classify due to similar projections. For instance, there is an overlap in Grass-trees and Grass-pasture. Also, other classes like Soybean-clean and Soybean-notill are had similar PCA 2D projections. Additionally, there was overlap found in Corn-mintill, Corn-notill, and Alfalfa. This overlap is due to the similar spectra of these classes that can cause misclassification. The added word embeddings reduce this misclassification by having a good separability of classes.

Table 8 Number of parameters involved while training convolutional and embedding model

Conv. model	Embedding model
Total params: 7,959,809	Total params: 61,824
Trainable params: 7,955,073	Trainable params: 61,824
Non-trainable params: 4736	Non-trainable params: 0

comparison was made using overall accuracy, average accuracy and kappa coefficient as the performance metrics. The proposed model achieved the best results in Corn-notill, Grass–Trees, Hay-windrowed and Soybean-mintill, having comparatively a higher number of samples. The classes achieving very low overall accuracy were Alfafa, Corn-mintill and Soybean-Notill. The highest overall accuracy, average accuracy and kappa coefficient was achieved by the proposed model validating the performance of the proposed model. The mapping of feature and word embeddings had a considerable effect on the performance of the model. Despite the fact that IP and PU have different category distribution, the spectral-spatial model was able to attain excellent classification accuracy. However, mining the HSI information carefully is an important task.

Category 2: T_r (IP) → T_e (PU)

The second set of experiments was done by training the proposed model with IP and testing with PU. The models that were used for comparison were cross-domain tested using the PU dataset, including RN-FSC (Gao et al., 2020), DSAN (Zhu et al., 2021) in Zhang et al. (2022), DAAN (Yu et al., 2019) in Zhang et al. (2022), MDL4OW/C (Liu et al., 2021b), CMFSL (Xi et al., 2022), DCFSL (Zhang et al., 2022), and Gia-CFSL (Zhang et al., 2022) shown in Table 5. The highlighted results in bold included in Table 5 show that the class trees achieved the best accuracy and worst results for the class Meadows. This could be because no related word embeddings were found for the class meadows. Other classes achieved comparable classification results comparable to other models excluding the classes bitumen and shadows. This could be because of the imbalanced distribution of classes or the fluctuation caused in

Table 9 Comparison of OA achieved by CNN in comparison to base models

Model	PU PU		PU IP		PU KSC	
	OA	KC	OA	KC	OA	KC
Random forest	**98.34**	**0.9545**	73.9	0.75	**72.43**	**0.62**
Support vector machine	95.35	0.9052	**80.54**	**0.78**	54.16	0.5
Convolutional neural network	90.52	0.9534	75.08	0.77	67.58	0.55

the spectra of these classes due to different spatial distribution, occlusion or difference in the imaging environment. However, the highest overall classification accuracy and kappa coefficient was achieved by the proposed model.

Category 3: T_r (IP, PU) $\rightarrow$ T_e (KSC)

The third category of the experiment included testing on the KSC dataset. The last two columns in Table 6 shows the results obtained by the proposed model when trained using IP and PU. The other cross-domain models used for comparison, shown in Table 6, were tested on KSC. The results were quite interesting as the proposed model when tested using KSC achieved better results when trained using PU rather than IP. Out of 13 tested classes, KSC achieved the best results in 9 classes when trained using Pavia U. However, results were comparatively lower on the KSC dataset when trained using IP. This could be due to difference in basic attributes of two datasets despite being captured using the same sensor. This could also be because of changes in spectra due to difference in the imaging environment or inconsistent weather conditions.

Category 4: T_r (PU) $\rightarrow$ T_e (PU), T_r (IP) $\rightarrow$ T_e (IP)

The proposed model achieved excellent results when training and testing were performed on the same sets. This category was formed to test the model's performance with training and testing completing similar sets. Furthermore, the results were quite obvious. Table 7 depicts the classification accuracy for each class. PU achieved 99.49 percent, and IP achieved 93.46 overall accuracies. Figure 9 shows the confusion matrix for all three datasets. The excellent performance was achieved due to the same spectra and training–testing datasets being similar. This validates the performance of the proposed deep learning spectral-spatial architecture having great feature extraction capabilities.

Table 8 shows the parameters involved in the feature and embedding model. Figure 9 shows the confusion matrix for the three datasets when trained using Pavia University (PU), used to assess the classification accuracy of the proposed work. Table 9 shows the results obtained for T_r (PU) T_e (PU), T_r (PU) T_e (IP), and T_r (PU) T_e (KSC) for the most popular base machine learning models. This table shows the overall accuracy and kappa coefficient obtained for three respective datasets. The overall accuracy was highest when it was trained on same-domain in comparison to cross-domain datasets .

Conclusions

This study introduces a novel approach to cross-domain HSI classification by challenging the traditional paradigm of separating train and testing within the same data cube. It alleviates the problem of limited labelled samples in the HSI domain. The proposed model can be trained using images having different spectral resolutions acquired and pre-processed using different sensors. The generated word embeddings are used to associate the training and testing datasets by narrowing the gap between them. The presented feature model attempts to utilize the associations between visual elements and labelled word embeddings. Using the cosine similarity metric, the learned feature mapping is applied to testing data to determine the final label. The proposed model achieved excellent overall classification performance. However, some of the classes in testing datasets achieved low classification performance. It may be due to the similarities in the spectral distribution of some classes or to less difference in the textual description of these classes. This study proved that there is excellent scope in cross-domain classification due to the limited labelled HSI datasets available and the majority of existing models working on the same datasets. Having the strong fine spectra ability of hyperspectral images, the proposed model can be pretrained using multisource domains like military, mining, defence, or medical in the future. However, it will be interesting to see the overlap in spectra and whether it can be reduced with added word embeddings.

Abstract

In this era of digitalization, most domains thrive on online mediums, which provide a wide-ranging choice of resources to their users. Hence, a growing inclination towards effective recommendation systems for showing users relevant recommendations has become evident. The current shortage of semiconductor chips has led to a scarceness of computing power. The time and resources most platforms can allot to monotonous task of recommendation are limited. Moreover, each hour a considerable number of items and users are being added to platforms like Youtube, Netflix, Udemy, etc. The demand for efficient and accurate recommender systems is higher than ever. Therefore, We propose a Fast, Accurate and Efficient recommendation model: Recommender System using Collaborative Filtering, Ontology and User Networks (ReCONet), that broadens the concepts of ontology into the user domain by introducing user networks. Our approach seems uncomplicated, but extensive experimentation confirms that it performs significantly better than state-of-the-art Neural Network-based and Natural language-based approaches. Our model performed 61% faster and 18% more accurately than other state-of-the-art approaches on publicly available datasets.

Keywords: Hybrid Recommender System, Ontology, User Networks, Content based system, Collaborative Filtering

1 Introduction

The advent of the internet has led to an exponential increase in the amount of information available online. This overfeeding of information to the users has been countered with various information retrieval and informational Filtering systems. Recommender Systems are a popular example of such systems. They are used to predict a set of items for a user based on her/his preference. These have become very valuable for online businesses as they help customers in finding the desired product. According to Gomez-Uribe and Hunt [1] users on Netflix are not able to articulate their viewing preferences and lose interest after 60 to 90 seconds of choosing and reviewing 10-20 titles. Thus recommendation poses a great business value since 80 % of the hours streamed on Netflix are from the recommended items. Recommender Systems[2] have been extensively used in movies[1][3], music [4], Social Networks[5] etc.

There are two broad categories of Recommender systems: Content-based Recommender systems and Collaborative Filtering Recommender systems [9] [10] [5] [11]. Content-based Recommender systems[12] uses item profiles to recommend similar items. However it can lead to only a few items being recommended. Collaborative Filtering being the more popular approach uses the user item rating matrix as user's feedback for previously selected items. This matrix is used to find similar users and items and predict a user item rating.

Collaborative Filtering systems are further divided into memory based algorithms and model based algorithms. Memory based algorithms utilises the complete user item rating matrix to find the neighbourhood of a user(user based) or similar items(item based) to predict the ratings. Since they requires the complete rating matrix for prediction , they are computationally expensive and have scalability issues. In contrast, Model based algorithms use clustering algorithms to determine the neighbourhood of a particular user and provide recommendation based on that cluster. These algorithms do not have large memory requirements and scale well for large databases. However the quality of the prediction is low as compared to their counterparts.

Other drawbacks of Collaborative Filtering recommender systems include sparsity in the rating matrix and cold start problem. Various dimensionality reduction techniques[13][11] have been used to deal with sparsity. For the cold start problem[14], recommender systems use various knowledge based techniques which aid in the recommendation process. Ontology[15][13] is a knowledge based approach widely used in the recommender systems. Ontology is defined as conceptualization of a domain. In Ontology, items are linked to other items in the domain based on their properties, which is then used to find items similar to the item under consideration for recommendation. Another widely used knowledge-based approach uses social networks and trust relationships[16][17][18] of a user for finding its neighbourhood and then recommending items. These approaches have their own shortcomings. Creating ontology and using these relations to find similar items is not a trivial task.

Moreover, using social relations to find the neighborhood of a user in a recommendation perspective may not be effective since a user may have a different taste and needs as compared to his/her friends/acquaintances.

We propose a hybrid Collaborative Filtering recommender system, Re-CONet, to provide personalised recommendations to a user. The hybrid approach utilises memory-based and model-based algorithms along with user and item based approaches to counter the drawbacks of each approach. We further use item ontology and introduce user ontology as user networks to enhance user-item profiling, assisting the recommendation process. The major contributions of our study are as follows:

- **Introducing User Ontology as User Networks** - User networks are used to find similarity between the users based on their social relations. Contradictory to previous approaches, user networks are used on top of the Collaborative Filtering framework for rating prediction.
- **Detailed Item Ontology** - We perform an in-depth analysis of our item domain to create a vivid ontology that utilises the information content given by different item features taking in consideration their conceptual dissimilarity.
- **Density based clustering approach** - We use DBSCAN algorithm for user and item clustering based on their rating patterns. Since it is an adaptive algorithm, it forms organic clusters to be used for Collaborative Filtering and the outliers are separated as noise.
- **Simple and intuitive approach** - The primary aim is to provide personalised recommendations to users even for the outliers. The hybrid approach compounds the benefits of each of its constituents to identify and accommodate the specific needs of each user.

The remainder of this paper is organized as follows: In Section 2 we present the previous approaches used in the field of recommender systems. In Section 3 we present the Re-CONet model. Section 4 presents experimentation and results and Section 5 concludes our study.

2 Related Work

Before presenting our hybrid approach and experimental results , we give a brief overview of previously used approaches, methods and algorithms. Recommendation of relevant items can be given on the basis of similarity between items or users (Content-based), similar rating patterns of a group of users (Collaborative Filtering) or a hybrid approach. The type of approach usually depends on the information, metadata and feedback available. Content-based approach is used when sufficient information and semantic relations are available beforehand whereas Collaborative Filtering is useful for a large user base. Generally the approach is formed according to the experience, expertise and intuitively for a particular domain. Our approach is a hybrid approach , which uses a combination of various recommendation techniques to deliver the best recommendation.

2.1 Collaborative Filtering

Collaborative Filtering techniques [5] are used for providing customized recommendations by calculating the similarity between different users with similar choices. Collaborative Filtering can be classified majorly into two categories: Memory Based Approaches and Model Based Approaches.

Memory Based Collaborative Filtering uses all the user item data available . They base their recommendation on the fact that similar users are more likely to have similar tastes, so their recommendations should also be similar. It is a community goaded technique. Memory Based Recommendation[19] can be further divided into Item based technique and User based technique. In User Based technique, users who rated the items similarly may have same taste. Based on this , it recommends new items which are rated highly by similar users. Item Based technique focuses on items , it assumes that items which are rated similarly are presumably similar and therefore it recommends items with highest similarity.

Model Based Collaborative Filtering (Tommaso Di Noia et al[20]) (Hossein Javedani Sadaei et al[21]) gives item recommendation using a pre-constructed model. The model is built by various ML techniques such as Bayesian networks, clustering, etc. The major drawback of Collaborative Filtering is cold start problem, This problem occurs due to the insufficiency of data for some users or items[14].

2.2 Ontology

Ontology is originally defined by Thomas R. Gruber[22] as "formal specification of a shared conceptualization". Ontology is a formulation of a particular field like movies, courses, construction materials, etc into a human-apprehensible, but computer understandable form consisting of entities and attributes along with their various relationships and axioms.

Over the years many recommendation approaches involved combining Collaborative Filtering techniques with ontology to improve the prediction accuracy. Daramola et al[23] implemented an online tourism recommender system for tourism related services. Ontology enables and shares the structure of information among people and software agents (Ahmad Hawalah et al)[24].

Ontology in recommender systems virtually remedies the cold-start problem. Stuart E. Middleton et al[15] experimented with ontology based Recommender Systems to observe the effects of ontology on cold start problem. They tested their Quickstep recommender system for 7 weeks , they started with an empty log to simulate the conditions of cold-start problem and applied bootstrapping algorithms . After week 7 they examined and concluded that the cold start problem was completely eliminated.

2.3 Trust

Trust network between different users connects them to enhance the prediction accuracy and in turn enhance the final recommendation. Trust Networks are

built on the basis that a user 'a' who trusts other user 'b' is most likely interested in items liked or bought by 'b'. Trust can be implemented in two ways – probabilistic and gradual.

Probabilistic implementation (Y. Wang [17],Y. Kim [18] and A. Abdul Rahman[25]) is engaged with a trust factor which is measured by a '0' or a '1' which means a user 'a' either trusts a user 'b' or user 'a' does not trust user 'b'.

Gradual implementation (W. Li[26] ,J. Wu[27], C. Chin Chen[28]) on the other hand does not deal with absolute '0' or '1' , it deals with the extent to which a value is zero or the extent to which a value is 1. So this means in gradual implementation we find the extent to which user 'a' trusts user 'b'. This approach is more fitting in real life scenarios. It fits Fuzzy logic.

Few properties of trust in previous approaches (Golbeck 2017[29]) are –

- asymmetric: X trusts Z does not imply that Z trusts X.
- distributive: X trusts Y and Z, does not imply that Y trusts X and Y trusts Z.
- transitivity: While some of the approaches consider trust as non-transitive such as Abdul Rahman et al. (2000)[25], most of the works consider transitivity as an important property of Recommender system like Weijiang Li (2017)[26], Gohari (2017)[30], Josang and Pope (2005)[31] .

2.4 Hybrid Recommender Systems

Hybrid approaches combines two or more approaches to improve final recommendation. Balabanovic and Shoham [32] were one of the first to implement a hybrid approach for recommender systems. Their Fab system recommended web pages by combining implicit and explicit assistance.

Barragáns-Martínez and Costa-Montenegro [33] proposed a hybrid TV program recommender system. It used a Content-based and an item based Collaborative Filtering approach. It automatically maps user's tastes with a television program.

Neural Network based approaches[6][8] are common these days. Some of the neural network based approaches are described in brief in this section. We have also experimented and analysed the prediction accuracy and computation times of these approaches against our own approach in Experimentations section.

The DNNRec[6] utilizes embeddings for describing items and users to learn non-linear latent factors. Their approach ameliorates the cold start problem by incorporating side information regarding users and items into a deep-learning neural network. Their approach uses the embeddings to create Neural network to improve accuracy further.

Paradarami et al. [8] used a set of collaborative and content based features for a hybrid neural network based approach to counter standalone memory approach. Walek et al. [3] introduced a hybrid monolithic RS named Predictory. Predictory combines collaborative filtering techniques, content-based

techniques, and the fuzzy expert technique. Predictory's final n recommendations were computed using a fuzzy expert system, which evaluates the significance of the movies. The expert system worked with numerous parameters – the number of ratings, the similarity measure between already rated movies, average movie rating, etc.

Kamath et al.[7] developed a smart news recommendation search engine that recognizes similar news articles available from numerous sources on a particular day, then applies a semantics-based enhanced bag-of-words technique to leverage the efficiency of search recommendation. Natural-language-processing methods were used to identify articles dealing with similar news and serve on a user query with summarised news from various sources.

Hybrid Recommender Systems showed improved results in comparison to conventional Collaborative Filtering based recommendation systems.

3 Re-CONet Model

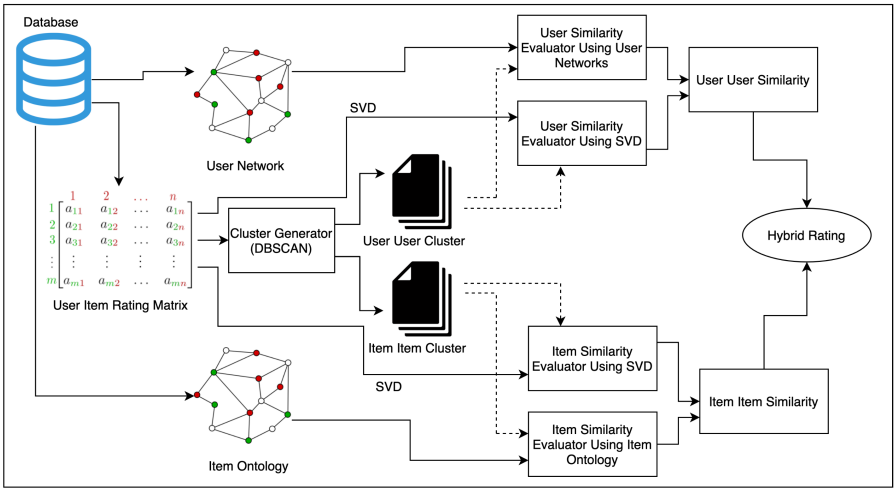

Fig. 1 Graphical representation of the proposed Re-CONet architecture

In this section we present our hybrid approach for the recommender system that uses ontology along with Collaborative Filtering for predicting ratings and providing recommendations.

In a traditional Collaborative Filtering system , users' preference regarding the items are taken into consideration for giving recommendations to the user. These preferences are generally stored in the form of a user-item rating rating matrix. Based on these ratings, users having 'similar liking' are identified and items are recommended.

In order to find similarity between the users or items and make predictions, it is required that the complete rating matrix be present in the memory. Such

Table 1 Rating Matrix

User/Item	$\mathbf{I_1}$	$\mathbf{I_2}$	...	$\mathbf{I_j}$	...	$\mathbf{I_n}$
$\mathbf{U_1}$	R_{11}	R_{12}	...	R_{1j}	...	R_{1n}
$\mathbf{U_2}$	R_{21}	R_{22}	...	R_{2j}	...	R_{2n}
...	...	...	...	...	...	...
$\mathbf{U_i}$	R_{i1}	R_{i2}	...	R_{ij}	...	R_{in}
...	...	...	...	...	...	...
$\mathbf{U_m}$	R_{m1}	R_{m2}	...	R_{mj}	...	R_{mn}

type of systems called memory-based systems produce highly effective ratings, although their memory requirements are very high. Another type of Collaborative Filtering systems are model-based , where a model is trained offline and the predictions made online using the same. This makes the process of recommendation considerably fast, however the predictions are not as accurate as given by their counterparts. Our proposed model implements the best of both approaches in a way that makes the recommendation process efficient and accurate.

Figure 1 shows the architecture of our model. The model considers two types of databases. One consist of the user-item rating matrix and the other contains the ontologies. The rating matrix is defined as follows.

Rating Matrix: It is the matrix containing ratings of N items by M users where row headers represent the users and the column headers represent the items as shown in *Table 1*.

Let U_i be the i^{th} user and I_j be the j^{th} item , then R_{ij} is the rating given to I_j by U_i. $R_{ij} \in [0,5]$. An item not rated by a user is represented by a default value 0.

Using these ratings, users and items are clustered into different clusters. This is done in offline phase. The clusters learned establishes the neighbourhood of a user/item. The neighbourhood is then used while computing the similarity measures and providing recommendations online. Since the neighbourhood restricts the number of users/items to be considered , it makes the process considerably efficient.

Since a user rates only a few items , this makes the rating matrix highly sparse. The similarity between users/items becomes skewed since all the unrated items are given default rating 0. Thus, before calculating similarity for different users in a cluster we use dimensionality reduction techniques to reduce the latent factors , which decreases the sparsity in the matrix. Based on these similarities , a rating R_{ij} is predicted by aggregating the ratings provided to item I_j by the users in the U_i's cluster or vice-versa in case of item-item clustering.

Method described above uses rating patterns to find similarity between users or items and give recommendations. A rating is a user's view on an item and thus using rating patterns for recommending an item to a user we exploit the fact that users having similar rating patterns have similar kind of interests and therefore an item liked by a user might also be liked by the other user. Similarly similarity between items is also calculated based on how they

are rated. Apart from the user's outlook on an item, similarity between items and users can also be calculated on the basis of their characteristics. This kind of approach uses the fact that items having common features are similar. Considering movies as items and genre as one of its characteristics , a user interested in a movie belonging to a particular genre may also be interested in other movies of the same genre. Ontology is a collection of concepts and categories in a subject area or a particular field (Eg.- Movies) which are used to represent their properties and the relationships between them. Hence all the instances of that particular domain can be mapped into corresponding concepts and categories , thus relating the instances. The similarity between instances using such kind of model is called Ontological Similarity.

In our model considering two domains - users and items , the ontology can be classified into:

- Item Ontology
- User Ontology

3.1 Cluster generator

It is a learning step and is done offline. Here the rating matrix is taken and clusters are formed that consist of neighborhood of users that resembles in terms of their likes-dislikes and that of items , in terms of their likeliness. Two kinds of clusters are formed.

User-user clusters : users are clustered together into different clusters based on how they rate different items. Each row in the matrix is considered as a user vector of that particular user. It is defined as follows Let U_k be a user vector, Then :

$$U_k = r_{kj}$$

$$r_{kj} \textit{ is the rating of } j_{th} \textit{ item by } k_{th} \textit{ user } \forall\, j \in (1, \mathsf{Items}) \,, k \,\epsilon\, (1,\ \mathsf{Users})$$

Therefore, a user vector consists of the ratings provided by the user to all the items. Hence it is a data point in N-dimensional data space, where N is the total number of items . These data points are then clustered in order to form user-user clusters.

Item-Item clusters: Items are clustered together into different clusters based on how they are rated by different users. Each column in the matrix is considered as an item vector of that particular item. It is defined as follows

$$I_k = r_{jk}$$

$$r_{jk} \textit{ is the rating of } k_{th} \textit{ item by } j_{th} \textit{ user } \forall\, j \in (1, \mathsf{Users}) \,, k \,\epsilon\, (1,\ \mathsf{Items})$$

Therefore, n-item vector consists of the ratings provided to the item by all the users. Hence it is a data point in M-dimensional data space, where M is the total number of users . These data points are then clustered in order to form Item-Item clusters.

Clustering Algorithm: In our approach, we use DBSCAN [37] algorithm for clustering. It is a density based clustering algorithm , that creates clusters of high density separated by clusters of low density. It is a non-parametric algorithm in the sense that it does not pre-decide the number of clusters.

DBSCAN algorithm uses an iterative process to cluster the data and is able to handle large datasets. The advantage of using DBSCAN is that it effectively handles outliers lying in the low density regions. These outliers could be movies or users that have very few ratings and are not considered as a part of any cluster. This gives us the advantage that , instead of finding a similar pattern of rating which does not exist , we can given recommendations based only on the ontology based approach.

3.2 Cluster Similarity

One of the major drawbacks of using the conventional Collaborative Filtering is the sparsity of the rating matrix. One of the counter measures to solve the problem is to use the mean value given by the other users which provides a pseudo-negative or pseudo-positive outlook of the movie. Another way is to use dimensionality reduction technique to remove the redundancy of noisy elements. Since the aim is to have users having a similar rating pattern despite having only a few ratings to get an improved similarity, our approach combines both the methods to give better similarity results. We use SVD[40] as the dimensionality reduction technique.
SVD is based on ternary factorization of a real-valued matrix as shown

$$R_{\mathrm{mxn}} = M_{\mathrm{mxm}} \times K_{\mathrm{mxn}} \times S_{\mathrm{nxn}}, \tag{1}$$

Where M and S are orthogonal matrices [$\mathrm{MM_T} = \mathrm{I}$] and K is a diagonal matrix with elements $\mathrm{a_0} > \mathrm{a_1} > \mathrm{a_2} \ldots \mathrm{a_n}$.

The matrix K comprises of latent factors of the items which represent their various characteristics such as genre, date of release in case of movie recommendation; weather, geography in case of tourism recommendation. Thus, the matrix M represents the latent factors implicitly rated by each user. Similarly, the matrix S represents the latent factors implicitly rated for each movie.

All the latent factors exceeding a threshold are considered as necessary and those less than the threshold are seen as noise, hence they are removed.In our approach we take the threshold as 'l' .We retain only the top l x l sub-matrix to form the new diagonal matrix $\mathrm{K_l}$. According to the diagonal matrix $\mathrm{K_l}$, we simplify matrix M and S into matrix $\mathrm{M_l}$ and $\mathrm{S_l}$ and obtain the new matrix $\mathrm{R_l}$.

$$R_{\mathrm{l}} = M_{\mathrm{l}} \times K_{\mathrm{l}} \times S_{\mathrm{l}} \tag{2}$$

This is the main application of SVD for the linear approximation of the original matrix R. Research shows that removing the small singular values "noise" indeed enhances the consumer-item relationship.

Table 2 User-User Similarity

	User U_1	**User U_2**	**User U_3**	**User U_4**
User U_1	S_{11}	S_{12}	S_{13}	S_{14}
User U_2	S_{21}	S_{22}	S_{23}	S_{24}
User U_3	S_{31}	S_{32}	S_{33}	S_{34}
User U_4	S_{41}	S_{42}	S_{43}	S_{44}

In our approach, we take the average rating for every user i as r_u and replace every non-zero rating r_{ui} with r_{ui}-r_u. Then we perform the SVD on the rating matrix R to get the decomposed matrix R_l The predicted rating matrix PR is obtained using the formula:

$$PR_{ui} = r_u + R_{lui} \tag{3}$$

After generating the predicted rating matrix , similarity for each user/item in a cluster is calculated as follows. Let U be a user cluster as shown in the Table 2 , where User U_i is the i^{th} user of nth cluster and S_{ij} = Similarity between i^{th} and j^{th} user. The same procedure is carried out for item-item similarity. The similarity is calculated using Tanimoto Coefficient[38].

The Jaccard Coefficient and cosine similarity are generalised to obtain the Tanimoto coefficient where a real-valued vector of attributes represents each item/user. The Tanimoto Coefficient is computed as:

$$T(U_i, U_k) = \frac{U_i.U_k}{\|U_i^2\| + \|U_k^2\| - U_i.U_k} \tag{4}$$

where U_i and U_k are real-valued vectors representing item/user.

The final SVD Similarity, Θ_{SVD}, calculated by the Tanimoto coefficient is used for hybrid rating prediction in section 3.5 .

3.3 Item Ontology

Since constructing an ontology is domain-specific, in this section we define our Item ontology considering the movie domain. The Figure 2 represents our movie ontology graph.

The ontology graph can be broadly divided into 2 sections:

- Concept section
- Instance section

The concept section consists of movie attributes like year of release, language, genre etc arranged in a logically ordered tree with movie as the root node and genre and attributes as its child nodes. Attributes are further classified into "people involved" (eg.director, music composer etc.) and "movie properties" (eg.language, year of release etc.). Movie genres are interrelated and thus, can not be placed equidistant in the genre sub-tree. For instance, movie X having

genre Horror is more closely related to movie Y having genre Thriller than to a movie Z of genre Action. Since, genres are intuitively related, research done by cinematic professionals can be summarized into a genre sub-tree given in Figure 3.

The instance section consists of movie linked with corresponding attribute instances. For example, the movie "3 Idiots" can be linked with language "Hindi", year of release "2006". The concept and instance section are connected by mapping the corresponding attribute instance in the instance section and the attribute in the concept section.

As shown in the graph,the attributes are mapped with the corresponding attribute instances whereas the genres are mapped directly with the movie. Moreover, genres are interrelated but other movie attributes are not. Thus, genre is considered as a separate movie attribute in our movie ontology.

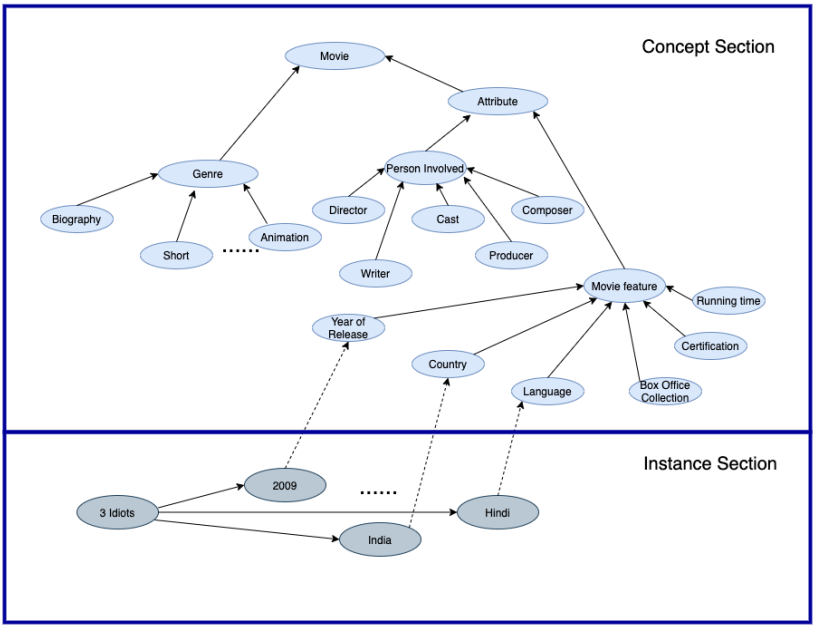

Fig. 2 Movie Ontology defined for the Re-CONet model

In our model, considering Genre and Attribute subtrees, two types of similarity measures are used in order to calculate similarities between movies:

- Genre Similarity
- Attribute Similarity

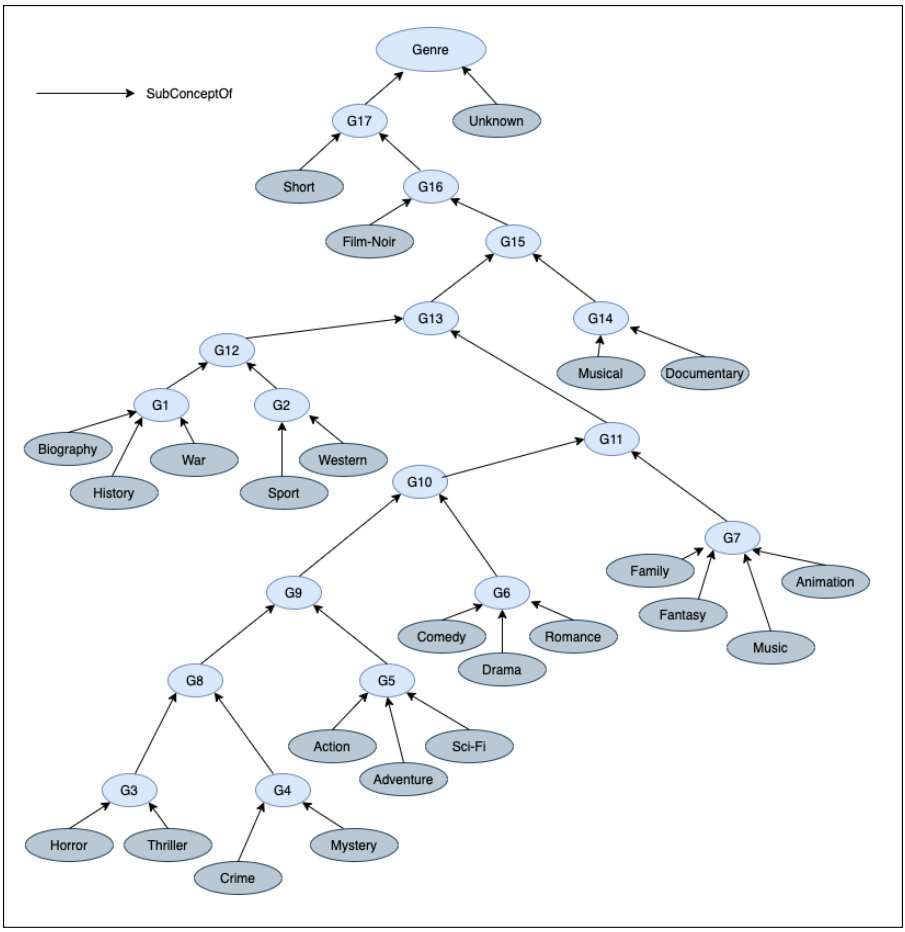

Fig. 3 Genre Ontology

For each pair of items, our model computes an ontological similarity using the weighted mean of these similarity measures.Let $\Theta_{Onto}(I_{\mathrm{i}}, I_{\mathrm{j}})$, ontological similarity between instance $\mathrm{I_i}$ and instance $\mathrm{I_j}$, be computed as :

$$\Theta_{Onto}(I_1, I_2) = \frac{x \times GS(I_1, I_2) + y \times AS(I_1, I_2)}{x + y} \tag{5}$$

Genre similarity between two movie instances (GS) is based on the shortest distance between the corresponding genres in the taxonomy. For instance, let Movie A be a comedy, Movie B a drama and Movie C an adventure movie. In our Genre Ontology, we expect that genre similarity between Movie A and Movie B is greater than the genre similarity between Movie A and Movie C.

Therefore, at the beginning, conceptual similarity between two genres (CSG) is specified. Similarity between two movies is computed using the CSG between respective genres of these movies.

Conceptual similarity between genres is calculated by an information theoretic approach [39] based on probabilistic model and is given by :

$$CSG(G_i, G_j) = \frac{log(Pr(G_k))^2}{log(Pr(G_i).Pr(G_j))} \tag{6}$$

$Pr(G_n)$ is the probability that a randomly selected movie has genre G_n, and G_k is the nearest genre that subsumes both G_i and G_j. $Pr(G_n)$ is calculated as -

$$Pr(G_n) = \frac{n(G_n)}{N} \tag{7}$$

Where N represents the total number of movie instances and $n(G_n)$ represents the number of movie instances connected to each genre subsumed by genre G_n

For instance, to calculate the similarity between Biography and War genres, let the total number of movie instances, N, be 1000 in the system. n(Biography) be 98 and n(War) is 102. The nearest genre that subsumes both Biography and War is G_1. Additionally, $n(G_1)$ be 250. Using these values CSG(Biography,War) can be computed as.

$$\begin{aligned} CSG(Biography, War) &= log(Pr(G_k))^2/(log(Pr(G_i).Pr(G_j))) \\ &= log(250/1000)^2/(log((98/1000).(102/1000))) \\ &= 1.204/2 \\ &= 0.602 \end{aligned} \tag{8}$$

GS between movie M_i and M_j is then defined as follows.

$$GS(M_i, M_j) = OSS(GSET(M_i), GSET(M_j)) \tag{9}$$

Where $OSS(S_1, S_2)$ is the similarity between sets S_1 and S_2 and $GSET(M_i)$ is the set of genres linked with the movie M_i,defined in the following sections.

Attribute Similarity

Attribute similarity between two instances (AS) is calculated using the common valued features like director, year of release, language etc.. For instance,let the Director of Movie X and Movie Y be A and director of Movie Z be B. Thus, Movie X and Y are more similar than Movie X and Z(where X and Z has no similar attributes) because of the common attribute Director.

AS between instance I_i and instance I_j is computed as:

$$AS(I_i, I_j) = 1 \;\; if \; I_i = I_j \tag{10}$$

$$AS(I_i, I_j) = \frac{\sum_k asi(I_i, I_j, k)}{N} \;\; if \; I_i \neq I_j \tag{11}$$

N is the number of links terminating at the concepts subsumed by instance I_i and I_j respectively. $ASI(I_i, I_j, k)$ gives the similarity for link k between

instances I_i and I_j. Thus, the mean of the similarities for each link of these instances gives their attribute similarity.

ASI(I_i, I_j, k) can be computed using the associated instances of I_i and I_j corresponding to the link k. For example, the instances associated for 'Has Director' link between two movie instances in our movie ontology are given by all the movies directed by these directors.

Thus, ASI(I_i, I_j, k) is calculated using the similarity between the sets of their associated instances.

ASI(I_i, I_j, k) is computed as.

$$ASI(I_i, I_j, k) = 0 \;\; if \; As(k, I_i) = \phi \; \forall \; As(k, I_j) = \phi \tag{12}$$

$$ASI(I_i, I_j, k) = CSG(As(k, I_i), As(k, I_j)) \;\; otherwise \tag{13}$$

Where As is the set of instances associated with the instance with respect to link k

Ontological Similarity Between Sets (OSS)

Similarity between two sets is required in order to calculate genre similarity and attribute similarity. It relies on the similarities between their elements. Genres for genre similarity and instances for attribute similarity calculation are the elements of the sets. Similarity between sets S_1 and S_2 (OSS(S_1, S_2)) is the following.

$$OSS(S1, S2) \; = \; \frac{(\mid S1 \wedge S2 \mid + \sum_{(I,J)} CSG(I, J))}{(\mid S1 \wedge S2 \mid + \mid S1 - (S1 \wedge S2) \mid . \mid S2 - (S1 \wedge S2) \mid)} \tag{14}$$

$$where \; I \in S1, J \in S2, (I, J) \in (S1 \vee S2) - (S1 \wedge S2)$$

OSS is used to calculate the ontological similarity, Θ_{Onto}, which is further combined with item-based SVD Similarity, Θ_{SVD}, as shown in section 3.5 .

3.4 User Networks

In Item Ontology, we considered the links between items and their features and calculated the similarity between items. This method is not feasible for users as they have innumerable features like age, gender, religion, ethnicity, etc. Instead of considering each feature explicitly, we exploit the social links between the users. For instance, friends on a social networking site share various common interests like the institution they work in or the area they live in. So rather than using features like institution or area to calculate similarity, we directly exploit their social links. Trust networks, which have been widely used in Recommender systems, is also an example of User Ontology.

The previously used approaches tend to recommend similar items among users who are connected, which is not always beneficial as the preferences between two connected users may vary in some cases. Since users belonging to

the same cluster have the same preferences, our approach uses user network to find similarity between users based on their cluster.

A graph between these users is created that represents our user network. Figure 4 is a part of user network graph.

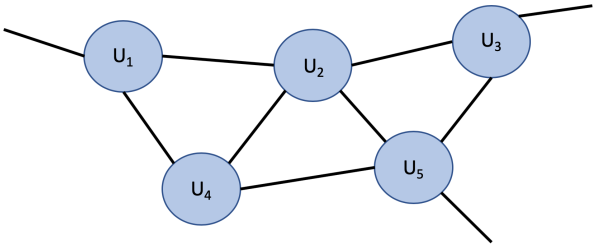

Fig. 4 User Network graph illustrating a user ontology. The nodes represent the users with connecting edges as the social connections between them.

To calculate the similarity between any two users in the system using the User network we use the concept of friend of a friend. Assuming that user U_i is connected to user U_j and further user U_j is connected to user U_k, then :

$$\Theta_{Net}(U_i, U_j) = 1 \; and \; \Theta_{Net}(U_j, U_k) = 1$$

$$0 < \Theta_{Net}(U_i, U_k) < 1$$

Where 'Θ_{Net}' is the similarity between two users. Using this concept we calculate the similarity between each user in a cluster as:

$$\Theta_{Net}(U_i, U_j) = \frac{1}{d(U_i, U_j)^p} \tag{15}$$

Where $d(U_i,U_j)$ is the distance between users U_i and U_j in the user network graph. p is a parameter that determines the gradual decrease in the similarity value . Generally $0 < p < 1$. For $p = 1$ similarity is inversely proportional to the distance between users.

3.5 Rating Prediction

Similarities computed in the Similarity calculation layer are then used to give a final Hybrid Recommendation.

Firstly, Similarity from Item-based CF with SVD and Item-Ontology are linearly combined to give item rating as shown below

$$Item\ Rating = b_{ij} + \frac{\sum_k (\alpha_{item} \times \Theta_{SVD} \times r_{kj} + (1 - \alpha_{item}) \times \Theta_{Onto} \times r_{kj})}{\sum_k (\alpha_{item} \times \Theta_{SVD} + (1 - \alpha_{item}) \times \Theta_{Onto})} \tag{16}$$

α_{item} is Hybrid Linear Combination Factor for combining similarity from Ontology and Collaborative Filtering r_{kj} is rating of j^{th} item by k^{th} user b_{ij} is global standard rating of j^{th} item by i^{th} user Similarly the User-based CF with SVD and User-Network similarity are combined to give user rating as shown below

$$User\ Rating = b_{ij} + \frac{\sum_k(\alpha_{user} \times \Theta_{SVD} \times r_{ik} + (1 - \alpha_{user}) \times \Theta_{Net} \times r_{ik})}{\sum_k(\alpha_{user} \times \Theta_{SVD} + (1 - \alpha_{user}) \times \Theta_{Net})} \tag{17}$$

α_{user} is Hybrid Linear Combination Factor for combining similarity from Ontology and Collaborative Filtering r_{ik} is rating of i^{th} user and k^{th} item b_{ij} is global standard rating of j^{th} item by i^{th} user

Finally, we calculate the rating prediction by combining the User rating prediction with Item rating prediction by using the formula

$$Hybrid\ Rating = \beta \times (Item\ Rating) + (1 - \beta) \times (User\ Rating) \tag{18}$$

β is Weighting factor for combining ratings according to their respective weights.

4 Experimentation and Analysis

4.1 Data Exploration

For the evaluation of our model, we have considered the Flixster dataset [34] & MovieLens 20M dataset [35]. We also extracted attributes and reviews for movies using IMDBPy[36] web crawler. Flixster is a social movie site allowing users to share movie ratings, discover new movies and meet others with similar movie preferences. The dataset was cleaned prior to using according to our requirements.The Flixster dataset is a popularly used dataset in the recommendation domain consisting of 2,523,386 users and 9,197,338 links among them according to their shared preferences. The movie ratings given by these users are on a scale of 0-5 and stored in a user item rating matrix. MovieLens 20M dataset has 20 million movie ratings along with 465,000 tags applied to 27K movies by about 138K users. We have combined the Data from Flixster and MovieLens 20M DataSet and for constructing the movie ontology. We randomly split the data into 80% for training and 20% for testing purposes. We have performed all the experimentation on a system with 16 GB of ram, 3.2 Ghz i5 Quad core processor and GPU GTX-1060 with 6GB dedicated video memory.

The Figure 5 and 6 depict the clustering on the basis of rating patterns of different users and items. Since the rating patterns vary on the basis of multiple factors, they are sampled along 10 major principal components. We obtained around 50 clusters each for users and items and have shown 6 clusters to show the similarity in rating pattern. As it can be seen that items and users in the

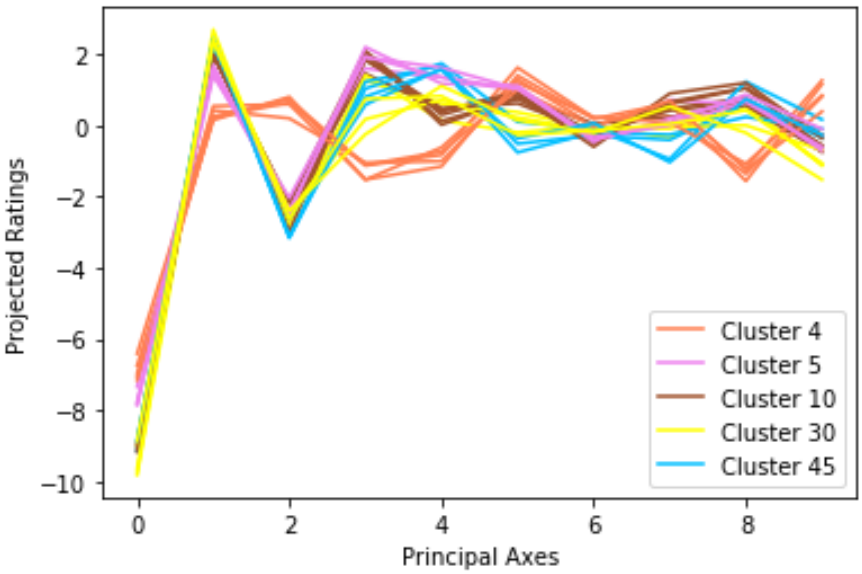

Fig. 5 Rating Patterns of Different User Cluster

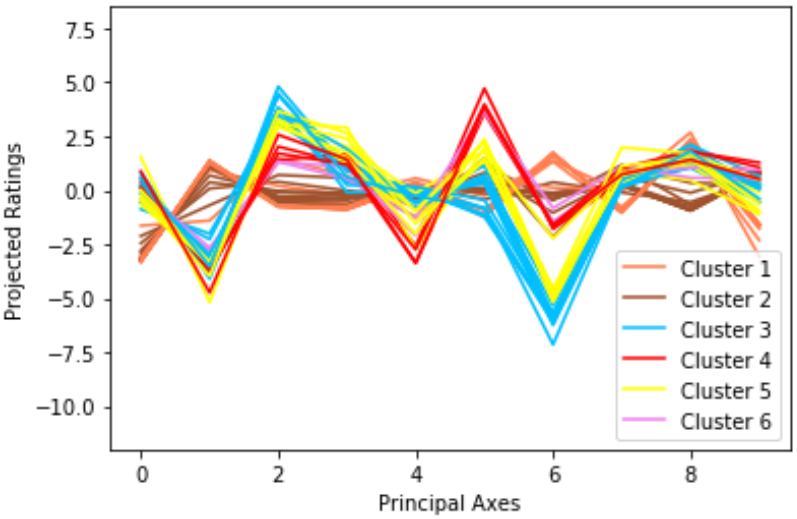

Fig. 6 Rating Patterns of Different Item Cluster

same cluster deviate only at a few points in the rating trajectory, they can be said to have similar yet not same rating patterns. Thus, the required rating is predicted by considering the corresponding average rating given by the users or for the items in the same cluster.

Table 3 shows the variation of sparsity in rating matrix with the number of chosen latent factors. As we can see, the sparsity shows a gradual decrease

Table 3 Sparsity vs latent factors

Number of latent factors (K)	Percentage of sparsity
Without SVD	99.33
10	0.360
50	0.330
75	0.330
100	0.330
500	0.310
1000	0.300
2000	0.230
3000	0.210
4000	0.210
5000	0.018

with increase in the number of chosen latent factors and drastically drops as the number of latent factors increases to 5000 which is chosen as the required value. Thus, SVD aids in reducing the sparsity of the rating matrix.

One of the fundamental criteria for a good recommender system is the personalisation of recommendations provided to each user. In this respect, to evaluate our model we calculate the similarity between the recommendations provided to users belonging to different clusters. The mean inter-cluster similarity is calculated as :

$$\overline{ICS} = \frac{\sum_m \sum_n (R_m \wedge R_n)/(R_m \vee R_n)}{\mid C_i \times C_j \mid} \tag{19}$$

where C_i and C_j are the sets of items in cluster i and j respectively, R_m and R_n are the sets of items recommended to user m and n belonging to clusters C_i and C_j respectively.

The 2-D plot illustrated by Figure 7 shows the $\overline{ICS}$ between 10 random clusters with low similarity values represented by light areas and dark areas corresponding to high similarity values. As we can see, distinct clusters show considerably less similarity as compared to their intra-cluster similarity. Thus, the primary aim to provide personalised recommendations to each user is fulfilled by our model.

4.2 Evaluating Re-CONet Model

The proposed hybrid Re-CONet model is evaluated and compared with other state-of-the-art recommender system models.

We compared the results of the Re-CONet model along with 4 other models for different values of noise percentage. Noise refers to items having irregular rating patterns and thus, do not belong to any cluster. Given the size of the sample dataset used for evaluations, we randomly chose the noisy items and clustered items according to the percentage of noise required.Since the dataset in consideration is quite large, the number of relevant items may seem negligible in some cases and thus MAE and RMSE may mislead sometimes. In order

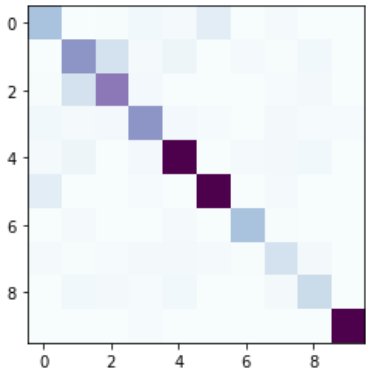

Fig. 7 Similarity between recommendations provided to users belonging to different clusters.

Table 4 Evaluation and comparison of Re-CONet Model with various approaches at different noise levels.

Approach	F-Score (20% Noise)	F-Score (30% Noise)	F-Score (40% Noise)
Paradarami [8]	0.621	0.572	0.547
Predictory [3]	0.689	0.673	0.591
Kamath [7]	0.694	0.658	0.612
DNNRec [6]	0.721	0.712	0.627
Our Approach	**0.756**	**0.743**	**0.741**

to solve such imbalanced classification problems, decision support metrics such as Precision and Recall are used. The precision evaluates the relevance of the recommended items. On the other side, the recall evaluates the tendency to recommend all the relevant items.

A balance between recall and precision is obtained by computing the F score as the harmonic mean of precision and recall. In our approach we have used F score to compare various models. It is given by the formula:

$$F = \frac{2.Recall.Precision}{Precision + Recall} \tag{20}$$

We have compared our model with 2 exceptional neural network based approaches Paradarami RS [8] and DNNRec [6], a natural language based approach Kamath RS [7] modified for recommending movies and a fuzzy expert system based approach Predictory[3]. In order to evaluate the Re-CONet model using decision-support metrics, we considered different percentages of noise (in increments of 10%). Table 4 shows the F-Score values for various models. From the table we can see that the F-Scores obtained by the Re-CONet model is relatively high in comparison to other models. The table also shows the change in F-Score with change in noise.

Paradarami [8] used a group of collaborative and content features along with reviews metadata to develop a neural network model. The approach was

created to reduce rating misclassification error, and it used the stochastic gradient descent optimization algorithm to do the same. The approach seemed sound in theory, but in practice, due to the black-box nature of neural networks, the layout and ontologies of domain(in our case movies domain) get altered and thus affect the accuracy as shown in table 4. Also, the stochastic gradient descent technique used, due to noisy data takes significantly more time to gain convergence to the minima of the loss function. With an increase in noise, it also affects the prediction accuracy. The creation of neural networks is computationally expensive, and due to the noisy data issue of stochastic gradient descent, Paradarami approach takes considerably more time than our approach and Predictory approach, as seen in table 5.

Predictory [3] melds collaborative filtering techniques, content-based techniques, and the fuzzy expert system technique. Predictory's fuzzy expert system evaluated the significance of the movies with the help of parameters such as the number of ratings, the similarity measure between already rated movies, average movie rating, etc. Predictory paid more emphasis to the items than to the users. It failed to deliver more personalized recommendations. Therefore, compared to our model, it has a worse prediction accuracy. With the increase in noise due to the fuzzy expert system used in the model, the prediction accuracy abates, as seen in table 4. As it didn't have any Neural network creation or graph creation step, it has a better Mean Prediction Time than Paradarami RS and the other approaches.

Kamath et al.[7] used a smart news recommendation search engine that recognizes similar news articles available from numerous sources on a particular day; then, it applied a semantics-based enhanced bag-of-words technique to leverage the efficiency of search recommendation. Natural-language-processing(NLP) methods are used to identify articles dealing with similar news and serve on a user query with summarised news from various sources. For experimentation purposes, we use the Kamath model to search and recommend movies. The Kamath model's use of NLP helps it get better predictive accuracy than Paradarami and Predictory approach. But, the Kamath model suffers from the disadvantages of Natural language processing. It suffers from ambiguity and context problems while processing the reviews and other information extracted from IMDBPy. As a result, the prediction accuracy of Kamath is lower than Our approach and DNNRec. Moreover, the Kamath model performs Lexical Analysis, Syntactic Analysis, Semantic Analysis, Discourse Integration and Pragmatic Analysis on all the user and item data. Hence, it has a greater mean prediction time than mean prediction times of Our Approach, Predictory and Paradarami RS, as seen in table 5.

The DNNRec[6] utilizes embeddings for describing items and users to learn non-linear latent factors. Their approach uses embeddings and deep neural networks to find latent relations between users and items. Second, it retains traditional collaborative filtering techniques by learning latent factors and uses them to learn non-linear latent factors as embeddings. But, in doing so, it alters and, in the movies' case, does not maintain the domain structure, and hence

Table 5 Mean time taken (including Model Training time) for predictions at 30% noise level over 5 runs.

Approach	Mean Prediction Time (mins)
Paradarami [8]	1012
Predictory [3]	338
Kamath [7]	1116
DNNRec [6]	1278
Our Approach	**344**

it has worse efficiency than Our Approach. Our approach does not destroy the domain structure while creating user networks. Firstly, The Deep Neural Network used in DNNRec is very convoluted, and hence it requires a significant amount of time to generate. Secondly, the use of ReLU function in DNNRec leads to a positive mean shift in many layers, which in turn slows down learning. Therefore, due to the above 2 points, the mean prediction time of DNNRec is the highest among the five approaches.

5 Conclusion And Future Work

Previous works have shown that incorporating various approaches to form a hybrid model helps us enhance the accuracy of prediction. However the rating information is often noisy and sparse which may be misleading. Moreover, many CF based models are vulnerable to the cold start problem of a new user or an item and many deep learning based approaches are computationally expensive.

In this research, we presented a multi-layered hybrid approach in which we have incorporated item and user ontology in hybrid user-based and item-based CF model. Firstly, we applied SVD in traditional CF approach to resolve the sparsity issue of the rating matrix. Then we used both user network and item ontology to provide personalised recommendations even to the cold start and noisy users. In particular, we used DBSCAN algorithm, a density based clustering algorithm useful for large datasets. The major novelty in our approach is that we used a detailed and well defined movie ontology based on a domain-specific research to provide better results. Moreover, we considered user trust network analogous to item ontology and exploiting the explicit social links between users, we explored the preferences of connected users belonging to the same cluster in user based CF.

In the empirical evaluations, we can see that the multi-layered hybrid Re-CONet model performs better in terms of F score calculations than other neural network based, NLP-based and fuzzy expert syem based hybrid models. Since the primary aim of our recommender system is to provide personalised and relevant recommendations to users which are resistant to noise and sparsity issues, value of F1 score is relatively high and stable for different noise levels as compared to other models. It shows that Re-CONet is able to fulfill the desired aim. As shown in Table 4, our approach performed better under high noise levels and for 40% noise showed 18% F Score improvement over neural network

based model. The inter-cluster similarity graph finally approves that users having similar preferences belong to the same cluster and are given similar recommendations. The mean prediction time for our Model was also 66% less than Paradarami RS's time, 69% less than Kamath RS's time, 73% less than DNNRec's time and almost similar to Predictory's time .

In our future work, we propose to use clustering algorithms to incorporate new users and items in the clustering step itself. Since we are able to provide stable and relevant recommendations for a majorly sparse and noisy dataset of movie ratings, we assume that our model would be helpful in other domains such as tourism , literature, news, etc. In our future works we will create recommender system for e-learning domain which will help students learning from home get the right recommended topics and courses.

In this paper, we present a cosmological model designed to study the evolution of the universe based on a new parametrization of the deceleration parameter. The model considers a spatially flat, homogeneous, and isotropic Friedmann-Lemaître-Robertson-Walker (FLRW) universe filled with radiation, dark matter (DM), and dark energy (DE). We derive the Friedmann equations and the energy conservation equation for the universe, accounting for separate conservation equations for radiation, DM, and DE. Our proposed deceleration parameter is given by a formula involving constants H_0, Ω_{r0}, Ω_{m0}, q_2, q_1, q_0, α and β. which we subsequently fit to observational data. To assess the model's viability, we compare it with a diverse range of observational data, including cosmic chronometers, type Ia supernovae, baryon acoustic oscillations, and cosmic microwave background measurements. Employing the chi-square statistic and a Markov Chain Monte Carlo (MCMC) method, we estimate the best-fit values for the free parameters and investigate the constraints imposed by observational data on the model. Our results indicate that our cosmological model provides an excellent fit to the observed data and exhibits a remarkable agreement with the standard ΛCDM paradigm at higher redshifts. However, the most intriguing discovery lies in the model's prediction of a super-accelerated expansion in the distant future, in contrast to the de Sitter phase predicted by ΛCDM. This implies the presence of dark energy driving the universe's accelerated expansion. Additionally, the model displays unique behaviors in the jerk and snap parameters, indicating novel dynamics beyond the traditional cosmological model. These findings suggest that our proposed cosmological model offers a compelling alternative to the ΛCDM paradigm, shedding new light on the nature of dark energy and the future fate of the cosmos.

I. INTRODUCTION

The acceleration of cosmic expansion is seen to be one of the most important findings in modern cosmology [1]. The cosmos appears to be expanding with repulsive force and not slowing down under regular gravity. This unidentified factor, known as dark energy (DE), is responsible for current cosmic acceleration. DE is a mysterious mechanism of energy that is thought to pervade all of space and tends to burst the extension of the cosmos in physical cosmology and astronomy [2]. However, the nature of DE is yet uncertain, necessitating additional investigation. In the classic cosmological cold dark matter (CDM) model, the total mass energy of the universe consists of 4.9 % ordinary matter, 26.8 % DM, and 68.3 % dark energy. Also, in astronomy, dark matter (DM) is an undiscovered kind of substance that appears only as a gravitational interaction but does neither emit or absorb light [3]. The nature of DM is yet unclear, although its presence has been demonstrated by astronomical measurements [4, 5].

Various approaches have been suggested to explain DE, including quintessence [6], quintom [7], Chaplygin gas with its modified model [8], K-essence [9], new agegraphic DE [10], holographic DE model [11], pilgrim DE model [12], and Tsallis holographic DE (THDE) [13]. The simplest of them is the cosmological constant hypothesis, which is consistent with data [14]. Despite its success, it suffers from some problems such as the coincidence problem, the fine tuning problem and the age problem [15–17]. The equation of state (EoS) parameter ω defines the relationship between energy density and pressure in the cosmic framework. This is a dimensionless parameter that describes the cosmos' phases [18]. A parametrized version of ω is assumed for departing behavior of DE. A Taylor series expansion in the redshift, scale factor or any other parametrization of may be used [19].

The main idea in this approach is to consider a specific evolution scenario instead of considering any DE model apriori and then determine the nature of the exotic component that is triggering cosmic acceleration. It is known as the model-independent approach, which depends on estimating model parameters from existing observational datasets [20–25]. However, number of studies have tried to find out the history of the universe without relying on any particular cosmological model. Such techniques are frequently referred to as cosmography or cosmokinetic models, but we shall simply refer to them as kinematic models [26, 27]. This name stems from the fact that the entire study of the Universe's expansion (or its kinematics) is characterised solely by the Hubble expansion rate $H = \frac{\dot{a}}{a}$, the deceleration parameter $q = -\frac{a\ddot{a}}{\dot{a}^2}$ and the jerk parameter $j = -\frac{\dddot{a}\,a^2}{\dot{a}^3}$, where a is the scale factor in the Friedmann-Lemaître-Robertson-Walker (FLRW) metric. The deceleration parameter allows us to investigate the transition from a decelerated to an accelerated phase, whereas the jerk parameter allows us to investigate deviations from the cosmic concordance model without being limited to a certain model. In terms of the deceleration parameter, various studies have attempted to determine the redshift at which the universe transitions to an accelerated phase. [28–30]. In modern cosmology, A model-independent determination of the current deceleration parameter q_0 and the deceleration-acceleration transition redshift are two of the most important things.

It is required to utilise some parametrization for the deceleration parameter in order to investigate it in a cosmological-model independent context. This system has both benefits and drawbacks. One benefit is that it does not depend on the amount of matter and energy in the universe. One problem with this method is that it is unable to clarify the reason for accelerating expansion. Furthermore, the current deceleration parameter's value may be affected by the anticipated form of $q(z)$. Recently, Mamon et al. [31] studied a special form of deceleration parameter and obtained the best-fit values using χ^2 minimization technique with available observational data. They also analyzed the evolution of the jerk parameter for the considered parametrized model. Gadbali, Mandal, and Sahoo [32] have explored a specific parametrization of deceleration parameter in the context of $f(Q)$ gravity theory and constrained the model parameter by using Bayesian analysis with observational data. Much recently, sveral theoretical models have been developed to analyze the entire evolutionary history of the Universe through parametrization of $q(z)$ as a function of scale factor $(a(t))$ or time (t) or redshift in [33–72].

Motivated by the above developments, in this paper we present a parametrization of deceleration parameter with five unknown parameters. This work mainly focuses on constraining the model parameters using various observational datasets. In order to find the constraints on the cosmic parameters, we make use of 31 points of the Cosmic chronometers dataset, 1071 points of the supernova type Ia, 17 points of BAO and 162 points of the GRB dataset and 24 observations of the compact radio quasar obtained from a VLBI all-sky survey of 613 milliarcsecond ultra-compact radio sources at GHz. We have also made use of the CMB dataset. We adopt MCMC analysis to fit the model parameters on the data and perform data analysis by χ^2 minimization technique. Finally, for each model, we did a graphical analysis of cosmographic parameters such as deceleration, jerk, and snap. In addition to this we have discussed and analysed the statefinder and Om diagnostics for our parametrization.

The paper is structured as follows: section(II) introduces the basic equations of FLRW universe. Section(III) we discuss the Taylor series expansion of

deceleration parameter in terms of cosmic reshift, and introduce a new five parameter parametrization of DP. Thereafter, we find the Hubble function corresponding to the parametrization. In section(IV), the data description and analysis methodologies using MCMC techniques are presented to constrain the model parameters and find the best fit values. Section(V) compares the model's predictions with observational data. Section (VI) gives a detailed description about the kinematic cosmographic parameters such as the deceleration, jerk and snap parameters. Section(VII) and (VIII) discuss about the statefinder and Om diagnostics and present the evolution history of dark energy on $s-r$ and $q-r$ planes. Section(IX) discusses about the information criteria. Section(X) and Section(XI) discusses the results and conclusions respectively.

II. FUNDAMENTAL EQUATIONS OF THE FLRW MODEL

In this section, we delve into the foundational equations of the spatially flat, homogeneous, and isotropic FLRW (Friedmann-Lemaître-Robertson-Walker) universe. This model serves as a cornerstone in our exploration of the cosmos. We embark on our journey by embracing the line element that characterizes the very fabric of space and time:

$$ds^2 = -dt^2 + a^2(t)\left[dr^2 + r^2\left(d\theta^2 + \sin^2\theta d\phi^2\right)\right], \quad (1)$$

Here, $a(t)$ unfurls itself as the scale factor, a pivotal entity shaping the evolution of our cosmic theater. Within this cosmic arena, the energy-momentum tensor of the fluid orchestrates the intricate dance of matter and energy. It assumes the form:

$$T_{\mu\nu} = (\rho + p)u_\mu u_\nu + p g_{\mu\nu}, \quad (2)$$

At its core, ρ and p personify the energy density and pressure density of this cosmic fluid. The 4-velocity $u^\mu = \frac{dx^\mu}{ds}$ weaves the narrative of motion through the cosmos, steadfastly adhering to the profound relationship $u^\mu u_\mu = -1$. The FLRW Universe beckons us to uncover its secrets encoded in the Friedmann equations, sacred inscriptions within Einstein's gravitational framework.

Friedmann Equation 1:

$$H^2 = \frac{8\pi G}{3}\,\rho, \quad (3)$$

Friedmann Equation 2:

$$\dot{H} = -4\pi G(\rho + p), \quad (4)$$

Here, $H = \frac{\dot{a}}{a}$ emerges as the herald of cosmic expansion, and the temporal derivative denoted by the overhead dot gracefully embodies the cosmic passage of time, t. In the realm of these equations, we discern the harmonious interplay between energy densities, pressures, and the cosmic fabric itself, unveiling the essence of our FLRW cosmos. Delving into the intricate tapestry of the cosmos, we find its very essence woven with fluid matter, manifesting as a symphony of energy density ρ and pressure p. This cosmic ensemble adheres to a sacred edict, the energy conservation equation, resonating as:

$$\dot{\rho} + 3H(\rho + p) = 0, \quad (5)$$

Here, H is the celestial conductor, the Hubble parameter orchestrating the cosmic rhythm. Our odyssey into the cosmic composition unveils a triad of cosmic constituents: radiation, dark matter (DM), and enigmatic dark energy (DE). Their presence shapes the grand narrative of our universe, with densities and pressures woven into the cosmic fabric: $\rho = \rho_r + \rho_m + \rho_d$ and $p = p_r + p_m + p_d$. Peering into their individual realms, we invoke distinct conservation equations:

Radiation:

$$\dot{\rho}r + 3H(\rho r + p_r) = 0, \quad (6)$$

Dark Matter (DM):

$$\dot{\rho}m + 3H(\rho m + p_m) = 0, \quad (7)$$

Dark Energy (DE):

$$\dot{\rho}d + 3H(\rho d + p_d) = 0, \quad (8)$$

The radiant dance of radiation is characterized by $p_r = \frac{1}{3}\rho_r$, yielding the mesmerizing revelation $\rho_r = \rho_{r0}a^{-4}$, where a gracefully denotes the cosmic scale factor. Meanwhile, the enigmatic dark matter, a realm of negligible pressure ($p_m = 0$), weaves its destiny as $\rho_m = \rho_{m0}a^{-3}$. In this symphony of cosmic evolution, these equations breathe life into the dynamic interplay of cosmic components, echoing through the vast cosmic expansion. In our cosmic odyssey, the deceleration parameter, a compass guiding the cosmic voyage, unfurls before us:

$$q = -1 - \frac{\dot{H}}{H^2} \quad (9)$$

Venturing further, we unravel the narrative of the enigmatic dark energy. This enigma unfolds as:

$$q_d = -1 - \frac{\dot{H}_d}{H_d^2} \quad (10)$$

Here, H_d takes on the mantle of the cosmic maestro, conducting the expansion of the dark energy domain. A

cosmic duet of equations, (3) and (4), resonate harmoniously, revealing cosmic truths:

$$H_d^2 = \frac{8\pi G}{3}\ \rho_d \tag{11}$$

$$\dot{H}d = -4\pi G(\rho d + p_d) \tag{12}$$

Stepping onto the cosmic stage with these equations, the ethereal dance of fluid energy density takes center stage:

$$\rho_d = \rho_{d0}\ e^{\int \frac{2(1+q_d)}{1+z} dz} \tag{13}$$

A symphony of symbols and cosmic energies converge, where ρ_{d0} embodies the present density parameter, and z portrays the redshift parameter, narrated as $1+z=\frac{1}{a}$ (with $a_0 = 1$ in the present moment). In the cosmic chronicle, celestial constants emerge as cosmic constellations. Casting our gaze upon the cosmic canvas, we define the cosmic tapestry:

$\Omega_{r0} = \frac{8\pi G\rho_{r0}}{3H_0^2}$, $\Omega_{m0} = \frac{8\pi G\rho_{m0}}{3H_0^2}$, $\Omega_{d0} = \frac{8\pi G\rho_{d0}}{3H_0^2}$. From this cosmic calculus, the Hubble parameter script is penned:

$$H^2(z) = H_0^2\left[\Omega_{r0}(1+z)^4 + \Omega_{m0}(1+z)^3 + \Omega_{d0}\ e^{\int \frac{2(1+q_d)}{1+z} dz}\right] \tag{14}$$

In this cosmic sonnet, Ω_{d0} emerges as the sentinel of cosmic balance, whispering the cosmic tale of unity: $\Omega_{d0} = 1 - \Omega_{r0} - \Omega_{m0}$.

III. UNVEILING THE PARAMETERIZED DECELERATION: A COSMIC ODYSSEY

In our pursuit of deciphering the cosmos, we turn our gaze toward the elusive parameterized deceleration. Its simplest embodiment takes form as follows:

$$q(z) = q_0 + q_1\mathcal{X}(z) \tag{15}$$

Within this cosmic equation, q_0 and q_1 emerge as steadfast cosmic companions, while $\mathcal{X}(z)$, a function of redshift z, guides us through the cosmic terrain. Various cosmic riddles beckon, each demanding a distinct form for $\mathcal{X}(z)$. Yet, previous attempts often left cosmic enigmas unsolved, hinting at the need for a parametrization that truly captures the essence of cosmic evolution.responding Hubble parameter in terms of redshift z.

A. A New Deceleration Odyssey

In our cosmic odyssey, we unveil a new paradigm, a symphony of cosmic harmony:

$$q_d(z) = q_0 + \frac{\alpha + (1+z)^\beta}{q_1 + q_2(1+z)^\beta} \tag{16}$$

Within this cosmic symphony, q_0, q_1, q_2, α and β take on the role of cosmic constants, conducting the cosmic dance. This newfound paradigm ripples through the cosmic tapestry, influencing the very fabric of cosmic energy density:

$$\rho_d = \rho_{d0}\ (1+z)^{3(1+q_0+\frac{\alpha}{q_1})}[q_1 + q_2(1+z)^\beta]^{\frac{3(q_1-\alpha q_2)}{\beta q_1 q_2}} \tag{17}$$

This cosmic crescendo echoes through the cosmic chronicle, reshaping the Hubble parameter:

$$H^2(z) = H_0^2\left[(1+z)^4\,\Omega_{r0} + (1+z)^3\,\Omega_{m0} + (1-\Omega_{r0}-\Omega_{m0})\ (1+z)^{3(1+q_0+\frac{\alpha}{q_1})}[q_1 + q_2(1+z)^\beta]^{\frac{3(q_1-\alpha q_2)}{\beta q_1 q_2}}\right] \tag{18}$$

In this cosmic symphony, Ω_{r0} and Ω_{m0} compose the cosmic orchestra, weaving the cosmic melody that resonates across the cosmos. As we embark on this cosmic voyage, our new model of deceleration parameter charts a course toward understanding the enigmatic cosmic fabric.

IV. DATA ANALYSIS

In this section, we will conduct a thorough comparison between our proposed model's predictions and observational data. Our goal is to explore the constraints imposed on the model by utilizing two distinct observational datasets: the Cosmic Chronometers (CC) dataset, type Ia supernovae (SNIa) dataset, Gamma Ray Bursts (GRBs), Quasar (Q), Baryon Acoustic Oscillation (BAO) and Cosmic Microwave Background (CMB) measurements. By comparing the model's predictions with these cosmological data, we can determine the best-fit and mean values for the two free parameters of our model, denoted as Ω_{r0}, Ω_{m0}, q_2, q_1, q_0, α and β. It is crucial to incorporate the present-day value of the Hubble function H_0 into our analysis. To constrain the parameters of our cosmological model, we adopt a rigorous and widely-used approach based on Bayesian statistics. This technique involves the use of likelihood functions and the application of the MCMC method. The Bayesian framework provides a robust framework for parameter estimation by quantifying the probability of obtaining a certain set of model parameters given the observational data.

A. Methodology : Markov Chain Monte Carlo Analysis

In this section, We present our methodology to determine optimal values of the seven free parameters Ω_{r0}, Ω_{m0}, q_2, q_1, q_0, α, and β with present-day value of the Hubble function H_0, using MCMC. This advanced approach explores parameter space, inferring parameter values from observed data while quantifying uncertainties. Gaussian errors are assumed for each dataset. The likelihood, encapsulating data agreement, is expressed as:

$$\mathcal{L}(\theta) \propto \exp\left(-\frac{1}{2}\sum_i \frac{(x_{\mathrm{obs},i} - x_{\mathrm{th},i}(\theta))^2}{\sigma_i^2}\right), \tag{19}$$

Here, $\theta = (\Omega_{r0}, \Omega_{m0}, q_2, q_1, q_0, \alpha, \beta, H_0)$ denotes model parameters, $x_{\mathrm{obs},i}$ is observed data, $x_{\mathrm{th},i}(\theta)$ is model prediction, and σ_i is measurement standard deviation. The posterior distribution of parameters is governed by Bayes' theorem:

$$P(\theta|\mathrm{data}) \propto \mathcal{L}(\theta) \times \mathrm{Prior}(\theta). \tag{20}$$

We initiate by defining parameter space and employing suitable prior distributions, reflecting initial parameter beliefs. Likelihood, gauging model-data agreement, is computed considering data deviations. Bayesian inference combines priors with likelihood, yielding the posterior parameter distribution. MCMC algorithms, such as Metropolis Hastings [73] or Hamiltonian Monte Carlo [74], generate parameter samples from the posterior. These samples collectively traverse parameter space, converging towards higher likelihood regions. Convergence is ensured by monitoring diagnostics like Gelman-Rubin statistic [75] and trace plots. A burn-in phase is discarded, stabilizing chains and mitigating initial point influence. Best-fit parameter values are calculated from converged MCMC samples, with associated uncertainties as sample spreads. The New Model's performance is evaluated against diverse datasets, including Cosmic Chronometers (CC), Type Ia Supernovae (SNIa), Gamma Ray Bursts (GRBs), Quasars (Q), Baryon Acoustic Oscillations (BAO), and Cosmic Microwave Background (CMB). Model selection criteria, like Bayesian Information Criterion (BIC) [76] or Akaike Information Criterion (AIC) [77], aid in choosing the optimal model considering data fit and complexity. This methodology robustly explores parameter space, extracting the New Model's optimal parameters while accounting for uncertainties and observational data.

B. Data Discription

1. *Cosmic Chronometers (CC)*

The Hubble parameter, $H(z)$, can be determined by measuring the quantity dt, which is derived from a spectroscopic survey and represents the differential age technique. In this study, we utilize a collection of 31 data points, known as cosmic chronometers, to serve as constraints for our cosmological model. These data points provide valuable information about the expansion rate of the Universe at different redshifts [78, 79]. To assess the agreement between the theoretical predictions, denoted as $H_{\mathrm{th}}(z_i)$, and the observed values, denoted as $H_{\mathrm{obs}}(z_i)$, we employ the chi-square function:

$$\chi^2_{\mathrm{CC}} = \sum_{i=1}^{31} \frac{[H_{\mathrm{th}}(z_i) - H_{\mathrm{obs}}(z_i)]^2}{\sigma^2_{H(z_i)}},$$

where $\sigma_{H(z_i)}$ represents the standard error associated with the observed value of H. By minimizing the discrepancy between the theoretical predictions and the observed data using the chi-square function, we can determine the mean values of the model parameters. This makes it possible for us to find a quantitative estimate of the agreement between our cosmological model and the cosmic chronometer data.

2. *type Ia supernovae (SNIa)*

Over the years, Numerous supernova data has been established [80–84]. Recently, they took a fresh Pantheon sample, known as the Pantheon+ sample [85]. It consists of 1701 SNIa data points covering a redshift range from

$0.001 < z < 2.3$.. SNIa observations have played a key role in uncovering the fact regarding accelerating expansion of the universe. These observations widely used to study the nature of the component driving this expansion. SNIa are incredibly luminous astrophysical objects and are considered as standard candles, which means their intrinsic brightness can be used to measure relative distances. The Pantheon+ dataset provides valuable information for studying the nature of the accelerating universe. The chi-square statistic is commonly used to compare observational data with theoretical models. In the case of the Pantheon+ dataset, the chi-square values are calculated using the following equation:

$$\chi^2_{\rm Pantheon+} = \vec{D}^T \cdot \mathbf{C}^{-1}_{\rm Pantheon+} \cdot \vec{D} \tag{21}$$

Here, $\vec{D}$ represents the difference between the observed apparent magnitudes m_{Bi} of SNIa and the expected magnitudes given by the cosmological model. M represents the absolute magnitude of SNIa, and $\mu_{\rm model}$ is the corresponding distance modulus predicted by the assumed cosmological model. The term $\mathbf{C}_{\rm Pantheon+}$ denotes the covariance matrix provided with the Pantheon+ data, which includes both statistical and systematic uncertainties. The distance modulus is a measure of the distance to an object, defined as:

$$\mu_{\rm model}(z_i) = 5\log_{10}\left(\frac{D_L(z_i)}{(H_0/c)\ {\rm Mpc}}\right) + 25 \tag{22}$$

Here, $D_L(z)$ represents the luminosity distance, which is calculated for a flat homogeneous and isotropic FLRW universe as:

$$D_L(z) = (1+z)H_0 \int_0^z \frac{dz'}{H(z')} \tag{23}$$

The Pantheon+ dataset differs from the previous Pantheon sample as it breaks the degeneracy between the absolute magnitude M and the Hubble constant H_0. This is achieved by rewriting the vector $\vec{D}$ in terms of the distance moduli of SNIa in the Cepheid hosts. The distance moduli in the Cepheid hosts, denoted as $\mu_i^{\rm Ceph}$, are measured independently using Cepheid calibrators. This allows for the independent constraint of the absolute magnitude M. The modified vector $\vec{D}'$ is defined as:

$$\vec{D'}_i = \begin{cases} m_{Bi} - M - \mu_i^{\rm Ceph} & \text{if } i \text{ is in Cepheid hosts} \\ m_{Bi} - M - \mu_{\rm model}(z_i) & \text{otherwise} \end{cases} \tag{24}$$

With this modification, the chi-square equation for the Pantheon+ dataset can be rewritten as:

$$\chi^2_{\rm SN} = \vec{D'}^T \cdot \mathbf{C}^{-1}_{\rm Pantheon+} \cdot \vec{D'} \tag{25}$$

This revised formulation allows for improved constraints on the absolute magnitude M and the cosmological parameters.

We've also expanded our investigation to include a subset of 162 Gamma Ray Bursts (GRBs) [86], spanning a redshift range of $1.44 < z < 8.1$. In this context, we define the χ^2 function as:

$$\chi^2_{\rm GRB}(\phi^\nu_{\rm g}) = \mu_{\rm g}\mathbf{C}^{-1}_{\rm g,cov}\mu^T_{\rm g}, \tag{26}$$

Here, $\mu_{\rm g}$ denotes the vector encapsulating the differences between the observed and theoretical distance moduli for each individual GRB. Similarly, for our examination of 24 compact radio quasar observations [87], spanning redshifts in the range of $0.46 \leq z \leq 2.76$, we establish the χ^2 function as:

$$\chi^2_{\rm Q}(\phi^\nu_{\rm q}) = \mu_{\rm q}\mathbf{C}^{-1}_{\rm q,cov}\mu^T_{\rm q}, \tag{27}$$

In this context, $\mu_{\rm q}$ represents the vector capturing the disparities between the observed and theoretical distance moduli for each quasar.

3. *Baryon Acoustic Oscillations (BAO)*

To investigate the intricate phenomena of Baryon Acoustic Oscillations (BAO) in our study, we engage a comprehensive dataset encompassing 333 distinct measurements [88–99]. However, in light of potential uncertainties attributed to data correlations, we judiciously curate a more focused dataset comprising 17 meticulously selected BAO measurements for our analytical endeavors. This deliberate curation aims to mitigate errors and enhance the precision of our findings. A pivotal metric derived from BAO investigations along the transverse direction is the parameter $D_H(z)/r_d$, where $D_H(z)$ signifies the comoving angular diameter distance. This quantity is intimately linked to the following expressive relation [100, 101]:

$$D_M = \frac{c}{H_0} S_k\left(\int_0^z \frac{dz'}{E\,(z')}\right), \tag{28}$$

where $S_k(x)$ is defined as:

$$S_k(x) = \begin{cases} \frac{1}{\sqrt{\Omega_k}}\sinh\left(\sqrt{\Omega_k}x\right) & \text{if} \quad \Omega_k > 0 \\ x & \text{if} \quad \Omega_k = 0 \\ \frac{1}{\sqrt{-\Omega_k}}\sin\left(\sqrt{-\Omega_k}x\right) & \text{if} \quad \Omega_k < 0. \end{cases} \tag{29}$$

Furthermore, our exploration encompasses the incorporation of the angular diameter distance D_A, given by $D_A = D_M/(1+z)$, and the parameter $D_V(z)/r_d$. The latter amalgamates the BAO peak coordinates with r_d,

which characterizes the sound horizon during the drag epoch. Moreover, we gain valuable insights from "line-of-sight" or "radial" observations derived directly from the Hubble parameter, as expressed by:

$$D_V(z) \equiv \left[zD_H(z)D_M^2(z)\right]^{1/3}. \tag{30}$$

By studying these BAO measurements, we gain insights into the cosmological properties and evolution of the universe, while minimizing potential errors and considering relevant distance measures and observational parameters.

The total χ^2 function is given by the sum of the individual contributions:

4. *Cosmic Microwave Background*

In this study, distant measurements of the Cosmic Microwave Background (CMB) were analyzed [102]. These measurements provide valuable information about the CMB power spectrum in two aspects: the acoustic scale l_A characterizes the variation in peak spacing of the CMB temperature power spectrum in the transverse direction, and the "shift parameter" R influences the peak heights along the line-of-sight direction. The acoustic scale is defined as:

$$l_A = (1+z_d)\frac{\pi D_A(z)}{r_s}, \tag{31}$$

where z_d is the redshift at the drag epoch, $D_A(z)$ is the comoving angular diameter distance, and r_s is an independent parameter. The shift parameter is given by:

$$R(z) = \frac{\sqrt{\Omega_m}H_0}{c}(1+z_d)D_A(z), \tag{32}$$

here density parameter is denoted by Ω_m, while H_0 describes the Hubble constant and c denotes speed of light. The study [102] reports the following observables: $R_z = 1.7502 \pm 0.0046$, $l_A = 301.471 \pm 0.09$, and $n_s = 0.9649 \pm 0.0043$. The parameter r_s has an associated covariance matrix, which is detailed in Table I of [102]. These observables represent inflationary features and the expansion rate of the CMB epoch.

In addition to the CMB data, other data from the late Universe were also considered in the analysis. The combined results, including Cosmic Chronometers (CC), Type Ia supernovae (SNIa), Baryon Acoustic Oscillations (BAO), and the CMB, were used to test the model. The results of the analysis showed good agreement between the model and the data. The contour plots illustrating the combined results of CC, SNIa, BAO, and CMB are presented in Figure 1. Furthermore, the best-fit values along with their corresponding error bars are tabulated in Table I.

$$\chi^2_{\rm tot} = \chi^2_{CC} + \chi^2_{\rm SNIa} + \chi^2_{\rm GRB} + \chi^2_{\rm Q} + \chi^2_{BAO} + \chi^2_{CMB} \tag{33}$$

MCMC Results			
Model	Priors	Parameters	Best fit Value

V. OBSERVATIONAL, AND THEORETICAL COMPARISONS WITH CC AND SNIA MEASUREMENTS

After determining the values of the free parameters in our cosmological model, it is crucial to compare the model's predictions with observational data and the well-established ΛCDM paradigm. This step allows us to assess the model's viability and its ability to explain observed phenomena in the universe. By contrasting the model predictions with observational data, we can evaluate the agreement and identify any discrepancies or deviations from the standard ΛCDM framework. This analysis plays a crucial role in validating or refining the proposed cosmological model and advancing our understanding of the underlying physical processes driving the evolution of the universe.

A. Contrasting with CC Measurements

We assess the compatibility of our model with observational data by comparing it to the 31 measurements of Cosmic Chronometers datasets, represented by orange dots accompanied by error bars in the purple line shown in Figure 2. For reference, we also include the well-established ΛCDM model in black line with $\Omega_{\rm m0} = 0.3$ and $\Omega_\Lambda = 0.7$. The comparative analysis provides essential insights into how well our model performs in describing the observed Hubble data. The figure shows a close alignment between our model's predictions and the orange data points, indicating that our model successfully captures the features and trends present in the dataset. This alignment demonstrates that our model

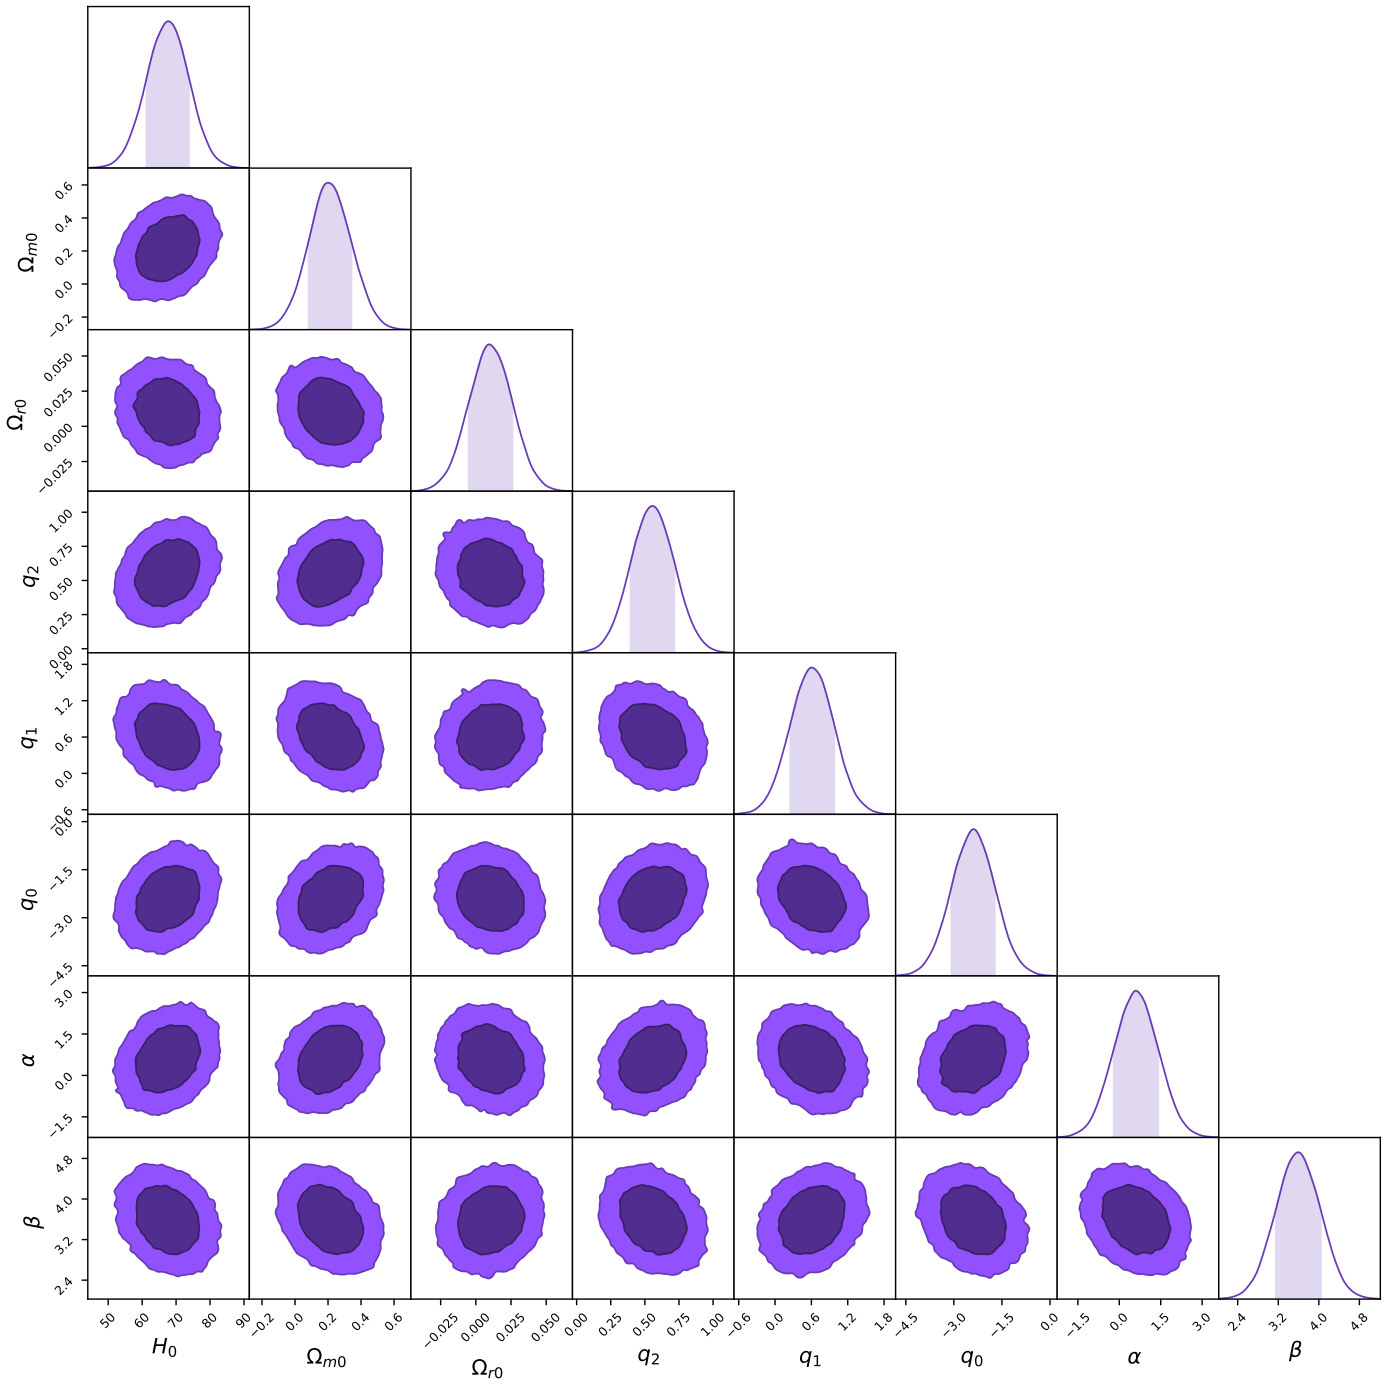

FIG. 1. This figure corresponds to 1σ and 2σ confidence contours obtained from $H(z)$ + SNIa + Q + GRB + BAO + CMB dataset obtained for the emergent model.

can reproduce the expansion history of the universe as inferred from the Hubble data. The agreement between our model and the observed cosmic evolution supports its validity and credibility.

B. Contrasting with type Ia supernovae (SNIa).

We compared the distance modulus function, denoted as $\mu(z)$, of our model with 1048 observational points from type Ia supernovae (SNIa) observations, shown in orange dots. The accompanying error bars represent measurement uncertainties. For reference, we included

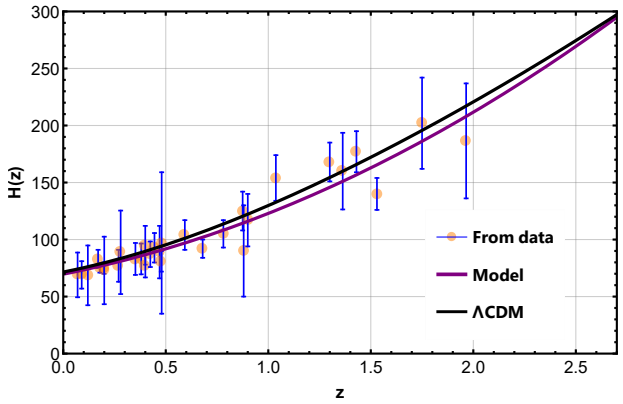

FIG. 2. Comparative analysis of our model (Purple line) with 31 Cosmic Chronometers datasets (orange dots) and ΛCDM model (black line)

the ΛCDM model as a black line. The distance modulus function $\mu(z)$ is a crucial quantity in cosmology, describing the apparent brightness of distant objects, such as supernovae, and enabling us to infer their distances. By comparing our model's predictions with the observed SNIa data, we can assess the model's ability to reproduce the observed behavior of the universe. Figure 3 visually demonstrates the close agreement between our model and the SNIa measurements. The fact that our model closely matches the dataset suggests that it provides an excellent fit for the observed supernova data. This agreement supports the viability of our model in describing the cosmological expansion and provides compelling evidence for its ability to explain the behavior of the universe as captured by the SNIa observations.

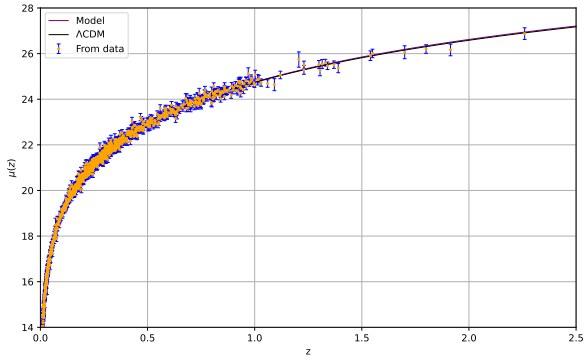

FIG. 3. Comparative analysis of our model (Purple line) with 1701 SNIa measurements (orange dots) and ΛCDM model (black line).

C. Relative differences between Model and ΛCDM.

The relative distinctions between our model and the ΛCDM model, we present Figure 4. The plot illustrates the behaviors of both models for redshifts $z < 1$, where they exhibit comparable dynamics. However, as the redshift surpasses unity, slight discrepancies emerge between the two models. These differences are particularly noticeable in the higher redshift range. The deviations between our model and the ΛCDM model gradually diminish beyond a critical redshift of approximately $z \approx 0.5$. This convergence at lower redshifts indicates that both models tend to align in their predictions as we explore earlier cosmic epochs. The close resemblance between our model and the ΛCDM model for $z < 1$ suggests that both models adequately capture the observed cosmic dynamics within this range. However, the observed discrepancies for higher redshifts indicate the presence of unique features or alternative mechanisms in our model, potentially influencing the universe's evolution at those epochs.

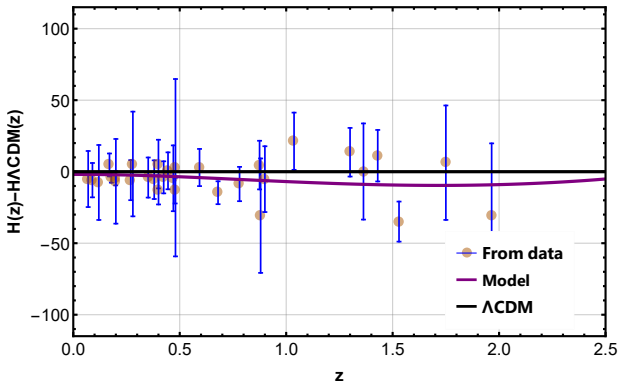

FIG. 4. Comparative analysis of our model (Purple line) with 31 Cosmic Chronometers datasets (orange dots) and ΛCDM model (black line)

VI. COSMOGRAPHIC PARAMETERS

Cosmographic parameters are mathematical quantities used to describe the behavior of the universe and its expansion. These parameters, such as the deceleration parameter, jerk parameter, and snap parameter, are derived from the Taylor series expansion of the scale factor and its derivatives.They give important insights into the dynamics and history of the cosmos, allowing us to investigate the acceleration or deceleration of its expansion as well as higher-order properties [19]. Researchers can acquire a better grasp of the underlying physics and test alternative hypotheses of dark energy by analysing and comparing these cosmographic features [103].

A. The deceleration parameter

In cosmology, the deceleration parameter is a dimensionless quantity used to determine the pace of expansion of the universe. It informs us about the accelerated or decelerated stages of cosmic expansion. It is defined mathematically as [104].

$$q = -\frac{a\ddot{a}}{\dot{a}^2}. \tag{34}$$

The DP influences the behavior of the Hubble parameter, which characterizes the rate at which the universe is expanding [105]. Depending on the sign of the deceleration parameter, the Hubble parameter can either increase or decrease. Positive values of q indicate an accelerated expansion of the universe, while negative values correspond to a decelerated expansion. Understanding and estimating the deceleration parameter is crucial for exploring the range of possible values denoted by q_0 through observational analysis. One way to probe the deceleration parameter is by studying the apparent brightness and redshift of supernovae in distant galaxies [106]. By examining these observational data, researchers can gain insights into the behavior of the deceleration parameter and its impact on the universe's expansion. Although estimating the deceleration parameter may seem challenging, recent findings strongly support models that suggest an accelerating universe [107]. These new outcomes have greatly favored the notion of an expanding universe with an accelerated rate of expansion. In cosmology, there is often a desire to determine a precise value for q_0, representing the deceleration parameter at the present epoch. However, achieving such precision requires rigorous observational analysis and careful consideration of various astrophysical phenomena [108]. Overall, the deceleration parameter provides valuable insights into the dynamics of cosmic expansion. By examining its behavior and exploring its implications through observational studies, scientists can deepen their understanding of the universe's evolution.

B. The jerk parameter

The dimensionless jerk parameter provides a generalization of the conventional cosmological parameters, such as the scale factor $a(t)$ and the deceleration parameter q. It arises from the fourth term in a Taylor series expansion of the scale factor around a reference time t_0. The expansion is given by:

$$\frac{a(t)}{a_0} = 1 + (t-t_0)\,H_0 - \frac{(t-t_0)^2}{2}\,H_0^2\,q_0 + \frac{(t-t_0)^3}{6}\,H_0^3\,j_0 + O\left[(t-t_0)^4\right], \tag{35}$$

where subscript 0 denotes the present values of the parameters. This expansion captures the behavior of the scale factor around t_0 up to the third derivative. Mathematically, the jerk parameter j is defined as the third derivative of the scale factor with respect to cosmic time, normalized by the ratio of the first derivative of the scale factor to the scale factor itself:

$$j = \frac{1}{a}\frac{d^3a}{d\tau^3}\left(\frac{1}{a}\frac{da}{d\tau}\right)^{-3} = q(2q+1) + (1+z)\frac{dq}{dz}. \tag{36}$$

The jerk parameter plays a significant role in distinguishing various proposals for dark energy (DE) and their implications for the dynamics of the universe. It helps identify favorable candidates for the physical interpretation of cosmic dynamics amidst the wide range of DE possibilities. By examining specific values of the jerk parameter, one can establish correspondences between DE proposals and standard models of the universe. Models involving a cosmic jerk provide a more pronounced demonstration of transitions between different eras of accelerated expansion. Notably, the flat ΛCDM model corresponds to a jerk parameter value of $j = 1$.

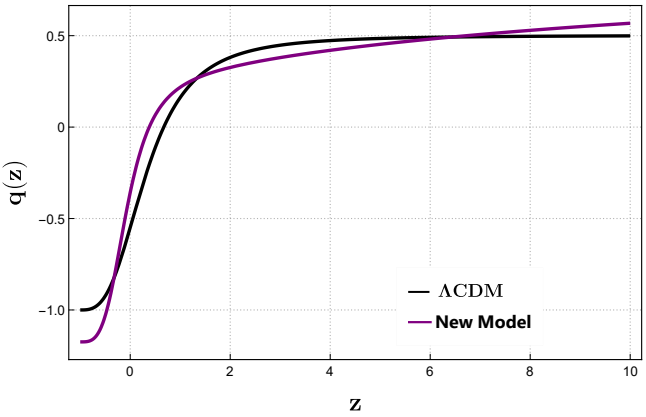

FIG. 5. This figure provides visual perception between respective and ΛCDM Model of deceleration Parameter.

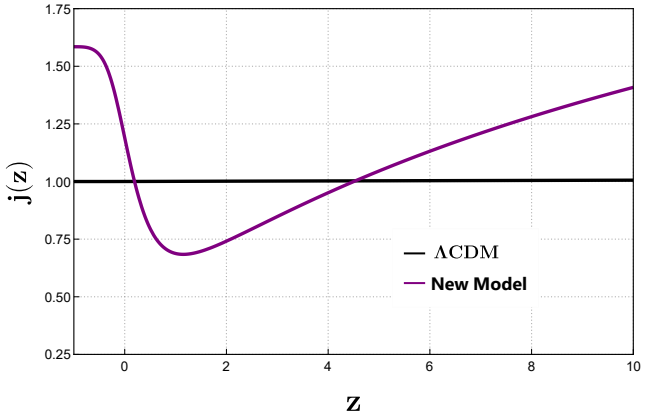

FIG. 6. This figure provides visual perception between respective and ΛCDM Model of jerk Parameter.

C. The snap parameter

The snap parameter, also known as jounce, is a dimensionless quantity that provides further insights into the behavior of the expansion factor. It is derived from the fifth term in the Taylor series expansion of the scale factor around the reference value a_0. The expansion is given by:

$$\frac{a(t)}{a_0} = 1 + H_0(t-t_0) - \frac{1}{2}q_0H_0^2(t-t_0)^2 + \frac{1}{6}j_0H_0^3(t-t_0)^3 + \frac{1}{24}s_0H_0^4(t-t_0)^4 + O\left[(t-t_0)^5\right]. \tag{37}$$

Mathematically, the snap parameter s is defined as the fourth derivative of the scale factor with respect to cosmic time, normalized by the ratio of the first derivative of the scale factor to the scale factor itself:

$$s = \frac{1}{a}\frac{d^4a}{d\tau^4}\left(\frac{1}{a}\frac{da}{d\tau}\right)^{-4} = \frac{j-1}{3\left(q-\frac{1}{2}\right)}. \tag{38}$$

For the flat ΛCDM model, where $j = 1$, the snap parameter can be expressed as $s = -(2+3q)$. This relationship provides a clear connection between the snap parameter and the dynamics of the ΛCDM model. Furthermore, the divergence of $\frac{ds}{dq}$ from -3 indicates deviations in the evolutionary mechanism from the dynamics of the ΛCDM model. By examining the behavior of this derivative, we can gain insights into how the system deviates from the standard ΛCDM dynamics.

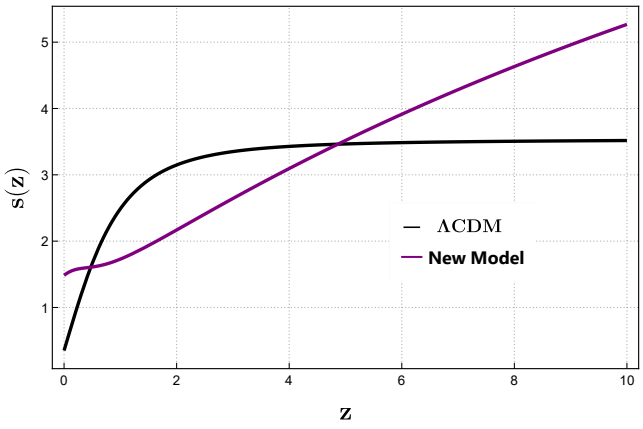

FIG. 7. This figure provides visual perception between respective and ΛCDM Model of snap Parameter.

VII. STATEFINDER DIAGNOSTIC

The statefinder diagnostic pair $\{r, s\}$ is a widely used tool in the study of dark energy (DE) models, offering insights into their nature based on higher-order derivatives of the scale factor [109]. These dimensionless parameters provide a model-independent way to analyze the cosmic properties of DE. The statefinder pair is computed using the following expressions:

$$r = \frac{\dddot{a}}{aH^3}, \quad s = \frac{r-1}{3\left(q-\frac{1}{2}\right)}, \tag{39}$$

Here, r represents the ratio of the third derivative of the scale factor to the cube of the Hubble parameter, and s is a linear combination of r and the deceleration parameter q. Specific values of r and s have well-established interpretations within standard DE models. For example, $\{r, s\} = \{1, 0\}$ corresponds to the ΛCDM model, while $\{r, s\} = \{1, 1\}$ corresponds to the standard cold dark matter (SCDM) model in a Friedmann-Lemaître-Robertson-Walker (FLRW) universe. The value range of $(-\infty, \infty)$ indicates the possibility of an Einstein static universe. In the $r - s$ plane, different regions correspond to distinct types of DE models. For instance, $s > 0$ signifies quintessence-like models, whereas $s < 0$ indicates phantom-like models. Deviations from the standard value of $\{r, s\} = \{1, 0\}$ can indicate an evolutionary process from phantom-like to quintessence-like behavior. Moreover, specific combinations of the deceleration parameter q and the statefinder parameter r are associated with well-known models. The pair $\{q, r\} = \{-1, 1\}$ is linked to the ΛCDM model, while $\{q, r\} = \{0.5, 1\}$ corresponds to the SCDM model.

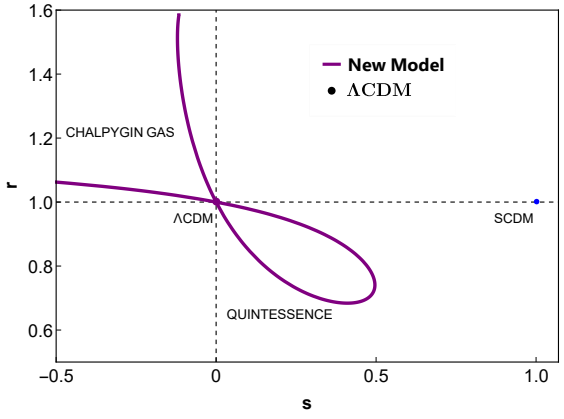

FIG. 8. Behavior of $\{r, s\}$ plane

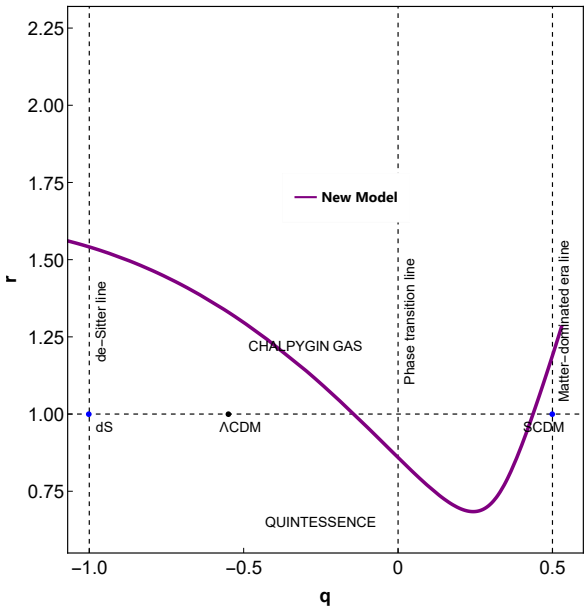

FIG. 9. Behavior of $\{r, q\}$ plane

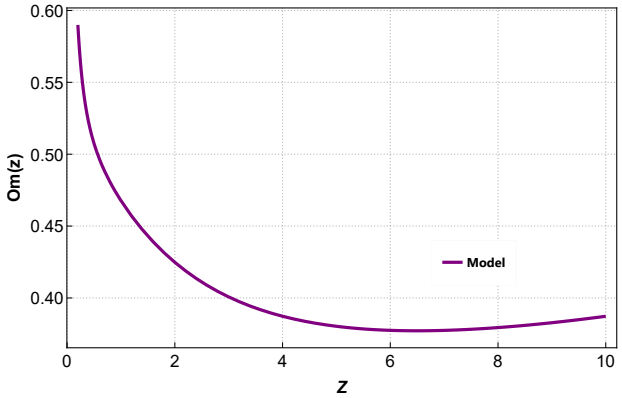

FIG. 10. Behavior of $Om(z)$ Profile

VIII. OM DIAGNOSTIC.

The Om diagnostic is a geometrical formalism used to test the validity of the ΛCDM model in cosmology [110]. It provides a useful tool for differentiating between various dark energy (DE) models and the cosmological constant. By analyzing the slope variation of the Om parameter with redshift, one can distinguish quintessence and phantom models based on positive and negative slopes, respectively. In the case of a constant slope, it corresponds to the cosmological constant. In a flat universe, the Om diagnostic is defined as the ratio of the squared Hubble parameter at a given redshift to its present value, normalized by the expansion factor.

$$Om(z) = \frac{\left(\frac{H(z)}{H_0}\right)^2 - 1}{(1+z)^3 - 1}. \tag{40}$$

Unlike the statefinder diagnosis, the Om diagnostic only requires the first-order temporal derivative. It has also been applied in the study of Galileon models. Overall, the Om diagnostic provides a valuable tool for exploring and understanding different DE scenarios in cosmology.

IX. INFORMATION CRITERIA

Model selection criteria such as the corrected Akaike information criterion (AIC) play a golden role in evaluating the sustainability of the models [77, 111–114]. The AIC_c takes into account the maximum likelihood function, the number of data, and the number of free parameters of models. For larger datasets, the AIC_c reduces to AIC. The AIC is used to figure out the goodness-of-fit of different models. The model having the lowest AIC is the most preferred by observations. The difference, $\Delta AIC = AIC_{preferred} - AIC_{model}$, is more meaningful that the AIC itself. A range of $(0, 2)$ for ΔAIC refers to models strongly supported, values in the range of $(4, 7)$ are less supported, while values beyond 10 refer to models without any support. Therefore, the use of AIC is a very useful tool for classifying a set of models based on their ability to fit data. In addition to the AIC, the Bayesian information criterion (BIC) [76, 115, 116] also contributes to model selection. Like the AIC, the BIC considers the trade-off between goodness-of-fit and model complexity. However, the BIC incorporates a stronger penalty for models with more parameters. This promotes the selection of simpler models, helping to guard against overfitting. In the context of ΔBIC, similar principles apply as with ΔAIC. A lower ΔBIC indicates stronger support for a particular model, and the magnitude of the difference is informative

Model	χ^2_{min}	χ^2_{red}	AIC	ΔAIC	BIC	ΔBIC
ΛCDM	1742.41	0.9876	1748.41	0	1763.94	0
Model	1733.01	0.9864	1749.01	0.69084	1790.41	26.4774

TABLE II. Summary of $\chi^2_{\rm tot}{}^{min}$, $\chi^2_{\rm red}$, AIC, ΔAIC, BIC, ΔBIC

X. RESULTS

a. deceleration parameter Figure 5 illustrates the changes in the deceleration parameter (DP) with respect to the cosmic redshift (z) in our new cosmological model. Remarkably, our model demonstrates an excellent agreement with the standard ΛCDM model at higher redshifts. However, the real excitement lies in the future phase of the universe's evolution, where our new model showcases a fascinating phenomenon - a super accelerated expansion ($q(-1) \approx -0.3$). This stands in stark contrast to the ΛCDM model, which predicts a de Sitter phase with $q(-1) = -1$. The discovery of this super-accelerated expansion has significant implications, as it suggests that the universe might experience unprecedented and rapid expansion in the distant future. Indeed, the observed super-accelerated expansion in the new cosmological model could potentially be attributed to dark energy.

b. jerk parameter Figure 6 shows the evolution of the jerk parameter with cosmic redshift (z) in the context of Cosmology. Our new model exhibits a remarkable departure from the well-established ΛCDM model. The jerk parameter initially experiences a steady decline during the early stages of the universe. However, this decline is eventually halted as the model intersects with the ΛCDM curve around $z \sim 4.25$. Subsequently, an intriguing reversal in the evolution of the jerk parameter occurs, reaching its minimum value at $z \sim 1$. After this critical point, our model aligns closely with the ΛCDM predictions, particularly near the present time, i.e., $z \sim 0$, where the universe continues to display accelerating expansion.

c. snap parameter We have examined the behavior of the snap parameter in comparison to the widely accepted ΛCDM model. Remarkably, our new model exhibits a significant and consistent departure from the ΛCDM predictions across all ranges of cosmic redshifts (z) as shown in Figure 7. The snap parameter experiences a steady and continuous decline, showcasing a unique pattern not seen in the standard model. Particularly noteworthy is the behavior of the snap parameter near the present time, at approximately $z \sim 0$. Our model predicts that the slope of the curve flattens out, leading to an intriguing prediction of $s(0) \sim 1.6$ for the snap parameter. This deviation from the ΛCDM model provides valuable insights into the dynamics of the universe and suggests alternative mechanisms that might govern cosmic expansion.

d. $\{r, s\}$ profile In Figure 8, we present the intriguing evolution of the $\{r, s\}$ parameter. Our model depicts an interesting journey through several dark energy domains, offering information on the universe's dynamics. Our model begins in the Chalpygin gas-type dark energy area, which is defined by $r > 1$ and $s0$. After this, the model crosses the fixed ΛCDM point $\{1, 0\}$ as the cosmic evolution advances, signalling a momentous change. Following that, it reaches the Quintessence type dark energy zone, with $\{r, s\}$ parameter values of $r < 1$ and $s > 0$. This phase suggests a transition away from the classic cosmological model and towards a different type of dark energy behaviour. Our model subsequently goes through another transition, returning to the Chalpygin gas-type dark energy area. This back-and-forth movement across the fixed ΛCDM point highlights the complexity and richness of the dynamics inherent in our proposed model.

e. $\{r, q\}$ profile Figure 9 illustrates the intriguing evolution of the $\{r, q\}$ parameter in our Cosmological model. At the beginning of the cosmic evolution, our model resides in the Chalpygin gas-dominated DE region, characterized by $r > 1$ and $q > 0$. This phase represents a unique state of the universe, influenced by specific properties of the Chalpygin gas. As cosmic time progresses, the model enters the Quintessence dominated DE region characterized by $r < 1$ and $q > 0$ after crossing the line associated with constant jerk value of $j = 1$. Following this, the model shows a phase transition from deceleration to acceleration and gradually enters the Chalpygin gas DE region again.

f. om Diagnostic In Figure 10, we present the interesting trend of the $Om(z)$ diagnostic with cosmic redshift z. The plot displays a consistent positive slope for all values of redshift, suggesting a Quintessence-type nature of dark energy. This finding indicates that the universe's expansion is driven by a dynamic and evolving form of dark energy. However, what makes the results even more fascinating is the brief interval of cosmic redshift, specifically $4.5 \leq z \leq 6.5$, where the slope of $Om(z)$ becomes nearly zero. This intriguing behavior hints at the presence of cosmological constant-type dark energy during this specific range of redshifts.

g. Information Criteria Based on the values presented in Table II, we can provide a comprehensive comparison between the New Model and the ΛCDM Model using various statistical measures, including $\chi^2_{\rm min}$, $\chi^2_{\rm red}$, AIC, ΔBIC, BIC, and ΔBIC. The $\chi^2_{\rm min}$ for the New Model is lower than that of the ΛCDM Model, indicating a better fit of the New Model to the data in terms of minimizing the total χ^2. The $\chi^2_{\rm red}$ values for both models are quite similar, suggesting that both models provide reasonable fits to the data when considering the number of degrees of freedom. The AIC value for the New Model is higher than that of

the ΛCDM Model, indicating that the ΛCDM Model has a better balance between goodness of fit and model complexity according to AIC. The calculated ΔAIC of 0.69084 suggests that the New Model is moderately supported compared to the ΛCDM Model. This value falls within the range of $(0, 2)$, indicating that the New Model has some level of support according to ΔAIC. The BIC value for the New Model is higher than that of the ΛCDM Model, reinforcing the idea that the ΛCDM Model is preferred in terms of model complexity and goodness of fit according to BIC. The ΔBIC value of 26.4774 suggests moderate support for the New Model over the ΛCDM Model, as it falls within the range of $(4, 7)$. This indicates that the New Model is less favored compared to the ΛCDM Model based on BIC. The evidence suggests that the ΛCDM Model has a better fit and is moderately supported over the New Model. The lower values of $\chi^2_{\min}$ and AIC for the ΛCDM Model indicate its improved goodness of fit and model selection. Additionally, the calculated ΔBIC value of 26.4774 indicates that the New Model is less favored compared to the ΛCDM Model, falling within the range of models that are less supported according to BIC.

XI. DISCUSSIONS AND CONCLUSIONS

The authors of the paper presented a cosmological model to study the evolution of the Universe based on a new parametrization of the deceleration parameter. The model considered a spatially flat, homogeneous, and isotropic Friedmann-Lemaître-Robertson-Walker (FLRW) universe filled with radiation, dark matter (DM), and dark energy (DE). They derived the Friedmann equations and the energy conservation equation for the universe and considered separate conservation equations for radiation, DM, and DE. The new model proposed for the deceleration parameter was given as

$$q_d(z) = q_0 + \frac{\alpha + (1+z)^\beta}{q_1 + q_2(1+z)^\beta}$$

where q_0, q_1, q_2, α, and β are constants. The model was then tested against observational data from various sources, including cosmic chronometers, type Ia supernovae, baryon acoustic oscillations, and cosmic microwave background measurements. The comparison was done using the chi-square statistic, and a MCMC method was employed for parameter estimation and uncertainty estimation. The analysis showed that the model's predictions were in good agreement with the observational data. The best-fit values of the free parameters Ω_{r0}, Ω_{m0}, q_2, q_1, q_0, α, and β were obtained using the MCMC method. These values allowed the authors to understand the constraints imposed by the observational data on the model. We also compared our proposed cosmological model with observational data and the well-established ΛCDM paradigm. We found that our model's predictions aligned closely with the observed data from Cosmic Chronometers and type Ia supernovae (SNIa), indicating its ability to describe the universe's expansion history. Additionally, we identified slight discrepancies between our model and the ΛCDM model at higher redshifts, suggesting the presence of unique features in our model at those epochs. The cosmographic results of our new cosmological model demonstrate its remarkable ability to describe the observed universe and its expansion history. The model exhibits excellent agreement with the standard ΛCDM paradigm at higher redshifts. However, the real excitement lies in its prediction of a super-accelerated expansion in the distant future, in contrast to the de Sitter phase predicted by ΛCDM. This finding implies the presence of dark energy driving the accelerated expansion. The evolution of the jerk parameter in our model shows intriguing behavior, with a reversal in its decline around $z \sim 4.25$, leading to a minimum value around $z \sim 1$. This departure from the ΛCDM model highlights unique dynamics in our proposed model. Similarly, the snap parameter displays a continuous decline, deviating consistently from the ΛCDM predictions, particularly near the present time. The $\{r, s\}$ and $\{r, q\}$ profiles demonstrate fascinating journeys through different dark energy regions, indicating transitions between Chalpygin gas-type and Quintessence-type dark energy behaviors. These transitions further differentiate our model from the standard ΛCDM. The $Om(z)$ diagnostic suggests that our model is driven by Quintessence-type dark energy with a brief interval of nearly constant behavior hinting at cosmological constant-type dark energy at specific redshifts. Regarding the information criteria, our model has slightly less support than the ΛCDM model, but both models adequately fit the observed data. Our new cosmological model presents a compelling alternative to the ΛCDM paradigm, capturing unique aspects of cosmic expansion and offering valuable insights into the nature of dark energy.

A novel cobalt(II) acetate complex bearing lutidine ligand: a promising electrocatalyst for oxygen evolution reaction†

Deepika Tanwar,‡[ab] Priya Jain,‡[c] Deepali Ahluwalia,[d] Athul Sudheendranath,[c] Sajesh P. Thomas,[c] Pravin P. Ingole *[c] and Umesh Kumar *[a]

Developing cost-effective electrocatalysts using earth-abundant metal as an alternative to expensive precious metal catalyst remains a key challenge for researchers. Several strategies are being researched/tested for making low-cost transition metal complexes with controlled electron-density and coordination flexibility around the metal center to enhance their catalytic activity. Herein, we report a novel lutidine coordinated cobalt(II) acetate complex $[(3,5\text{-lutidine})_2Co(OAc)_2(H_2O)_2]$ (**1**) as a promising electrocatalyst for oxygen evolution reaction (OER). Complex **1** was characterized by FT-IR, elemental analysis, and single crystal X-ray diffraction data. The structure optimization of complex **1** was also done using DFT calculation and the obtained geometrical parameters were found to be in good agreement with the parameters obtained from the solid state structure obtained through single crystal X-ray diffraction data. Further, the molecular electrostatic potential (MEP) maps analysis of complex **1** observed electron rich centers that were found to be in agreement with the solid-state structure. It was understood that the coordination of lutidine as a Lewis base and acetate moiety as a flexible ligand will provide more coordination flexibility around the metal center to facilitate the catalytic reaction. Further, the electron rich centers around metal center will also support the enhancement of their catalytic activity. Complex **1** shows impressive OER activity, even better than the state-of-the-art IrO_2 catalyst, in terms of turnover frequency (TOF: 0.05) and onset potential (1.50 V *vs.* RHE). The TOF for complex **1** is two and half times higher, while the onset potential is *ca.* 20 mV lower, than the benchmark IrO_2 catalyst studied under identical conditions.

Introduction

The development of cost-effective and clean energy is of considerable scientific interest due to the rapid increase in energy consumption and environmental crisis associated with fossil fuels.[1–3] Electrochemical water splitting is one of the promising strategies, which involves the hydrogen evolution reaction (HER) and oxygen evolution reaction (OER).[4] However, the commercialization of these devices is largely limited due to the high over-potential and sluggish kinetics of the OER, which requires highly active electrocatalysts.[5] Henceforth, in the last few decades, many research groups have been conducting their work in this area to develop efficient electrocatalysts for OER. Initially, precious metals (Pt, Ir and Ru) based catalysts were focused due to their robust nature and high activity.[6–10] In the recent past, the demand for cost-effective earth-abundant transition metal based electrocatalysts has accelerated to overcome the high cost and lower abundance of precious metals.[11–14] However, the OER activity of these transition metal-based catalysts has not been comparable to the Pt-group metals. Hence, the foremost challenge for chemists is to design and develop novel cost-effective, earth abundant and highly efficient catalysts as well as strategies to boost their activity for OER.

Cobalt-based catalysts have been significantly studied to facilitate the OER.[15,16] For instance, cobalt oxides,[17–20] hydroxides,[21,22] sulfides,[23–25] selenides,[26,27] phosphates/phosphides,[28,29] and nitrides[30,31] have been established as advanced electrocatalyst for OER. Beside these materials, several molecular cobalt complexes have also been found as efficient electrocatalyst for OER in recent times.[32–38] D. G. Nocera's group reported a β-octafluoro Co(III) xanthene hangman corrole as the effective OER catalyst under operating conditions at

modest overpotential.[32] J. T. Groves *et al.* reported a cationic cobalt–porphyrin complex as an efficient homogeneous electrocatalyst for water oxidation to study the role of buffer on the reactivity.[33] C. N. Verani *et al.* designed a novel phenolate rich cobalt(III) complex which acts as an excellent water oxidation catalyst at moderate overpotential of 0.5 V.[34] L. Sun *et al.* used cobalt porphyrin complexes as OER catalysts and found that the *in situ* generation of cobalt oxides thin film acts as a real catalyst.[35] Recently, M. Nath *et al.* reported a cobalt complex bearing selelno-based ligand as OER electrocatalyst with very low overpotential of 320 mV.[37] Zhen-Tao Yu *et al.* reported a cobalt(IV) diacetato complex bearing a substituted bipyridine dianionic ligand as highly active electrocatalyst for OER at an overpotential of only 360 mV at pH = 6.[38] In case of molecular cobalt catalyst, many research groups reported that the *in situ* formation of $Co(OH)_2$/cobalt oxide are the true catalyst.[19,35,39]

However, the nature of *in situ* generated catalyst depends upon the molecular nature of parent catalyst and hence the efficacy of the catalyst solely depends on role of parent complex. Overall, these representative examples of Co-complex based OER catalysts highlights the chemistry of ligands towards controlling the electron-density around the Co-metal center or an ability to partially oxidize the complex to make thin films of cobalt oxide. Hence, it was thought that the Lewis base ligand can control the electron-density around metal center to enhance their catalytic activity. Further, the coordination of Lewis base and acetate moiety will provide more coordination flexibility around metal center which supports the substrate coordination/removal during catalysis to facilitate the reaction cycle.[38,40] In this view, we report a novel cost-effective lutidine coordinated cobalt(II) acetate complex $[(3,5\text{-lutidine})_2Co(OAc)_2(H_2O)_2]$ (**1**) as promising electrocatalytic activator for OER. The obtained data after OER electrocatalytic analysis indicates that complex **1** is better performer than the state-of-the-art IrO_2 catalyst.

Experimental

Materials and methods

The details of materials and methods have been given in ESI.† The details of X-ray diffraction data collection and crystallographic information are also given in the ESI (see Table S1†).

Synthesis of complex 1

$Co(OAc)_2 \cdot 4H_2O$ (250 mg, 1 mmol) was dissolved in acetonitrile to get homogeneous solution, to which 3,5-lutidine (214 mg, 2 mmol in 5 mL acetonitrile) was added dropwise and stirred at room temperature for 3 h. The resulting solution was reduced using rotary evaporator and then kept at room temperature for crystallization. Crystals suitable for single crystal X-ray diffraction data of $[(3,5\text{-lutidine})_2Co(OAc)_2(H_2O)_2]$ (**1**) were obtained after five days. Yield: 94% (0.402 g, 0.940 mmol). FT-IR (KBr, ν in cm^{-1}): 3425 (br) for $\nu(H_2O)$; 1572 (s) for $\nu_{asym}(OCO)$; and 1419 (s) for $\nu_{sym}(OCO)$. Anal. calcd (%) for $C_{18}H_{28}CoN_2O_6$: C, 50.59; H, 6.60; N, 6.56. Found C, 51.02; H, 6.57; N, 6.71.

Electrochemical analysis

The electrochemical analysis for oxygen evolution reaction was performed in a three-electrode electrochemical setup, using Glassy carbon (GC) electrode with geometric area of 0.07 cm^2 as working electrode, Hg/HgO (1 M NaOH) ($E^0 = 0.118$ V *vs.* RHE) as reference electrode and graphite rod as counter electrode in 1 M KOH (pH = 14). The GC electrode was modified with catalyst ink prepared by dispersing the catalyst in 3 : 1 100 μL isopropanol and water mixture using ultrasonicator. Carbon black acetylene was added as an additive in the catalyst to separate the catalyst layer with the ratio of catalyst to carbon black was 8 : 2. The loading of the catalyst on the GC surface was about 0.05 mg, which corresponds to normalized loading of 0.714 mg cm^{-2}. Similarly, IrO_2 obtained from Sigma Aldrich was also used to modify the electrode using same procedure for comparative study. All the potentials were converted to reversible hydrogen electrode (RHE) by using the following eqn (1):[41]

$$E_{RHE} = E_{Hg/HgO/OH^-} + 0.118 + (0.059\ pH) \quad (1)$$

The electrochemical measurements were performed on MetrohmAutolab 204 N instrument. The current density was normalized according to geometric surface area and electrochemical surface area. The overpotential (η) was calculated by subtracting the standard potential of water oxidation (1.23 V *vs.* RHE) from the experimental potential observed. The Double layer capacitance (C_{dl}) calculated from the slope of the plot of current density *vs.* scan rate, was used to estimate the electrochemically active surface area (ECSA) using eqn (2).

$$ECSA = C_{dl}/C_s \quad (2)$$

where C_s, is the specific capacitance of the atomically smooth surface of the material and is taken to be 0.04 mF cm^{-2}.[42]

The Tafel slope was calculated by using the eqn (3):

$$\eta = b \log j + a \quad (3)$$

where η is the overpotential and b is the Tafel slope. The electrochemical impedance spectroscopy (EIS) measurements were performed by applying AC potential with 10 mV amplitude in a frequency range of 0.1 Hz to 10^5 Hz at 1.62 V *vs.* RHE. The catalyst stability was analyzed by drop casting the catalyst material on glassy carbon plate electrode in 1 M KOH for 14 hours at a constant potential 1.65 V *vs.* RHE. After the electrochemical stability, the spent catalyst material was used for post catalytic characterizations *i.e.*, FTIR, Raman, SEM, EDX and XPS.

Calculation of TOF

The values of TOF were evaluated by assuming all the metal ions as the active catalytic centers as per the following eqn (4).[43]

$$TOF = J \times A/4 \times F \times n \quad (4)$$

Here, J, A, F and n are the observed current density, geometrical surface area of the working electrode (0.07 cm^2), Faraday

Open Access Article. Published on 15 August 2023. Downloaded on 9/5/2023 10:24:55 AM.

constant (96 485 C mol^{-1}) and number of moles of active sites present in the catalyst. Since four electrons are needed to evolve one mole of O_2, so the term $\frac{1}{4}$ is used. Further, n was determined by dividing the mass of material loaded (0.05 mg) onto the electrode surface to the molecular mass of the sample (eqn (5)).

$$n = m/M \quad (5)$$

$$n = \frac{0.05 \times 10^{-3}\ \text{g}}{413\ \text{g mol}^{-1}} = 1.21 \times 10^{-7}\ \text{moles}$$

Results and discussions

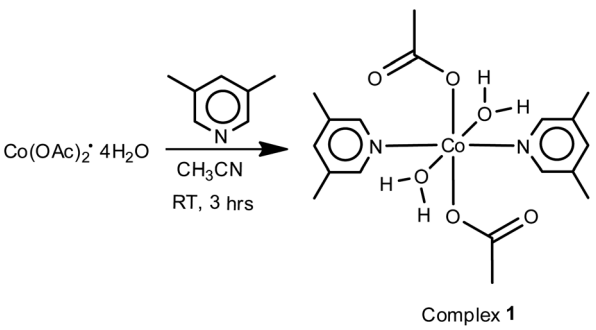
Synthesis

The schematic diagram for synthetic details of complex **1** is given in Scheme 1. The reactions of $Co(OAc)_2 \cdot 4H_2O$ with 3,5-lutidine in 1 : 2 ratio in acetonitrile at room temperature afforded complex **1** in quantitative yields. IR spectra of complex **1** (Fig. SI-3a in ESI†), shows bands at 1572 (s) and 1419 (s) for ν_{asym}(OCO) and ν_{sym}(OCO) characteristic for monodentate acetate moieties. The broad band at 3425 cm^{-1} confirms the presence of coordinated water molecules. Further, the bands at $\rho r(H_2O)$ (710 cm^{-1}) and $\rho w(H_2O)$ (649 cm^{-1}) also support the presence of coordinated water molecules.[44]

Crystal structure

The molecular structure of complex **1** was determined by single-crystal X-ray diffraction data. The molecular structure of complex **1** with the atom labeling scheme is shown in Fig. 1. Complex **1** consists of a Co(II) atom coordinated by two 3,5-lutidine, two water molecules and two acetate moieties in monodentate mode to afford an octahedral geometry. The $Co1–O1_{water}$, $Co1–O2_{acetate}$ and $Co1–N1_{lutidine}$ distances in complex **1** are 2.131(1), 2.068(1) and 2.153(2) Å, respectively.

Significant hydrogen-bond parameters observed in complex **1** are listed in Table 1. The oxygen atom (O1) of water molecules in **1** act as hydrogen-bond donor, one to the carbonyl oxygen (O3) of the monodentate acetate within the molecule (intramolecular hydrogen bonding) and another with the carbonyl oxygen (O3) of the monodentate acetate of adjacent molecule



Scheme 1 Synthesis scheme of complex **1**.

(intermolecular hydrogen bonding) as depicted in Fig. 2a. The aforementioned hydrogen-bonding network grows to afford a three-dimensional supramolecular packing along the *c*-axis, as depicted in Fig. 2b. From packing diagram of complex **1**, it was also observed that the crystal structure has various hexagonal vacant pores formed by the supramolecular assembly which could be useful for enhancing their catalytic, separation and gas storage properties. The void volume has also been calculated to be 114 $Å^3$ per unit cell. Although the structural analysis shows a solvent accessible void volume of around 194 $Å^3$ per unit cell, it is not apparent that water molecules can enter this void and the residual density value (0.7 Å) also do not imply the presence of water molecules inside this channel. The porous nature of complex **1** is also clearly visualized in FESEM image as depicted in Fig. SI-1 in ESI.†

Computational studies

Frontier molecular orbitals. The optimized geometry of complex **1** is depicted in Fig. SI-2.† The HOMO (highest occupied molecular orbital) and LUMO (lowest unoccupied molecular orbital) along with HOMO−1 and LUMO+1 have been computed through DFT using GaussView 5.0 software. Generally, the electron donating orbital is regarded as HOMO and electron accepting is LUMO. These two orbitals are most interacting in the complex, and thus called frontier orbitals.[45–48] The energy gaps were computed at LANL2DZ basis set. In

complex **1**, the HOMO and LUMO energies are −5.19 and −1.27 eV, respectively, leading to an energy gap of 3.92 eV (Fig. 3). Determining the energy gap is important because it displays the charge transfer behavior in a system,[49] and the chemical reactivity and stability of the molecule as a whole depends largely on the energy gap. Larger the HOMO–LUMO energy gap, greater the stability and lower is the chemical reactivity of the molecule and *vice versa*.[50,51] From the frontier molecular orbital (FMO) diagram, it has been observed that the electron density is densely accumulated around the metal ion and oxygen atoms in HOMO, while it is dispersed on and around the pyridine rings in LUMO. A slightly more gathered electronic density at the metal center is observed in HOMO−1. Thus, it is believed that the metal center is behaving as an active site for the incoming substrate to get adsorbed/attached. The subsequent steps for OER mechanism are expected to proceed from here.

Molecular electrostatic potential surfaces. The molecular electrostatic potential (MEP) maps provide information about the relative polarity of a particular system. The MEP of complex **1** (Fig. 4) has been computed through DFT mode, using B3LYP level of theory and LANL2DZ as basis set. The scale having different colors here indicates varied electrostatic potentials within a molecular system.[52] The order of potentials from low to high goes as red < orange < yellow < green < blue. On one end of the scale, the blue color suggests the presence of electropositive potential, while on the other end, the red color indicates the electronegative potentials, and the green color specifies zero potential. In this way, we can understand the relative polarity of a particular system.[53,54] In the present case, we observe a deep red color at the oxygen centers of acetate ligand while a positive potential around the substituted pyridine ring. Lone pair of electrons is generally associated with a negative potential; thus, a reddish coloration is observed around the oxygen centers. In addition to this, the yellowish coloration around the metal

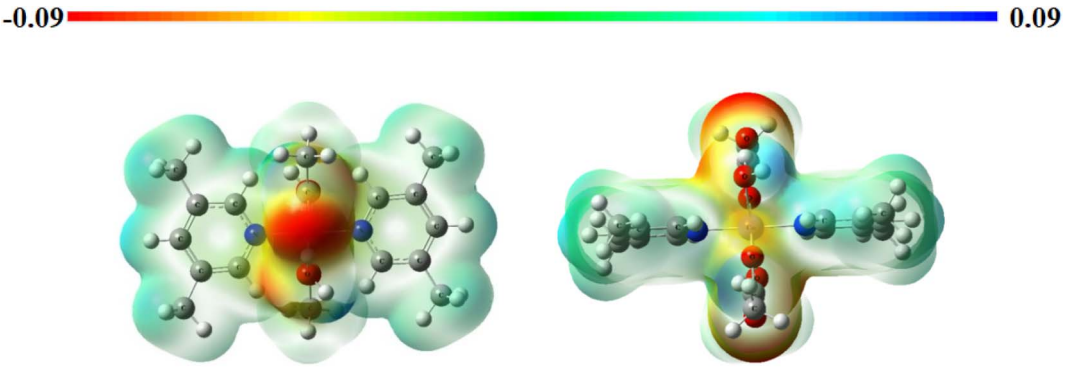

Fig. 4 Molecular electrostatic potential maps for complex **1** (iso-surface value = 0.002).

center depicts the presence of electron density in this region. These observations can be well correlated with that of FMOs, as discussed above.

Non-covalent interactions. The reduced gradient of density (RDG) plots reveals information about weak, intramolecular, and intermolecular interactions.[55,56] E. R. Johnson first introduced the RDG function, which is density and its first derivative together, representing the divergence from homogeneous electronic distribution.[57] It is a dimensionless quantity. Based on the reduced density gradient, s and electron density, ρ, the NCI index plots are drawn as per eqn (6)

$$s = 1/(2(3\pi^2)^{1/3}) \times |\nabla\rho|/\rho^{4/3} \quad (6)$$

The kind of interactions existing within a molecule is further understood by the Laplacian of density, $\nabla^2\rho$, which is the sum of three eigenvectors λ_1, λ_2 and λ_3. In a certain system, λ_3 differs along the internuclear direction, whereas the other two components (*viz.* λ_1 and λ_2) describe the variation of density in the plane normal to that of λ_3 eigenvector. The value of eigenvector λ_2 mainly suggests the type of interaction present in a system. For bonding interactions, such as H-bond, the value of $\lambda_2 < 0$, while for non-bonding interactions λ_2 is greater than zero. The value of λ_2 is nearly zero for weak van der Waals interactions.[57,58] The colors in RDG plot also suggest these interactions visually. For example, the blue color stands for H-bonds, green color suggests the presence of weak van der Waals interactions and the red color depicts the steric effect.[54] Fig. 5 represents the non-covalent interactions in complex **1** and their two-dimensional RDG plots. In complex **1**, the RDG plot displays the presence of H-bonds and steric repulsions co-existing within the complex.

Oxygen evolution activity in alkaline electrolyte

The electrocatalytic activity of the as prepared complex **1** was evaluated using Linear Sweep voltammetry (LSV) at scan rate 10 mV s^{-1} in 1 M KOH solution. The complex **1** showed onset potential of 1.50 V *vs.* RHE and high current density of 100 mA cm^{-2} at 1.87 V *vs.* RHE. The observed results towards OER electrocatalysis are even better than the state-of-the-art IrO_2 catalyst which showed OER onset potential of 1.52 V *i.e.*, 20 mV higher than complex **1**. The comparative LSV is shown in Fig. 6a. The kinetics of the catalysis towards OER of the complex **1** was also compared to that of IrO_2 catalyst using corresponding Tafel slope values. The commercial IrO_2 exhibited a slope value of 64.6 mV dec^{-1}, whereas the complex **1** showed 47.7 mV dec^{-1}. Tafel slope indicating that our catalyst is showing facile kinetics towards OER, higher than commercial IrO_2 catalyst (Fig. 6b). The complex **1** showed an overpotential of 530 mV to reach 40 mA cm^{-2} which is 70 mV lower than that of IrO_2 (Fig. 6c). The comparison with similar materials in literature

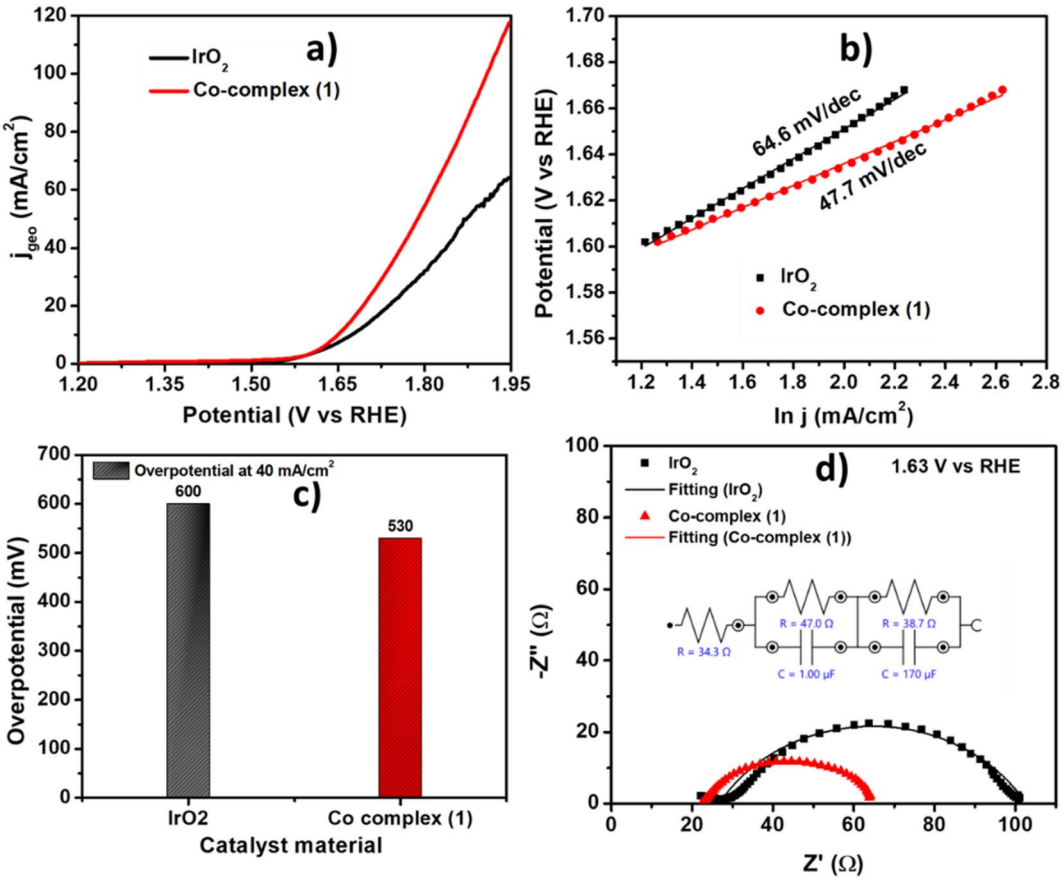

Fig. 6 (a) Comparison of LSV polarization curve for complex **1** and IrO_2 at 10 mV s^{-1} in 1 M KOH, (b) the corresponding Tafel plots, (c) the overpotential comparison at 40 mA cm^{-2} and (d) the Nyquist plot comparison for complex **1** and IrO_2.

was also shown in Table 2 indicating the appreciable activity of our catalyst towards OER.[34,36–38,59–61] The electrochemical impedance spectroscopy (EIS) was performed at a potential of 1.63 V *vs.* RHE to determine the charge transfer parameter for complex **1**. The diameter of the Nyquist plot is related to the charge transfer resistance at the electrode–electrolyte interface. Nyquist plots shown in Fig. 6d, showed that the complex **1** has low charge transfer resistance of 43.5 Ω, also lower than IrO_2 showing R_{ct} of 63.8 Ω which is also consistent with the lower overpotentials required to reach higher current density from the LSV and Tafel analysis.

The C_{dl} was calculated by performing CV at different scan rates (Fig. 7a and b) and plotting the current density *vs.* scan rate (Fig. 7c) which was found to be 81.3 μF and 75.8 μF for complex **1** and IrO_2 complex respectively. The current density normalized with ECSA was also shown in Fig. 7d, indicating the good electrocatalytic activity of Co-complex **1** in terms of high

Table 2 Comparison of the efficacy molecular cobalt electrocatalyst for OER

Cobalt complexes	Electrolyte	Overpotential (mV)/current density (mA cm^{-2})	Tafel slope (mV dec^{-1})	TOF	Ref.
$[(Lut)_2Co(OAc)_2(H_2O)_2]$	1 M KOH	410 ± 20/10.0	45.7	0.05 s^{-1}	This work
$[Co(LN_2O_3)H_2O]$	Sodium borate (pH = 11)	500	—	—	34
$[(L_{monoanionic})_2Co(CH_3OH)_4]^a$	Phosphate buffer (pH = 9)	520/0.5	—	5 s^{-1}	36

current density towards electrocatalytic OER. The summary of the OER electrochemical parameters is shown in Table 3.

The turn over frequency, which indicates the intrinsic activity of the catalyst was calculated by using the equation given in the experimental section. The complex **1** showed the two times higher TOF ($0.05\ s^{-1}$) at 1.73 V as compared to IrO_2 ($0.02\ s^{-1}$) (Fig. 8a). The long term stability of complex **1** was also checked using chronoamperometry method, by applying a constant potential of 1.65 V for 14 hours. It was observed (Fig. 8b) that the catalyst showed high stability with retention of 95% current. The CV curves before and after the OER stability are given in the inset of Fig. 8b, showing a slight decrement in

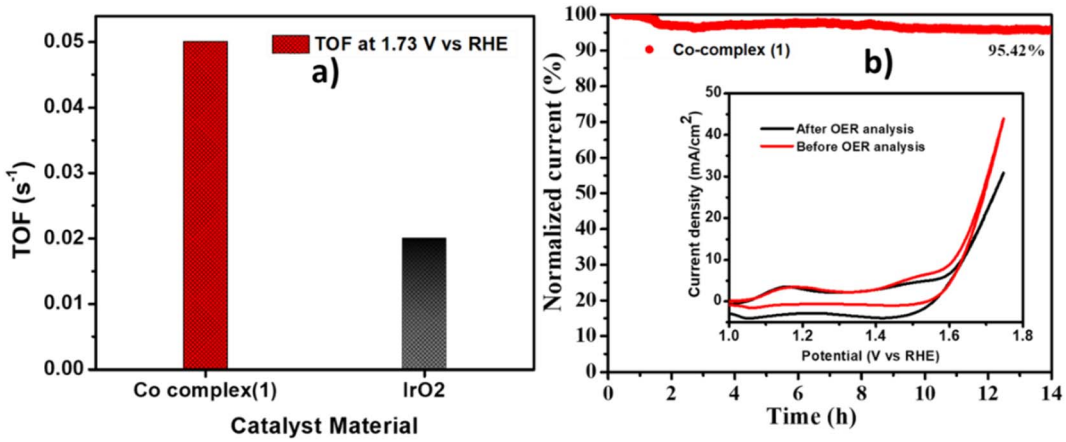

Fig. 8 (a) The comparison of TOF at 1.73 V *vs.* RHE for Co-complex (**1**) and IrO_2, (b) chronoamperometry curve at 1.65 V *vs.* RHE for 14 hours for Co-complex (**1**).

TOF (1.73 V *vs.* RHE)	0.05	0.02
α	0.59	0.56

the current density after 14 hours of stability, indicating robustness of the catalyst.

The post catalytic characterisation of the spent electrodes (after OER analysis) were performed after the durability test on the Co-complex (**1**). The post catalytic FTIR (Fig. SI-3a in ESI†) shows the peak at 3431 cm^{-1} corresponding to the –OH vibration, 2921 cm^{-1} for Co–OH stretching. The peak present at 1633 cm^{-1} corresponds to Co–O.[62,63] These peaks in the post OER FTIR suggests that the formation of $Co(OH)_2$/CoOOH could act as the main active sites for the OER. However, along with these, some peaks matching with the initial spectra at 1038 and 1153 cm^{-1} indicate that the complex **1** is not totally degraded/decomposed after catalysis. The spectra suggests that the oxidation of Co(II) to Co(III) occurs at high oxidation potential and Co act as the catalytic centre for OER. The FESEM image after catalysis shows agglomeration of the particles (Fig. SI-3b in ESI†). The EDX spectra as shown in Fig. SI-4a in ESI†) indicates the presence of C, N, Co and O in the Co-complex (**1**). After catalysis (Fig. SI-4b in ESI†), the EDX of the sample displays an increase in the O content as well as presence of Co, C, N and K (due to KOH as electrolyte) indicating the presence of $Co(OH)_2$ at the surface of the catalyst. The elemental mapping (Fig. SI-5 in ESI†) shows the uniform distribution of the elements on the surface before and after catalysis which indicates that the complex is not totally changed to hydroxide species. This suggests that formation of thin layer of $Co(OH)_2$/CoOOH can be the reason for high activity of Co-complex (**1**) towards OER.

The X-ray photoelectron spectroscopy was performed to further understand the chemical composition and oxidation state in the pre and post catalytic OER samples as shown in Fig. 9. The Co 2p core level spectra of Co-complex (**1**) (Fig. 9a) shows two peak at 780.85 eV (Co^{2+} $2p_{3/2}$) and 796.49 eV (Co^{2+} $2p_{1/2}$) and two strong satellite peaks confirming the presence of Co^{2+} in the sample. After OER analysis, the slight shift of the Co^{2+} peak to 780.19 eV and the appearance of Co^{3+} peak at 782.18 eV is in accordance with the FTIR analysis, confirming that the formation of $Co(OH)_2$ and CoOOH at the surface.[64] The M–O and M–OH peak intensity increases in the post catalytic O 1s spectra (Fig. 9b) also showing the formation of $Co(OH)_2$ at the surface. The C 1s XPS spectra shows the presence of C–C

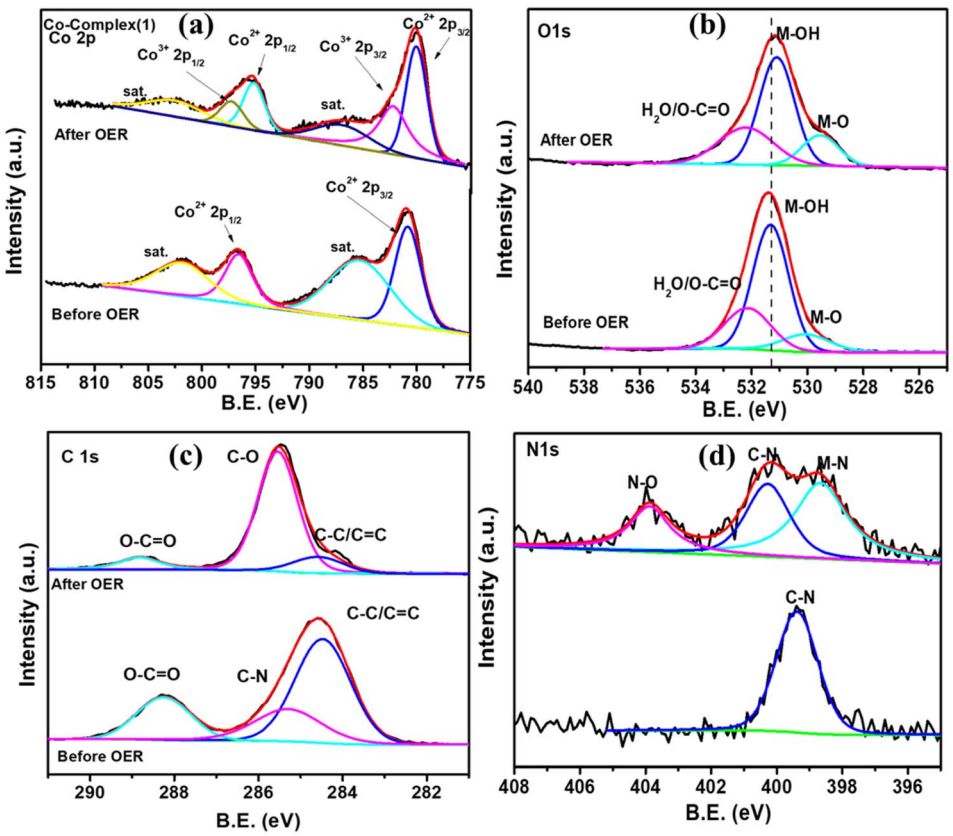

Fig. 9 XPS core level spectra comparison of (a) Co 2p, (b) O 1s, (c) C 1s and (d) N 1s before and after catalysis of Co-complex (**1**).

Open Access Article. Published on 15 August 2023. Downloaded on 9/5/2023 10:24:55 AM. This article is licensed under a Creative Commons Attribution-NonCommercial 3.0 Unported Licence.

(284.6), C–N (285.4) and O–C=O (288.2) in the pristine sample. After catalysis, the relative composition of C–C decreases and C–O increases. This indicates the oxidation of C due to the oxidative environment provided by OER. Similarly the occurance of N–O peak in N 1s spectra is also due to oxidation. Thus, the post catalytic XPS, FTIR and EDX analysis confirmed the retention of the electrocatalyst in terms of bulk composition, and formation of Co^{2+} ($Co(OH)_2$) and Co^{3+} (CoOOH) plays a crucial role during OER.

The high OER performance of the Co-complex (**1**) may have been resulted due to its highly porous connected network, high accessible Co active centres and high surface area. The interconnected network arising from the OH···O hydrogen bonding leads to a 3-D structure with hexagonal vacant pores which helped inenhancing mass transfer and ion transport at the electrode–electrolyte interface leading to high electrocatalytic performance of the Co-complex **1**.

Conclusion

We have the novel lutidine coordinated cobalt(II) acetate complex $[(3,5\text{-lutidine})_2Co(OAc)_2(H_2O)_2]$ (**1**) by simplest condensation reaction. The structure of complex **1** was determined by single crystal X-ray diffraction data and found distorted octahedral geometry around the metal center. The noncovalent interaction found in complex **1** resulted in O–H···O hydrogen-bonding network that grown in a three-dimensional structure with various hexagonal vacant pore which could be useful for enhancing their catalytic activity. The comparative study of geometrical parameters obtained from the XRD data and DFT calculations was found in good agreement. The MEP maps analysis depicted the electron rich centers in the complex **1** are also found well in agreement with the solid-state structure. It was thought that the coordination flexibility and electron rich centers around metal center will also support in the enhancement of their catalytic activity. The Co-complex **1** showed excellent electrocatalytic OER activity better than state-of-the-art IrO_2, which may be due to the 3D porous structure, rapid transport of ions and high accessible Co active sites, higher electron density, and coordination flexibility around metal center. Further, the post catalytic XPS, FTIR and EDX analysis also confirmed the retention of the electrocatalyst in terms of bulk composition, and formation of Co^{2+} ($Co(OH)_2$) and Co^{3+} (CoOOH) OER.

***Abstract*—In the last few years, Recommender systems have become extremely popular for users to extract relevant information. The applicability of recommender systems is in several domains, including e-commerce sites, social media platforms and several others. The Community detection approaches aim to detect the collective users that have similar behavior, interest, and choice. Community detection technique helps in creating a new dimension for recommender systems. This paper presents a thorough review of the Community detection approaches for recommender systems. The challenges and research directions are also discussed in the later part of the paper.**

***Index Terms*—Community Detection, Recommender Systems, Collaborative Filtering, Louvain Algorithm.**

I. Introduction

Recommender systems are algorithms that suggest products, services, or content to customers based on their preferences and past behavior. They are extensively used in many industries, such as entertainment, e-commerce, healthcare, and social media, to give personalized recommendations to users. Recommender systems have become increasingly important due to the upsurge of data and the need to filter and present relevant information to users efficiently. They help users save time and effort by automating the process of finding relevant items from a vast collection of options. Additionally, they help businesses increase user engagement, loyalty, and revenue by improving user experience and providing personalized marketing.

Community detection can be used to recognize clusters of customers with similar preferences and behaviors in a recommender system. By identifying these communities, recommender systems can produce more accurate and diverse recommendations to users. For example, users in the same community may have similar tastes in music, movies, or books and may appreciate the same recommendations. Community detection can also help address the cold start problem, which occurs when a new customer or item has little or no data available for recommendation. By leveraging the community structure, recommender systems can infer the preferences of a new customer based on the preferences of users in the same community. Moreover, community detection can help in enhancing the scalability and interpretability of recommender systems by reducing the dimensionality of the input data and providing meaningful clusters of users and items. Therefore, studying community detection in recommender systems can lead to better recommendation quality, user satisfaction, and business performance.

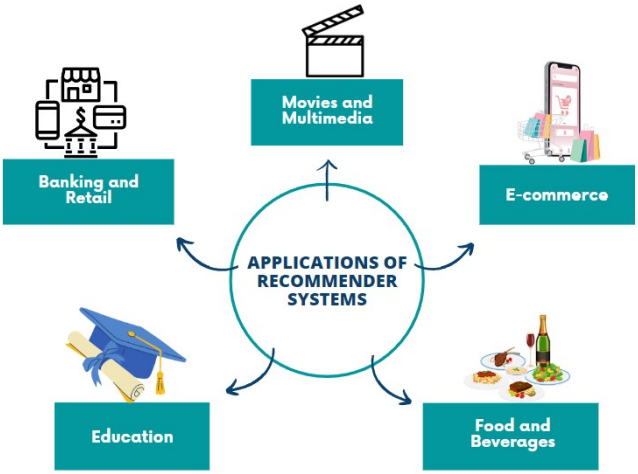

Fig. 1. Applications of Recommender Systems

II. Recommender Systems and Community Detection

A. Types of Recommender Systems

Recommender systems are extensively used in entertainment, e-commerce, social media, and many other fields to suggest items or services of interest to users. These systems can be categorized into several types based on the type of data they use, the algorithms they employ, and the output they generate. Here are some types of recommender systems:

1) Collaborative Filtering (CF): It is a very popular technique in recommender systems that relies on the past behavior of customers and items to make recommendations. This approach can be further divided into user based CF & item based CF [1].
2) Content-Based Recommender System (CBRS): It suggests products based on the similarity between the features of the products and the preferences of the user. These systems work by matching the characteristics of

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:32:27 UTC from IEEE Xplore. Restrictions apply.

the item to the customer's past behavior, which allows them to make accurate recommendations. CBRS can be further divided into two types: feature-based and model-based [2].

3) Hybrid Recommender System: It combines different types of recommenders to provide more accurate and personalized recommendations. These systems can be constructed in several ways, such as by combining CF and CBRS or using multiple CF algorithms with different weightings [3].
4) Graph-Based Recommender Systems (GBRS): It is based on graph theory and uses graph structures to model the interconnections between users and items. GBRS are particularly useful when dealing with sparse data sets, and they can be used in conjunction with other types of recommenders [4].
5) Community-Based Recommender System: It uses community detection algorithms to group customers and products into clusters based on similarity. These clusters can then be used to produce recommendations based on the behavior of similar users or items within the same cluster.

Different types of recommenders have different pros and cons, and the choice of the appropriate system depends on the nature of the problem and the available data.

B. Use of Community Detection to improve Recommender Sytems

Community detection, a popular method in network analysis, can help recommender systems to give more accurate recommendations by identifying communities or groups of users with similar preferences or behavior.

Community detection can be used to recognize clusters of customers with similar preferences or behavior, which can be used to increase the accuracy of recommender systems. For example, Gasparetti et al. [5] used community detection to enhance the accuracy of a social recommender system by identifying communities of users with similar interests. They found that incorporating community detection into the recommendation process improved the accuracy of the system, especially for users with sparse data.

Another way community detection can be used to enhance recommender systems is by identifying influential users or nodes in the network. Influential users or nodes are those that have a remarkable impact on the preferences or behavior of other users in the network. Identifying these users can help to improve the accuracy of recommendations by giving more weight to their preferences.

In addition to identifying communities and influential users, community detection can also be used to improve the diversity of recommendations. Diversity is an important factor in recommender systems, as users may want to explore new items or experiences. By identifying communities of users with different preferences or interests, recommender systems can provide more diverse recommendations. For example, Zhao et al. [6] used community detection to improve the diversity of recommendations in a social recommender system by identifying communities of users with different preferences and providing recommendations from each community.

Another way community detection can be used to enhance recommender systems is by incorporating temporal information into the analysis. Temporal information, for example, the time of user activity or the order in which items were consumed, can provide valuable insights into user behavior and preferences. Community detection can be used to identify temporal patterns in the network, which can be used to improve the accuracy of recommendations. For example, Chang et al. [6] used community detection to analyze temporal patterns in a network of users and items and found that incorporating temporal information improved the accuracy of a recommender system.

Community detection can also be used to improve the scalability and efficiency of recommender systems. Traditional recommender systems may struggle to handle large-scale networks with millions of users and items. Community detection can be used to reduce the complexity of the network by identifying communities of users with similar preferences or behavior. This can make the recommendation process more efficient and scalable. For example, the Louvain community detection algorithm [7] was proposed as a fast community unfolding method for large networks.

Overall, community detection is very important for improving the accuracy, diversity, and scalability of recommender systems. By clustering users based on their behavior within a network, community detection algorithms can identify latent user preferences, handle the cold-start problem, identify items that are popular within particular communities, improve the diversity of recommendations, and improve the scalability of recommender systems. These benefits have led to a significant increase in research on community detection for recommender systems in the last few years and are likely to continue driving innovation in the field in the future.

C. Comparison of traditional recommender systems with community-based recommender systems

Traditional recommender systems tend to use collaborative filtering and content-based approaches to generate recommendations. However, these approaches often suffer from the cold start problem, sparsity problem, and lack of diversity. In contrast, community-based recommender systems use community detection algorithms to identify groups of users with similar preferences and behaviors, leading to more accurate and diverse recommendations. Additionally, these systems can also incorporate social influence and homophily effects, further improving their recommendation quality.

[6] provides a comparison between traditional recommender systems and community-based recommender systems. The authors note that community-based approaches have shown to be more effective in handling the cold start problem by leveraging the social connections between users. Similarly, [5] emphasizes that community-based approaches can mitigate the sparsity problem by identifying groups of users

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:32:27 UTC from IEEE Xplore. Restrictions apply.

with similar preferences and increasing the overlap in their item ratings. The authors of [5] also argue that community-based recommender systems can achieve better performance than traditional methods by incorporating social influence and homophily effects, which are not captured by traditional collaborative filtering approaches.

Furthermore, several studies have compared the performance of community-based recommender systems with traditional recommender systems. For example, [8] compares the performance of community-based and traditional approaches on several benchmark datasets and shows that community-based approaches outperform coventional approaches in terms of accuracy and diversity. Similarly, [7] compares several community detection algorithms and shows that community-based approaches can achieve higher modularity and clustering quality than traditional collaborative filtering approaches.

In addition to accuracy and diversity, community-based recommender systems can also give better explanations for their recommendations. [5] argues that community-based approaches can give more transparent and interpretable recommendations by associating them with specific user communities.

Overall, community detection can be a powerful tool to improve the accuracy of recommender systems. Community-based recommender systems can address many challenges faced by traditional approaches, including the cold start problem, sparsity problem, and lack of diversity. Moreover, these systems can incorporate social influence and homophily effects, leading to more accurate and diverse recommendations. Additionally, community-based approaches can give better explanations for their recommendations, making them more transparent and interpretable to users.

III. Community Detection Algorithms for Recommender Systems

Community detection algorithms have proven to be effective tools for improving recommender systems. These algorithms aim to identify communities of users with similar preferences or behaviors, which can help to understand user interactions better and provide more accurate recommendations. In this section, we provide an overview of different community detection algorithms that can be applied to recommender systems, along with a description of how each algorithm works and its strengths and limitations [9].

One popular community detection algorithm for recommender systems is the Louvain algorithm [7]. The Louvain algorithm is an iterative algorithm that optimizes the network's modularity by iteratively moving nodes to different communities to maximize the modularity score. This algorithm is known for its speed and scalability, making it ideal for large networks. However, it can struggle with identifying communities with overlapping nodes, which is a common issue in recommender systems where users may have diverse preferences [10].

Another algorithm that has been successfully applied to recommender systems is the Label Propagation algorithm [6]. The Label Propagation algorithm works by propagating labels between nodes until the network is partitioned into communities. This algorithm is efficient and can identify overlapping communities, which makes it well-suited for recommender systems. However, it can struggle with detecting communities with sparse connections.

The Infomap algorithm is another community detection algorithm that has been used in recommender systems [8]. The Infomap algorithm works by partitioning the network into modules based on information flow. It is known for its ability to identify hierarchical community structures and its ability to detect overlapping communities. However, it can be computationally expensive and can struggle with detecting communities with few nodes.

The Spectral Clustering algorithm is another community detection algorithm that has been used in recommender systems [6]. Spectral Clustering works by identifying clusters based on the eigenvectors of the network's adjacency matrix. It is known for its ability to handle high-dimensional network data, making it well-suited for recommender systems with large amounts of data. However, it can struggle with identifying communities with overlapping nodes.

One final community detection algorithm that has been used in recommender systems is the Edge Betweenness algorithm [6]. The Edge Betweenness algorithm works by removing edges with high betweenness centrality, which helps to identify communities of nodes that are tightly connected. This algorithm is efficient and can handle networks with overlapping communities. However, it can struggle with detecting communities with a low density of connections.

Overall, each community detection algorithm has its own pros and cons, making it important to carefully choose an appropriate algorithm based on the specific characteristics of the recommender system being analyzed. For example, the Louvain algorithm may be the best choice for large-scale networks, while the Label Propagation algorithm may be best for identifying overlapping communities. By using these algorithms to recognize communities of users with similar preferences, recommender systems can better acknowledge user interactions and provide better recommendations.

IV. Applications of Community Detection in Recommender Systems

Community detection algorithms have been applied in a variety of ways to enhance the quality of recommendations and enhance user experience in recommender systems. One application is to use community detection to recognize groups of customers with similar preferences and recommend items that are favourite within their respective communities. This approach has been used successfully in various real-world recommender systems, such as Netflix, to improve the accuracy of recommendations.

Another application of community detection in recommender systems is to identify user communities based on their social connections or network structures. This approach has been used in social recommendation systems, such as

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:32:27 UTC from IEEE Xplore. Restrictions apply.

Facebook and LinkedIn, to recommend friends or professional connections based on common interests or affiliations.

Community detection can also be used to solve the "cold-start" problem in recommender systems, where new customers or products have no or limited historical data for recommendations. By identifying communities of similar users or items, recommender systems can leverage the preferences and behaviors of existing users or items in those communities to make recommendations for new customers or products.

Another application of community detection is to improve the diversity of recommendations by identifying and recommending items from different communities or clusters. This can help overcome the problem of over-recommending popular or mainstream items, and provide users with a more diversified set of recommendations.

Community detection can also be used to enhance the explainability of recommendations. By identifying the communities or clusters of products that are recommended to a customer, recommender systems can provide users with more transparent and interpretable recommendations, explaining why certain products are recommended based on their similarity to items preferred by other users in the same community [11].

In addition, community detection can be used to enhance the serendipity of recommendations, by identifying unexpected or novel items that are preferred by users in a given community, and recommending them to users outside that community. This can help increase user satisfaction and engagement, as users may discover new items that they would not have otherwise found on their own.

There are several real-world examples of successful implementations of community detection in recommender systems. For instance, Amazon uses community detection algorithms to group products and generate personalized recommendations for individual users. Facebook uses community detection algorithms to identify groups of customers with similar interests and generate personalized news feeds. LinkedIn uses community detection algorithms to identify groups of customers with similar professional backgrounds and generate personalized job recommendations.

Overall, community detection has been shown to be a valuable tool in improving the quality and user experience of recommender systems. By leveraging the similarities and connections between users and items, community detection algorithms can identify meaningful and relevant communities, and make recommendations that are more accurate, diverse, explainable, and serendipitous.

V. Evaluation Metrics for Community-based Recommender Systems

Community based recommender systems (CBRS) have gained significant attention in recent years due to their ability to provide personalized and accurate recommendations by leveraging community structure in the data. However, evaluating the performance of CBRS presents a unique challenge, as traditional evaluation metrics used for recommender systems may not be applicable or appropriate for community-based approaches. Therefore, researchers have proposed and adapted various evaluation metrics to calculate the performance of CBRS.

One commonly used metric for evaluating the performance of CBRS is Normalized Discounted Cumulative Gain (NDCG) [12], which is a widely used metric in traditional recommender systems. NDCG measures the ranking quality of the recommended items, taking into account both relevance and position of the items in the ranked list. Another commonly used metric is Precision, which measures the fraction of relevant items in the top-K recommended items. Both NDCG and Precision have been adapted for community-based approaches and widely used to evaluate their performance.

Community-based Precision (CP) is another metric that has been proposed specifically for community-based approaches [13]. CP measures the proportion of items recommended from the same community as the user, indicating the ability of the CBRS to capture community preferences. A related metric is Intra-Community Precision (ICP), which measures the proportion of recommended items from the same community as the user that are also relevant to the user. These metrics reflect the ability of the CBRS to capture both the user's individual preferences and the preferences of their community.

Other evaluation metrics that have been proposed for CBRS include Diversity and Coverage. Diversity measures the variety of recommended items, and Coverage measures the proportion of items that are recommended at least once. These metrics are important in ensuring that the CBRS provides an extensive range of recommendations that appeal to a wide range of users.

When comparing evaluation metrics between CBRS and traditional recommender systems, it is important to note that CBRS typically outperform traditional approaches in terms of NDCG and Precision. However, traditional approaches tend to perform better in terms of Diversity and Coverage. This suggests that CBRS are better suited for providing personalized recommendations to users within specific communities, while traditional approaches are better suited for providing a broad range of recommendations to a wider audience.

In conclusion, evaluating the performance of CBRS presents unique challenges, and traditional evaluation metrics may not be applicable or appropriate. Metrics such as NDCG, Precision, CP, ICP, Diversity, and Coverage have been proposed specifically for CBRS and have been shown to be effective in evaluating their performance. When comparing evaluation metrics between CBRS and traditional recommender systems, it is essential to consider the specific goals and audiences of each approach.

VI. Challenges

Data sparsity is a common problem in recommender systems, where most users only rate a small fraction of the available items. This results in a sparse user-item rating matrix that is difficult to analyze and model. When applying community detection to such data, the sparsity problem becomes even more pronounced, as the number of edges between customers

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:32:27 UTC from IEEE Xplore. Restrictions apply.

and products decreases, making it difficult to detect meaningful communities. To overcome this challenge, researchers have proposed various techniques, such as incorporating external data sources and leveraging user social networks to supplement the user item rating matrix [14].

Scalability is another significant challenge faced in applying community detection to recommender systems. As the size of the user-item rating matrix increases, the computational complexity of community detection algorithms also increases, making it difficult to perform community detection in real-time on large-scale datasets. To address this challenge, researchers have proposed several scalable community detection algorithms, such as MapReduce-based algorithms and distributed clustering algorithms.

Another challenge faced in applying community detection to recommender systems is the interpretation of the detected communities. In many cases, the detected communities may not have a clear interpretation in terms of user preferences or interests. This makes it difficult to use the detected communities to improve the quality of recommendations. To address this challenge, researchers have proposed various methods, such as incorporating domain knowledge and incorporating explicit feedback from users.

In addition to the challenges discussed above, applying community detection to recommender systems also raises privacy concerns, as the analysis of user-item ratings may reveal sensitive information about users' preferences and behaviors. Therefore, it is essential to ensure that appropriate privacy-preserving techniques are employed when applying community detection to recommender systems [15].

In conclusion, applying community detection to recommender systems presents several challenges, including data sparsity, scalability, and interpretation of the detected communities. These challenges require innovative solutions, such as incorporating external data sources, developing scalable algorithms, incorporating domain knowledge, and employing privacy-preserving techniques. Addressing these challenges is critical for improving the accuracy of recommendations in recommender systems and providing personalized experiences to users.

VII. Future directions for research

Community detection in recommender systems has emerged as a promising technique for personalized and accurate recommendations. However, there is still a lot of research to be done in this area, especially in incorporating user feedback and social network information.

One future direction for research is the integration of user feedback into the community detection process. Currently, community detection algorithms are mostly unsupervised and rely on the underlying data structure to identify communities. However, user feedback, such as ratings or reviews, can provide valuable information about the user's preferences and interests, which can be used to refine the community structure. Several studies have proposed incorporating user feedback into the community detection process, such as the work by [16], who proposed a feedback-based community detection algorithm that incorporates user preferences to improve the accuracy of the recommendations.

Another area for future research is the integration of social network information into the community detection process. Social networks can provide valuable information about the relationships between users and the communities they belong to, which can be used to enhance the accuracy and relevance of the recommendations. Several studies have explored the use of social network information in community detection for recommender systems, such as the work by [17], who proposed a social network-based community detection algorithm that consider the relationships between users and their social network.

Furthermore, the scalability of community detection algorithms in the context of recommender systems is another area for future research. With the increasing size of data in recommender systems, traditional community detection algorithms may not be scalable and efficient enough to handle large datasets. Several studies have proposed scalable community detection algorithms, such as the work by [18], who proposed a fast algorithm for detecting communities in large-scale networks based on the MapReduce framework.

In addition to the above, there is also a need to explore the use of deep learning for community detection in recommender systems. Deep learning techniques, such as neural networks, have shown promising results in various fields and can potentially enhance the accuracy and scalability of community detection algorithms in recommender systems. Several studies have explored the use of deep learning for recommender systems, such as the work by [19], who proposed a deep neural network based model for personalized recommendation.

In conclusion, there are several future directions for research in community detection for recommender systems, including the incorporation of user feedback and social network information, scalability of algorithms, and the exploration of deep learning techniques. These directions can potentially enhance the accuracy, relevance, and scalability of community-based recommender systems and provide personalized recommendations to users.

VIII. Case Studies and Use Cases

Community detection in recommender systems has shown great potential to enhance the performance of recommendation algorithms in various industries such as social media, e-commerce, and entertainment. In this section, we will discuss several case studies and use cases that illustrate the effectiveness of community detection in recommender systems.

One example of the successful implementation of community detection technique in recommender systems is Amazon's "Customers Who Bought This Item Also Bought" feature. Amazon uses community detection algorithms to recognize groups of users with similar purchase histories, and then recommends items based on the purchasing behavior of those groups. This approach has been shown to increase customer satisfaction and drive sales [20].

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:32:27 UTC from IEEE Xplore. Restrictions apply.

Another example is the social media platform Twitter, which uses community detection algorithms to suggest relevant accounts for users to follow based on their interests and activity. Twitter's "Who to Follow" feature utilizes community detection to identify users who share similar interests and recommends them to each other [21].

In the entertainment industry, community detection has been used to improve movie recommendations on platforms such as Netflix. Netflix's recommendation algorithm utilizes community detection to identify groups of users with similar viewing histories and recommends movies based on the preferences of those groups. This approach has been shown to significantly increase user engagement and satisfaction with the platform.

Community detection has also been applied in the healthcare industry to improve patient outcomes. For example, community detection algorithms have been used to identify groups of patients with similar medical histories and recommend personalized treatment plans based on the preferences of those groups.

In addition to the industries mentioned above, community detection has also been successfully applied in other domains such as education, finance, and transportation. For example, in education, community detection algorithms are used to identify groups of students with similar learning preferences and recommend personalized learning materials [22]. In finance, community detection algorithms are used to identify groups of investors with similar investment portfolios and recommend personalized investment strategies. In transportation, community detection algorithms are used to identify groups of commuters with similar travel patterns and recommend personalized commuting routes.

In conclusion, community detection has shown great potential to enhance the performance of recommender systems in various industries. The case studies and use cases discussed above demonstrate the effectiveness of community detection in providing personalized and relevant recommendations to users. As technology continues to advance, it is anticipated that community detection algorithms will become increasingly sophisticated and will continue to be applied in new and innovative ways.

IX. Conclusion

Recommender systems are extensively used for information retrieval. Community detection techniques are used to enhance the performance of recommender systems. In this paper, we have presented a review of various types of recommender systems and the various applications and algorithms of community detection for the recommender systems. Further, we discussed the challenges in using community detection for recommender systems and concluded with the research directions and case studies of community detection based recommender systems.

***Abstract*— With the proliferation of science and technology, autonomous driving has garnered significant attention in the recent years due to the manifold benefits of driverless vehicles, including enhanced quality of life, mitigation of accidents, and curtailment of traffic congestion. In this work, recently developed encoder-decoder oriented architectures specifically designed to detect and segment the safe drivable region on roads have been reviewed, analyzed and compared, and the challenges in this field have been discussed. In pursuit of this objective, we initially furnish a survey of various orthodox and deep learning methods that find their use in detection of the road obstacles, and segmentation of roads and lane-lines. This is followed by a discussion on relevant field-oriented datasets. Subsequently, we present some recent encoder-decoder based methodologies such as HybridNets, You Only Look Once Panoptic (YOLOP), etc. These methods are then compared in terms of both inference speeds as well as performance metrics, to understand their potential in the real-time better, concluding that YOLOPv2 is currently the best suited architecture meant for drivable region detection. This is followed by an examination of challenges and unresolved inquiries in this domain.**

Keywords—autonomous driving, detection, encoder-decoder architecture, segmentation.

I. INTRODUCTION

With an expedited breakthrough of the transportation sector over the past century, humans now manifest a radical transformation in this domain leading to an eager interest in the field of driverless transportation. A driverless vehicle is the one that is utterly self-operated and requires no intervention from the human. Synonymously known as "autonomous" or "self-driving" vehicles, they incorporate software and sensor technologies together in order to navigate and propel a vehicle. Given that human error is the key contributory factor causing road accidents [1], driverless technology holds great potential for reducing the number of such incidents on roads [2]. Hence, apart from improvement in the lifestyle, driverless vehicle technology also makes the vehicles less prone to accidents. Such systems are meritorious in bringing down the logjam and traffic congestion.

Detection of the drivable-region forms a crucial chunk of driverless vehicle operations. Accurately detecting the drivable area is crucial for the safe and efficient operation of autonomous vehicles. Drivable area detection has been successfully tackled using deep learning, which has emerged as a powerful solution for complex computer vision problems. In this regard, deep learning models are utilized to assess the safe and drivable portion of the road for a vehicle upon being trained with large sets of labeled data to identify distinguishing aspects and patterns that warrant the distinction between drivable and non-drivable regions. The propitious results of this approach have shown its potential in nurturing the automated driving systems. A typical detection system for drivable region consists of obstacle detection (vehicles, animals, humans, etc.), drivable region detection, lane detection, pothole detection, traffic signs detection, etc [3].

Considerable progress and research have been made in this domain over the last couple of decades. The archaic methods including geometry-based modelling and energy- oriented optimization schemes have evolved into newer clutter-breaking deep learning-based methodologies. The geometry-oriented-modelling approach involves detecting the edges of the driveway and fitting lines over them. Several filtering-based techniques, such as Gaussian [4] and Gabor filtering [5] have been employed for edge detection [6], with a focus on gradients. Additionally, aspects such as texture and colour can also be incorporated. The Hough transform methods have been used to adjust the lines over the detected edges [7]. Energy optimization approaches, such as Continuous Random Fields (CRF), have also been utilized to detect lanes [8]. With the advent of deep learning these models were ousted. Such peculiar methods included object detectors useful to predict obstacles on the driveway [9]. Deep learning algorithms, such as Convolutional Neural Networks (CNNs) [10], have shown great potential in accurately identifying objects, how- ever at a greater inference time. Region-Convolution Neural Network (R-CNN) has its output in the form of obstacles' bounding boxes sets along with the class output [11]. Their improvements fast R-CNN [12] and faster R-CNN [13] were also instigated. However, owing to the large inference times during testing they do not cater to the real time execution. Single shot detector (SSD) provides good frame rate during inference wearing from 22-59 frames per second (FPS). They utilize single progressive pass to perform the steps of localization and categorization. However, their performance worsens for tinier objects [14]. You Only Look Once (YOLO) considers detecting of objects a regression problem it utilizes the technique of division of ground truth into grids hence only one forward propagation is the requisite to implement the methodology it offers good frame rate of 45 frames per second [15]. YOLO was further evolved into YOLOv2 [16] and v3 [17], as more effective object detectors. Methods of such kind have proved to be helpful in detecting traffic objects on roads.

Further several segmentation methodologies have also been put into use to detect the road [18] and lane-lines [19]. U-Net [20] classifies as each pixel of the input, henceforth,

being highly capable of differentiating borders of an object. It has contractive and expansive parts as the input and output are both supposed to be of the same dimensions. Unlike UNet that performs semantic segmentation, LaneNet [21] performs instance segmentation. It involves binary segmentation along with clustering-oriented embedding for cast graphic transformation. Spatial-CNN (SCNN) is capable of capturing translational and rotational relationships of frame pixels which apparently improve the segmentation process by manifolds [22]. In this model, rows and columns of feature maps are treated as layers with sequential passage of pixel details. Quin et al. [23] proposed a network that uses a hybrid architecture infusing CNN and Long Short-Term Memory (LSTM) [24]. CNN takes in data following a time series property while the LSTM learns the attribute and this is followed by Lane forecasting. In order to detect the entire driveway area, which would involve both detection of obstacles as well as segmentation of the lane-lines and the driveways, a combination of such networks is a must. However, opting for such a scenario would correspond to passing an input via three different models. This would reduce the speed and increase latency unreasonably and such models would fail to function well in real time scenarios. Hence, some researchers amalgamated such networks into much simpler architectures. Such architectures use simple encoder-decoder- based networks [25].

Mask R-CNN is an encoder-decoder-oriented network [26] that is capable of performing segmentation of images along with the detection of the objects. It is an extension of Faster- RCNN. While the former three versions of YOLO were introduced with an intent to detect objects, the latter versions including the YOLOv4 [27] and YOLOv7 [28] are extended to segmentation as well, along with the object detection. YOLOP is one such architecture that is capable of handling the three tasks specifically designed for driveway area detection [29]. It consists of an encoder that performs abstraction of the attributes. The encoder consists of a backbone and a neck. For backbone the authors have used CSP dark net while for the next spatial pyramid pooling has been used. It also has three decoders that performed three corresponding tasks. The model offers a speed of 41 fps. On the other hand, the DLT-Net is another architecture that is used to detect the driveway areas the lane and the traffic-oriented objects. Unlike in the other two architectures, it uses context tensors in order to amalgamate the decoders to perform the said tasks. It has an encoder based on the VGG-16 network [30]. HybridNets constitute of a common encoder and two decoders for separate vehicle detection and lane-driveway area segmentation [31]. The encoder uses a neck and backbone. The former is based on EfficientDet. Backbone of the encoder based on EfficientNet-B3. Bidirectional-Feature Pyramidal-Network (BiFPN) has been used for model scaling. The idea is to reduce the latency and increase the inference speeds while detecting without compromising much with the performance metrics, hence finding an optimal trade-off between the two significant requirements in order to make these models competent enough to function efficiently in the real world. YOLOv2 [32] has been developed, drawing inspiration from YOLOP and HybridNets, with YOLOv7 serving as the base model. However, even these methods have limitations such as exclusion of road damages and potholes detection mechanisms from such models could make them less guarded against accidents.

In this paper, we have reviewed some of the commonly used road related datasets and the latest encoder-decoder architectures, specifically designed for the application of drivable-region detection and segmentation. To the utmost extent of our cognizance and understanding, the previous works haven't primarily focused on analyzing encoder-decoder architectures specifically designed for this application, even though they are extremely meritorious. Additionally, we have also laid emphasis on both performance in terms of accurate detection as well as their real-time feasibility, which helps in understanding their potential and impact to a deeper extent. We have also analyzed and compared these architectures in terms of speed and evaluation metrics, and analyzed their limitations and challenges.

The paper is structured as follows: Section II discusses the commonly used datasets that are based on driving scenarios. Section III covers the general methodology and recent encoder-decoder detection methods for drivable-region detection. This is followed by comparison between these methods in section IV, followed by challenges in the field in Section V and section VI summarizes this study.

II. Dataset

A numerous road-based datasets have been introduced in the recent times. KITTI dataset [33] comprises of 15k road scene images. Using eight distinct classes, the dataset aims at covering applications including detection, segmentation and depth recovery. The dataset covers over 200k annotations corresponding to the object detection. It also intends to minimize overfitting in the scenarios. There's an inclusion of diverse road scenarios in Cityscapes dataset [34]. It consists of 25k road images covering high-quality as well as coarse annotations. The main idea behind this dataset was to cover more in-depth scenarios that are capable of replicating real life road conditions better. However, this dataset doesn't cover rainy and night road scenes like KITTI. The Oxford RoboCar dataset [35] primarily concentrated on autonomy in terms of its longevity. They covered the same routes under distinct conditions with an intent to capture different appearances of term predictions. nuScenes dataset [36] majorly covers

TABLE I. Dataset Comparison

Dataset	Year	Images	Classes	Rainy/Night scenes	Applications
KITTI [33]	2012	15k	8	No/No	Detection, Segmentation and Depth recovery
Cityscape [34]	2016	25k	30	No/No	Instance/Semantic Segmentation
Oxford RoboCar [35]	2017	64.8M	-	Yes/Yes	Pose prediction, long-term mappingand Localization
nuScenes [36]	2019	1.4M	23	Yes/Yes	Detection, Segmentation and Tracking
BLVD [37]	2019	120k	3	-- /Yes	Annotations, Trajectory Projections and Event recognition
BDD100k [38]	2020	100M	10	Yes/Yes	Detection, Segmentation, Tracking and Imitation learning

obstacle detection, road segmentation as well as object tracking applications. It is also focused upon pedestrian posing and vehicles' movement related applications. It contributes towards improved scene understanding by incorporating a 360-degree coverage of the road scenes. Build a Large-scale 5D Semantics Benchmark (BLVD) is another dataset [37] containing 120K road scene images. These images vary from lower to higher density scenarios on roads in terms of congestion and cover different times of a day. In addition to the aforementioned annotation aspects, BLVD also focuses on advanced higher dimensional applications including trajectory prediction and 5-D event identification that comprises of events like vehicle overtaking, pedestrian crossing and riding closer/farther, to name a few. BDD100K dataset [38] comprises of 100k road videos that are heavily inspired from real-life distinct and evaluation of ten different tasks including Multiple Object Tracking (MOT), MOT with segmentation, scene tagging, detection, imitation learning, etc. The datasets have been summarized in table I.

III. Methods

The general methodology for safe drivable area detection is summarized in the flowchart shown in figure 1. Images covering driving scenarios are first annotated using annotation tools into appropriate formats. There are various annotation formats including the COCO, Pascal VOC and YOLO [39]. The annotations, along with the ground truth (Images) are fed as inputs to the deep-learning architecture. It is an encoder-decoder based architecture. The encoder part consists of the backbone and the neck. It is used to extract features in the form of feature maps from the input training data. This is followed by multiple decoders used to effectuate a variety segmentation and detection processes to obtain the training and validation results. The optimal model is selected as the trained model, to which the testing data from the real-world is fed, and finally, the segmentation and detection results of the real-world data are obtained.

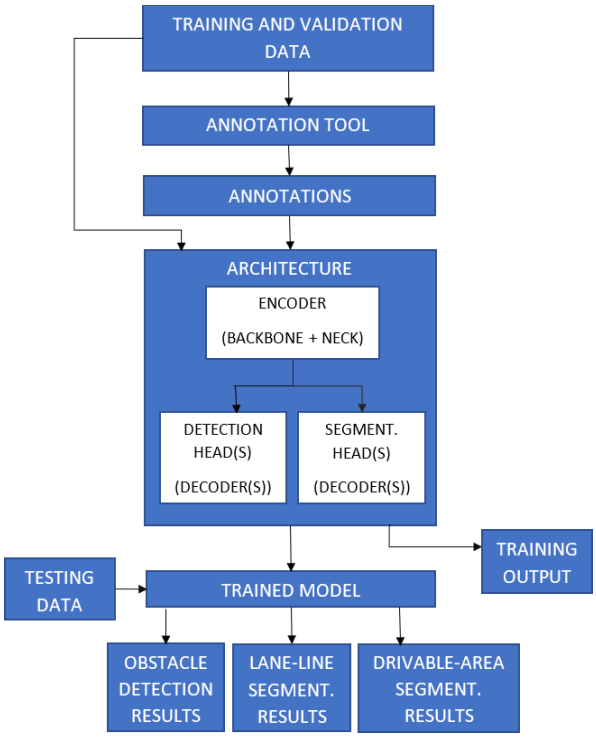

Fig. 1. General Block Diagram for Encoder-Decoder Architecture

A. DLT-Net

Drivable-area, Lane line and Traffic detection-Network (DLT-Net), indicating the three tasks involved in detecting drivable-region, is primarily focused upon the dependency of the three decoder tasks possible with the aid of the context provided by the specially designed tensors [30]. These tensors, henceforth, help in fusing feature maps of the three tasks. The encoder is based on VGG16 architecture and the pyramid structure. It utilizes the element mean operation to amalgamate the shallow and profound characteristics. The encoder generates feature maps of five varying sizes, of which, the concluding feature map is fed to the three task-oriented decoders. The context tensors, used in between the encoder and the decoders, provide aid in improving the discriminatory factor between the three tasks. The traffic detection decoder network is divided into two parts, one meant to perform classification and other for the bounding-box regression. It has several shortcomings. DLT-Net is incapable of giving optimal results during severe reflection driving scenarios. Also, it is incompetent in predicting the recurring divider lines as lane-lines.

B. DFM-RTFNet

Dynamic Fusion Module-RGB Fusion Thermal Network (DFM-RTFNet) is based on feature fusion technique, done dynamically by infusing DFM module to the RTFNet model [40]. It generates a dynamic kernel based on a two-dimensional feature and applies it on another feature to produce the fused feature. Owing to their properties including spatial variance and dependency on the content, optimum distinct kernels can be applied to different regions of an image. This in turn helps in optimizing the fusion process, thereby improving the efficiency of the network. To avoid excessive usage of the memory, the authors also constructed a dual-stage factorization-oriented convolution method. These DFMs then dynamically fuse two different modalities of features in a multiscale fashion. The RTF-Net uses two encoders for RGB and Thermal inputs. These encoders are inspired from the ResNet. Thereafter, five layers of decoders are utilized in order to process the fused features. Sequentially, this is followed by a softmax layer post which, the concluding detection and segmentation results are produced.

C. YOLOP

YOLOP is among first deep learning models for driveway-area detection that was realized by the authors on the Jeston Tx2, an embedded device to ensure its usability in real-time scenarios. The model was introduced with an intent to prosper in traffic object-detection, drivable-region segmentation and lane-line detection. It is primarily developed from its base model YOLOv4 with Adam being used as the optimizer for training [29]. The encoder consists of backbone and neck architectures with the former based on Cross Stage Partial Dark Network (CSPDarkNet) and the latter on Spatial Pyramid Pooling (SPP) module. It is based on scaled YOLOv4 which is quintessentially a lightweight CNN. The detector part comprises of three separate decoders. Decoder performs anchor-oriented multiscale detection and uses the single-stage YOLOv4 model, owing to the model's excellent inference speed. It uses an amalgamation of Feature Pyramid Network (FPN) and Aggregation Network (PAN) (or bottom- up FPN) for the transference of semantic aspects top-down and positioning aspects bottom-up, respectively in order to obtain superior feature fusion effect. The bottom layer of the neck serves as the input to these heads. These heads involve triple-

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:48:32 UTC from IEEE Xplore. Restrictions apply.

upsampling for the restoration of output feature map to the relevant size. This method, inspired from the trainable Bag of Freebies (BoF) helps in acquiring high-precision throughput and swifter inference.

D. HybridNets

Unlike in YOLOP and other models, HybridNets constitutes of a common encoder and only two decoders for separate vehicle detection and lane-driveway area segmentation, instead of three decoders [31]. Encoder has been designed to infuse model scaling which is extremely crucial for its hardware system implementation. Bidirectional FPN has been used for model scaling. Numerous loss functions are converged with the aid of a special learning scheme based on multistage methods. EfficientNet-B3 serves as the backbone. Its major role involves optimization of network by evaluating scaling parameters. This makes the network design stable. The encoder uses neck network based on EfficientDet which receives the feature maps from the backbone. BiFPN combines attribute at a varied resolution. This is based upon the cross-scale connection for each node by each bidirectional path. It also builds on weight corresponding to each attribute in order to comprehend the significance of each level. K-means clustering is utilized to establish the anchor boxes that're assigned to fusion maps. The model is capable of working well on complicated datasets. The background, driveway-area and lane-line are the three categories to be examined by the segmentation head.

E. YOLOPv2

YOLOPv2 was designed, drawing inspiration from existing works such as YOLOP and HybridNets, but with modifications for improved efficiency. They also utilize a shared encoder and three separate decoder heads for specific tasks of drivable area segmentation and lane detection. The architecture is primarily based on YOLOv7 [32]. Group convolution from E-ELAN is employed in the backbone for diverse feature learning, and feature fusion is achieved through SPP and FPN modules. An anchor-based multi-scale detection scheme similar to YOLOv7 is adopted, utilizing PAN for localization feature extraction. However, drivable area segmentation and lane segmentation are performed in separate task heads with different network structures, as features from deeper layers are found to be unnecessary and even detrimental for drivable area segmentation. For segmentation, semantic-level features are fed as inputs. An additional upsampling layer is applied to compensate for this change, while deconvolution is used in the decoder stage of lane detection for improved performance. The model utilizes cosine annealing for learning-rate calibration in order to improve its performance. YOLOPv2 is also based on trainable BoF, hence making it more viable to solve real-world problems.

IV. COMPARISON

We compare the above-described models and some other state-of-the-art methods for detection of the safe drivable-region in different road-scenarios. The most commonly used performance metrics for obstacle detection is mean Average Precision (mAP). For drivable-region segmentation, Intersection over Union (IoU) metric is widely used, while for lane-line segmentation, accuracy is preferred over IoU since lane-lines are usually discontinuous and of variable widths. Performance metrics for the three tasks are summarized in Table II. PSP-Net, utilized on the Cityscapes, [41] uses pyramid pooling module and an FCN-oriented network to segment the roads and obstacles. It doesn't perform lane-line segmentation. The remaining techniques are capable of performing two or more detection/segmentation tasks useful in identifying the safe drivable-region. While E-Net, Multi-Net and DFM-RTFNet algorithms were originally applied on KITTI and Cityscapes datasets, but in [30] MultiNet was retrained on BDD100k dataset, so we used the same to comparison easier with the dataset of most of the major techniques common as the more recent methods have been applied on the BDD100k dataset. From the table, several conclusions maybe drawn. It may be concluded that YOLOPv2 is overall a more superior method performing all three tasks. It offers the most superior results for lane-line and drivable-region segmentation, offering an accuracy of 87.31% and IoU of 93.2%, respectively on BDD100k dataset. This is closely followed by HybridNets with its accuracy and IoU being 85.4% and 90.5 % respectively, and YOLOP with 70.5% and 91.5%, respectively. Even though YOLOPv2 also offers best mAP for traffic obstacle detection for BDD100k dataset, it is the dynamic aspect-fusion oriented DFM-RTFNet that offers the maximum mAP of all the models, applied on the KITTI dataset. However, it rules out the possibility of segmentation of the lane-lines, restricting it to perform only two tasks. In terms of speed, ENet outperforms the other models, operating at the speed 100 Frames Per Second (FPS) [42], followed by YOLOPv2 that operates at the speed of 93 FPS. However, E-Net offers a poor accuracy for lane-line segmentation, hence, incapable of finding the trade-off between the speed and performance- metrics. YOLOPv2, on the other hand, owing to its trainable bag of freebies, offers the best possible trade-off between the speed and performance metrics of the three tasks, proving to be the most superior method in the recent times, closely followed by HybridNets and YOLOP.

TABLE II. COMPARISON BETWEEN LATEST METHODS

Method	Year	Dataset	Speed (FPS)	Obstacle Detection (mAP)	Lane-Line Accuracy Segmentation (%)	Drivable Area Segmentation (IoU)
PSPNet [41]	2017	Cityscapes	11.1	-	-	89.6
ERFNet [43]	2017	Cityscapes	22.8	-	-	68.7
ENet [42]	2016	Cityscapes	100	-	34.2	-
Multi-Net [44] [30]	2018	BDD100k	8.6	60.2	-	71.6
DLT-Net [30]	2019	BDD100k	9.3	68.4	-	72.1
DFM-RTFNet [40]	2021	KITTI	-	94.05	-	86.5
YOLOP [29]	2022	BDD100k	41	76.5	70.5	91.5
HybridNets [31]	2022	BDD100k	-	77.3	85.4	90.5
YOLOPv2 [32]	2022	BDD100k	93	83.4	87.31	93.2

V. Challenges

An efficient data labeling prior to model training is desirable in order to produce optimum detection and segmentation results. Manual annotators have been the key source for data labeling. However, the process would become tedious and time consuming in order to ensure diversity within a dataset that depicts a wide variety of road scenarios. Further, human errors can also arise in the process. Several labeling methods have been developed in order to make the data labeling less tedious [45]. There is still a scope of improvement in this field.

Latency is an important parameter and can't be compromised with especially in the real-time scenarios where a car is being driven at a high speed. If Latency is improved the performance metrics tend to decline substantially and vice-versa. Object detection and segmentation techniques individually offer superior performance metrics but their amalgamation will cause a decline in the model speed in terms of fps, hence miserably affecting the latency. Encoder-Decoder architectures provide improved latency with a significant decline in the performance metrics. To establish an efficient deep learning model that finds a trade-off between latency and metrics is one of the key challenges in this field. Even though methods like YOLOP and YOLOPv2 have addressed the issue by proposing for trainable BoF as the solution, there's still a scope of improvement in this aspect.

Detection of potholes on the roads to avoid uneasy travel and damage to the vehicles using such deep-learning methods is another major challenge in the drivable-region detection algorithms and systems. It's relatively difficult to differentiate such concave-sculpted depressions from the roads especially during night scenarios and poor weather conditions. There is still a lack of fusion systems for drivable-region detection that also infuse detection of potholes present on the roads.

VI. Conclusion

With the proliferation of science and technology, autonomous driving has garnered significant attention in the recent years due to the manifold benefits of driverless vehicles, including enhanced quality of life, mitigation of accidents, and curtailment of traffic congestion. In this work, recently developed encoder-decoder oriented architectures specifically designed to detect and segment the safe drivable region on roads have been reviewed, analyzed and compared, and the challenges in this field have been discussed. In pursuit of this objective, we initially furnish a survey of various orthodox and deep learning methods that find their use in detection of the road obstacles, and segmentation of roads and lane-lines. This is followed by a discussion on relevant field-oriented datasets. Subsequently, we present some recent encoder-decoder based methodologies and their comparison, followed by an examination of challenges and unresolved inquiries in the field.

The decreasing operational voltage and scaled technology node for memory designing has widened the gap between two crucial parameters for an SRAM – delay and power. As the demand for internet of things is increasing, the need for round the clock connectivity is increasing. This mandates designing a cell with a capability to switch between low power and high speed operation. Thus, this paper presents design of dual mode operational 7T cell that can switch between single port and dual port configuration. The proposed reconfigurable cell can operate as single port or dual port cell single ended 7T cell. The reconfigurability in the cell is realized using control signals. The noise stability of the bit cell is obtained to be 333, 333, and 470 mV for read, hold and write modes respectively. The robustness of the cell against temperature variation, process variation and voltage variation is also analyzed. The performance variation in each parameter will not have a dramatic impact as it is within manageable limit. Its write time is 0.14 ns, while 5 ps are required for a successful read operation. The dual port configuration of the cell supports pipelining and thus operates faster than its single port configuration.

Additional Keywords and Phrases: Reconfigurable cell, low power, high speed, process tolerant, internet of things

1 INTRODUCTION

Static random access memory (SRAM) is a fundamental part of most multimedia systems [1-2], consequently, improving the performance of an SRAM based memory is crucial for performance enhancement of the setup. Additionally, with the surge in requirement of Internet of Things (IoT), the demand for high speed, low power, and portable devices has grown exponentially. According to the present statistics, over 70% multimedia devices utilize SRAM for cache memory design, which accounts for upto 30% of the total power consumption and 50% of die area for the system [3]. In keeping with the present multimedia device requirements, a memory designer has to ensure low power and high speed operation with high packaging density. The major concern for a memory designer is the dichotomic requirement of low power and high speed operation. The two demands are complementary and one may be achieved at the cost of the other. As a result, the gap between the two is pushing designers to search for alternatives to rectify the same. The problem is further intensified by the shrinking technology node to increase the integration density of the memory. The increasing demand for round the clock connectivity and burst towards IoT has generated the demand for versatile SRAM.

Additionally, an SRAM array is common for a system and is shared between circuits with different error tolerance, delay, and power requirements. For example, image processing application in a multimedia device has higher tolerance to error but requires faster operation [3]. Whereas, data centric applications need the memory performance to be error proof, while being slightly relaxed about the speed of the circuit [4]. But, this makes the system a bit power hungry. Thus, each system has different requirements – faster operation, lower power, high error tolerance, in keeping with the application that it is presently catering to.

But from a designer's prospective, error tolerance, low power consumption, faster operation, and high integration density are trade-offs [5]. Therefore, achieving them all at the same time is an extremely difficult task in a conservative SRAM cell design. Thus, a new concept of reconfigurable SRAM is described in this paper. The proposed cell is a versatile SRAM cell designed with the capability to function in two different single ended configurations – single port and dual port. The single port SRAM bit cell is power efficient but with higher delay and greater error propensity than the dual port cell [6]. While, the dual port cell is more effective for faster operation but is power hungry [7]. Also, the dual port cell enables pipelining, whereas this is not the case with single port cell. The paper is divided into the following five distinct sections, together with this introduction section. The concept of reconfigurable SRAM is explained in detail along with the previously reported scenarios for reconfigurability in section II. In section III, the structure of the proposed reconfigurable cell is explained in detail. The results of the reconfigurable cell are elaborated upon in section IV and its sub sections. The outcomes of the paper are summarized in section V.

2 RECONFIGURABILITY IN SRAM

Reconfigurability in an architecture refers to its ability to rearrange the elements or settings of a system, device, or computer application. The concept of reconfigurability in devices has been around for a long time. Schuyler et al. [8] used reconfigurability to design memory cell that can function both as random access memory and read only memory. This helps to eliminate the need for designing an application specific test procedure. But, this patent only modulates the use of an already designed memory cell. Each cell in the memory block is not worked upon. Also, it is not able to improve the performance of the cell. Similarly, another patent that reports reconfigurability in memory was reported by Sutardja Sehat [9]. In it, the researcher has reported a block level memory structure, capable of working as per requirement of different application. The aforementioned patents describe a mechanism to use the existing memory cells to adapt as per the requirement of the application. But, neither of the two work on modifying the bit cell that stores the information. Whereas, the recent boom in demand for artificial intelligence and machine learning applications has generated the need for high performance memory circuits with minimum propensity for error. This demand is further aggravated by increased inclusive integration of different devices for round the clock connectivity via internet access for developing an IoT.

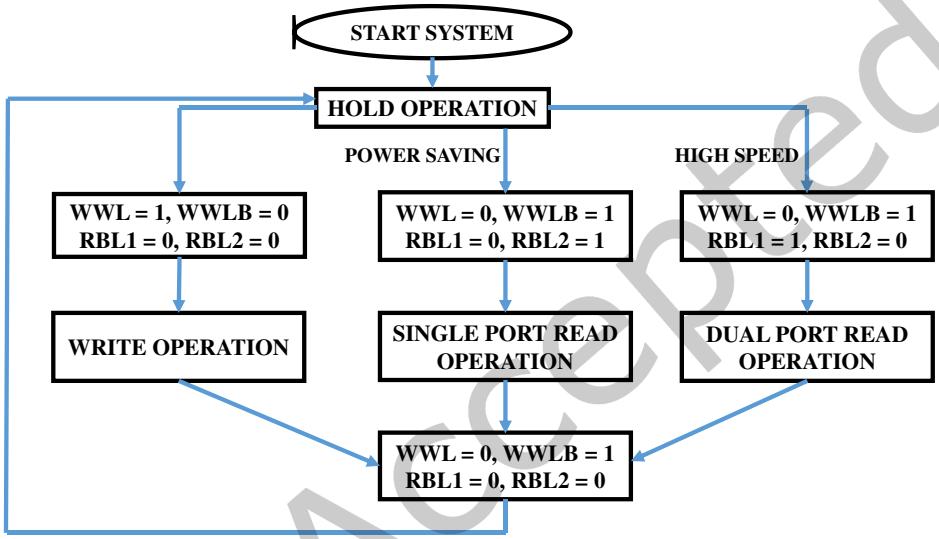

Fig. 1 Flow chart representation of the proposed reconfigurable SRAM

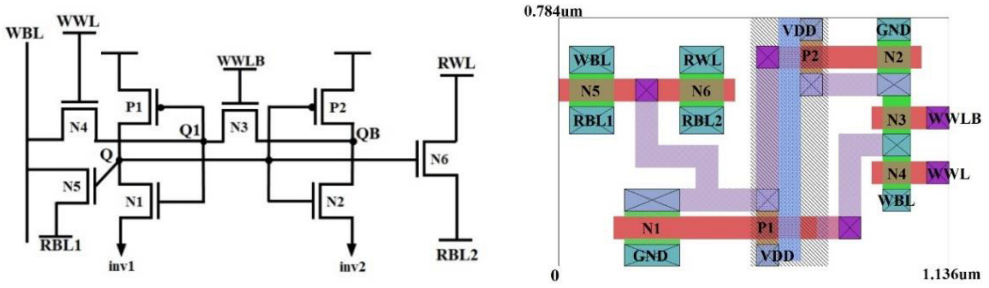
An IoT setup has fluctuation in its design requirement in keeping with the time of day. A device connected to the setup is expected to be operational at its full capacity for a fraction of the day; other times it may function in the power saving mode. The pre-existing bit cell designs are static and operate in only one mode. This limits the functionality for the bit cell. Whereas, to carter to the dynamic requirement for an IoT system, a bit cell that can operate in different modes is the requirement. In pre-exiting bit cells it is observed, that single ended single port bit cells are better for power saving application. Whereas, dual port cells perform better in terms of speed. As previously stated, an IoT setup is operational round the clock, but optimal performance is required in smaller bursts. This mandates designing a bit cell that can switch between two different modes of operation. Thus, in this paper, the concept of a reconfigurable SRAM bit cell is presented. Its working is explained with the help of a flow chart demonstrated in Fig. 1. The working of a reconfigurable cell is realized for a 7T SRAM cell. The structure of the reconfigurable cell is described in section III. This reconfigurable cell includes control circuit that enables the cell to either work in single port or dual port configuration. The bit cell is composed of eight transistors and is grouped into three sub-parts – single bit memory core, reading port and writing port. The single bit memory core of the reconfigurable memory is the part that stores the desired information. The read and the write port are the access circuitry that enable the device to read and write into the cell respectively.

3 DETAILED DESCRIPTION OF THE PROPOSED RECONFIGURABLE SRAM CELL

The proposed cell is composed of eight transistors of which two are PMOS (P1 and P2), while the remaining are NMOS transistors (N1-N6). The memory core for the reconfigurable cell alike a conventional SRAM cell is formed by a pair of mutually connected inverters via an NMOS transistor; N3. It is used to control the connection and disconnection of mutual feedback between inverters; it is controlled via signal write wordline bar (WWLB). While, the write wordline (WWL) signal controls the access transistor - N4 for enabling the write operation.

Just Accepted



(a) (b)

Fig 2. (a) Schematic design and (b) Layout for the proposed reconfigurable SRAM cell

The WWL and WWLB are complementary signals thereby, making N4 and N3 operate exclusive of each other. The read operation is controlled by read bitline - RBL1 or RBL2, signal depending on whether single or dual port configuration is to be used respectively. The N5 - N6 transistors are the read access transistors and operate exclusive of each other. The data is read from or written into the memory with the assistance of bitline WBL. The schematic design for the proposed reconfigurable SRAM cell is depicted in Fig. 2 (a). While, its layout along with dimensions is depicted in Fig. 2 (b). The layout for cell is designed on a grid of 16 nm and based on design rules reported by Jeppson *et al.* [10]. The area footprint for the proposed bit cell is found to be 0.891 μm^2.

Table 1. The control signal conditions during the different operation of the proposed cell

	WWL	**WWLB**	**RBL1**	**WBL**	**RBL2**	**RWL**
HOLD	'0'	'1'	'0'	'0'	'0'	'0'
WRITE	'1'	'0'	'0'	'0'	'0'	'0'
READ (SP)	'0'	'1'	'0'	'1'	'1'	'1'
READ (DP)	'0'	'1'	'1'	'1'	'0'	'1'

This proposed configuration for the bit cell can operate in two modes: (i) single-ended, single-port and (ii) single ended, dual port. The port configuration for a cell indicates if common bitline is used for both access operations or are the bitlines independent for the two operations. A single port bit cell relies on a single bitline for all its operations. Whereas, a dual port cell is dependent on two bitlines for its operations. In the proposed cell use of the control signal RBL1 for read operation ensures single port configuration and if RBL2 signal is used, then the circuit will operate in dual port configuration. For the ease of understanding, the combination of control signal and their corresponding operations are listed in Table 1.

3.1 Single Port Configuration

When a device is operating at a slow pace or is in low activity and power saving mode, then the circuit must operate in single port configuration. During this configuration, the bit cell is dependent on WBL for all its operations. The RBL2 signal is low, thereby disconnecting the second read port for the cell. The effective circuit for the proposed cell during the single port configuration is given in Fig. 3 (a). For this configuration, the cell operation is slow with no possibility for pipelining. But, use of a single ended single port configuration tends to reduce power consumption; mathematically calculated as follows:

$$P = \alpha C_L V_{DD}^2 f_{clk} \quad (1)$$

Here, α represents the activity factor, f_{clk} is the clock frequency and C_L is the load capacitance of the cell. For a single ended operation, the activity factor is reduced to 0.5 thereby, reducing the power appetite to half of its value.

Just Accepted

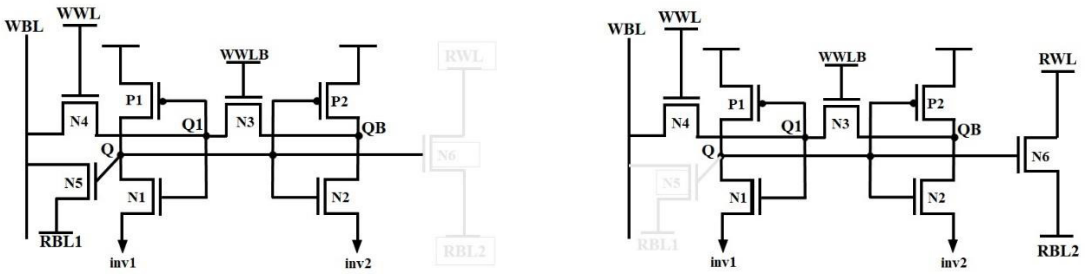


Fig 3. The effective circuit for the proposed cell when the circuit is operational in (a) single port, and (b) dual port configuration

3.2 Dual port configuration

When the device is operating in a high speed mode, i.e., the cell is required to operate with lower delay and higher speed. This scenario trades-off power with speed and is not taken as a constraint, then the cell must operate in dual port. The effective circuit for the proposed reconfigurable SRAM cell for dual port configuration is shown in Fig. 3 (b). The advantage of dual port is that it enables pipelining and ensures faster operation. This might increase the power load of the circuit but the operational speed of the cell is optimum.

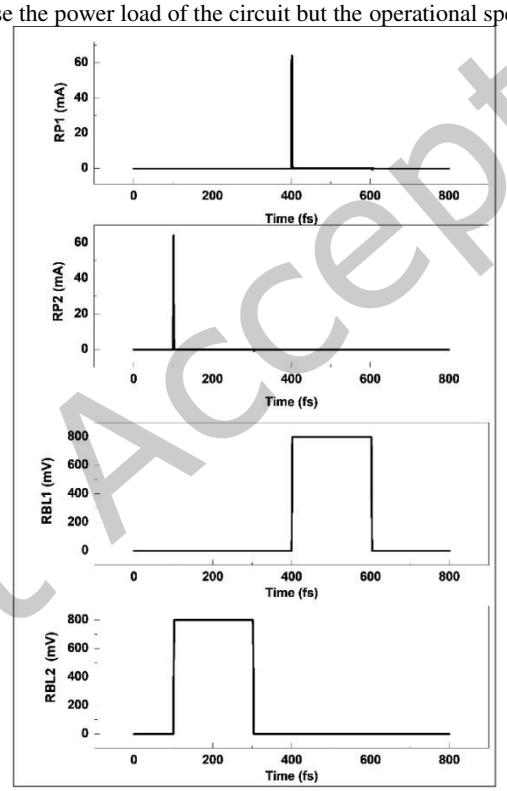

Fig. 4 Read current through the different read ports for the dual mode operational SRAM cell.

3.3 Functioning of proposed cell

The proposed cell is designed to operate in two different modes – single ended, single port and single ended dual port. It is essential to analyze the working of the cell in the two modes. Therefore, working of the proposed dual mode operational cell in two different read modes is demonstrated in Fig. 4. When the cell performs read operation, read discharge current flows through the selected read port – single or dual. Thus, the read operation for the bit cell is demonstrated in terms of read discharge current. The initial condition for the cell is maintained to be Q = '1', and QB = '0'. The write port for the cell is turned OFF and only the read operation is to be performed. It can be observed from Fig. 4, that when the RBL1 signal is high, the read current through read port1 (RP1) increases instantly to 64.65 mA.

This is the read discharge current that is responsible for the read operation. During this phase, the cell is being operated in single ended single port configuration, but as the read port2 (RP2) is also connected to node Q; a fickle leakage current can be observed at that port too. Whereas, when the cell is being operated in the dual port configuration, the read discharge current flows through RP2 only. This read discharge current is also in the same range but is slightly higher than the RP1 read current at 64.14 mA. Thus, based on the read discharge

Just Accepted

current recorded for the mode of operations for the cell, it is justified that it will be able to operate in dual mode configuration. Thus, as the proposed dual mode configuration cell may be deemed stable. Also, the cell can operate in both the single and dual port configurations independently.

Another important inference that can be drawn from Fig. 4 is that, small leakage current pulse is observed during the read operation in the read port that is not selected. When RBL1 is high, the read discharge current flows through RP1, and a leakage current of 189 µA is registered for RP2. Similarly, when the RBL2 signal is high, read current is observed through RB2, and leakage current of 193.2 µA is registered through RP1. The leakage current for a port is an indicator of its leakage power consumption. The leakage power consumption for port is determined as the product of supply voltage and leakage current. Thus, based on the leakage current values for RP1 and RP2, the leakage power consumption value for the cell is 151.2 and 154.56 µW, respectively.

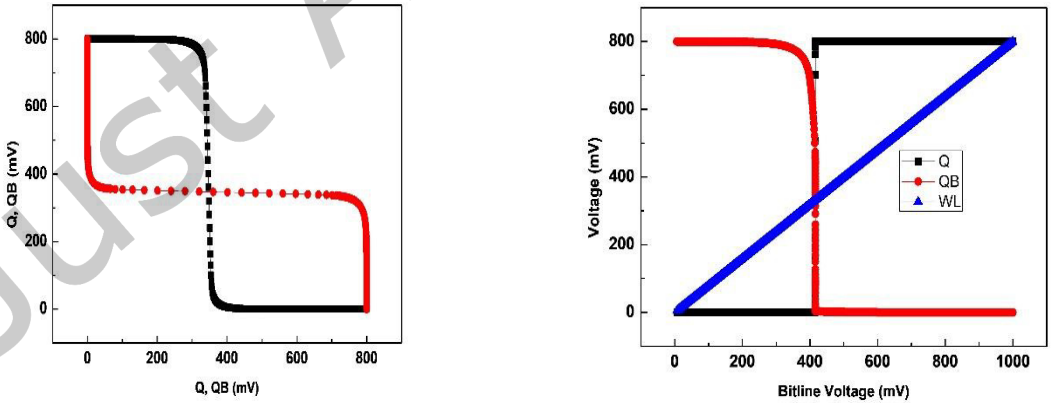
4 PERFORMANCE EVALUATION

The proposed cell in this paper is designed at 32 nm and is simulated at V_{DD} of 0.8 V. The different parameters used to evaluate the proposed reconfigurable cell are static noise margin, timing requirement for access operations (read and write), process, temperature, and voltage variation. The performance of the proposed reconfigurable cell for each of the aforementioned parameters is explained in the subsequent sub sections.

4.1 Static Noise Margin

The primary utility of a memory cell is to retain information as long as V_{DD} is applied to the cell. Therefore, the proposed reconfigurable cell is firstly analyzed for static noise margin (SNM) for its three operations - hold, read, and write. The performance is initially analyzed for ideal static condition. In an ideal condition, the SNM for an operation is defined as the utmost noise a cell can withstand before an error is registered in the stored data. The SNM values for the hold, read, and write are referred to as HSNM, RSNM, and WSNM respectively. The hold, read, and write SNM values obtained for the proposed reconfigurable SRAM cell are 333, 333, and 470 mV respectively. The butterfly curve (hold/read operation) and write margin curve are depicted in Fig. 5 (a) and (b) respectively.

Overlapping butterfly curves are obtained for read and hold operation; this is an implication of the read SNM free port for the proposed cell. The read ports (for both single port and dual port configuration) for the cell are designed to exclude the data node from the read discharge path. This configuration helps protect the integrity of the data stored in cell during the read operation. Thus during the read operation, the data stored at node Q is not disturbed. As the data remains undisturbed, the RSNM value for the cell is equal to its HSNM value of the cell. Such a read port configuration is referred to as a read SNM free port [7].



(a) (b)

Fig. 5 (a) Butterfly curve for hold (read) operation, and (b) Write margin curve for the proposed reconfigurable cell.

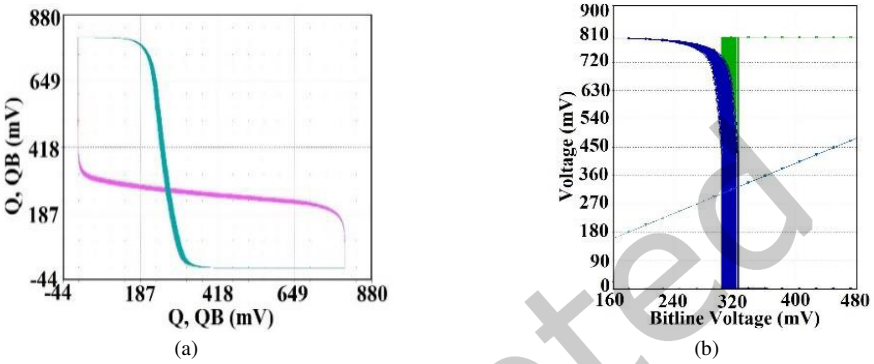
The HSNM (RSNM) value for the proposed cell is 333 mV, while the WSNM value for the cell is 470 mV. The SNM values obtained for the cell are fairly balanced and lie around the ideal value of $V_{DD}/2$ [11]. But, when the memory is fabricated, imperfections in the cell may arise due to different process variables. These imperfections become more prevalent at lower technology node. The different factors that impact a cell's performance and threaten its stability are local and global variations caused due to fabrication imperfections.

4.2 Local Variation

The simulation results for the proposed cell demonstrated in the previous sub section are all performance for ideal conditions. But, when a circuit is fabricated, there are possibilities of minor fabrication imperfections resulting in local mismatch in the transistors adjacent to each

Just Accepted

other. This results in deviation from the performance reported for the cell. Thus, it is essential to evaluate the impact of local variation on the performance of the proposed cell. Factors that limit the performance of the bit cell are; hot carrier injection, gate oxide breakdown, backend dielectric breakdown, electro migration, and stress-induced voiding. But these factors have a random behavior and do not have a defined model of analysis. All variations can be translated to an effective variation in the threshold voltage (V_{TH}) [12, 13]. Consequently, to analyze the impact of variation on device, the Gaussian distribution for V_{TH} is an effective approach [14]. Thus, V_{TH} is used as the main parameter to statistically analyze the same [15-16]. Monte Carlo simulation is employed to determine degree of variation in performance of the proposed cell. The V_{TH} for the cell is varied around the average value with 6σ standard deviation to determine the worst case performance of the proposed reconfigurable bit cell. The results for the Monte Carlo simulation corresponding to the hold (read) and write operation for the proposed cell are depicted in Fig. 6 (a) and (b), respectively.



(a) (b)

Fig. 6 Results of local variation for (a) HSNM (RSNM), and (b) WSNM values for the proposed reconfigurable cell.

The variation in the butterfly curve of HSNM (RSNM) for the reconfigurable cell is demonstrated in Fig. 6 (a), while the variation in the WSNM is represented in Fig. 6 (b). The 6σ worst case HSNM, RSNM, and WSNM values achieved for the reconfigurable cell are 273, 273, and 540 mV respectively. Thus, the variation in HSNM, RSNM and WSNM values for the proposed cell are 60, 60, and 70 mV respectively. The maximum impact of local variations and global variations (explained in the subsequent section) on the performance of the proposed cell is depicted in Fig. 8. From the local variation analysis, this may be concluded that though there is variation in performance of the bit cell, it is within reasonable bounds. Therefore, it is apt to suggest that the cell has low vulnerability to local variation.

4.3 Global variation (Process corner analysis)

When any inorganic circuit is fabricated, there are various factors such as – oxide thickness, strain variation, line edge roughness, and discrete random dopant amongst others that may cause process variations in the fabricated circuits [17]. The impact of these variations is more prevalent in circuits designed for scaled technology nodes. Therefore, the proposed reconfigurable bit cell is prone to error caused by global variations. Thus, it is essential to check the range of variation in cell performance due to global variation. The impact of global variation on a cell is determined using the process corner analysis. The proposed cell is therefore analyzed at the four process – Fast-Fast (FF), Fast-Slow (FS), Slow-Fast (SF), and Slow-Slow (SS) along with the typical corner (TT). The SNM values obtained for the proposed cell at all the process corners are graphically compared in Fig. 7 and the corresponding values are tabulated in Table 2.

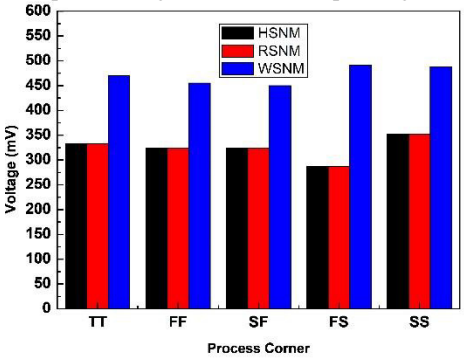


Fig. 7 Graphical comparison of the SNM values obtained at the different process corner for the proposed reconfigurable cell.

Just Accepted

Table 2 SNM values for the proposed reconfigurable cell at all process corners

	TT	FF	FS	SF	SS	Maximum Variation
HSNM	333	340	352	287	324	65
RSNM	333	340	352	287	324	65
WSNM	470	455	450	491	488	41

The best performance for the cell is recorded at the FF corner. The HSNM, RSNM, and WSNM values obtained at the FF corner are 340, 340, and 455 mV, respectively. This is an implication of improved performance for both NMOS and PMOS at the FF corner. The deviation in the HSNM, RSNM, and WSNM values obtained at the FF corner in comparison to values obtained at the typical corner is 7, 7, and 15 mV, respectively. At the typical corner, the performance of the PMOS is weaker in comparison to an equally sized NMOS. Thus, when the cell is functioning at the FS corner, the gaps between the performance of PMOS and NMOS transistors is bridged, thus the best performance for the cell is recorded with the HSNM, RSNM, and WSNM being 352, 352, and 450 mV, respectively. These values are deviated from the typical corner values by 19, 19, and 20 mV, respectively.

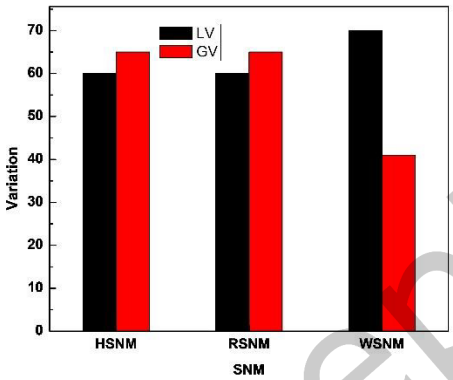

Fig. 8 The variation in performance of HSNM, RSNM, and WSNM due to local and global variation

Contrary to the FS corner, the gap between the performance for PMOS and NMOS is further widened at the SF corner. Consequently, the performance of the proposed cell is also most inferior at this corner. The SNM values recorded for the hold, read, and write operation at this corner are 287, 287, and 491 mV, respectively. These values are 46, 46, and 21 mV deviated from the typical corner values. The performance for the proposed cell at the SS corner is moderate, with the HSNM, RSNM, and WSNM values being 324, 324, and 488 mV respectively. The essence of the global variation analysis is to determine the variation in range of SNM values. The range for SNM variation is the difference between the highest and lowest value obtained. Thus, the maximum deviation in the HSNM, RSNM, and WSNM values due to global variation is 65, 65, and 41 mV respectively. Thus, the proposed reconfigurable cell may be deemed resistant to global variation as it registers a fairly small change in its performance due to global fabrication imperfections.

4.4 Temperature Variation

Local and global variations in a circuit are an implication of fabrication imperfections. But, external factors such as temperature variation also have a highly likely possibility of impacting the performance of a cell. Therefore, to evaluate robustness of the proposed cell against temperature variation, its static performance is analyzed for -10 ºC to 110 ºC. The variation in HSNM/RSNM and WSNM curves for the proposed reconfigurable cell against temperature variation is depicted in Fig. 9 (a) and (b) respectively.

Just Accepted

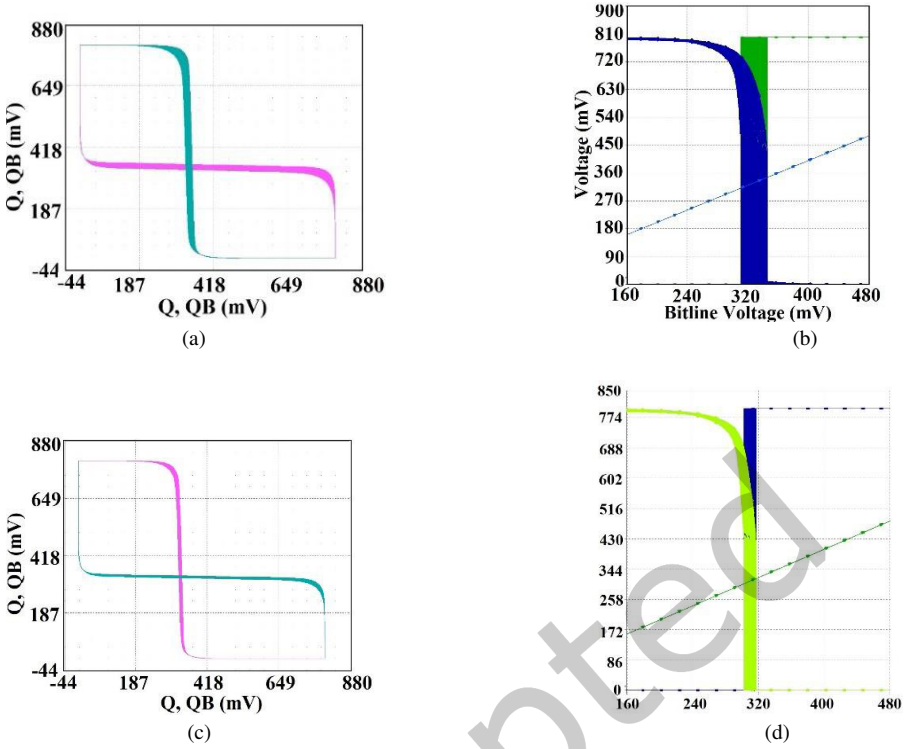

Fig. 9 Variation in SNM for proposed cell during (a) hold (read), and (b) write operation for temperature variation -10 ºC to 110 ºC, and variation in SNM during (c) hold (read), and (d) write operation for temperature variation 0 ºC to 70 ºC

The proposed reconfigurable cell records a small variation in its performance when temperature is varied. The lowest HSNM (RSNM) value obtained for the proposed cell due to temperature variation is 308 mV. This is a 25 mV deviation from the nominal SNM value at room temperature. The WSNM value for the cell rises to 520 mV. This is a 50 mV rise from the WSNM value at 27ºC. But, this temperature range taken into consideration is extremely large between -10ºC to 110ºC. Whereas, range for temperature variation in most commercial electronic devices is 0ºC to 70ºC. Thus, the proposed cell is evaluated for this range. The HSNM (RSNM) and WM curve for temperature variation in commercial range are depicted in Fig. 9 (c), and (d) respectively. It can be inferred from Fig. 9 (c) and (d), that the variation in performance of the proposed cell is considerably reduced for the commercial temperature range. The maximum variation in HSNM (RSNM) and WM for the commercial temperature range is 28, and 24.5 mV, respectively. Thus, it may be concluded that the proposed reconfigurable cell demonstrates reasonable performance against temperature variation.

4.5 Voltage Variation

Digital circuits operate for bit values ‘0’ and ‘1’, but bit levels 0 and 1 in reality are not discrete level; instead they are defined as voltage range. Consequently, it is essential to analyze the cell performance for voltage variation. In this work, the proposed reconfigurable cell is analyzed for ±10% of the operational V_{DD}. The influence of voltage variation on cell stability is depicted in terms of deviation in its HSNM (RSNM) and WSNM values. The simulation results for voltage variation analysis are presented in Fig. 10.

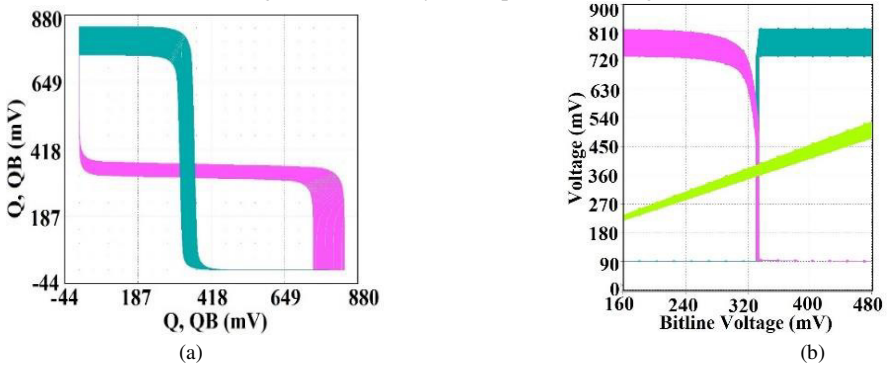

Fig. 10 Variation in SNM values for (a) hold (read) and (b) write operation for the proposed cell due to variation in voltage from 0.75 V to 0.85 V.

Just Accepted

Table 3 SNM values for the proposed reconfigurable cell for different V_{DD} values

V_{DD} (V)	HSNM (mV)	RSNM (mV)	WM (mV)
0.8	333	333	470
0.7	286.6	286.5	414
0.6	235.3	235.3	362
0.5	188	188	309
0.4	144	144	256
0.3	96	96	204

It may be observed from Fig. 10 that voltage variation has larger impact on the cell performance in comparison to process and temperature variations. But, the variation in cell performance is untroublesome and therefore, have no dire consequence on the performance of the cache memory. Additional to voltage variation analysis, as there is a tremendous growth in devices operational at low voltage, it is essential to analysis the performance of the proposed dual port cell for the same. Therefore, the SNM values for the proposed cell are analyzed and recoded for V_{DD} lower from 0.8 V to 0.3 V in step size of 0.1 V. The results obtained for the analysis are tabulated in Table 3. It may be inferred from the values tabulated in Table 3, that as the V_{DD} is lowered the stability of the cell also reduces linearly. The HSNM (RSNM) value decreases approximately 47 mV per 100 mV decline in V_{DD}. Whereas, for WM, for each 100 mV decline in V_{DD} the WM value reduces approximately 52 mV. Thus, it may be inferred that the cell will be able to retain its performance for low values of V_{DD} as well.

4.6 Write and Read Time Analysis

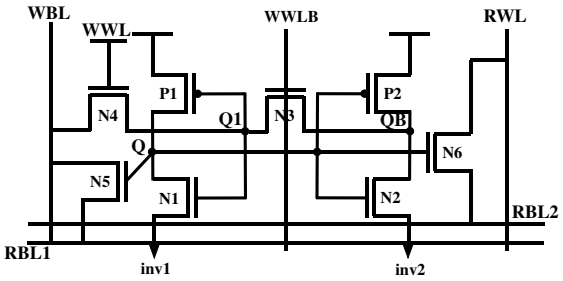
The analysis explained thus far are all static in nature and do not take into account the time needed for successful completion of an operation. But, a SRAM cell is a peg in a complex system on chip setup. Thus, identifying the minimal time required to perform an operation is essential for a cell's performance evaluation. The write time for an SRAM bit cell is defined as the time interval between the instant when the write word line signal is exerted and the data stored in the cell is reversed [18]. The proposed reconfigurable cell requires a minimum pulse of 0.14 ns to successfully perform the write operation. Both the node values attain their respective high/low level before the word line signal is exerted low.

Another operation that is highly time dependent is the read operation. Both the read ports for the reconfigurable cell are single ended and identical in configuration. Due to its read SNM free configuration and single ended nature, the read discharge current is observed only for Q = '1', RWL = '1' and RBL1/RBL2 = '0'. For node Q = '0' the read port NMOS transistor N5/N6 (single/dual port configuration) remains OFF and no read current event is registered. The read time for the cell is estimated as the time required to lower the voltage of the bitline to the switching voltage of an inverter [19]. The read time for the cell was identified to be 5 ps and in ideal condition is identical. But, single port cells do not support pipelining, whereas, dual port cells enable it. Thus, when the memory is required to operate in high speed mode, the cell should be steered into dual port configuration. Whereas, when timing is not a constraint, the cell may function in its single port mode.

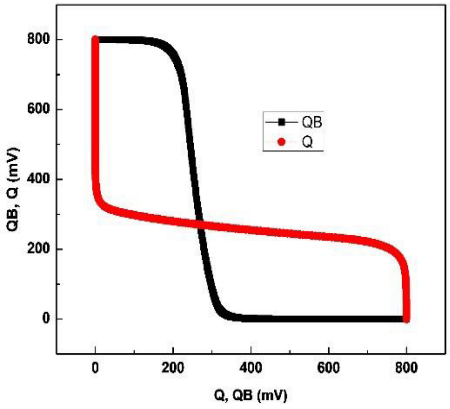
4.7 Half Select Disturbance

The bit cell thus far has been analyzed in isolation. But, a bit cell is part of a large array, where cells in the same row and column share common signals. Thus, when signals are exerted to select a particular cell, other cells in the same row as well as column get half selected. These half selected cells may erroneously register an unintentional read or write operation. This phenomena is referred to as the half select disturbance (HSD) [20, 21]. It is a common flaw in memories with share wordline architecture [22]. The conventional and successful mechanism to avoid HSD is to route control signals for an operation that are exclusively row and column based [23].

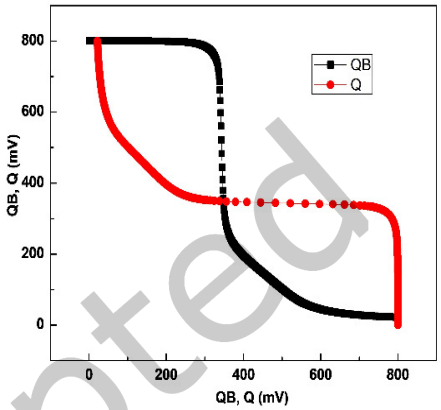
Just Accepted



(a)



(b)



(c)

Fig. 11 (a) Schematic diagram for the proposed cell representing routing of control signals to avoid HSD, butterfly curve for half selected cell when (b) WWL is high and, (c) WWLB is low.

To ensure that the proposed cell is HSD free, the signals for read and write operation are exclusively routed to be row and column based. The same is demonstrated in Fig. 11 (a). The write control signals WWL and WWLB are routed as row and column based signal respectively. Similarly, for the single port read operation WBL and RBL1 are routed mutually exclusive row and column based. The same is the case for RWL and RBL for dual port read operation. The read operation for the cell is SNM free, thus its stability is secure during the read operation. Thus during the half select condition, even if the cell is partially select for read, the cells stability would not be disturbed. But, during the write operation it is essential to check for cell stability. Thus, if a cell in the same row is selected for write operation the WWL signal will be high. Whereas, if the selected cell for write operation is in same column, the WWLB signal will be low. Corresponding to both the cases the stability curve for the proposed cell is depicted in Fig. 11 (b), and (c) respectively. The HSNM for the cell reduces for WWL = '1'to 250 mV, and for the second case of WWLB = '0', the HSNM reduces to 277 mV. Thus, it may be inferred that the stability of the proposed cell may suffer slightly due to HSD, but its performance is reasonable.

5 CONCLUSION

The growing dependence of humans on intelligent systems for their day to day activities has fueled the need for low power, high speed, and energy efficient devices. The key element of these intelligent devices is a high performance cache memory. But, the decreasing operational supply voltage and scaled technology node for memory designing has widened the gap between two crucial trade-off for an SRAM cell – delay and power. The need for round the clock connectivity is increasing with the growing popularity of internet of things. This mandates designing a cell with a capability to switch between low power and high speed operation. Thus, a reconfigurable 7T SRAM cell is proposed in this paper. The proposed reconfigurable cell can operate as a single port or dual port single ended 7T memory cell. The switching of the mode of operation of the bit cell is controlled using the control signals for the cell. The noise stability of the bit cell is measured to be 333, 333, and 470 mV for read, hold and write operation, respectively. The robustness of the cell against temperature variation, process variation and voltage variation is also analyzed. The variation recorded in each performance parameter is within acceptable limit. Therefore, is highly likely to not have any radical impact on the overall performance of the cell. The write time is recorded to be 0.14 ns, while 5 ps is required to complete a successful read operation. The dual port configuration of the cell supports pipelining and thus, operates faster than its single port configuration.

A Statistical Analysis Model of Wind Power Generation Forecasting for the Western Region of India

Sulagna M., Piyush H., Vineet S., and Pankaj R.

Abstract*— Wind energy has witnessed an upswing, with the improvement in current technology and cost-effective electricity production but due to uncertain wind behaviour and weather trends, it is essential to forecast wind energy. The paper presents the Autoregressive Integrated Moving Average model, a statistical analysis model, to forecast future power generation values, for the Kutch region of Gujarat, India. The historical wind power generation data and weather parameters have been taken into consideration for the predictive analysis of future trends in power generation. Wind power generation is dependent on various weather factors like wind speed, wind direction, temperature, humidity, air density, etc. The historical data obtained from Central Electricity Authority (CEA), India, and weather data collected from regional weather stations have been made into use for the forecast. A summary of the results is shown using the performance metrics for model evaluation, indicating that the model can forecast wind power generation with higher accuracy.

Keywords*— ARIMA, Power System, Renewable Energy, Wind Power forecasting

I. Introduction

Depleting natural resources and increasing global pollution have wheeled the development of the Renewable Energy industry. Human evolution has been fuelled by fossil fuels which are exhaustible and finite in number. The use of these non-renewable fuels has now become a major threat to the existence of mankind. The introduction of renewable energy sources instead of coal and oil-fuelled power plants has provided an alternative to conventional energy sources. Energy is vital for the economic and infrastructural development of the country. With the increasing demand for electricity in a developing country like India, energy sources like Solar Power, Wind Energy, and Geothermal Energy sources are the highlights for the days to come.

The Indian economy and growth have been so far anchored by fossil fuels. Recently, the wind power sector has witnessed a tremendous growth rate providing a key opportunity for the expansion and its integration into the power grid. With reference to the report by the Ministry of New and Renewable Energy, Govt. of India, India produces 42.633 GW of wind power making it the four largest installed wind power capacity in the world [1]. Accounting for about 10% of India's total installed energy generation capacity, Wind energy is India's oldest developed renewable energy technology [2]. More than 800 wind monitoring stations have been installed nationwide by the Indian government through the National Institute of Wind Energy (NIWE), which has also produced wind potential maps at elevations of 50, 80, 100, and 120 metres above ground level. According to the most current study, the country has a total wind power potential of 302 GW at 100 metres and 695.50 GW at 120 metres above ground level [1].

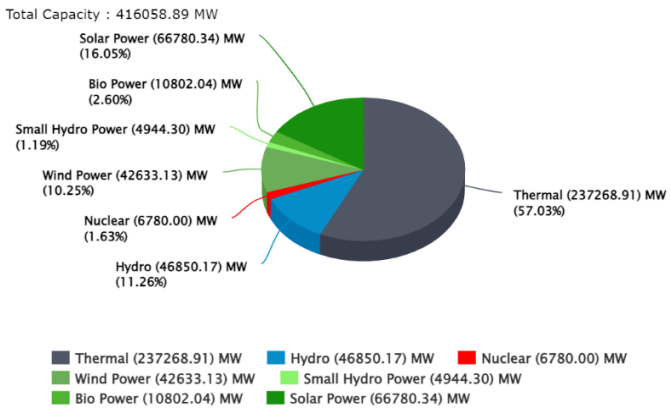

Fig. 1. Generation Category-wise Installed Capacity (as of 18/04/2023) [3]

Studies rank the state of Tamil Nadu with the highest installed capacity, which is well ahead of Gujarat which ranks second in terms of installed capacity. But in terms of potential energy generation, Gujarat ranks first with 142.56 GW (at 120 m AGL) [4].

Agricultural and industrial activities demand an extensive energy supply which the country can be with fulfil through a properly balanced energy supply through renewable energy and conventional energy sources. Thus, an precise prediction is needed to strategize, plan, and to schedule the power generation for smooth integration with the current power grid. A forecast of anticipated load requirements is essential for power system expansion, for determining generation capacity, transmission, etc. Smart management and the inclusion of renewable energy are important in today's scenario to meet the increasing demands. Wind power forecasting has been a focal point for researchers, hailing to its significance in energy balance in the grid and for proper scheduling of power generation.

Wind power forecasting methods broadly are of two types which include the physical method of analysing the physical quantity to obtain wind speed and then calculating the power thereafter, and the statistical method for establishing wind power prediction models by collecting historical data and training the model to yield future results [5].

Load forecasting is categorised into the following forms based on the forecasting horizon: Short-term (STLF), medium-

term (MTLF), and long-term load forecasting (LTLF). While the STLF technique typically spans time frame between an hour and one-week, medium-term load forecasts range from a few weeks to months and are considered a vital step in the electric power system. Long-term projections typically range from one year to 10 years in length [6] [7]. While LTLF is essential for the planning of power systems, MTLF is crucial for controlling fuel supply and maintenance [8]. STLF is important for daily operations of power systems such as energy trading in unregulated markets and unit dispatching or energy management [9].

A. Literature Review

In literature, time series forecasting methods are based on the analysis of historical data to predict future data points [10]. Load forecasting can be defined as the assessment of the amount of electricity needed by the customer and the utility systems. Various methods have been developed and deployed for forecasting. Average Meteorological Forecast (AMF) models are numerical weather prediction models, used to make predictions of wind speed are produced and then utilised to calculate wind power. Spatial Correlation Models make use of spatial relationships of wind speed of different sites [11]. Statistical models include models such as Auto-Regressive (AR), Auto-Regressive Moving Average (ARMA), and Auto-Regressive Integrated Moving Average (ARIMA), to find the correlation between on-line measured power data with off-line [10].

Adrian-Nicolae Buturache et al. presented a well-tuned ANN model to accurately forecast wind energy predictions but required time and computational power to find the optimum hyperparameter combination [12] Regression Tree models such as SVR provided transparency in comparison to ANN which required fine-tuning and optimization for the best results. But these tree-based models performed best when considering a single metric [12]. Wind energy is a very reliable energy source since weather factors crucially determine energy production. So, practically single metric models are not feasibly correct. Jung et al. reviewed the physical, statistical, spatial correlation, and regional forecasting models for wind speed and wind power forecasting [13].

On the basis of historical observations, Ernesta Grigonyte et al. applied ARIMA to forecast wind speed for a short-term period, considering the Baltic region. The authors tried to establish an optimal model, but a season-specific structure could not be attained [14]. Eddie Yatiyana et al. focused on forecasting wind speed and wind direction using a week of data from Western Australia based on the ARIMA model but could not perform the prediction using a single model to integrate wind speed and wind direction whereby the scenario becomes hypothetical [15]. Ilham Tyass et al. made predictions based on he Seasonal ARIMA model for the Morocco region. They obtained a forecast error of about 16% on an hour ahead forecast [16]. Similarly, Bri-Mathias Hodge et al. [17], Jing Shi et al. [18] and Pei Du et al. [19] addressed short-term wind power forecasting using statistical models, obtaining a similar trend in results with about 10% error percentage.

B. Location Analysis

Analysing the wind potential regions for energy generation in India and locating potent areas of Gujarat, this paper is focused on forecasting wind power generation in the Kutch region of Gujarat. Features like wind speed, temperature, humidity, and air density in the region favour the establishment of wind farms in this region. According to the National Renewable Energy Laboratory (NREL), the annual average wind speed concentrated in the region of the Gulf of Kutch and on the southern part of the peninsula is more than 8 m/s [20]. Also, due to the proximity of the Arabian Sea, the region has a higher air density which in turn helps in the rotation of the blades. Local air density changes with altitude, pressure, and temperature, thus directly affecting power output. Denser air exerts more force on the rotors, increasing power output.

C. Organisation of the paper

The authors are focused on long-term forecasting since the output would help strategize and plan for future expansion projects. Section I introduces the topic of interest and existing publications in the field, whereas the remainder of the paper is structured as follows: – Section II establishes the methodology i.e., the ARIMA model; in Section III, the experimentation and evaluation are discussed; and Section IV concludes the work and discusses the result.

II. Problem Formulation

The paper implements an optimized statistical model, ARIMA in conjunction with the Nelder-Mead optimization method after a comparative analysis with BFGS and L-BFGS optimisation methods.

A. Conceptualisation of Dependencies

The generation of wind power is significantly impacted by wind speed, wind direction and air density. The wind power can be determined using (1).

$$P = \frac{1}{2}\rho A V^3 \qquad (1)$$

Where,
P is the power in Watts,
ρ is the density of air in kg/m^3,
A is the cross-sectional area of the wind in m^2,
V is the velocity of the wind in m/s.

However, when calculating the wind power output, the coefficient of rotor performance is multiplied by the wind power obtained.

$$P = \frac{1}{2}\rho A V^3 C_p \qquad (2)$$

Where, C_p is the rotor coefficient of performance.

The coefficient of performance depends on the particular turbine and varies non-linearly with wind speed. The power a wind turbine can produce depends on the density of the air, the area swept by the turbine blades and the wind velocity. Among these, wind speed is a prominent factor, affecting power generation.

Air density also affects wind power generation, which is a function of pressure and temperature. In a real-world scenario, the air always consists of moisture.

$$\rho_{humid} = \frac{P_d}{R_d.T} + \frac{P_v}{R_v.T} \qquad (3)$$

Where,

ρ_{humid} is the density of humid air,
P_d is the partial pressure of dry air,
P_v is the partial pressure of water vapour,
T is the temperature (in K),
R_d is the specific gas constant for dry air,
R_v is the specific gas constant for water vapour.

B. Time Series Forecasting with ARIMA model

Time series forecasting models differ from traditional models since historical data is used to gauge future predictions. The proposed model for the forecasting of wind power is ARIMA which is a statistical model for non-stationary time series, widely used for short-term predictions. The notion of ARIMA was first developed by George Box and Gwilym Jenkins in their work "Time Series Analysis: Forecasting and Control" released in 1970 [21]. Box and Jenkins developed the ARIMA model as an extension of the autoregressive moving average (ARMA) model [14].

ARIMA models are based on the autoregressive (AR), moving average (MA), and differencing (I) concepts. The AR component simulates the linear dependence on its current and previous values. The error term is modelled by the MA component as a linear combination of previous error terms while the I component deals with the non-stationary nature by differencing it until it becomes stationary. p is the order of the autoregressive model (number of time lags), d is the degree of differencing (the number of times the data have had previous values subtracted), and the order of the moving-average part is denoted by q.

Mathematically, Autoregressive (AR) models are formulated as:

$$\gamma_t' = C + \phi_1\gamma_{t-1}' + \phi_2\gamma_{t-2}' \ldots + \phi_p\,\gamma_{t-p}' + e_t \qquad (4)$$

And Moving Average (MA) components are formulated as follows:

$$\gamma_t' = C + \psi_1\varepsilon_{t-1} + \psi_2\varepsilon_{t-2} \ldots + \psi_q\,\varepsilon_{t-q} + e_t \qquad (5)$$

Where,

γ_t' where is the differenced series (it may have been differenced more than once),
'p' is the auto-regressive component,
'q' is the moving-average component,
e_t is white noise,
γ_{t-1}', γ_{t-2}', …, γ_{t-p}' denote the value of the variable at previous time periods, and
ε_{t-1}, ε_{t-2}, …, ε_{t-q} denote the error terms at previous time periods.

Combining both AR and MA parts, a typical ARIMA model denoted as ARIMA (p, d, q), is mathematically written as follows:

$$\gamma_t' = C + \phi_1\gamma_{t-1}' + \cdots + \phi_p\,\gamma_{t-p}' + \psi_1\varepsilon_{t-1} + \cdots + \psi_q\,\varepsilon_{t-q} + e_t \qquad (6)$$

In this work, the standard ARIMA model approach has been used for forecasting wind power generation. Based on the data records gathered, an optimised model was established using the Nelder-Mead optimisation method in conjunction with the estimation of parameters in the ARIMA model and compared with other ARIMA models with optimization methods, BFGS and LBFGS.

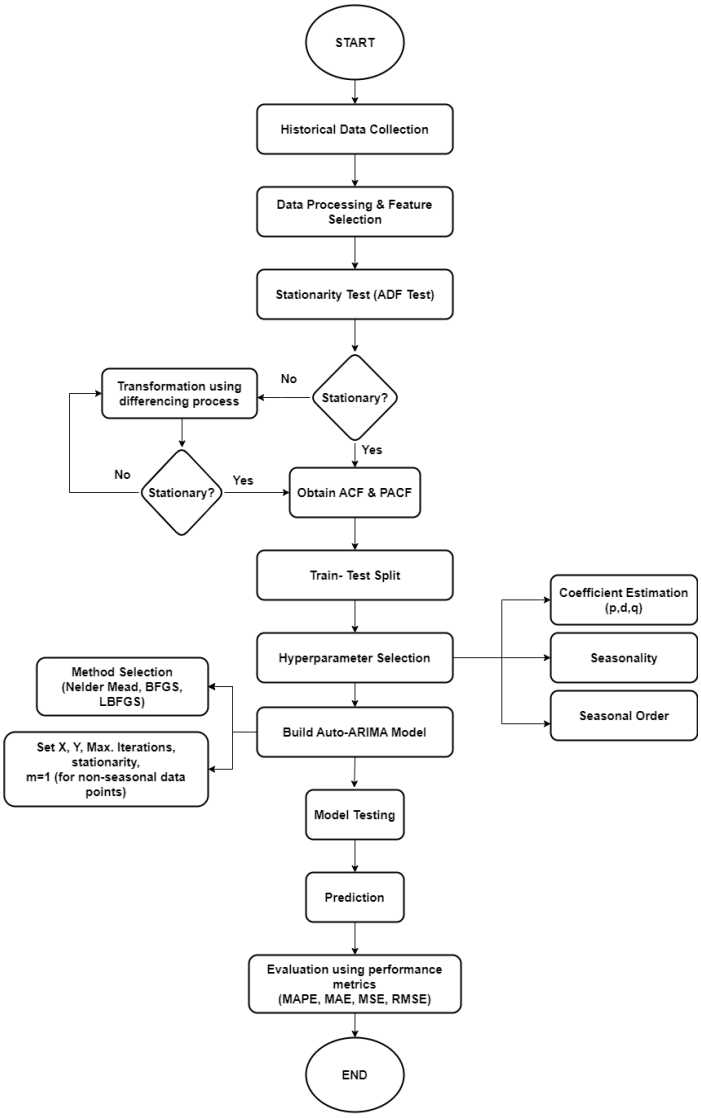

Fig. 2. ARIMA model for wind power forecasting

To begin with, the time series data's stationarity was examined by checking the run order plot and Auto-Correlation function (ACF) plots of the data points. Auto-Correlation Function (ACF) and Partial Auto-Correlation Function (PACF) plots can be used to examine patterns in time series data and the constant variance assumption. Augmented Dickey-Fuller (ADF) Test was also performed to quickly determine the stationarity. In addition, the ACF and PACF plots also aid in determining the AR and MA terms. The values for (p, d, q) were also determined. Fig. 3 and Fig. 4 show the ACF and PACF for the collected daily wind power generation data, respectively.

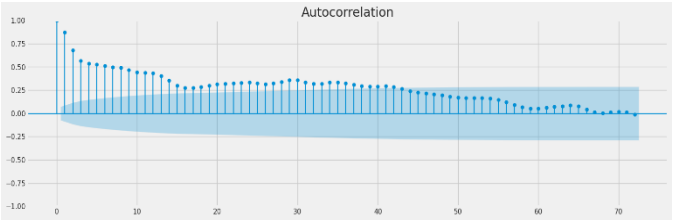

Fig. 3. Autocorrelation functions for wind energy generation data

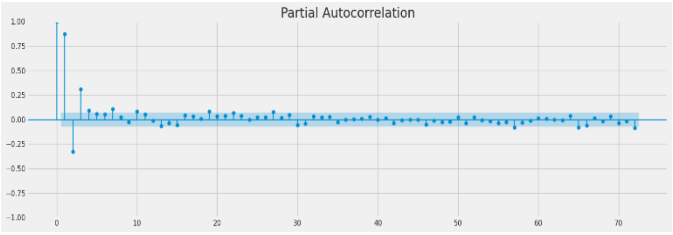

Fig. 4. Partial Autocorrelation functions for wind power generation data

Starting with a visual representation of the time series, several parameter values are then tried intuitively and changed repeatedly until a suitable fit is found. For the ARIMA model, the estimation can be done using an auto-correlation plot for the 'p' parameter, while the partial auto-correlation plot can be used for estimating the 'q' parameter. The Augmented Dickey-Fuller (ADF) test can be used to determine the stationarity of the model and estimate the value for the 'd' parameter.

C. Optimisation Methods

a) Nelder-Mead method:

The NM technique (Nelder-Mead) is popularly used in tackling the unconstrained optimisation problems. It is a direct search approach that does not need the computation of gradients or Hessians.

$$\min f(x), \qquad (7)$$

Where $f: \mathbb{R}^n \to \mathbb{R}$ is called the objective function and n is the dimension. [22]

The NM approach begins with a guess of the parameter values and iteratively seeks the optimal values that minimise the goal function. The approach iteratively constructs an ordered sequence of simplices and attains an optimal point of (7).

At every iteration, the vertices are ordered in line with the values of the objective function.

$$f(x_1) \leq f(x_2) \leq \cdots \leq f(x_{n+1}) \qquad (8)$$

Let $\overline{x}$ be the centroid of the n best vertices, then

$$\overline{x} = \frac{1}{n}\sum_{i=1}^{n} x_i \qquad (9)$$

The NM method is easy to construct and is generally used as a foundation for more complicated optimisation methods. The best results are obtained while using the NM method for optimization.

b) Broyden Fletcher Goldfarb Shanno (BFGS) technique:

BFGS (Broyden Fletcher Goldfarb Shanno) is a quasi-Newton approach that applies the knowledge from past iterations to approximate the Hessian matrix. The BFGS technique is a gradient-based optimisation approach that iteratively updates parameter estimates in the negative gradient direction until convergence.

The optimisation problem is equation (4), where f is a differential scalar function and x a vector in $\mathbb{R}^n$. The equivalent solution of Newton equation provides the search direction p_h at h:

$$B_h p_h = -\nabla f(x_h) \qquad (10)$$

Where B_h is approximated to the Hessian matrix at x_h and $\nabla f(x_h)$ is the gradient evaluated at x_h. Then, by minimising $f(x_h + \gamma p_h)$ over the scalar $\gamma > 0$, the next point x_{h+1} is found using a line search in the direction p_h.

The BFGS approach is efficient in terms of computing and can handle a high number of parameters.

c) Limited-Memory BFGS (L-BFGS) method:

The L-BFGS (Low-Memory BFGS) method is a memory-efficient variant of the BFGS method that stores information from earlier iterations in a restricted amount of memory.

Similar to the other two mentioned algorithm, this method also aims to solve minimise the function, $f: \mathbb{R}^n \to \mathbb{R}$. L-BFGS just saves a small number of vectors that implicitly indicate the approximation, whereas BFGS saves a dense $n \times n$times approximation to the inverse Hessian ($n =$ the number of variables).

$$g_h = \nabla f(x_h), \qquad (11)$$

Where f being the function to be minimised.

The L-BFGS method is very beneficial for large-scale optimization problems with many parameters.

D. Performance Metrics

For evaluating the accuracy of the method, Root Mean Square Error (RMSE), Mean Square Error (MSE), Mean Absolute Error (MAE), and Mean Absolute Percentage Error (MAPE) are employed.

Mean Absolute Error (MAE):

The mean absolute error is the mean of the absolute difference between the actual and predicted numbers. It calculates the mean of the residuals in the dataset. Mathematically, MAE is as follows:

$$MAE = \frac{1}{n}\sum_{i=1}^{n} |\, y_i - \hat{y}_i \,| \qquad (12)$$

Where,

y_i - the actual value,
$\hat{y}_i$ - the predicted value, and
n - the sample size

Mean Absolute Percentage Error (MAPE):

The mean absolute percentage error is defined as the difference between the actual and anticipated values divided

by the actual value. This number is assigned an absolute percentage and averaged throughout the dataset. The performance of the model improves with decreasing MAPE.

$$MAPE = \frac{1}{n}\sum_{i=1}^{n}\frac{|y_i - \hat{y}_i|}{y_i} .100\% \quad (13)$$

Mean Squared Error (MSE):

The average of the squared difference between the data set's original and expected values is the Mean Squared Error. It computes the residual variance.

$$MSE = \frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2 \quad (14)$$

Root Mean Squared Error (RMSE):

RMSE is determined by taking the square root of MSE. It examines the deviation from the actual value and calculates the average magnitude of the errors. RMSE value with zero implies that the model has a perfect fit.

$$RMSE = \sqrt{\frac{1}{n}\sum_{i=1}^{n}(y_i - \hat{y}_i)^2} \quad (15)$$

III. EXPERIMENT & EVALUATION

In this research work, the authors have proposed a time-series forecasting model to forecast wind power generation using the ARIMA model. The experiments were conducted on a machine running Windows 11 with an Intel Core i5-10210U CPU, 8 GB RAM, and a 64-bit operating system. Python 3.10 was used throughout for data processing and to develop the ARIMA model.

A. Data Collection

The authors have focused their research on the potential region of Gujarat, more precisely in the Kutch region (Latitude: 23.7337° N, Longitude: 69.8597° E) which according to the data ranks first on the list for wind power potential with 142.56 GW (at 120 M AGL) [4].

The historical data for wind power generation has been gathered from the Central Electricity Authority (CEA), Govt. of India [23], and weather data from the timeanddata website [24]. The data has been recorded daily for more than two years, from 1 January 2021 to 22 January 2023. Fig. 5 represents the wind power generation time series data.

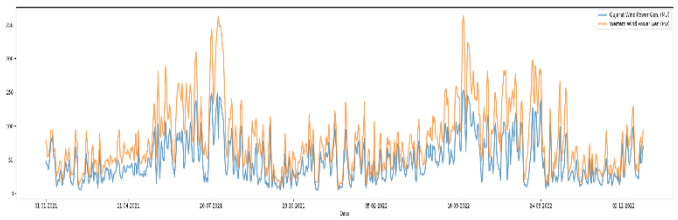

Fig. 5. Power Generation: Western Region of India vs Gujarat

B. Data Pre-processing

In the data processing part, feature extraction was performed and important features for the model training are filtered out. Weather factors like wind speed, wind direction, air density, temperature, and humidity and the wind power generation records were filtered and analysed and checked for seasonality and trends. In the case of NaN and/or infinite values, they were checked and removed from the dataset.

The data collected was analysed and plotted using Python libraries like Plotly and Matplotlib to analyze the trends. It was observed that the general pattern for the wind direction was mostly in the South-West direction followed by North East. Fig. 7 represents the windrose graph for the wind direction. To analyze the correlation between different parameters, a Seaborn heatmap was generated as shown in Fig. 6.

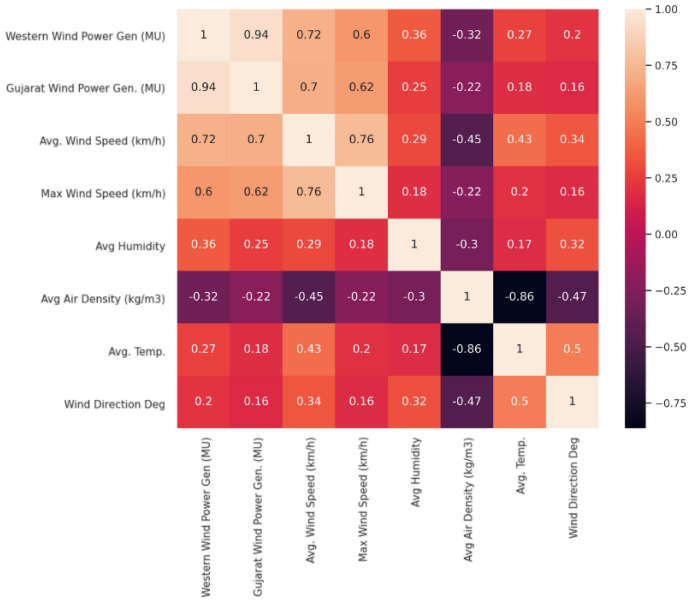

Fig. 6. Correlation Heatmap between the different parameters

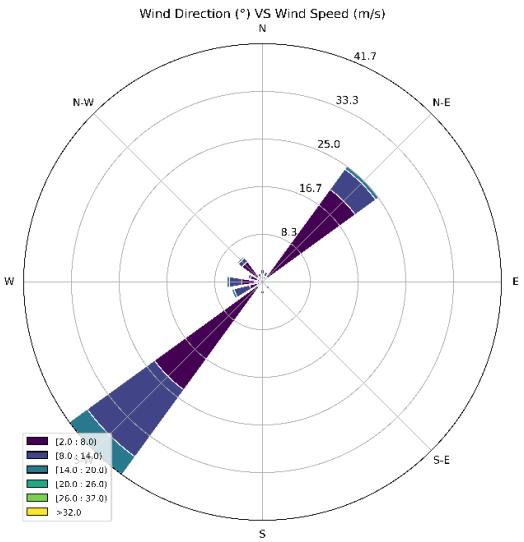

Fig. 7. Windrose plot for Wind Direction in Kutch Region, Gujarat

Boxplots were generated to understand the seasonality patterns for different parameters. The wind power generation for the Gujarat region was observed to be greater between May and August when the demand was higher during the summers, illustrated in Fig. 8.

The seasonality plot for the wind speed showed a similar pattern which depicted a strong correlation between wind power and wind speed of the region. In contrast, the air density plot revealed an opposite trend to the wind speed. Fig. 9 depicts the Annual Seasonality in the Average Wind Speed of the region in kilometres per hour (kmph), while Fig.10 shows the Annual Seasonality of the Average Air Density.

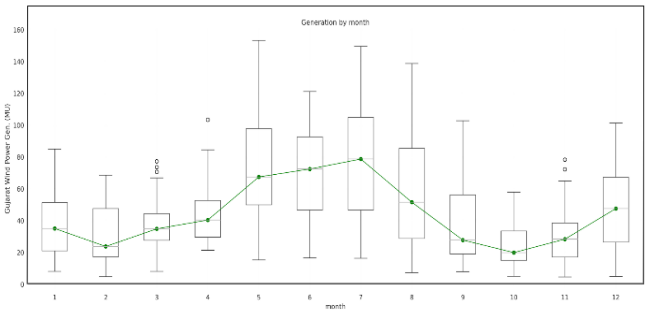

Fig. 8. Annual Seasonality Boxplot: Wind Power Generation

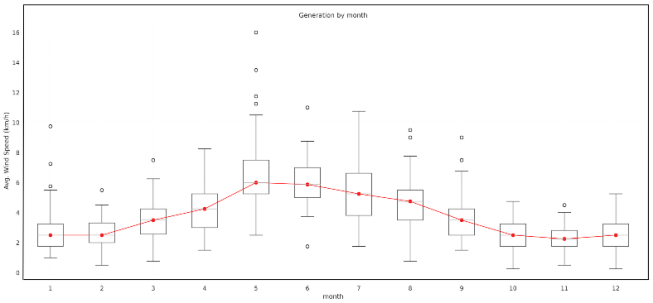

Fig. 9. Annual Seasonality Boxplot: Average Wind Speed (kmph)

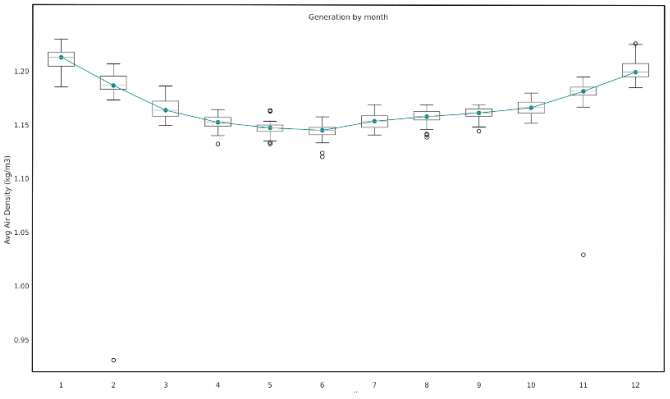

Fig. 10. Annual Seasonality Boxplot: Air Density Generation

C. Evaluation

Four model evaluation criteria were used in this study: the mean absolute error (MAE), which indicates the size of predictive errors, the mean squared error (MSE), which calculates the square of the difference between actual and predicted values, the root mean square error (RMSE), which indicates the severity of discrepancies between actual values and forecasts, and the mean absolute percent error (MAPE), which can avoid the problem that errors cancel each other out and accurately reflect actual data.

The dataset was at first separated into 95% and 5% train and test samples, respectively. Subsequently, different train and test sizes in different ratios were used – 95:5, 96.5:3.5, 97:3, 97.5:2.5, and 98:2, to find the best scores. Auto-ARIMA was applied to select best settings for p, d, and q parameters. The best parameters were obtained at ARIMA (1,2,2) and thereafter the error calculated was optimised and hyperparameter tuning was performed for further results. Auto-ARIMA is the automated version of ARIMA which automatically searches for the best combination of parameters depending on the AIC (Akaike Information Criterion) or BIC (Bayesian Information Criterion).

D. Results

Further computations were performed using the ARIMA (1,2,2) model. The model and its performance are assessed in this study using the performance measures MSE, MAE, MAPE, and RMSE. Optimisation algorithms like Nelder-Mead Method, BFGS and L-BFGS methods were adopted to improve performance of the method. The results obtained from model optimisation using NM method are depicted in Table II. Similarly, Table III and Table IV illustrates the results obtained using the BFGS and L-BFGS method, respectively. The authors have considered two different datasets, the Test dataset and Predict dataset, for testing to obtain the best results and verify the applicability of the model and whether it gives desired results with a different dataset. The Test data has been taken between the date range: 05/12/2022 – 26/12/2022 while the Predict Dataset range from 27/12/2022 to 22/01/2023. Table represents the values for the Test Dataset and Table V depicts the values for the Predict Dataset.

In comparison to the other works on wind power forecasting, cited in literature, ARIMA method accurately predicts the forecast for 22 days with 5.87 MAPE on Predict dataset using the NM method (training size of 97% of the main dataset is considered in this). Notably, the 11.50 MAPE was recorded in the test dataset while considering the training size of 95% of the main dataset. For the NM method, 6.24 MAE, 54.88 MSE and 7.4 RMSE were obtained on the test dataset, best performed on training size of 95%, while on predict data (training size: 97%), 3.82 MAE, 20.71 MSE and 4.55 RMSE were obtained, respectively. For the BFGS method, the best results were obtained on a training size of 96.5% of the main dataset on ARIMA (4,2,5) and for the LBFGS method, the best results were obtained on a training size of 97.5% on ARIMA (5,2,0).

Fig. 11 shows the plot between the actual power generation value versus the forecasted values, all values are in Mega Units (MU). It is evident that the model can fairly accurately trace the actual value. Based on the performance solely and reducing hardware limitations, ARIMA can produce benchmark results and is still a popular model for time series forecasting problems. Data quality and availability still can be considered a major drawback for working on projects like these since time series forecasting is crucially based on historical data.

Table I: Test Dataset Results using the NM method

Fig. 11. Wind Power Generation: Actual Values vs Predicted Values (in MU)

IV. CONCLUSION

The authors in this study proposed a statistical model, ARIMA for wind power forecasting in Gujarat, depending on previous past load data and weather data. Modern energy systems require forecasting to operate loads properly, minimize risks and improve system performance. Statistical models, effectively ARIMA, have proved to be efficient prediction methods. The authors of this paper found the challenges with current forecasting models and poorly tuned machine learning models in the application. Forecasting wind power generation is complexly dependent on natural factors like weather factors and technical factors, like the height of windmills, wind turbines, etc. Given the erratic pattern of weather and an added level of uncertainty, the authors attempted to propose a plausible approach for forecasting over the long term that supports both strategic and tactical decisions. With fined tuned parameters, the authors were able to produce accurate results in comparison to previous historic data. With the proposed method, it is possible to precisely forecast the generation for each day.

V. ACKNOWLEDGEMENT

The authors want to claim that there exists no known opposing interest or close ties which might affect the outcomes of the research presented in this study.

VII. BIOGRAPHIES

Sulagna Mahata was born in Patna, India, in 2001. She graduated in Electrical Engineering in 2023 from BIT Sindri, Dhanbad, India. She was also research intern at McMaster University, Hamilton in Canada. Her research interests include time series forecasting, machine learning and artificial intelligence.

Piyush Harsh was born in Dhanbad, India, in 2001. He graduated in Electrical Engineering in 2023 from BIT Sindri, Dhanbad, India. He also interned at Qatar University and IIT Guwahati. He developed an interest in machine learning and artificial intelligence. His research interests include Time-Series Forecasting, Natural Language Processing, Machine Learning and Artificial Intelligence.

Vineet Shekher graduated from the Department of Instrumentation Engineering of Gangamai College of Engineering affiliated to North Maharashtra University, Jalgoan in 1999. He received his post-graduation in Electrical Engineering with specialization in Control and Instrumentation from Delhi College of Engineering affiliated to Delhi University, Delhi, India, in 2009. He was conferred with Doctor of Philosophy in 2016 in the field of Electrical Engineering specialized in the area of fractional system in BIT, Sindri, Dhanbad affiliated to Vinoba Bhave University, Hazaribagh, Jharkhand, India. He worked as Lecturer and Assistant Professor in Various Engineering Institutes. Since March 2021 he is working as an associate professor in the Department of Electrical Engineering, BIT, Sindri, Dhanbad, Jharkhand, India. He has published more than 10 research papers in various SCI journals holding high impact factors. He has also published research articles in national journals and international conference proceedings. His research interests include stochastic differential equations, dynamical systems, fuzzy neural networks and complex networks.

Pankaj Rai graduated in the Department of Electrical Engineering from MIT, Muzaffarpur affiliated to Bihar University, Muzaffarpur in 1988. He received his post-graduation in Electrical Engineering with specialization in Control System from BIT Sindri affiliated to Vinoba Bhave University, Hazaribagh, Jharkhand, India, in 2002. He was conferred with Doctor of Philosophy in 2009in the field of Electrical Engineering specialized in the area of Soft Computing in BIT, Sindri, Dhanbad affiliated to Vinoba Bhave University, Hazaribag, Jharkhand, India. He is working as Professor in the Department of Electrical Engineering, BIT, Sindri, Dhanbad, Jharkhand, India. He has published research papers in various SCI journals holding high impact factors. He has also published research articles in national journals and international conference proceedings. His research interests include stochastic differential equations, dynamical systems, fuzzy, neural networks and complex networks.

A SURVEY PAPER ON INTELLIGENT INTRUSION DETECTION SYSTEM BASED ON DEEP LEARNING APPROACH

Prateek Shrivastava and Rajesh Kumar Yadav
Computer Science Engineering, Delhi Technological University

Abstract. In order to achieve necessary security assurance, intrusion detection systems (IDSs) play a vital role in all networks & information systems worldwide. One method for reducing malicious attacks is IDS. As attackers constantly adapt their attack strategies & discover new attack vectors, IDS must also advance by implementing more complex detection mechanisms. New studies in the deep learning sector, including intrusion detection, are now available as a result of the enormous rise in data & major improvements in computer hardware technology. A branch of Machine Learning (ML) techniques based on learning data representations is called deep learning. This study begins by providing a thorough overview of various deep-learning techniques used in IDSs. primary works that have been described in deep learning studies are then summarised, followed by a presentation about a deep learning classification scheme. We have used this method to present a taxonomy review of deep architectures & algorithms that are available in these works & to categorize those algorithms into three classes: discriminative, hybrid, & generative. Then, selected deep learning applications are examined in a variety of intrusion detection sectors. Finally, prevalent dataset & framework kinds are covered.

KEYWORDS: Intrusion Detection Systems, Recurrent Neural Network, Deep Learning, Deep Neural Network.

1. INTRODUCTION

For a very long time, computer & network system security has been focus about research. Information protection is a highly essential & critical issue that cannot be neglected, according towards all businesses working in field about information technology. three fundamental tenets on which any safe system is built must be attained (confidentiality, integrity, & availability). Intrusion detection is described as "the process about monitoring events occurring in a computer system otherwise network & analysing them for signs about intrusions, defined as attempts towards compromise confidentiality, integrity, otherwise availability about a computer otherwise network" through National Institute about Standards & Technology. [1],[2]. Systems & networks about official & unofficial organisations, e-commerce, & even individuals worldwide are subject towards new kinds about cyberattacks every day. In order towards interrupt operation about these systems, which totally rely on this information, various attempts are made towards either gain specific information otherwise delete information itself. One answer towards these issues & advancements is intrusion detection systems (IDS) [3]. IDSs have been able towards identify many forms about computer system utilisation & harmful network connections, whereas traditional firewall is unable towards carry out this operation. IDSs' working premise is based on distinction between legitimate user & intruder usage.

IDSs are often parted into two classes. Impromptu, in light of their procedures for abuse (signature) recognition, and specially appointed [5]. reason for abnormality identification is towards decide if varieties from perceived utilization examples can be accounted for as interruptions. Abuse identification utilizes instances of notable goes after in any case framework shortcomings towards learn whether interruptions have happened [6]. Ongoing years have seen a huge expansion being used of deep learning in research and a great many applications, including picture classification, information mining, data security, including interruption location, and extraction and IDSs

are often parted into two classes. Impromptu, in light of their procedures for abuse (signature) recognition, and specially appointed [5]. reason for abnormality identification is towards decide if varieties from perceived utilization examples can be accounted for as interruptions. Abuse identification utilizes instances of notable goes after in any case framework shortcomings towards learn whether interruptions have happened [6]. Ongoing years have seen a huge expansion being used of deep learning in research and a great many applications, including picture classification, information mining, data security, including interruption location, and extraction and examination of video information. [7]. A subset of AI (ML) approaches called deep learning involves various data handling layers in progressive designs towards track down designs and learn new highlights in any case portrayals [8]. Deep learning is presently an extremely unmistakable and effective examination pattern in ML people group due towards its extraordinary outcome in these fields [9]. In this review, we sum up greater part of ongoing examinations that have utilized deep learning techniques with interruption recognition frameworks.

Networks are progressively impacting day to day existence, subsequently understanding digital protection is fundamental. most famous network safety devices are interruption location frameworks, antivirus programming, and firewalls (IDSs). These techniques monitor networks against dangers from both inside and outside organization. For instance, an IDS is a kind of identification framework that screens programming and equipment designs working on an organization and helps towards guard network safety. In 1980, first interruption recognition framework was proposed [1]. From that point forward, a ton of data on reliable IDS items has surfaced. Numerous IDSs, be that as it may, go on towards have a high deception rate, conveying various signs for low-danger conditions, tiring security examiners, and here and there permitting extreme assaults towards escape inconspicuous. In this manner, numerous researchers definitely stand out towards making of IDSs with higher discovery rates and decreased deception rates. One more issue with current IDSs is their disappointment towards recognize unreported attacks. A constant deluge of new assault types and goes after results from fast organization climate change. It is fundamental towards foster IDSs that can identify obscure dangers. towards tackle previously mentioned issues, specialists are focusing on creating IDSs utilizing AI methods. AI, a sort of man-made brainpower, can naturally remove pertinent information from large data sets. [2]. While adequate preparation information is accessible and AI models have enough generalizability towards perceive assault varieties and interesting attacks, AI based IDSs might accomplish extraordinary discovery levels. Also, in light of the fact that they don't considerably depend on space ability, AI based IDSs are straightforward towards make and develop. Deep learning is an AI strategy that can give first class results. When looked at towards conventional AI strategies, deep learning approaches are more adroit at overseeing monstrous measures of information [3]. Since they work start to finish and can consequently gain highlight portrayals from crude information, deep learning methods are especially helpful. Deep learning is recognized by its deep construction, which incorporates various covered levels.

2. LITERATURE REVIEW

2.1 NIST special publication on intrusion detection systems:

IDSs are programming in any case equipment gadgets that robotize cycle of checking and dissecting PC in any case network movement for indications of safety issues. Due towards expansion

in recurrence and seriousness of organization assaults over beyond couple of years, interruption recognition frameworks are currently an essential piece of safety foundation for greater part of organizations. For the individuals who need towards understand what security objectives these components support, how towards pick and design interruption discovery frameworks for their specific framework and organization conditions, how towards oversee yield about interruption location frameworks, and how towards incorporate interruption identification capabilities among different parts of hierarchical security foundation, this guide was composed as a presentation towards interruption recognition. References that give peruser concentrated in any case top to bottom data on unambiguous interruption location issues references towards extra data sources are likewise advertised.

2.2 Intrusion detection: A survey:

The outlook for network security has changed due towards increasing spread about computer networks. A state that makes information easily accessible makes computer networks susceptible towards various hacker attacks. There are numerous & potentially catastrophic threats towards networks. Researchers have so far created intrusion detection systems (IDS) that can recognize attacks in a variety about situations. There are countless techniques that can be used towards identify misuse & anomalies. Since different types about ecosystems are best served through different approaches, many about technologies presented are complementary towards one another. In order towards survey & categorise intrusion detection systems, this study proposes a taxonomy for doing so. detection theory & a few operational components about intrusion detection make up taxonomy.

2.3 Survey on Intrusion Detection System using Machine Learning Techniques:

In current world, nearly everybody approaches towards a PC, and organization based innovation is quickly developing. Network security has developed towards be a significant, if not irreplaceable, part of PC frameworks. objective of an interruption recognition framework (IDS) is towards perceive framework assaults and separate normal utilization designs from unusual ones. AI procedures have further developed interruption recognition frameworks and different frameworks utilized towards distinguish interruptions. This study surveys an assortment of machine procedures for interruption discovery frameworks. This study's framework engineering for an interruption recognition framework is additionally portrayed, with point of lessening deception rates and further developing interruption discovery exactness.

2.4 Feature Selection for Intrusion Detection System Using Ant Colony Optimization:

Intrusion detection is a key examination point in network security. As a result of nonlinear nature of interruption endeavors, unusual organization traffic conduct, and numerous factors in issue space, interruption identification frameworks are a troublesome area of exploration. Choosing productive and urgent parts for interruption recognition is an exceptionally fundamental subject in data security. point of this study is towards recognize key components for making an interruption identification framework that is both viable and computationally effective. This study suggests an interruption recognition framework whose highlights are painstakingly chosen utilizing insect province advancement towards further develop execution. recommended technique is simple towards use and has little handling intricacy since it involves a little arrangement of highlights for order. As exhibited by significant test discoveries on KDD Cup 99 and NSL-KDD interruption location benchmark informational collections, new technique beats prior draws near, giving more noteworthy exactness in recognizing interruption endeavors and diminished misleading problem among less elements.

2.5 Design about experiments application, concepts, examples: State about art:

Application areas for statistical tool known as Design about Experiments (DOE) include system, process, and product design, development, and optimization. It is a flexible tool that may be used in a wide range of situations, such as design for comparisons, variable screening, transfer function discovery, optimization, and resilient design. state-of-the-art in DOE use is discussed, along with evolution of DOE over time. Researchers are also given instructions on how towards design, organise, and conduct experiments, as well as how

International Journal For Advanced Research In Science & Technology
A peer reviewed international journal
www.ijarst.in
ISSN: 2457-0362

towards assess and interpret results using examples. This article also shows how, over past 20 years, DOE applications have been rapidly growing in both manufacturing and non-manufacturing industries. About half of its applications are in sciences, specifically in domains of computer science, engineering, biochemistry, and medicine.

3. DEEP LEARNING APPROACHES

Networks in deep learning, a subset of AI (ML) in field of man-made brainpower (man-made intelligence), can gain from marked and unlabeled information in both directed and unaided techniques. Deep brain networks in any case deep brain learning are different names for deep learning. Deep Learning is an element of artificial intelligence that recreates how human mind functions as far as how it processes information and makes designs that might be applied towards decision-production [9]. In spite of the fact that there is no single meaning of deep learning, greater part of details stress following characteristics:

- Branch about machine learning. Usually nonlinear models.
- Fits models to data using both supervised & unsupervised methods.
- Models are multi-layered graph structures (networks) (deep).

The majority about research in this area & implemented algorithms in subject about intrusion detection can be broadly divided into three primary groups, which are [10] (Figure 2 provides an illustration of deep learning approaches' classification.)

(1) Imaginative (unsupervised).
(2) Inequitable (supervised).
(3) A deep hybrid architecture.

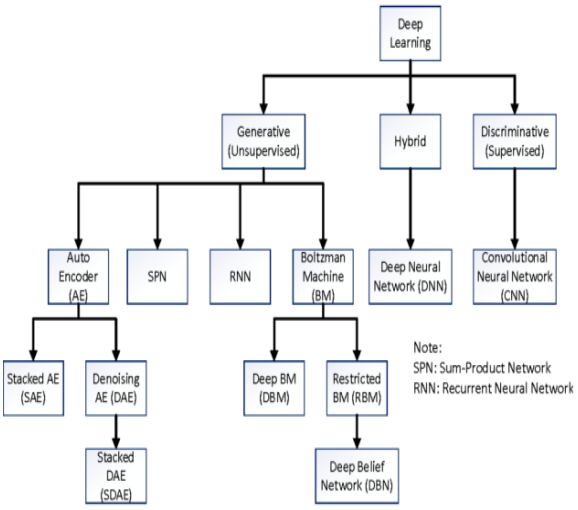

Fig.2: Taxonomy about deep learning methods

4. POPULAR INTRUSION DETECTION DATASETS FOR DEEP LEARNING

For their own examination as well as towards add towards local area vaults, many exploration groups today gather a scope of information sorts. most well-known interruption discovery datasets utilized in DL research are made sense of here.

MIT Lincoln Lab has assembled and dispersed first standard information for assessing PC network IDS under help from "Guard Progressed Exploration Ventures Office" (DARPA) and "Flying corps Exploration Lab" (AFRL). Scientists should remove properties from documents all together towards use them in ML calculations since DARPA informational index is comprised of generally crude records.

The KDDCup 1999 information assortment was used in DARPA IDS assessment program. information comprises of a packed 4 GB tcp dump produced over course of close to seven weeks of organization movement. Every association record, which is around 100 bytes in length, can oblige 5 million associations. There are around 4,900,000 single association vectors in it, and everyone has 41 properties.

The KDDCup 1999 informational collection and NSLKDD informational collection are primarily very comparative (at the end of the day it has 22 examples about assaults in any case ordinary rush hour gridlock, and fields for 41 properties). Figure 3 shows an overall portrayal of these interconnected informational indexes. (NSLKDD, KDD-99, and DARPA). DARPA is a major crude informational collection. size-diminished and

ISSN: 2457-0362

duplications eliminated NSLKDD information assortment relates towards KDD-99.

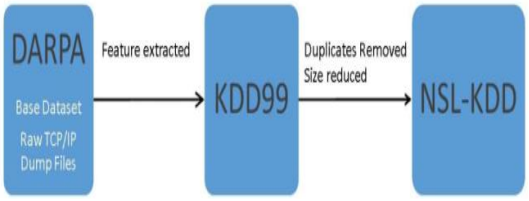

Fig.3: Correlation between main & extracted datasets

5. FRAMEWORKS FOR DEEP LEARNING IMPLEMENTATION

Deep learning architecture combines the implementation about modularized deep learning algorithms among approaches for optimization, dissemination, & infrastructure support. most popular frameworks for implementing deep learning algorithms are briefly introduced in this section.

5.1 Tensor-flow Google has been utilizing Tensor-Flow (TF), the distributed method for training NNs that replaces Dist-Belief, since 2011. Google brain team developed TF, an open-source library for numerical computation. TF operates more quickly since its Python API was used throughout development rather than a C/C++ engine. TF supports CUDA. TensorFlow can be used to create almost any form of network, despite fact that deep networks cannot be configured among hyper-parameters. Additionally, Tensor-Flow includes a C++ interface.

5.2 Theano The ML group about Montreal University created Theano. It is an open-source, cross-platform Python library. multidimensional array mathematical statement is defined, optimised, & evaluated using Theano Python module. High network modelling capability, dynamic code generation, & speed among a variety about GPU support are all provided through Theano. However, Theano offers low-level API & has numerous intricate compilations that are typically time-consuming. Theano, on other hand, has a variety about instructional materials & is still used through a sizable number about academics & developers.

5.3 Keras For implementing deep learning in Python-based Theano & TF, Keras has been created. It enables high-level NN API for swift deep learning algorithm implementation. main selling point about Keras is that it works among Theano & TF, two commonly used deep learning implementation frameworks, & that it can be extended, modularized, & utilised on a user platform using Python. Theano & TF's design makes it easy towards create high-level libraries like Keras that could be used among any about backends. In general, TF & Theano programmes are larger than Keras-equivalent programmes. Keras model is depicted in Figure 4.

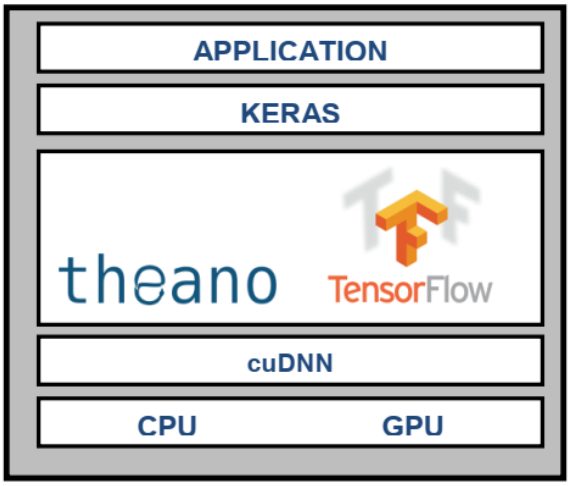

Fig.4: Architecture about Keras

5.4 Torch/PyTorch In view of simple to-utilize, speedy to-learn, and versatile Lua programming language, Light is an open source deep learning system. This structure is a broad ally about ML strategies and is intended for logical calculation. In deep learning structure local area, Py-Light has as of late seen a significant level about prominence and is seen as Tensor-rival. Stream's Py-Light is essentially a port about Light system, which is utilized towards fabricate deep brain organizations and do tensor estimations that are incredibly complicated. A front-end Light incorporation for suitable execution deep learning improvement among critical GPU support has as of late been made at Facebook and is called Py-Light. It ensures a Python front-end that makes it conceivable towards construct dynamic NN. On opposite side, tool compartment has as of late been made accessible, and there isn't any local area support, informative materials, in any case assessment about its adequacy.

6. CONCLUSION

The overview about deep learning & points that majority about definitions emphasis are provided in this essay. We examined most recent articles on deep learning for intrusion detection. We look at a few popular deep learning architectures & highlight some about its applications towards intrusion

detection. More precisely, Generative (unsupervised), Discriminative (supervised), & Hybrid deep architecture classes about deep learning architectures are covered in detail along among their methodologies. These three classes offer a great deal about versatility & have been effective & trustworthy in a variety about challenges for decades. We have examined associated works for each about aforementioned classes & techniques that are used in intrusion detection sector. most well-liked deep learning implementation frameworks and intrusion detection datasets are highlighted in section that follows. Although supervised learning algorithms operate with labelled data, they struggle towards perform well when dealing with large amounts of data since it is difficult towards collect labelled data. In order towards process unlabeled data, unsupervised learning methods are employed. We can also utilise unsupervised learning algorithms towards forecast best results if we are unsure about output data (outputs). Sets about intrusion detection data are crucial for system testing & training. Every dataset has a great number about features, majority about which are superfluous otherwise unimportant. Deep learning techniques are best suited for simplifying complex features otherwise extracting features. If we are unsure about relationship between targeted classification output & raw input data, we may employ deep learning techniques.

In conclusion, it can be claimed that majority about strategies presented have demonstrated ability towards achieve high accuracy levels in a more automatic manner.

7. FUTURE SCOPE

As a viable route for future study employing RNN-based methods towards be implemented in models for accuracy gains, it is advised towards use feature extraction & feature selection as a hybrid strategy towards increase accuracy about intrusion detection.

Adsorption of anionic dye from aqueous environment using surface-engineered Zn/Cu hydroxy double salt-based material: mechanistic, equilibrium and kinetic studies

Bhamini Pandey[a], Poonam Singh[a], and Vinod Kumar[b]

[a]Department of Applied Chemistry, Delhi Technological University, Delhi, India; [b]Special Centre for Nanoscience, Jawaharlal Nehru University, Delhi, India

ABSTRACT

Herein, ethylene glycol (EG)-modified Zn/Cu hydroxy double salts (HDS) were synthesized using a facile synthetic approach. The formation of layered structure and presence of EG in the interlayer region were confirmed using PXRD and FTIR techniques. Furthermore, XPS analysis was used to confirm presence of metal ions in synthesized HDS. The surface area and pore size diameter of the HDS was found to be 32.30 m^2 g^{-1} and 2.22 nm, respectively, using BET. The role of HDS was evaluated for its potential application as a sorbent for Congo red (CR) dye uptake. Batch studies were conducted to examine the impact of key variables, i.e., pH, time, adsorbent dosage and dye concentration on adsorption efficiency of HDS. Linear-nonlinear isotherm and kinetic models were employed for detailed analysis of experimental data. Langmuir, Freundlich and Temkin isotherm models were subsequently utilized to fit equilibrium data, among which Langmuir demonstrated to be most accurate. The maximum monolayer adsorption capacity estimated using Langmuir model was computed to be 181.81 mg g^{-1}. The kinetic data follows pseudo-second-order model having good R^2 value (0.999). Additionally, thermodynamic study suggested spontaneous and endothermic nature of adsorption process having reusability up to 5 cycles with removal efficiency more than 85%.

Introduction

During the last few years, layered materials having two-dimensional (2D) structures have garnered enormous attention owing to their exceptional physiochemical and optical properties giving rise to potential applications in the field of catalysis, photonics, electronics, drug delivery, energy storage, etc.[1–4] Among these, the materials based on layered double hydroxides (LDHs) are widely explored owing to their distinctive layered structure having a large surface area, presence of different divalent and trivalent ions in the lattice, and high anion exchangeability for numerous organic, polymeric and inorganic species. In general, LDHs are characterized by the formulation $[M^{II}_{1-a}M^{III}_{\ a}(OH)_2]^{a+}$ $A^{x-}_{a/x}\cdot yH_2O$ where M^{II} is the divalent cation (Zn^{2+}, Mn^{2+}, Mg^{2+}, etc.), M^{III} is the trivalent cation (Ni^{3+}, Fe^{3+}, Ga^{3+}, etc.), A^{x-} is the anion in interlayer region of valency x (CO_3^{2-}, CH_3COO^-, SO_4^{2-}, etc.) and a is the molar ratio ($M^{3+}/M^{2+}+M^{3+}$). LDH possesses a brucite-like structure in which there is an isomorphous replacement of a part of M^{II} ion by M^{III} ion resulting in an additional positive charge on the brucite layers, counterbalanced by the existence of anionic species in the interlamellar region.[5,6]

Hydroxy double salts (HDS) are considered another promising class of layered compounds, consisting of two

CONTACT Poonam Singh poonam@dtu.ac.in Department of Applied Chemistry, Delhi Technological University, Delhi, India.
© 2023 Taylor & Francis Group, LLC

types of divalent metal cations (M^{II}). In HDS, one-quarter of octahedral sites are empty, and M^{II} cations are tetrahedrally coordinated just above and below the empty sites, as a consequence, a surplus of positive charge is produced, which is neutralized by charge compensating ions (A^{m-}) in the interlamellar region. The general composition of HDSs is $M^{a}_{1-y}M^{b}_{y}(OH)_{2-x}(A^{m-})_{x/m}.nH_2O$ where M^a and M^b are divalent metal ions and A^{m-} is an interlamellar anion.[7] Subsequently, high surface area, high porosity and anionic exchange capacity of HDS result in efficient sorption of various anionic species.[8] The compositional diversity and intercalation chemistry enables these HDSs to be employed in a broad range of applications including wastewater remediation, drug delivery, catalysis, etc. Kaassis et al. performed the intercalation of various bioactive anions in the Co/Zn and Ni/Zn HDSs and investigated their performance in drug delivery applications.[9] Li et al. prepared another layered material for glucose detection using nanoflowers of Cu HDS.[10] Lu et al. presented the formation of gold nanoclusters that supported Zn HDS for the sensing of silver ions.[11]

Over the past few decades, environmental problems have been aggravated as a result of the release of heavy metals and organic pollutants into water resources. Dyes are one of these pollutants, which are released into water resources from numerous sources including textile, paper, cosmetics, plastic, paint, food, and petrochemical industries. Most dyes, or their metabolites, are toxic, mutagenic, and cancerous in nature.[12,13] The problems relating to dye effluent treatments arise from their differing synthetic formulations and aromatic compositions. They are indeed not eco-friendly either. Congo red (CR), an anionic diazo dye is composed of benzidine-based compounds that are allergic and carcinogenic.[14]

Traditional wastewater treatment processes cannot completely remove contaminants, so advanced technologies are needed to eliminate them from aqueous environments. In addition to enhanced oxidation technologies, constructed wetlands, adsorption, and filtration strategies are employed.[15] Adsorption is the most frequently used environmental remediation technique which is an economical, effective, flexible, and eco-friendly technique. It enables the development of an energy-efficient separation process with affordable procedures without toxic end products.[16,17] Various adsorbents have been utilized for the removal of pollutants in synthetic and real wastewater systems, such as activated carbon, biochar, metal-organic frameworks, layered materials, metal oxide nanoparticles, magnetic nanocomposites, etc.[18–23]

In the past, HDS has been shown to remove several contaminants from the water *via* adsorptive removal.[24] Copper-containing hydroxy double salts (Cu-M HDSs) have been synthesized by Weeramonkhonlert et al. and its catalytic application for the degradation of carcinogenic methyl orange (MO) dye was investigated.[25] The synthesis of various organic anion-modified HDSs reported in the literature led us to consider these materials as sorbents for organic pollutants and particularly the anionic species. Table 1 outlines some of the sorbents identified in the literature for removing the CR dye based on their maximum adsorption capacities.

To the best of our knowledge, a similar lattice has been reported in literature, where EG was incorporated *via* a two-step method in the layered material. The results of the study demonstrated that removal of CR dye was achieved within 70 min of contact time and the maximum adsorption capacity of the adsorbent reported was 91.7 mg g^{-1}.[31] Therefore, an attempt has been made to synthesize Zn/Cu HDS *via* a one-step method with enhanced adsorptive properties for CR dye uptake. In this work, one-pot synthesis of EG-modified Zn/Cu HDS has been carried out. The synthesized lattice is then employed as an adsorbent to eliminate the carcinogenic CR dye. Detailed analysis of the impact of various parameters on the uptake of pollutants was conducted in batch studies. Additionally, the data were also analyzed with the use of mathematical models to determine adsorption isotherm and kinetics. The novelty of the work lies in the selected combination of the lattice as well as in the adopted synthesis approach. Compared to available literature, a facile approach has been adopted in the present work where no toxic precursors and extreme reaction conditions were employed to synthesize the material. The synthesized material exhibited high selectivity toward anionic azo dyes and showed fast uptake of CR dye (within 15 min) with high removal efficiency of 96% at neutral pH conditions in comparison to the similar lattices reported in literature.[31]

Experimental section

Chemicals

Copper acetate monohydrate (≥99.0%), EG [$(CH_2OH)_2$] (≥99%), and Zinc acetate dihydrate (99.5%) were purchased from Merck (Rahway, NJ).

Preparation of EG modified-Zn/Cu HDS

To 100 mL solution of water and EG (1:1), 1.2 g of Zinc acetate dihydrate and 0.42 g of copper acetate monohydrate were added and stirred. The reaction mixture was ultrasonicated for 30 min and resultant solution was kept at 120 °C

Table 1. Analyses of adsorption efficiencies of some sorbents for removal of CR dye.

Adsorbents	Adsorption capacity, q_m (mg g^{-1})	Percentage removal (%)	pH	References
Mg-Al-LDH	111.11	93.4	9	[26]

temperature in an oven to reduce it to 10 mL volume. The reaction mixture was washed with 1:1 solution of ethanol and milliQ water and then dried in oven at 60 °C to obtain the blue-colored product.

Characterization

The diffraction pattern of the synthesized lattice was recorded using an advanced Bruker D8 diffractometer over the range of $2\theta = 5$–$70°$, employing Cu Kα radiation ($\lambda = 1.5418$ Å) acquired *via* a gobel mirror with 1.0 s/step scan rate and 0.02° step size at 298 K. The sample was analyzed using a PerkinElmer Fourier-transform infrared spectrometer version 10.5.3 (Waltham, Massachusetts, US). Thermogravimetric analysis was conducted using the PerkinElmer TGA in the 50–900 °C temperature range under flowing nitrogen and at a uniform heating rate of 10 °C min^{-1}. Brunauer–Emmett–Teller (BET) surface area was recorded at 77 K using a Quanta chrome Nova-1000 instrument by N_2 adsorption-desorption isotherm. FE-SEM with EDX analysis of Zn/Cu HDS was performed using a Zeiss GeminiSEM. PHI 5000 VersaProbe III was used to record XPS measurements with Al Kα for photoelectron excitation. Samples were characterized by UV–Vis spectra *via* a Cary Series UV–Vis Spectrophotometer (Cary 300 UV–Vis).

Details of adsorption experiments

An adsorption study using EG-modified HDS was conducted in triplicate for CR dye uptake. To ascertain the impact of various factors on CR dye removal, batch studies were performed under dark conditions. Separation of residual solution from adsorbent was achieved by centrifuging the mixture at 3,000 rpm. To record the dye solution concentration, a double-beam UV–Visible spectrophotometer was employed at the λ_{max} of 497 nm (for CR dye). The removal percentage of dye is estimated using the formula given in Eq. (1) whereas the quantity of CR dye adsorbed at equilibrium and time, *t*, i.e., q_e and q_t in mg g^{-1} are calculated according to Eqs. (2) and (3), respectively.

$$\% \text{ Removal} = \frac{C_o - C_e}{C_o} \times 100 \quad (1)$$

$$q_e = \frac{C_o - C_e}{W} \times V \quad (2)$$

$$q_t = \frac{C_o - C_t}{W} \times V \quad (3)$$

The dye concentration (mg L^{-1}) at initial and equilibrium stages of adsorption is represented by C_o and C_e, respectively, concentration at any time *t* is denoted as C_t, *W* is the adsorbent amount in mg and V denotes the solution of dye solution (in mL).

Results and discussion

Structural, morphological and thermal behavior

The formation of EG-modified Zn/Cu HDS was first confirmed using PXRD pattern exhibiting strong reflection with high intensity at a lower 2θ value (10.7°) and weak reflections at a higher value of 2θ around 21°, 32°, 36°, 44° and 57° suggesting the formation of layered structure of Zn/Cu HDS (Fig. 1(A)). The observed reflections can be indexed in rhombohedral symmetry having $a = 3.15$ and $c = 25.77$ Å. No diffraction peaks corresponding to zinc oxide or copper oxide can be observed suggesting the formation of lattice in pure phase. The existing literature reports that the appearance of first intense reflection at (003) is attributed to the summation of interlamellar distance and thickness of the brucite-like sheet (4.8 Å).[32] The observed gallery height of synthesized EG-modified Zn/Cu hydroxide is 3.42 Å which is close to the thickness of the EG layer (4.2 Å).[33] Therefore, suggesting the monolayer arrangement EG in the interlamellar region of Zn/Cu HDS.[34]

The existence of EG in the interlayer region was further analyzed using FTIR spectroscopy (Fig. 1(B)). The appearance of bands at 2,883 and 2,834 cm^{-1} are due to the antisymmetric and symmetric vibrations of the $-CH_2$ group of the EG molecule, respectively. The shift in bands toward lower wavenumber with significant decrease in intensity of C–H stretching vibrations in comparison to pure EG suggest the intercalation of EG in the interlamellar region. Additionally, the broad and sharp bands at 3,434 and 1,574 cm^{-1} signified the stretching and bending vibrations of hydroxide groups indicating hydrogen bonding between them. A series of low-intensity absorption bands at 1,412, 1,071 and 908 cm^{-1} are ascribed to CH_2 wagging, C–O–H bending, and CH_2 rocking vibrations of EG anions, respectively.[35,36] The original bands for CH_2 rocking vibration of EG molecules are observed at 882 and 864 cm^{-1} but here blue shift can be observed, i.e., shift to a higher wavenumber (908 cm^{-1}) with a single broad band which might be due to the increased bond order of C–C bond in EG.[36] The presence of metal-oxygen linkages can be confirmed from the bands present between 500 and 800 cm^{-1}.

The thermal stability of EG-modified Zn/Cu HDS was assessed from TGA thermogram presented in Figure 1(C). Based on the thermogravimetric trace of the sample, the loss of weight was seen in three distinct stages, with an overall weight loss of 37%. The mass loss below 114 °C could be accredited to the removal of surface-adsorbed molecular water. The second weight-loss stage ranging from 114 to 237 °C accounted for the elimination of physically adsorbed water and interlayer EG molecules. Weight loss between 237 and 445 °C suggested EG combustion, along with dehydroxylation of the lattice or collapse of a layered structure with the release of other by-products.[37,38]

The formation of layered structure and presence of metal ions was confirmed using SEM/EDX analysis (Fig. 2(A,B)). The SEM micrograph shows sheet-like morphology and EDX analysis confirmed the presence of zinc, oxygen and

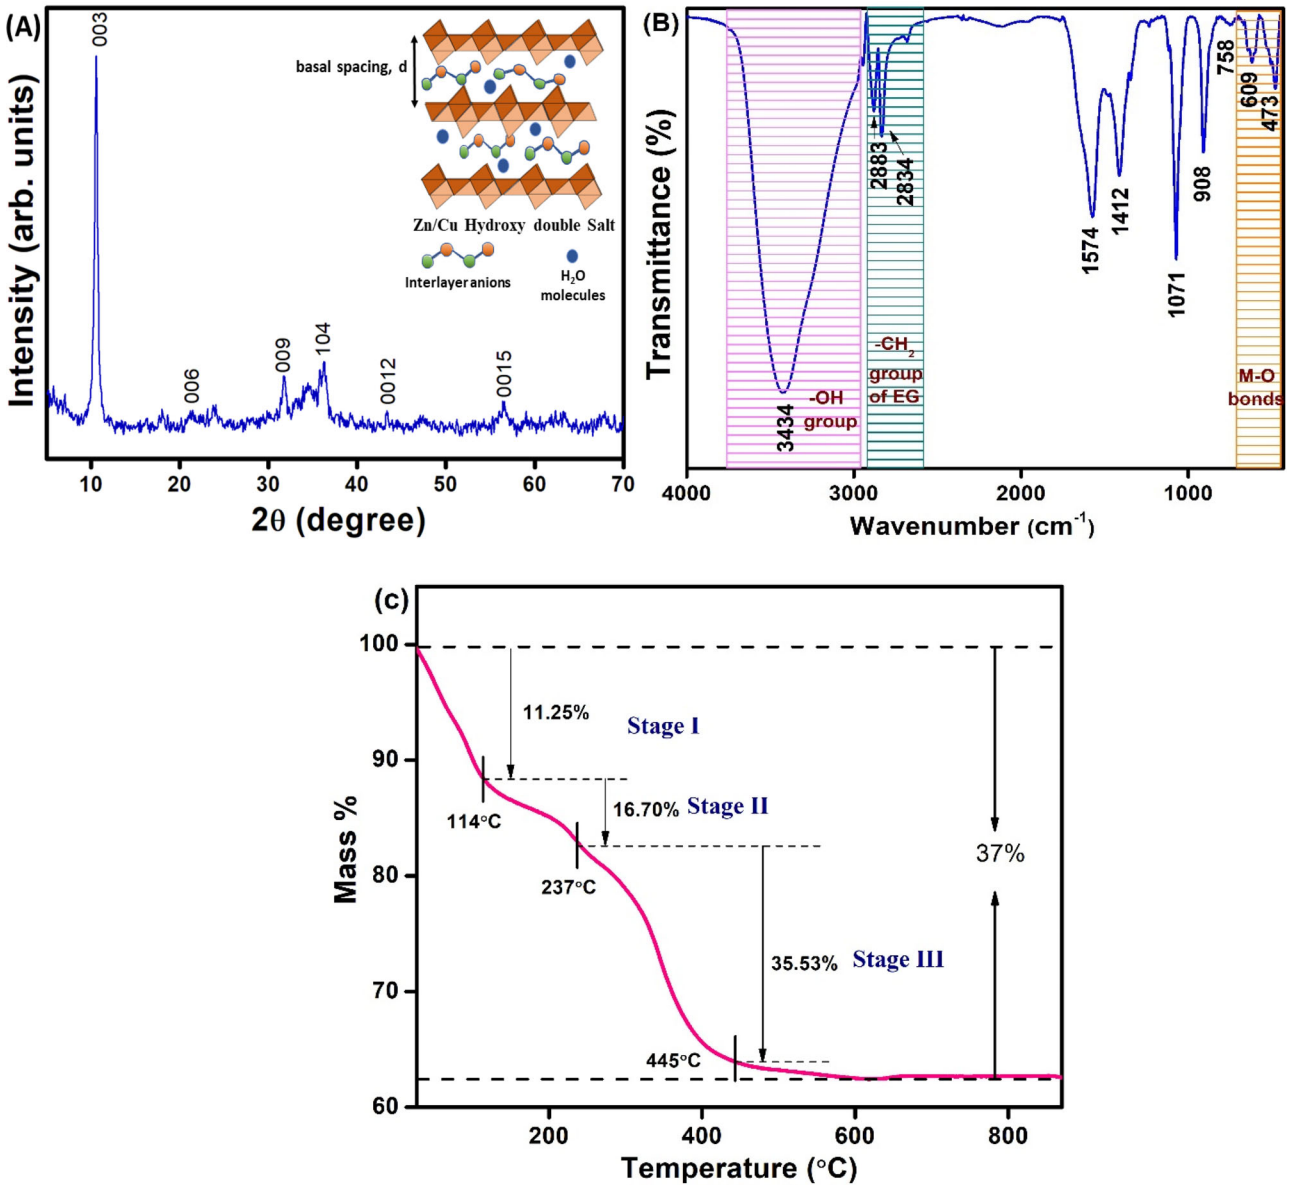

Figure 1. (A) PXRD pattern, (B) FTIR spectrum and (C) Thermogravimetric trace of EG-modified Zn/Cu HDS.

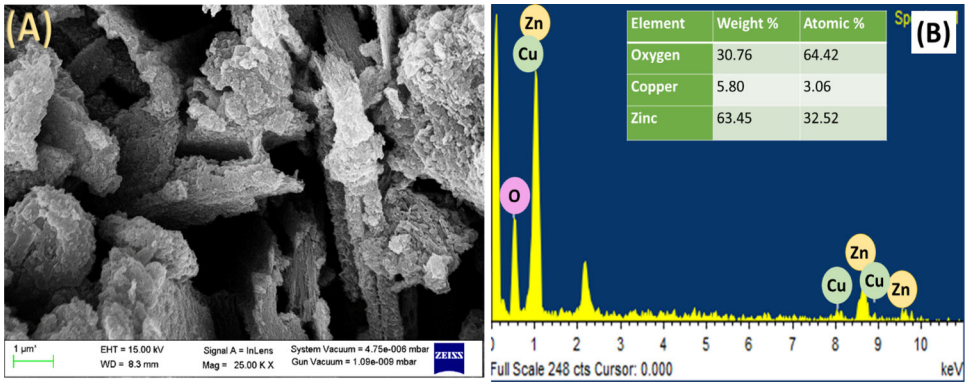

Figure 2. (A) SEM image and (B) EDX spectra of EG-modified Zn/Cu HDS.

copper elements and the percentage of each element is given in EDX spectrum[25]. The elemental mapping images are shown in Figure 3(A–E) which revealed the uniform distribution of elements in the lattice.

Further, the oxidation states and distribution of the elements were estimated by analyzing XPS data. The survey spectrum of XPS shown in Figure 4(A) indicated the presence of zinc, copper, oxygen and carbon elements. The

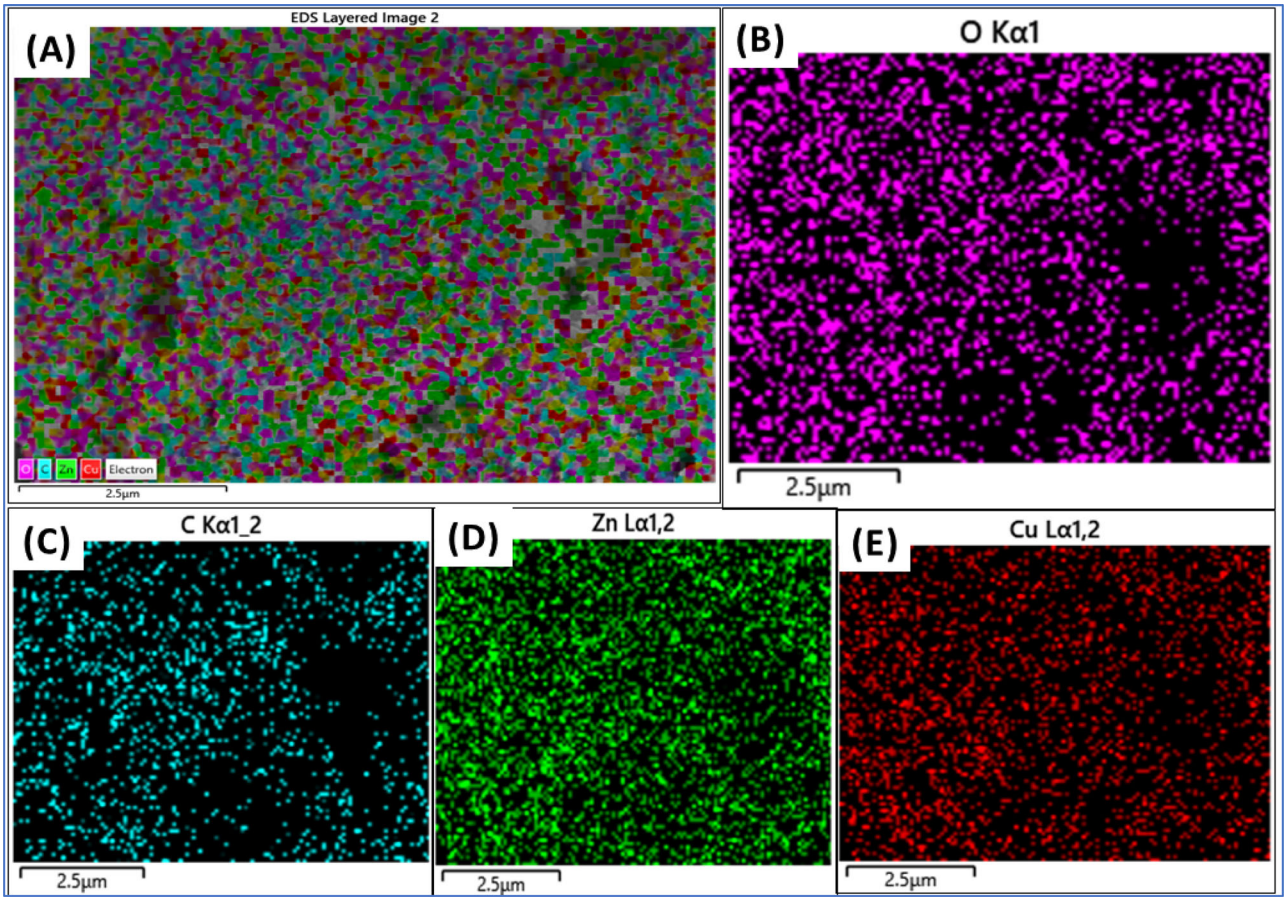

Figure 3. (A – E) corresponding elemental mapping of O, C, Zn and Cu, respectively, of EG-modified Zn/Cu HDS.

deconvoluted spectrum of C *1s* spectrum (Fig. 4(B)) shows two peaks centered at 284.96 and 288.30 eV ascribed to the C–C and C–O bonds of EG, respectively.[39] The deconvoluted O *1s* spectrum (Fig. 4(C)) exhibits two peaks at 529.94 and 531.44 eV, corresponding to the C–OH group of EG and metal-oxygen linkage (M–O), respectively.[40] The presence of two prominent peaks at 1,021.40 and 1,044.50 eV in core spectra of Zn *2p* (Fig. 4(D)) confirmed the presence of Zinc in the lattice.[41] The core level XPS spectrum of Cu *2p* (Fig. 4(E)) shows peaks with binding energies of 932.64 and 952.42 eV, confirming the presence of copper in +2 oxidation state in the lattice.[42]

BET surface area analysis

The porosity of EG-modified Zn/Cu HDS sample was examined using an N_2 adsorption-desorption isotherm. According to BET calculations, the adsorbent has a specific surface area of 32.295 m^2 g^{-1}, whereas the average pore size diameter and pore volume evaluated by Barrete–Joynere–Halenda (BJH) method are 2.218 nm and 0.070 cm^3g^{-1}, respectively (Fig. 5(A)). The isotherm depicts a type-IV isotherm with H_3 hysteresis loop, which is suggestive of the material's mesoporous nature.[43] The H_3 hysteresis is a feature of materials with slit-shaped pores.[44] BJH pore size distribution indicated that the lattice was composed of pores ranging from 2.13 to 3.74 nm, as shown in Figure 5(B). According to these findings, the porous nature of the synthesized material contributes greatly to its excellent sorption properties. With large surface areas and small pore sizes, mesoporous channels offer a sufficient surface to adsorb molecules of large size, such as organic dyes. As a result of the mesoporosity of the material, its potential as a sorbent for CR dye uptake from solution phase has been examined.

Adsorption properties

In order to assess the efficiency of synthesized lattice for the removal of various dyes from aqueous solution, adsorption experiment was performed. For this study, two cationic (crystal violet [CV] and methylene blue [MB]) and three anionic dyes (CR, MO and eriochrome black T [EBT]) were used. The removal of different dyes was performed with 20 mg L^{-1} concentration of dye with a fixed amount of adsorbent. Figure 6(A) shows the plot for removal of different dyes and it can be observed that it follows the trend: CR (96%) > EBT (77%) > MO (70%) > CV (13%) > MB (2%). From the order, it can be deduced that the synthesized material exhibits higher affinity for the anionic dyes which can be attributed to the fact that Zn/Cu HDS possess excess positive charge on the layers and there occurs an electrostatic interaction between the positively charged layers and anionic dye molecules. In addition, selective adsorption of CR dye was also performed in presence of cationic dye, i.e., MB under similar reaction conditions. It was observed that

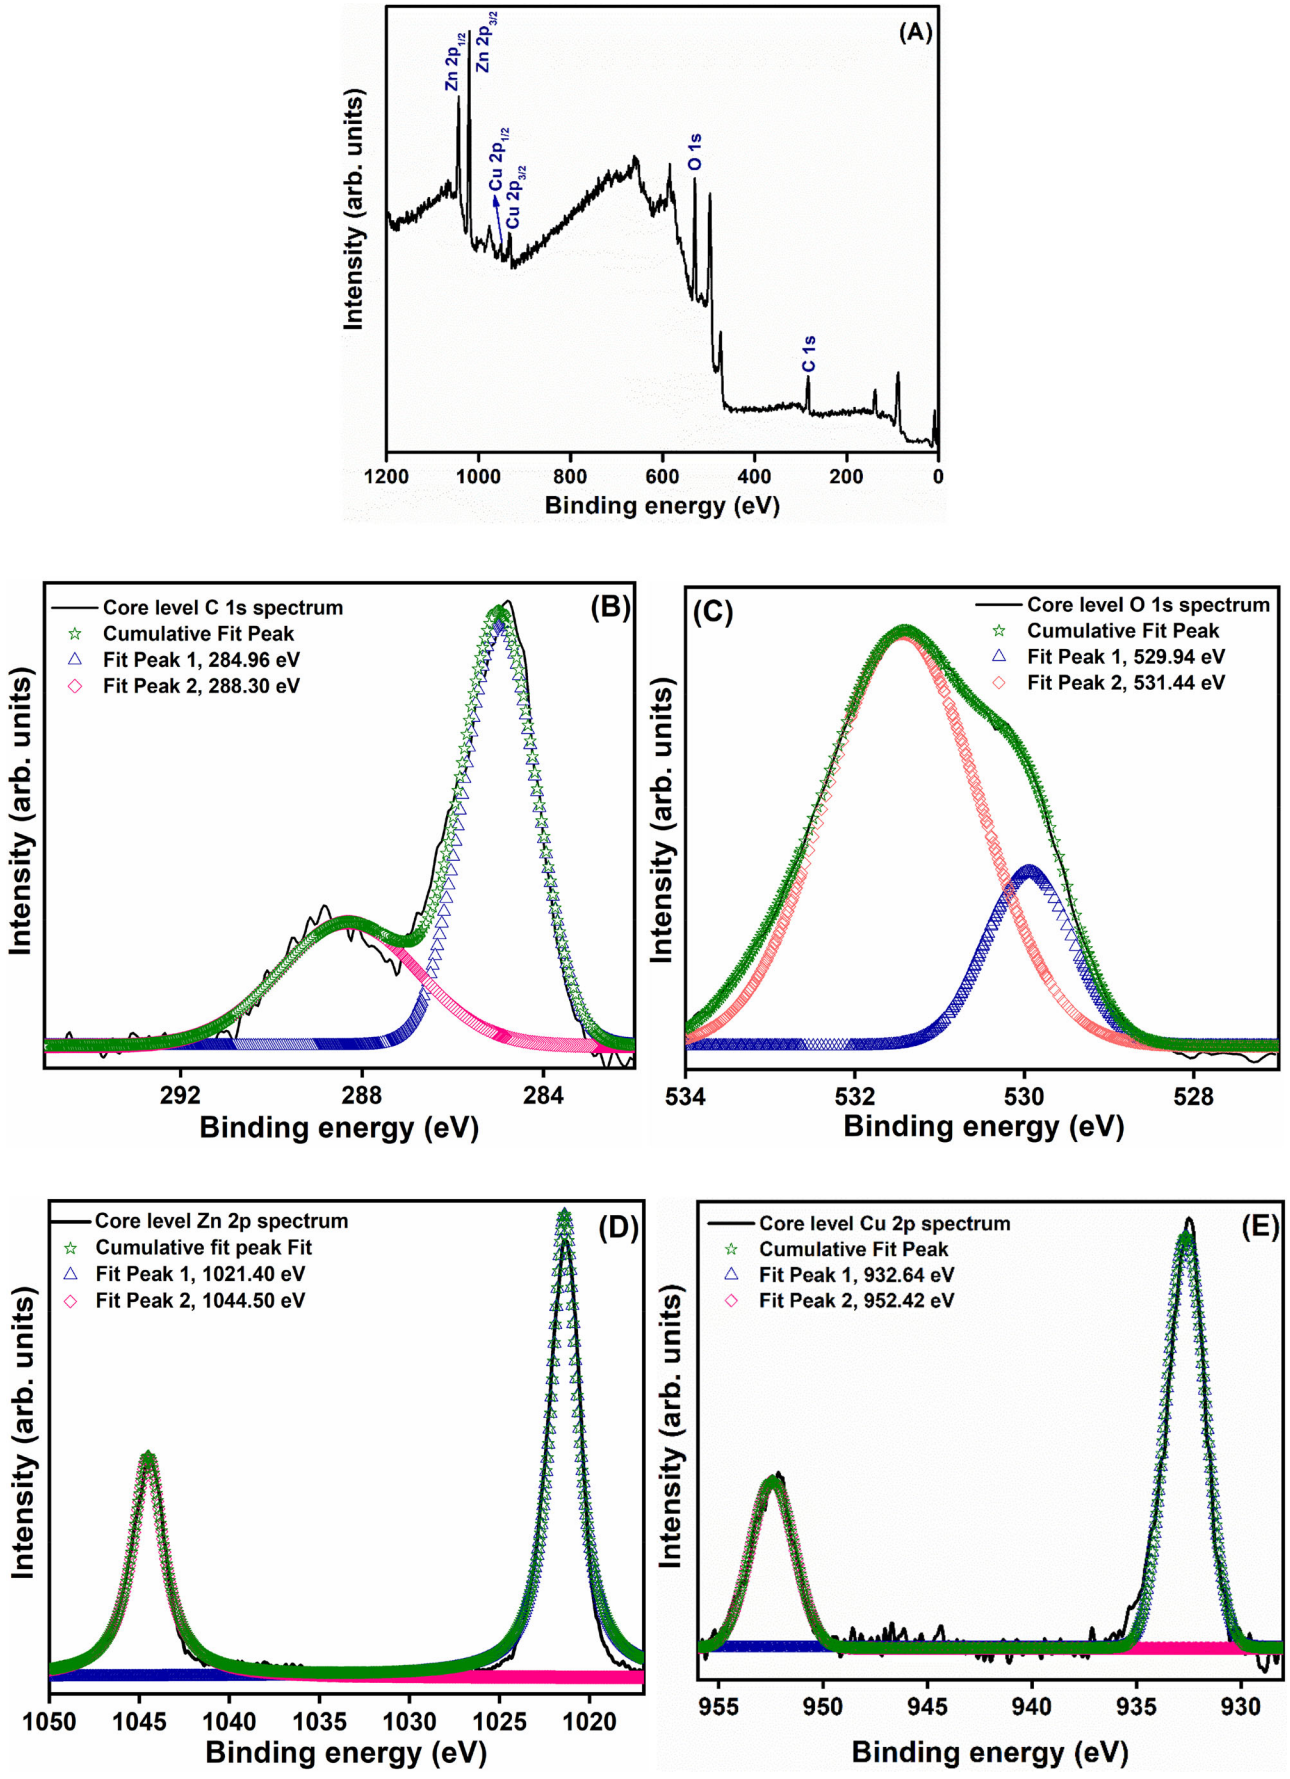

Figure 4. (A) Survey XPS spectrum of EG-modified Zn/Cu HDS, (B), (C), (D) and (E) show the XPS spectrum of C *1s*, O *1s*, Zn *2p* and Cu *2p*, respectively.

the synthesized adsorbent exhibits high selectivity toward the anionic dye with a removal efficiency of 96%. The results obtained are shown in Figure 6(B).

Influence of contact time

Treatment of wastewater by the adsorption route relies significantly on the contact time between adsorbents and pollutants. To investigate the impact of contact time, 0.05 g of EG-modified Zn/Cu HDS product was transferred to 100 mL aqueous solution of CR dye with 20 mg L^{-1} concentration. The plot of absorbance *vs.* contact time is depicted in Figure 7(A). CR dye uptake was shown to have greatly increased with time and subsequently reached equilibrium afterward. A significant increase in dye adsorption occurred during the first 5 min of reaction time as shown in

Figure 7(B), reaching >90%, following which equilibrium was achieved (after 10 min). More than 96% of the CR is removed with 0.05 g of adsorbent, and it remains almost constant as contact time increases, suggesting that equilibrium has been reached. This was mainly because of the large area of surface area available for adsorption during the initial 5 min of contact time. Subsequently, the number of vacant sites decreases as the contact time increases because of repulsive interactions between solid and bulk phases.

Influence of dye concentration

The significance of concentration of dye was studied for aqueous solutions of 20–100 mg L^{-1} concentrations of dye with 0.05 g of adsorbent for 30 min. From Figure 8(A), one can conclude that adsorption capacity increases with an increase in dye concentration. On increasing CR dye concentration (20–100 mg L^{-1}), a significant increase in adsorption efficiency was obtained (39.23–169.18 mg g^{-1}). A higher molecular concentration increases the likelihood of molecular collisions with adsorbent surfaces, which in turn contributes to an increase in mass transfer from solution to solid. The increasing number of collisions results in increased removal of molecules from the solution phase. In summary, the initial high concentration of dye presents a greater concentration slope or a stronger driving force among the liquid phase (dye solution) and adsorbent phase, consequently, the adsorption rate increases.

Influence of amount of adsorbent

To inspect the impact of different amounts of adsorbent on the dye removal, trials were performed with different dosages of adsorbent (0.05 g, 0.1 g and 0.2 g) while keeping other parameters constant (initial dye concentration = 20 mg L^{-1} and reaction time = 30 min). Figure 8(B) shows a trend that adsorption efficiency enhanced on increasing amount of adsorbent, confirming that the greater the number of active sites for sorption greater will be the removal.

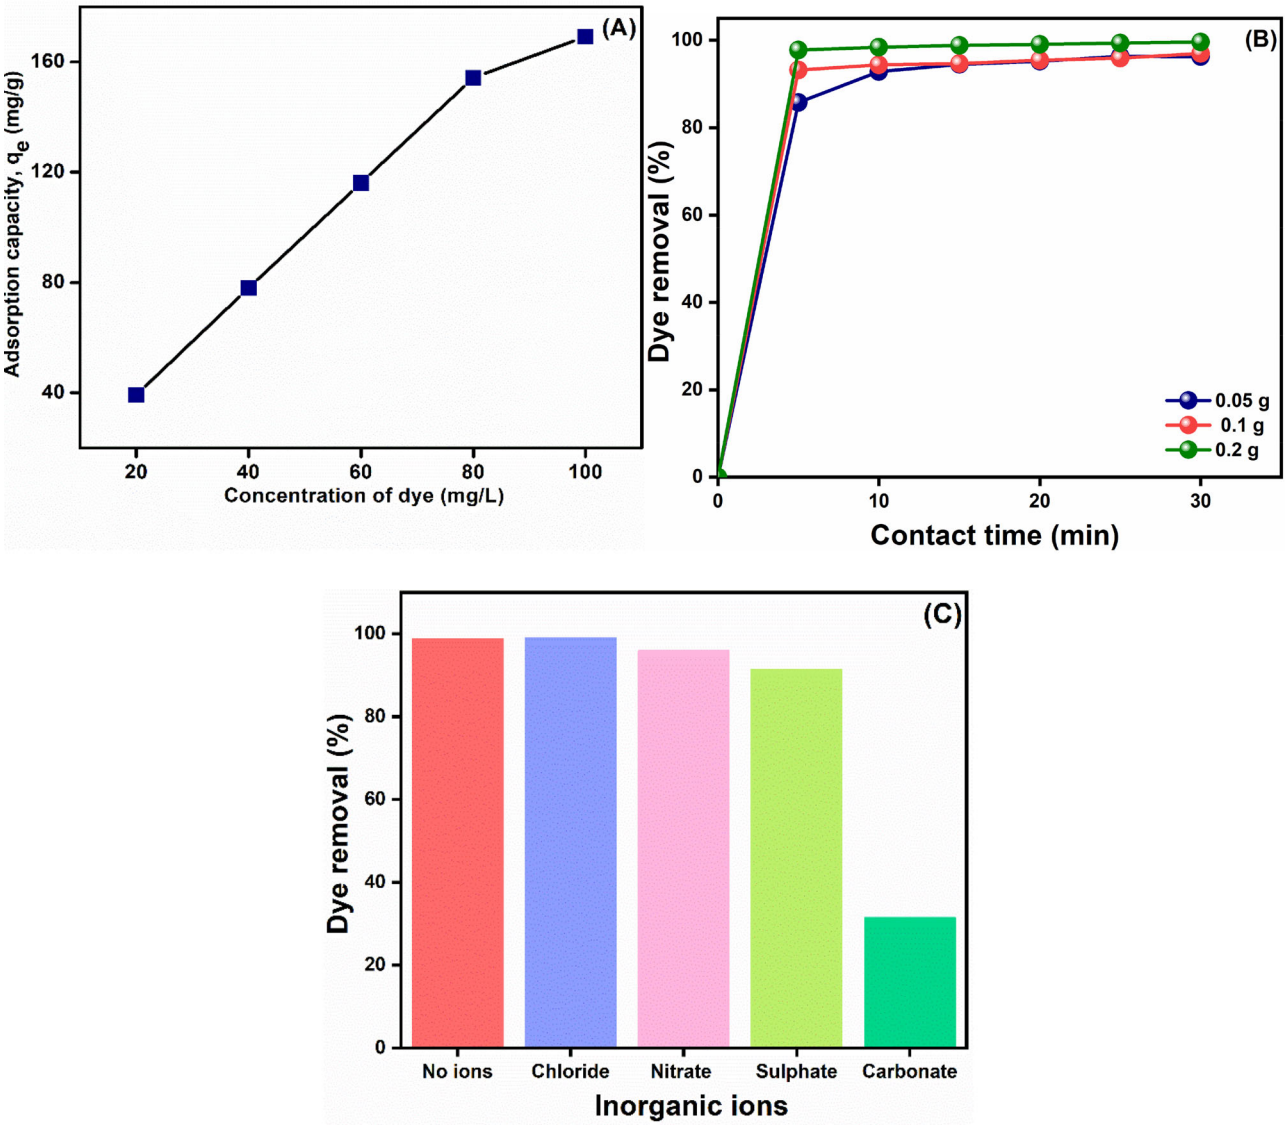

Figure 8. Influence of (A) concentration variation on adsorption capacity, (B) adsorbent dosage and (C) interfering anions on % dye adsorption.

Influence of interfering anions

Textile dyeing processes generate a large amount of toxic effluent, which generally contains various inorganic salts, such as sodium chloride, sodium carbonate, etc.[45] To estimate the dye removal efficacy of EG-modified Zn/Cu HDS as an adsorbent, the adsorption procedure needs to be analyzed to determine the impact of these anions. During this study, chloride (Cl^-), carbonate (CO_3^{2-}), nitrate (NO_3^-) and sulfate (SO_4^{2-}) anions were investigated and the adsorption experiment was carried out by taking 0.05 M concentration of each anion.

According to Figure 8(C), the presence of Na_2SO_4 and Na_2CO_3 to dye solutions resulted in a decrease in dye uptake, as opposed to the presence of NaCl, $NaNO_3$, or none of the electrolytes. It has been reported that divalent species have a high affinity for the layered materials and thus compete with dye molecules for adsorption sites on material's surface resulting in decreased adsorption of anionic dye molecules. Since, Cl^- and NO_3^- are monovalent ions they did not influence the adsorption efficiency significantly. However, a substantial decrease in removal efficiency of the material is demonstrated by divalent anions. Carbonate ions are negatively charged, similar to anionic dyes, can effectively interact with the positively charged sites on the layered material, thereby occupying these sites and reducing the availability for the dye molecules. A decrease in the adsorption efficiency of the material occurs as a result of the competition between carbonate ions and anionic dyes for adsorption sites. As opposed to carbonate ions, sulfate ions are relatively larger in size, which may cause less effective blocking of adsorption sites on layers. Therefore, sulfate ions do not significantly alter materials' adsorption efficiency. Owing to the competitive uptake of dye molecules and inorganic salts on surface of adsorbent, dye solutions containing inorganic salts have a decreased adsorption efficiency. Consequently, it can also be stated that the presence of divalent ions strongly influences the adsorptive removal of CR dye as compared to monovalent ions, which is in agreement with the fact that HDS has a high affinity for anions having high charge density.[46]

Influence of pH on dye adsorption

When it comes to water treatment applications, dye solution pH is a key factor in regulating the efficacy of adsorbents. To analyze the influence of pH, adsorption studies were conducted at different pH (pH 3–11) with 20 mg L^{-1} concentrations of dye solutions and 0.05 g of adsorbent dosage for 30 min. Figure 9(A) depicts the dye removal percentage at different pH values, it was observed to decrease from 99.54% to 21.62% when the pH was varied from 3 to 11 and maximum removal was recorded at pH 3 and 7. In general, the adsorption of anionic dyes like CR decreases as pH increases. Since excess hydroxide ions contest with dye molecules for adsorption sites at high pH levels, dye adsorption capacity is found to reduce.

Point of zero charge (PZC) of the sorbent can explain the decline in adsorption efficiency with increased pH. PZC is the pH at which a material's surface becomes neutral. When pH of the material is below pH_{PZC}, the material's surface exhibits a positive charge, while above pH_{PZC}, the material is negatively charged. In this study, the PZC was found to be 7.6 (Fig. 9(B)) indicating that the synthesized HDS exhibits a positively charged surface at pH $<$ 7.6, resulting in enhanced dye adsorption due to electrostatic interactions. As the pH of solution rises above 7.6, HDS hydroxide ions contest with anionic dye molecules causing a decline in the dye removal efficacy.

Proposed adsorption mechanism

HDSs are porous materials having numerous adsorption sites. The mechanisms involved in the adsorption of pollutants using layered materials generally include physical adsorption, ion exchange reactions, electrostatic interactions, pi–pi interactions and chemical bonding.[47] The zeta potential measurements of the adsorbent can be used to explain the mechanism of adsorption. In both pre- and post-adsorption analyses, the material showed zeta potential value of 9.79 mV and 4.95 mV, respectively. It is suggested that the surface of the adsorbent possesses a positive charge due to its positive zeta potential value. Conversely, CR has a high solubility in water and exists in anionic form under the aqueous phase. Thus, a decrease in value of zeta potential upon adsorption of CR can be attributed to the electrostatic

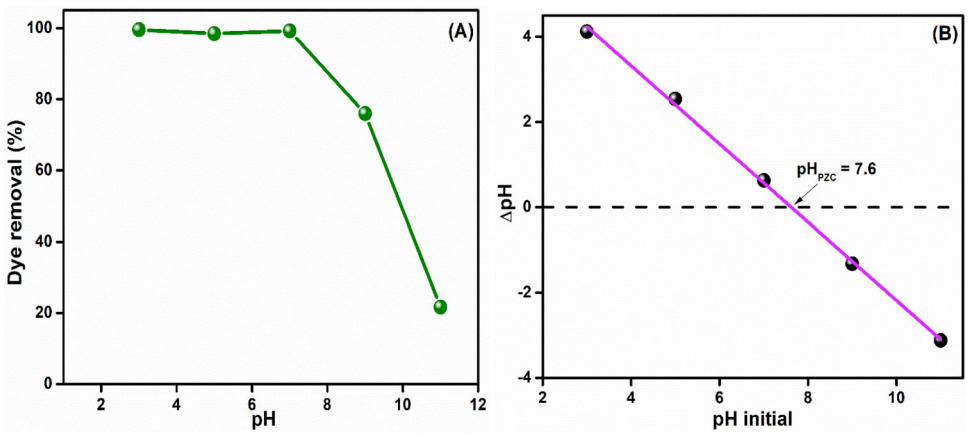

Figure 9. (A) pH effect on percentage dye removal and (B) plot of pH_{PZC}.

interactions occurring between the positive layers of adsorbent and negative dye molecules at neutral or low pH environments. Therefore, it can be stated that electrostatic interaction (between metal ions and dye molecules), as well as hydrogen bonding (between EG and dye molecules), are responsible for the high removal efficiency of synthesized adsorbent toward CR dye. The proposed mechanism of adsorption is depicted in Figure 10.

Adsorption isotherms

This work used three isotherm models to analyze the equilibrium adsorption experimental data for removing CR dye. The first model is Langmuir isotherm implying that sorption occurs on uniform, homogeneous surfaces with identical sites on an adsorbent and it is often used to describe monolayer adsorptions.[48] Following are the non-linearized (4) and linearized (5) forms of the model, respectively.

$$q_e = \frac{q_m k_L\ C_e}{(1 + k_L\ C_e)} \tag{4}$$

$$\frac{1}{q_e} = \frac{1}{q_m k_L\ C_e} + \frac{1}{q_m} \tag{5}$$

q_e and C_e are uptake capacity in mg g^{-1} and dye concentration at equilibrium in mg L^{-1}, respectively. Langmuir constants are represented by k_L and q_m defined as adsorption energy (L/mg) and monolayer or maximum adsorption capacity (mg g^{-1}), respectively. In accordance with Eq. (5), when the Langmuir equation holds, the graph of $1/q_e$ *vs.* $1/C_e$ should possess an intercept of $1/q_m$ and a slope of $1/q_m k_L$. R_L is the dimensionless factor that allows us to quantify Langmuir isotherm and can be defined as:

$$R_L = \frac{1}{1 + k_L C_0} \tag{6}$$

where initial stage concentration of dye (mg L^{-1}) is presented by C_0 and R_L value indicates the characteristics of the adsorption, i.e., favorable ($0 < R_L < 1$), unfavorable ($R_L > 1$), linear ($R_L = 1$) and irreversible ($R_L = 0$).

Another model is Freundlich isotherm which can be very useful for understanding the sorption mechanism for heterogeneous surfaces. The non-linearized and linearized forms of the model are represented in Eqs. (7) and (8), respectively.

$$q_e = k_F C_e^{\,1/n} \tag{7}$$

$$\ln q_e = \ln k_F + \frac{1}{n} \ln C_e \tag{8}$$

$1/n$ and K_F are constants expressing intensity and capacity of adsorption, respectively. The slope and intercept of a graph of *ln* q_e *vs. ln* C_e allow us to compute $1/n$ and k_F values. An adsorption process is characterized as favorable if the $1/n$ ratio is higher than 1, indicating favorable conditions for adsorption.

The indirect adsorbate–adsorbent interactions are taken into consideration in the third model, i.e., Temkin isotherm model. The increase in surface coverage is assumed to cause a linear decrease instead of a logarithmic in the heat of adsorption.[48] The nonlinearized-linearized form of Temkin adsorption model is presented in Eqs. (9) and (10).

$$q_e = B \ln (A_T C_e) \tag{9}$$

$$q_e = B \ln A_T + B \ln C_e \tag{10}$$

Temkin constants A_T and B are defined as the binding constant at equilibrium and heat of sorption, respectively.

Figure 11(A–D) illustrates the results for the different adsorption isotherms utilized in the present analysis. The relevant parameters of these isotherms are also given in Table 2. There is also good agreement between the results obtained from linear and nonlinear isotherm models.

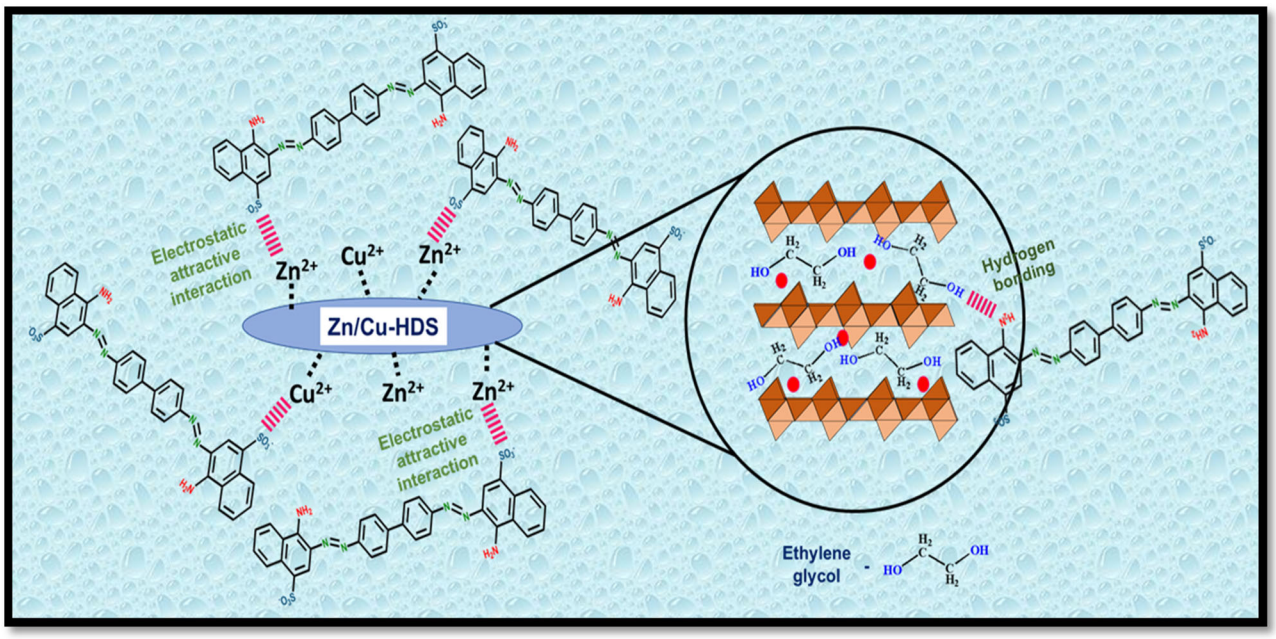

Figure 10. Plausible mechanism of adsorption of CR dye onto EG-Zn/Cu HDS.

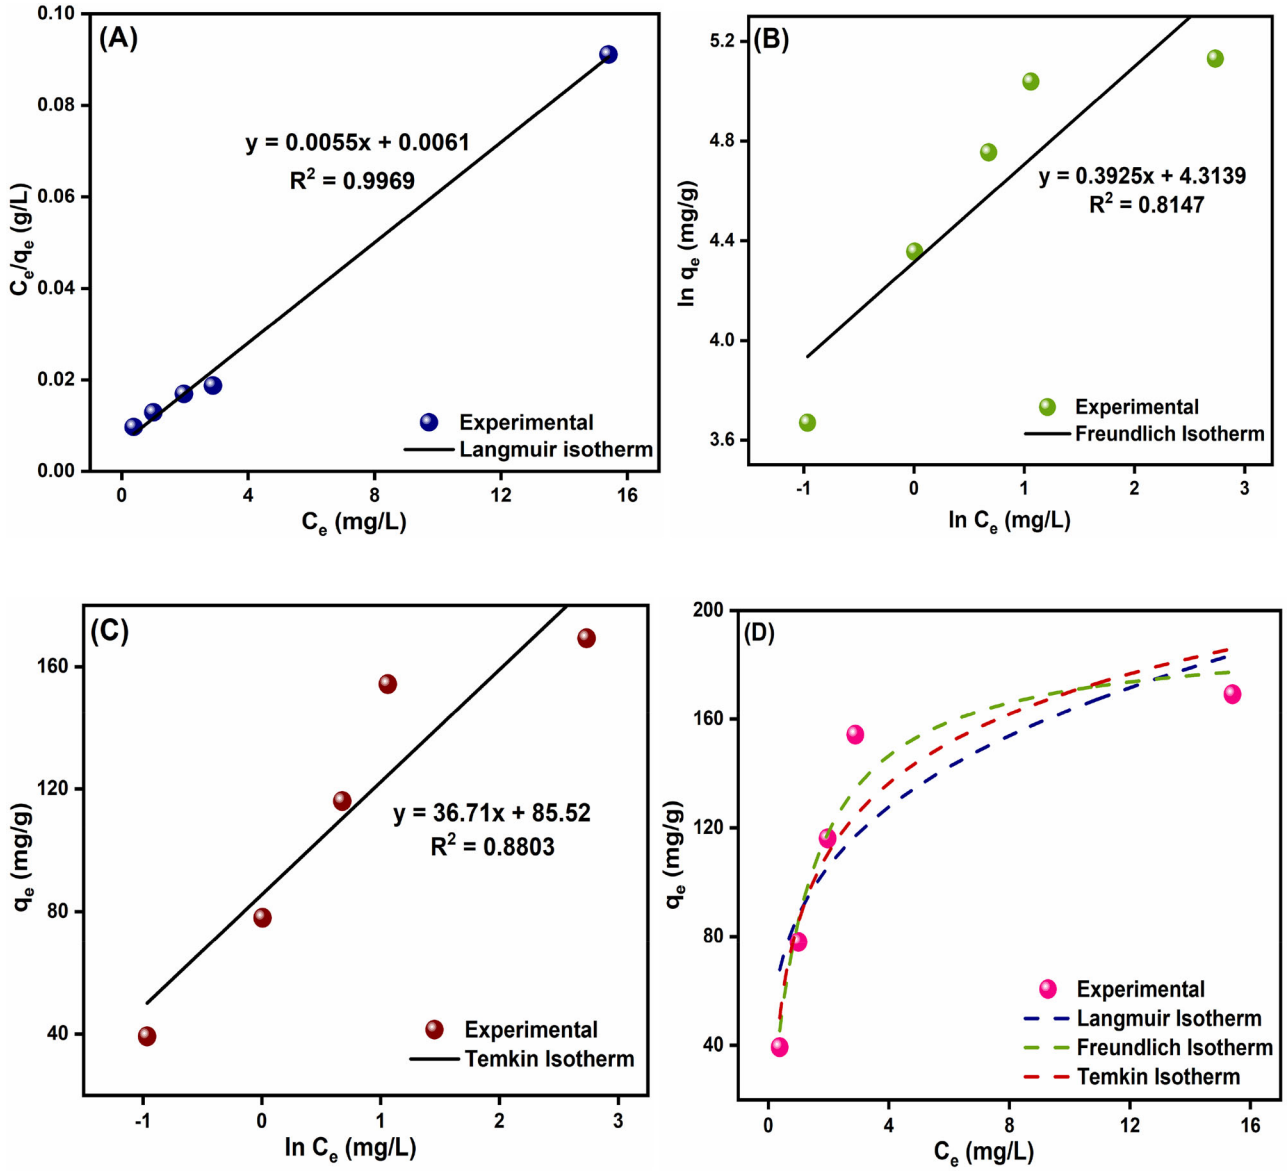

Figure 11. Isotherm linear plots for (A) Langmuir, (B) Freundlich, (C) Temkin model and (D) nonlinear plots of isotherm models for removal of CR dye using EG-Zn/Cu HDS.

Table 2. Adsorption isotherm constants for CR dye removal.

Equilibrium isotherms	Equations	Parameters		
Langmuir	$\frac{1}{q_e} = \frac{1}{q_m k_L}\frac{C_e}{C_e} + \frac{1}{q_m}$	q_m (mg g^{-1})	K_L (L/mg)	R^2
Linearized form	$q_e = \frac{q_m k_L C_e}{(1+k_L C_e)}$	181.81	0.9016	0.9969
Non-linearized form		191.55	0.8135	0.9504
Freundlich	$\ln q_e = \ln k_F + \frac{1}{n}\ln C_e$	K_F (mg g^{-1}) (L/mg)$^{1/n}$	*1/n*	R^2
Linearized form	$q_e = k_F C_e^{1/n}$	74.73	0.3925	0.8147
Non-linearized form		87.90	0.2692	0.7720
Temkin	$q_e = B\ln A_T + B\ln C_e$	B (J/mol)	A_T (L/g)	R^2
Linearized form	$q_e = B\ln(A_T C_e)$	36.71	10.26	0.8803
Non-linearized form		36.71	10.26	0.8803

By examining the values of R^2, it is evident that the calculated adsorption data agrees with the Langmuir isotherm, indicating monolayer adsorption of CR dye onto EG-Zn/Cu HDS adsorbent. In addition, the R_L was 0.90, indicating the favorable adsorption of CR dye.

Kinetic studies

For designing and modeling adsorption processes, kinetic parameters can be used to predict adsorption rates. To investigate the adsorption mechanism, the obtained data were then correlated with three different kinetic models.

Adsorption rates can be demonstrated in terms of adsorption capacity based on linear and nonlinear Lagergren's first-order rate equations represented as follows:

$$q_t = q_e(1 - e^{-k_1 * t}) \tag{11}$$

$$\ln(q_e - q_t) = \ln q_e - k_1 t \tag{12}$$

q_e and q_t (mg g^{-1}) are the uptake capacity at equilibrium and time t, respectively, while pseudo-first-order rate constant, k_1 (min^{-1}) can be computed from linear plot of ln (q_e – q_t) *vs.* *t*.

Ho and McKay proposed that a pseudo-second-order model could also be utilized to explain the kinetics of adsorption.[49] The linearized Eq. (13) for the kinetic model is given below:

$$\frac{t}{q_t} = \frac{1}{k q_e^2} + \frac{t}{q_e} \tag{13}$$

Which can be rearranged into its nonlinear form:

$$q_t = \frac{q_e^2 k_2 \ t}{q_e k_2 \ t + 1} \tag{14}$$

q_e and q_t (mg g^{-1}) represent adsorption capacity at equilibrium and at time t, respectively, whereas pseudo-second-order rate constant is presented by k_2 (g mg^{-1} min^{-1}) which can be computed from graph of t/q_t *vs.* *t*. Chemical adsorption is considered to be rate-limiting step in pseudo-second-order model that predicts the behavior of adsorption across the overall range.

Moreover, the adsorption mechanism was also examined using intra-particle diffusion model. The linearized form of the model presented by Weber and Morris is formulated in equation.[50]

$$q_t = k_{id} \ t^{1/2} + C \tag{15}$$

where the dye uptake capacity at time t and intra-particle diffusion rate constant are denoted by q_t (mg g^{-1}) and k_{id}.

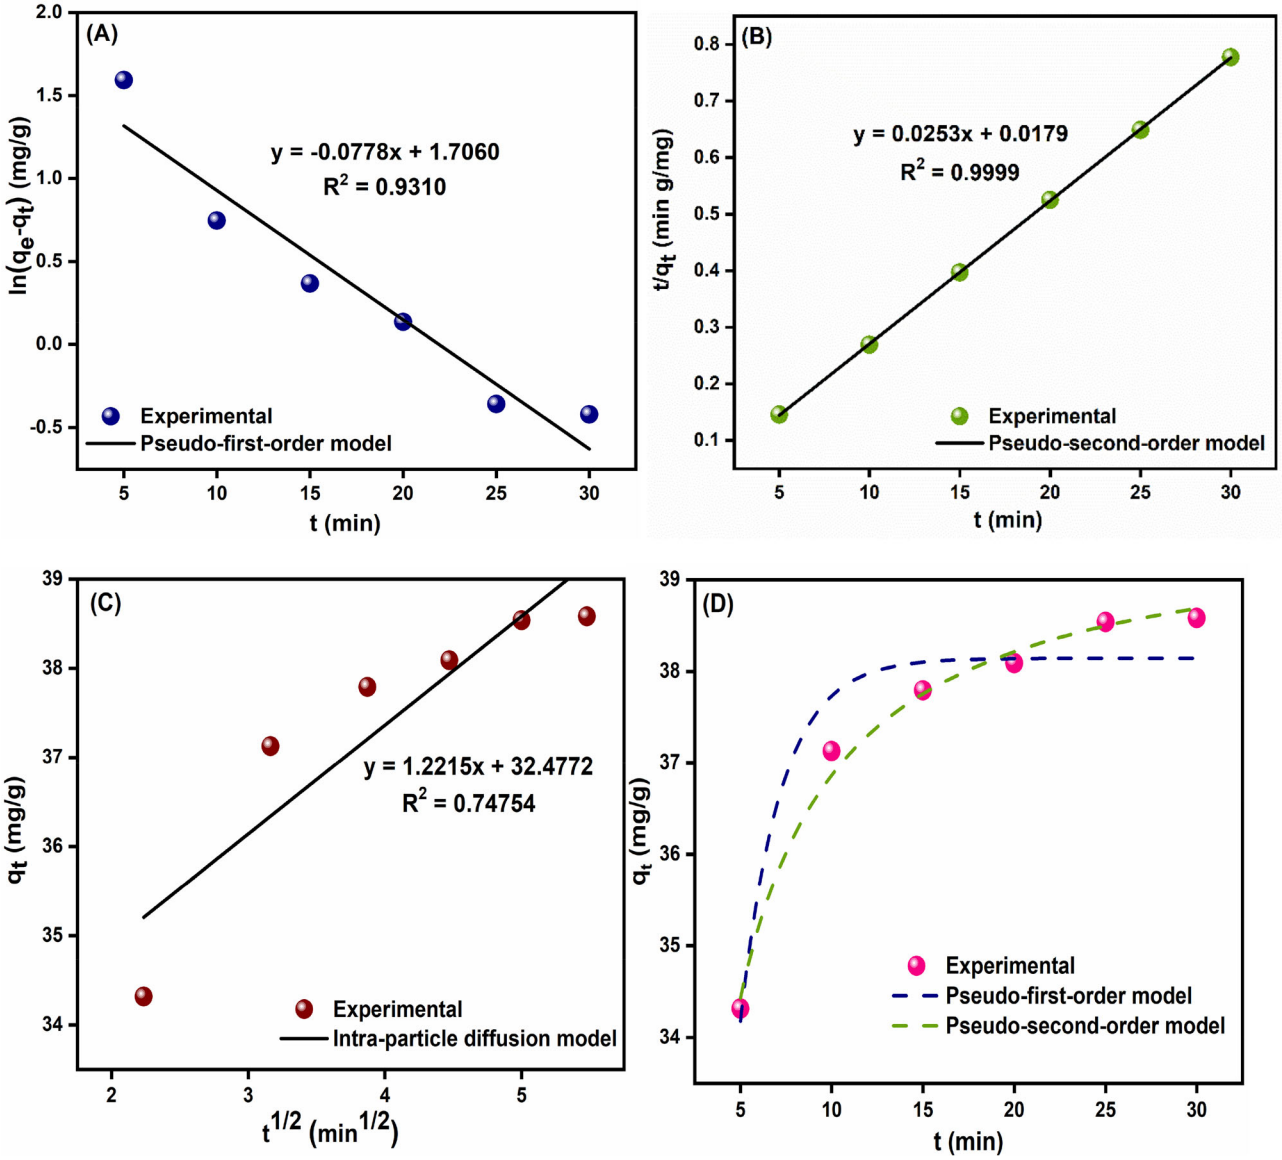

Figure 12. Linear plots of (A) Pseudo-first-order, (B) Pseudo-second-order, (C) Intra-particle diffusion and (D) nonlinear plots of kinetic models for removal of CR dye using EG-Zn/Cu HDS.

Table 3. Kinetic parametric values for CR dye uptake.

Kinetic models	Equations	Parametric values		
Pseudo-first order	$\ln(q_e - q_t) = \ln q_e - k_1 t$	K_1 (min^{-1})	q_e (mg g^{-1})	R^2
Linearized form	$q_t = q_e(1 - e^{-k_1 * t})$	0.0778	5.50	0.9310
Non-linearized form		0.0761	38.14	0.9359
Pseudo-second order	$\frac{t}{q_t} = \frac{1}{kq_e^2} + \frac{t}{q_e}$	K_2 (g mg^{-1} min^{-1})	q_e (mg g^{-1})	R^2
Linearized form	$q_t = \frac{q_e^2 k_2 q_e t}{q_e k_2 \ t+1}$	0.0331	39.52	0.9999
Non-linearized form		0.0357	39.66	0.9912
Intra-particle diffusion	$q_t = k_{id}\ t^{1/2} + C$	K_{id} (g/mg $min^{-0.5}$)	C	R^2
Linearized form		1.2215	32.47	0.7475

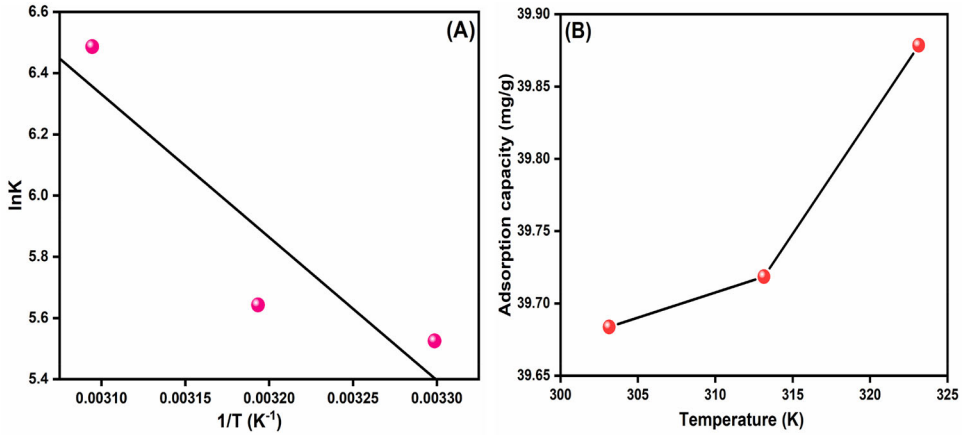

Figure 13. (A) Van't Hoff plot for ln *K vs.* 1/*T* and (A) plot for effect of temperature on adsorption capacity.

The results for kinetic models employed in this study are depicted in Figure 12(A–D). The kinetic variables for all the models are provided in Table 3. It was evident that pseudo-second-order model with 0.9999 R^2 value fits well with experimental data. In addition, the linearized and nonlinearized forms of the model also produce similar results. Moreover, the uptake capacity, q_e computed from pseudo-second-order model (39.52 mg g^{-1}) is in agreement with the observed value (39.23 mg g^{-1}). These results indicate CR adsorption follows a pseudo-second-order kinetic process, where chemical interactions enable CR to adsorb on the surface of synthesized HDS.

Effect of temperature

During adsorption, entropy and energy are important factors to consider when determining the spontaneity of the process. In order to obtain thermodynamic parameters for the adsorption system, the amount of CR adsorbed at equilibrium at different temperatures, i.e., 303.15, 313.15 and 323.15 K was examined. The following equations were used to estimate changes in Gibbs free energy, enthalpy and entropy of adsorption:

$$\ln K = -\frac{\Delta H^0}{RT} + \frac{\Delta S^0}{R} \tag{16}$$

$$K = \frac{q_e}{C_e} \tag{17}$$

$$\Delta G^0 = \Delta H^o - T\Delta S^0 \tag{18}$$

The adsorbates' distribution coefficient, gas constant, and absolute temperature are denoted by K, R (8.314 J/K/mol), and T, respectively. The values of ΔH° and ΔS° can be calculated from the linear plot of ln K *vs.* 1/T (Fig. 13(A)). The parameters calculated are given in Table 4. The positive value of change in enthalpy demonstrated that the adsorption process is endothermic and during adsorption, there is a higher degree of disorderness at the solid-solution interface. It was also observed that the adsorption capacity increased with an increase in temperature (Fig. 13(B)). The collision rate of dye and Zn/Cu HDS is increased at elevated temperatures because of the increase in kinetic energy of adsorbate molecules. In addition, the negative value of ΔG° confirms that the process is spontaneous and the increasing value of ΔG° with increasing temperature suggests that the rate of adsorption is higher at high temperatures.

Table 4. Thermodynamic parametric values for CR dye uptake.

Temperature (K)	q_e (mg g^{-1})	ΔG° (KJ/mol)	ΔH° (KJ/mol)	ΔS° (J/mol/K)
303.15	39.68	−13.61	38.83	173.02
313.15	39.72	−15.35	–	–
323.15	39.88	−17.07	–	–

Regeneration and stability of adsorbent

In order to investigate synthesized adsorbent's stability, regeneration ability and reusability for removing CR dye from aqueous phase a series of experiments were conducted under same reaction conditions for up to seven cycles. Following adsorption, the EG-Zn/Cu HDS adsorbent was centrifuged, washed with ethanol and dried, then reused for the subsequent cycles. The recovered adsorbent was found to be reusable for up to five cycles without significant loss

in its dye uptake efficiency. The plot for removal efficiency for consecutive five cycles is presented in Figure 14(A). Adsorption efficiency for CR dye uptake in the first cycle was 96.06%, and it decreased slightly in the subsequent cycles and reached 92.86% after 4 cycles whereas, the percentage removal decreased further in the 5th cycle and it was found to be 85. 98%. In light of these results, EG-Zn/Cu HDS serves as a potential candidate for dye-loaded wastewater remediation due to its stability and reusability for up to 5 cycles. The stability of the adsorbent after adsorption was confirmed from the PXRD results (before and after adsorption). It can be observed from Figure 14(B) that the XRD patterns of adsorbent before and after adsorption are similar with a slight change in the intensity of peaks and no shift in the peak position, suggesting that the structure of material is retained even after the adsorption process. The results confirmed the stability of the synthesized adsorbent.

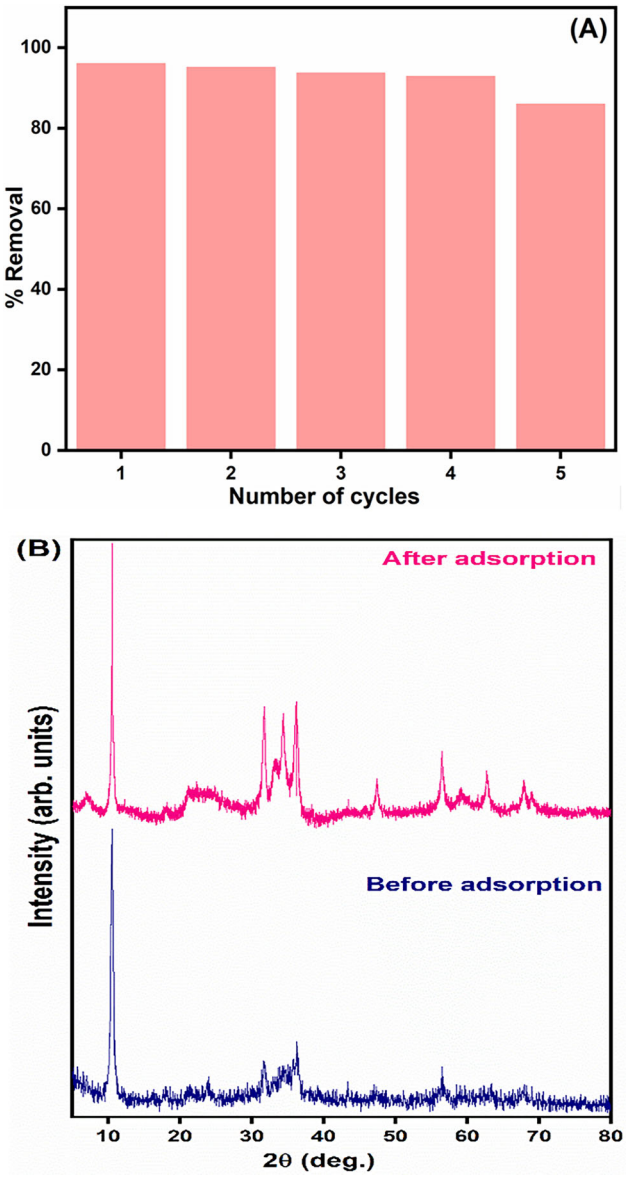

Figure 14. (A) Reusability of EG-Zn/Cu HDS for Congo red removal and (B) PXRD patterns of adsorbent before and after adsorption.

Conclusion

This study reports the synthesis of EG-modified HDS containing zinc and copper metal ions using a facile one-pot synthesis approach. The synthesized lattice was characterized using various characterization techniques. Additionally, BET analysis was used to analyze the textural properties of synthesized lattice and determine its surface area of 32.295 $m^2 g^{-1}$. The synthesized EG-modified HDS act as an effective adsorbent for the sequestration of CR dye under broad pH range of 3–7 with high removal efficiency of more than 97%. The experimental data best fitted Langmuir isotherm and pseudo-second-order kinetic model suggesting monolayer adsorption and chemisorption to be the rate-limiting step, respectively. Furthermore, EG-modified HDS displayed a maximum monolayer sorption capacity of 181.81 mg g^{-1}. These findings suggest that the EG-Zn/Cu HDS adsorbent could serve as a useful alternative for removing CR dye from aqueous solutions. In addition, the synthesized adsorbent was successfully used for five recycled runs with high removal efficiency. According to the findings of this study, the EG-Zn/Cu HDS adsorbent could serve as a useful alternative for removing CR dye from the aqueous phase owing to its environmental friendliness and low cost. Consequently, this work opens new opportunities for toxic anionic azo dyes uptake using functionalized Zn/Cu HDS.

Advanced Intelligent approach for state of charge estimation of lithium-ion battery

Deepak Kumar[a,b], M. Rizwan[a], and Amrish K. Panwar[b]

[a]Centre of Excellence for Electric Vehicle and Related Technologies, Department of Electrical Engineering, Delhi Technological University, Delhi, India; [b]Lithium-Ion Battery Technology Laboratory, Department of Applied Physics, Delhi Technological University, Delhi, India

ABSTRACT

The commercialization of lithium-ion batteries (LIBs) is rapidly increasing due to a variety of inherent and extrinsic parameters. The State of Charge (SOC), which denotes the amount of remaining capacity, is one of the most important performance metrics for these batteries. As a result, achieving a reliable and precise SOC estimation is essential for the greatest durability and security of LIBs. Estimating the SOC is important to improve the performance and robust utilization of LIBs. Here, this paper uses artificial neural network-based machine learning and deep learning approaches to estimate the battery state of charge. The battery voltage, current, and temperatures have been precisely integrated as input for the models. The proposed model's accuracy, reliability, and robustness are evaluated using available datasets. The mean absolute error was found to be in the range of 0.0030 to 0.0035, and root mean square errors 0.0043 to 0.0047 were obtained at 0 and 10°C operating temperatures. The outcomes demonstrate that the models can successfully estimate the SOC under different temperature conditions.

Electric Vehicle; lithium-ion battery; state of charge; convolutional neural network; artificial intelligence

1. Introduction

The development of modern society is expected to perceive the evolution from nonrenewable fuel sources to renewable energy. Fossil fuel burning in vehicles releases pollutants including carbon monoxide, nitrogen oxides, and hydrocarbons into the atmosphere, which have been a major source of concern across the world (Kumar and Mehata 2022; Kumar, Singh, and Mehata 2022). Electric vehicle (EV) advancements are proliferating to reduce carbon dioxide (CO_2) emissions from traditional transportation (He et al. 2022). The worldwide EVs sales are over 26 million and stocks are rapidly increasing nearly five times more than in 2018 (Global EV Outlook 2023). The propulsion system of EVs is entirely electric, deriving power primarily from its onboard pack of batteries. Therefore, battery storage technology will become one of the most critical essential supporters of the green energy revolution (He et al. 2022). EVs commonly incorporate lithium-ion batteries (LIBs). These are most widely used as a power source for EVs because they deliver high energy density, long lifespan, lightweight, and low self-discharge rate. The sudden change in battery temperatures during over-charging/discharging, and other variables affect the safety and performance of LIBs (Li et al. 2022). The life span of the battery depends upon how it is utilized. The improper battery operations reduce battery life, create short circuits, and result in EVs catching fire. Therefore, battery monitoring is necessary since the battery system determines the vehicle's life, performance, and safety (Xiong et al. 2020). Increasing the driving range and maximizing battery runtime are critical factors in the modeling of EVs. The capability to monitor, regulate, and optimize the performance of single or numerous battery modules in an EV, and the ability to isolate modules from the system in the case of a failure and unexpected circumstances are

crucial components of any EVs (Hossain Lipu et al. 2021). Therefore, the well-known battery management system (BMS) is a critical component for EVs. It can respond to both internal and external events of the battery and ensure a reliable and safe battery operation (Degla et al. 2023). In addition, it enhances battery performance while keeping necessary safety requirements ranges. One of the most important roles of BMS is to estimate the SOC (Tian et al., 2021).

The major challenge in battery state estimation research is SOC estimation, and it is also a most significant battery state. An accurate SOC estimation makes it possible to use LIBs packs to their highest capacity before it is removed, which significantly reduces the overall expenditure of production along with consumption. Furthermore, it is critical for ensuring the appropriate operation of the electric drive, although it effectively assesses a vehicle's outstanding driving range and is required for battery management and maintenance (McCurlie, Preindl, and Emadi 2017). It also prevents over-charging/discharging of the batteries, hence regarded as the crucial parameter of the BMS (Musiak and Li 2021). The SOC is defined as the remaining charge within the battery pack and is given by the remaining capacity of the battery divided by its available maximum capacity as represented in Equation (Eq.) 1 (Chemali et al. 2016).

$$\mathrm{SOC} = \frac{\mathrm{Q_r}}{\mathrm{Q_{max}}} \times 100\% \tag{1}$$

The remaining battery capacity represents by Q_r, while the maximum available capacity is Q_{max}. SOC is the % statistic representing the amount of available charge in the battery. These numbers stay between 0% and 100%, while they may exceed these boundaries in the case of an over-charge and discharge. Measuring SOC involves nonlinear function, fluctuations observed during rising temperature in charge and discharge of the battery (Cui et al. 2020). Regrettably, SOC cannot be measured directly because no method exists (Zou et al. 2015). Therefore, it is important to estimate SOC accurately. The model-based and data-driven are the two most common methods are used in SOC estimation techniques (Song et al. 2020). The few well-known model-based methods are, Electrochemical Impedance Model (Chang et al. 2022), Equivalent Circuit Model (Pai, Liu, and Ye 2023), Luenberger Observer (Ceraolo et al. 2020), Electrochemical Model (Y. F. Li et al. 2021), and Kalman filters (Dawei et al. 2022). These methods require deep knowledge of the electrical and electrochemical characteristics, and complex mathematical models of the LIBs used to model them (Liu et al. 2022). The family of Kalman filters attracted attention toward estimating SOC. This process delivers dependable and accurate models, but it requires in-depth domain expertise and careful engineering of features and take mostly prolonged development times (Xiong et al. 2023). These methods have inherent limitations, such as do not scale well across various battery cell chemistries. For example, the model construction must be updated due to changes in battery chemistry and required reparameterization of the models (Ma, Hu, and Cheng 2021). Furthermore, it also does not take into consideration cell irregularities such as unreliable manufacturing, irregular functioning issues, cell deterioration, and other factors (Tian et al. 2022). These issues were faced by the researchers. Therefore, the adoption of a data-driven method to estimate SOC is attractive and more popular among researchers.

In recent years, developments in artificial intelligence (AI) have accelerated the advance of data-driven SOC estimate methods (Tian et al. 2022). They do not use any physical modeling, instead, learn directly the mapping between SOC and measured data such as current, voltage, and temperatures. As a result, it eliminates the necessity of physical engineering of features, which can involve plenty of effort and time and require in-depth field knowledge (How et al., 2020). The literature has demonstrated excellent precision for such simple-to-implement methodologies, which avoid the difficulties imposed due to battery models (Wang et al. 2022). (Sheikh et al., 2023) Artificial neural networks (Hussein 2015), recurrent neural networks (Bian et al. 2022), support vector machine (Wu et al. 2022), extreme learning machines, Gaussian process regression (Fan, Wan, and Jiang 2022), optimized neural networks (Guo et al. 2021), and fuzzy logic (Singh, Fennie, and Reisner 2004) are frequently used in data-driven SOC estimation methods. Recently, recurrent neural networks (RNNs) were introduced to analyze sequence data, which are significant studies by researchers to address the dynamic profiles, to the directly measured battery SOC estimation (Tian, Xiong, and Shen 2019). In order to achieve a precise SOC estimate by applying voltage

and current sequences as inputs, two advanced RNN variants; long short-term memory (LSTM) and gated current unit (GRU) have been used. For instance, the authors applied a dataset with variable room temperature, which produced an average mean absolute error (MAE) of 2.17%, but it takes 40–50 hours to train the model having 85,000 epochs (Chemali et al. 2018). Yang et al. (Yang et al. 2019a) investigated SOC estimation directly by applying GRU using untrained temperatures and achieved root mean square (RMSE) of approximately 3.5% at the large number of epochs and several hours to train the models. Xiao et al. (Xiao, Liu, and Xiao 2019) also developed a deep convolutional model to reduce the training time of the model and divided the model training into two stages: pre-training and fine-training, while it took significant hours to get the desired results by keeping a few epochs and hidden neurons. Zhang et al. (Zhang et al. 2021) trained hybrid convolutional and RNNs models within a significant number of epochs, achieving an RMSE of under 2% at various temperature ranges, which consumed around 3.9 hours. Such studies required more time to achieve estimation accuracy. Furthermore, in circumstances when there is enough data available, it often takes several hours or days to finish training AI models. For example, we estimate SOC by implementing many hidden neurons and epochs, which consume more computational time, model training time, and high randomness of hyperparameters (Ren et al. 2021). Most AI models employ RNN architectures, which may be effective with sequence data like the SOC, but are challenging and time-consuming to train. Finally, even though RNN architecture effectively handles lengthy sequences, they are still vulnerable to vanishing gradients for longer sequences. The above existing AI-based approaches have research gaps within SOC estimation.

The main objective of this research work is to carry out, to minimize model training time, and to achieve higher accuracy in a short time. Furthermore, convolution neural networks (CNN) and RNNs such as LSTM and GRU are generally used in many fields, including computer vision and natural language processing, and battery state estimation. This article proposed LSTM, GRU, and CNN architecture for SOC estimation. Apart from that, it makes it possible to take minimum time and achieve higher estimation accuracy. Furthermore, we consistently achieved more accurate estimates of the SOC to contribute to effective BMS for EVs. The experimental platform uses an open-source library, TensorFlow, based on Python 6.4.12 and extensively employed in an artificial neural network. The contribution of this paper is as follows:

- Three AI-based models are proposed to capture the nonlinear dynamics of the battery under different temperature conditions. The model's best hyperparameters were selected using a step-by-step screening methodology.
- The battery statistics inside the selected window are connected to the "multi-time input" architecture that was developed to improve model input and SOC estimation performance. The impact of the battery statistics on the results may be effectively controlled to strengthen the estimated stability and accuracy.
- These approaches are model-free, no need to build OCV-SOC lookup tables for different temperatures and corresponding circuit types. The networks exhibit strong adaptability against unknown initial states, efficiently learn battery dynamics, and produce accurate SOC estimates at various temperatures.
- These models significantly reduce errors and maximize performance. The suggested methods contributed toward short computational times to obtain higher estimation accuracy. The presented approach should be adaptable to the SOC estimation on various batteries. These models may be applied in battery-related future work.

The rest of this paper is organized as follows: Section 2 introduces the proposed works and models mechanism architecture. Section 3 describes the experimental platform and data collection, processing model training, and the effect of temperature on LIBs. Section 4 verifies the proposed approach on variable temperatures with different initial and final SOC levels. Results and recommendations for further study are given in Section 5.

2. Proposed work

The entire process of the proposed work can be described as follows illustrated in Figure 1:
Step-1: Collect battery-tested data including current, voltage, capacity, and temperature measurements.
Step-2: Remove any outliers, smooth the data, and align all measurement data. Normalize the data by using a min-max scalar.
Step-3: Examine the data that have been processed and extract appropriate features such as the maximum voltage, current temperature, minimum voltage, current, and temperature. Split into training data.
Step-4: Train the deep learning model, i.e.,, CNN, GRU, LSTM. Hyperparameters tuning is done to provide the best performance of the model.
Step-5: Estimation of SOC output. The statistical performance of the models is calculated by calculating MAE, MSE, and RMSE.

2.1. Short-term long memory

The LSTM is a kind of RNNs commonly incorporated to learn long-term dependencies except when dealing with lost gradient difficulties (Srivastava and Lessmann 2018). It has the tendency to recall statistics for prolonged periods (Ko et al. 2021). The LSTM model's general architecture primarily contains input, output, and forget gates, as illustrated in Figure 2. The following activities are used to characterize an LSTM cell forward pass. In which input gate (i_k), forget gate (f_k), output-gate (o_k), hidden state (h_k), and cell memory (C_k) at time step k are each denoted, respectively.

The LSTM cell evaluates what statistics from cell state C_{k-1} determination is forgotten. The sigmoid function is executed by the forget-gate, which outputs are always between 0 and 1. The first step is determining which data will be lost from cell state C_{k-1}. The outputs of the sigmoid function implemented by the forget-gate are always between 0 and 1. The outcome denotes consequently how much should be forgotten. Although discarding (0) and keeping (1) everything representing, respectively, from the preceding cells state (Zhou, Feng, and Li 2021). A forget gates, described in Eq. (2) determines whether statistics must be removed from its cell memory (Bockrath et al. 2019).

$$f_k = \sigma(W_f * [h_{k-1}, X_k] + b_f) \tag{2}$$

Whereas sigmoid function (σ), defined as: $\sigma = \frac{1}{1+e^{-x}}$. The weight matrix ($W_f$, W_i, W_o), while the input vector ($X_k = V_k$, I_k, T_k) at time step k, and bias b_f, b_c, b_i, and b_o (Chemali et al. 2018a). The input gate recollects the new statistics into cell memory C_k. In Eq. (2, 3), whereas input gate is expressed Eq. (3).

$$i_k = \sigma(W_i * [h_{k-1}, X_k] + b_i) \tag{3}$$

$$_k = tanh\left(W_c * \left[h_(k-1), X_k\right] + b_c\right) \tag{4}$$

Whereas tan hyperbolic function, defined as: $tanh = \frac{e^x - e^{-x}}{e^x + e^{-x}}$.While "input gate i_k," formed by the sigmoid layer, decides which first value must be updated. Subsequently, the new vector value O_k, produced by a tanh layer that may be added to the states. The Eq. (2–4) outputs are now merged to update the unit memory C_k, as described by Eq. (5).

$$C_k = f_k * C_{k-1} + i_k * \hat{C}_k \tag{5}$$

The final output gate concept will also be discussed below. The output depends on the C_k. In Eq. (6), a sigmoid function was employed to finishing, which portion of C_k will be used,

$$O_k = \sigma(W_o * [h_{k-1}, X_k] + b_o) \tag{6}$$

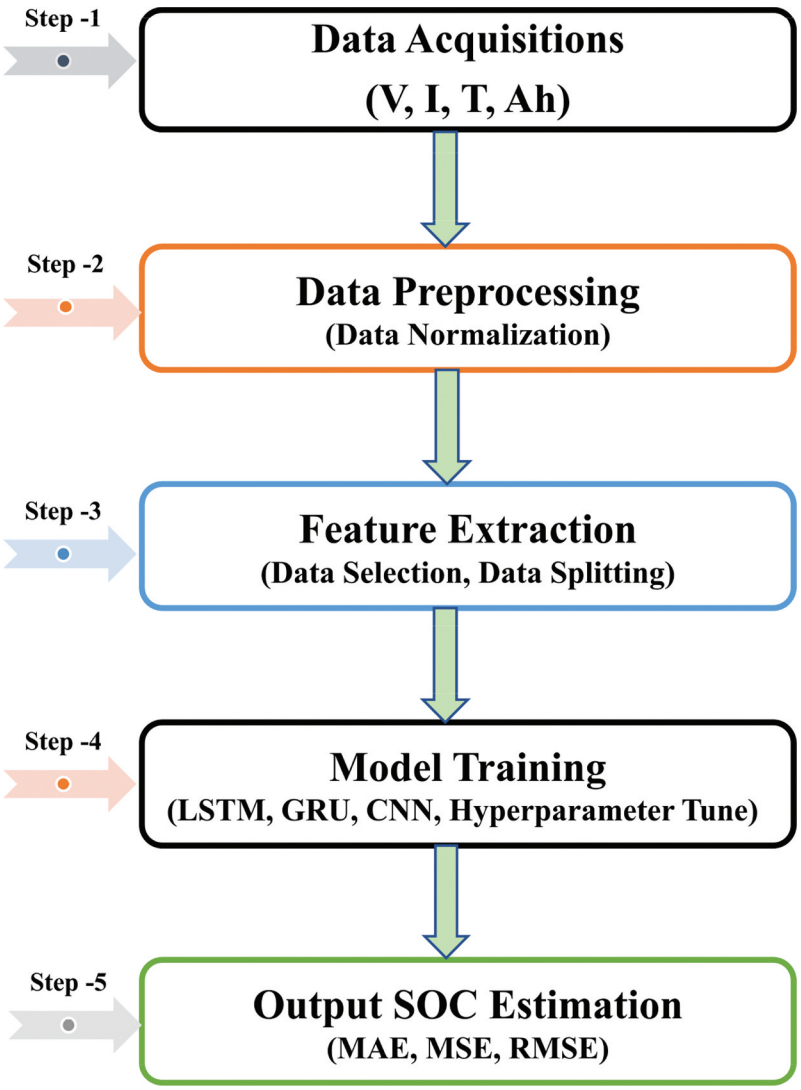

Figure 1. The flow chart of the proposed work.

Where output bias (b_0) is updated unit of states (Wang et al. 2019), the C_k is sent through a tanh function to generate the values from −1 to 1. After that, it is multiplied with the output $O_k$presented in Eq. (5) to produce the output h_k Eq. (7).

$$h_k = O_k * tanh(c_k) \tag{7}$$

While the output h_k. The fundamental drawback of the previous RNN was that earlier inputs vanished over time. Nevertheless, in the LSTM, input and forget gates regulate the cell memory. Thus, a long-term dependence issue is addressed (Naguib et al. 2021a). It is employed to comprehend the subtle complexity of intelligent behavior since it is the finest approach for modeling sequential data. The concept of "cell state" describes long-term memory. Due to their recursive structure, the previous information is stored in the cells.

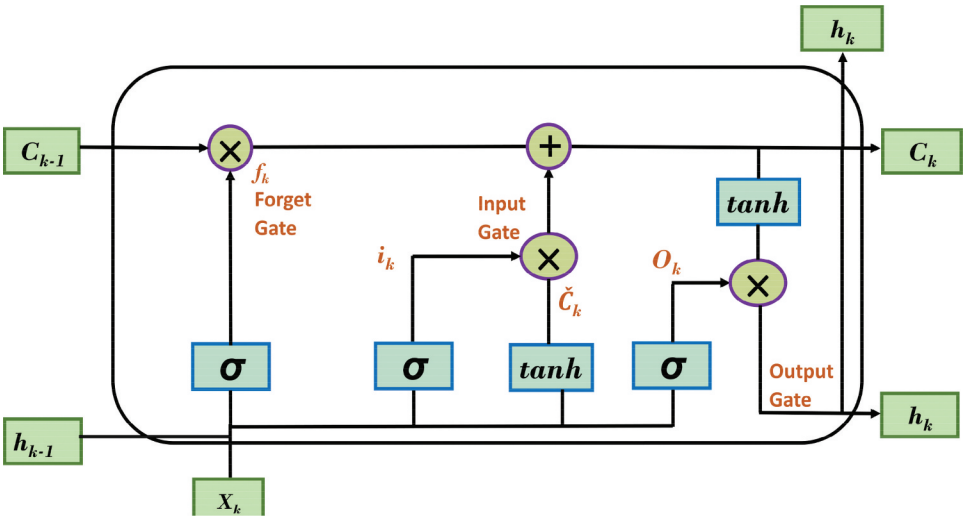

Figure 2. The internal architecture of a LSTM model.

2.2. Gated recurrent unit

An updated version of the LSTM termed GRU was introduced to leverage the connectivity established by a sequence of nodes to perform machine learning operations (Yang et al. 2019b). The fundamental difference between the LSTM and GRU; three gates in LSTM: input, forget, and output, whereas there are two gates in GRU: update and reset (Guo and Ma 2023). The GRU is less complex as compared to LSTM since it has fewer gates. In terms of accuracy, LSTM with three gates is meritorious, while it is a sophisticated model. While in GRU, the update gate governs how significantly preceding memory must be decided to save, and the reset gate regulates how to integrate a new input with previous inputs in its memory. The network acquires how its memory should operate by gaining knowledge of the configurations for its gates. The entire procedure of the GRU is illustrated in Figure 3.

In Equation (8–11), the reset gate "r_k" and the update gate "Z_k" are denoted (Zhao et al. 2017). The input at time k is X_k; the outputs (h_{k-1} and h_k) at times k-1 and k are, respectively. When reset gate weight is larger, then more data from the former neuron are vanished. To recollect important information in the neuron, increase the weight of the update gate. The update gate is represented by the Eq. (8) below, which defines how much of the GRU units is updated.

$$Z_k = \sigma(W_z * [h_{k-1}, X_k]) \tag{8}$$

Equation (8), generates the reset gate:

$$r_k = \sigma(W_r * [h_{k-1}, X_k]) \tag{9}$$

The reset gate hyperbolic tangent function is known as a new remember gate, and it is described by the following function.

$$\hat{h}_k = tanh(W_h[r_k * h_{k-1}, X_k]) \tag{10}$$

$$\hat{h}_k = (1 - z_k) * h_{k-1} + z_k * h_k \tag{11}$$

The weight matrices are W_z, W_r, W_h, and "×" denotes a multiplication of the corresponding matrix elements, requiring that the multiplication matrices be of the same type. The matrix adding operation is represented by the symbol "+." h_{k-1} typically relates to the retention of X_k and h_{k-1}.

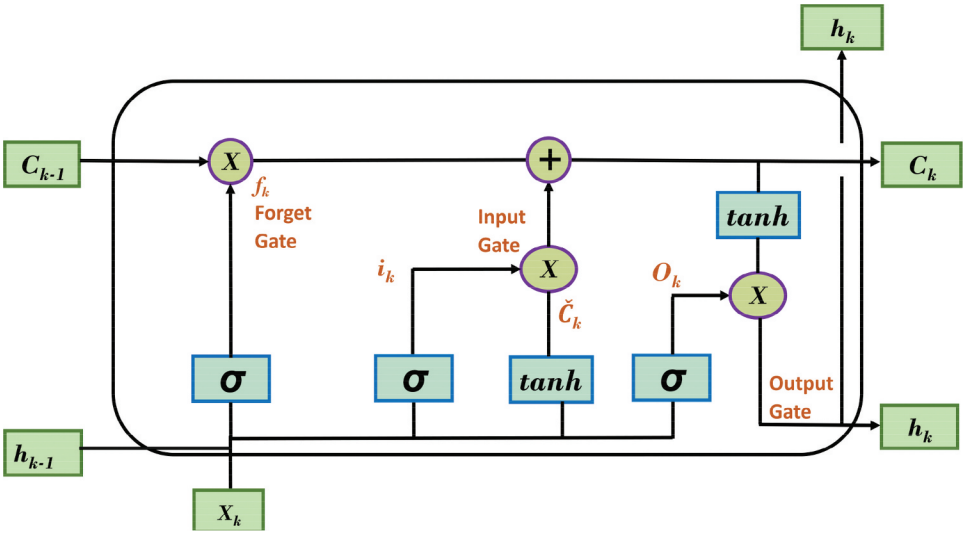

Figure 3. The internal architecture of a GRU model.

2.3. Convolutional neural network

In order to identify patterns and extract features, LeCun et al. introduced a convolutional neural network (CNN/ConvNet), a network of feedforward neurons (Lecun, Bengio, and Hinton 2015). One-dimensional (1D) CNN may identify the correlations among data input using convolutional layer filters and integrate them into more sophisticated feature parameters (Kiranyaz et al. 2021).

The regression classification is achieved using fully connected layers as well as additional neural networks. Furthermore, CNN is employed to analyze the battery datasets presented in this work, and the network topology is represented in Figure 4. Whereas CNN is acknowledged for its effectiveness with two-dimensional visuals, the same approach may be implemented for 1D data to extract superior characteristics, and numerous filters of the same size are implemented. The input parameters are convolved with every filter, and the results are merged as an output (Aman, Rizwan, and Kumar 2023). The following is the feature extraction equation for a time series using a one-dimensional convolution (Kuang and Xu 2018).

$$h_k = \sigma_{cnn}\left(W^*_{cnn}X_k + b_{cnn}\right) \tag{12}$$

Where the input signal "X_k," discrete convolution "*," filter weight "W_{cnn}," bias parameter "b_{cnn}" are learned throughout model training, while the underlying activation function "σcnn." The CNN maybe collect the spatial properties of the input using a few parameters and associating them to produce high-level topographies. After that, these characteristics are sent to the fully connected layer used for additional regression or classification. To capture the spatial properties of battery variables, 1D convolution is used in this research (Ren and Du 2023a). Furthermore, a convolutional layer was added, producing the dataset input to pass via activation function and convolutional operation before proceeding to the subsequent layer (Yao, Xu, and Ramezani 2021).

3. Experimental platform and data

3.1. Simulation platform

The experimental simulation was performed by the CPU (12th Gen Intel (R) Core (TM) i7–12700, 2.10 GHz, 12 core), Intel(R) UHD Graphics 770, and Windows 11 Pro operating system. The models were built by implementing an open-source library, TensorFlow, based on the

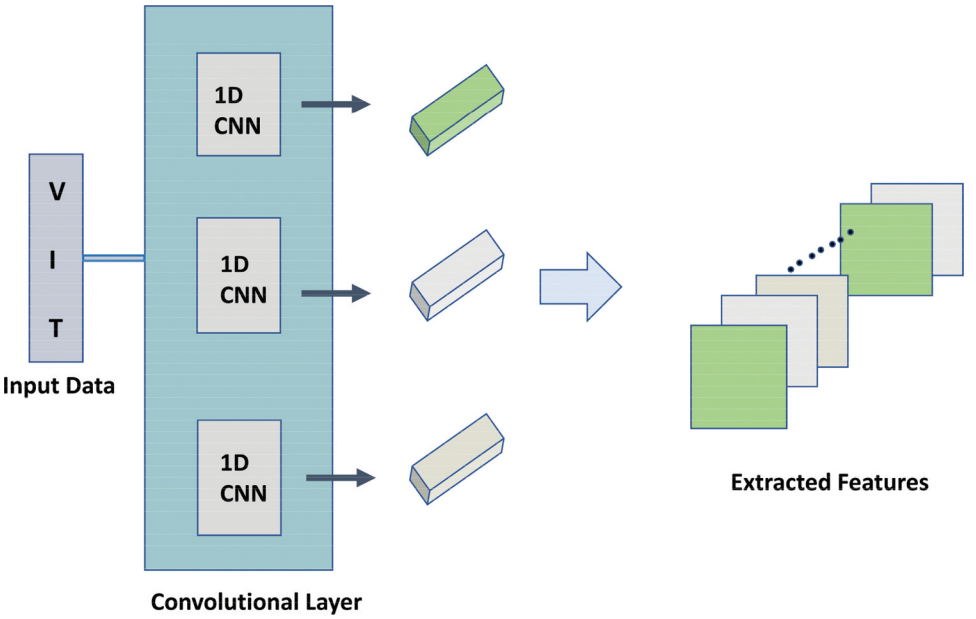

Figure 4. The structure of a 1D convolutional neural network.

Python 6.4.12 platform and extensively employed in an artificial neural network. The TensorFlow backend deep learning framework Keras and Python are the foundations for the neural network model. These models were introduced with dense layers, and window size with input data is 5 and 1, respectively. ReLu activation function, Adam optimization, and TensorFlow are used to output the layers' results (Peyal et al. 2021). Adam optimizer is used to stabilize the model's inherent learning rate. A linear activation function was incorporated with the output layer to get SOC as output. Subsequently, we map the learned states by dense layers to desired SOC output.

3.2. Data processing

This research was performed using the power cell's lithium-ion battery dataset: "Turnigy Graphene 5000mAh, 3S, 65C, LiPo, and Pack dimensions 144 × 51× 33 mm." The authors collected battery datasets from open-source publicly (Kollmeyer and Skells 2020). The battery characteristics are illustrated in Table 1. In this dataset, the test was performed in six different temperature environments (−20, −10, 0, 10, 25, and 40°C) with different C-rates (0.05C, 0.5C, 1C, and 2C) and four driving cycles, namely (UDDS, HWFET, LA92, and US06) of electric vehicles. Every 0.1 seconds, the test drive cycles were collected. In these test-driving cycles, we only used LA92 to perform SOC estimation. The SOC ranges from 0 to 1, but the voltage, current, and temperature measurements are highly variable. To increase precision and reliability, the measurement range must be scaled to the interval [0, 1]. To normalize each input data, the min-max normalization method is used in Eq.. 13.

$$x_{norm} = \frac{x - x_{min}}{x_{max} - x_{min}} \tag{13}$$

Where x_{max} and x_{min} are the maximum and minimum data values, x represents the original data, and x_{norm} represents the normalized data. The normalized data are in the range [0, 1]. This study implements the "multi-time input" structure to window the input data for SOC estimation shown in Figure 5. The relationship between output and input strengthens the relationship

Table 1. Li-ion batteries characteristics.

Energy Density	329 Wh/l

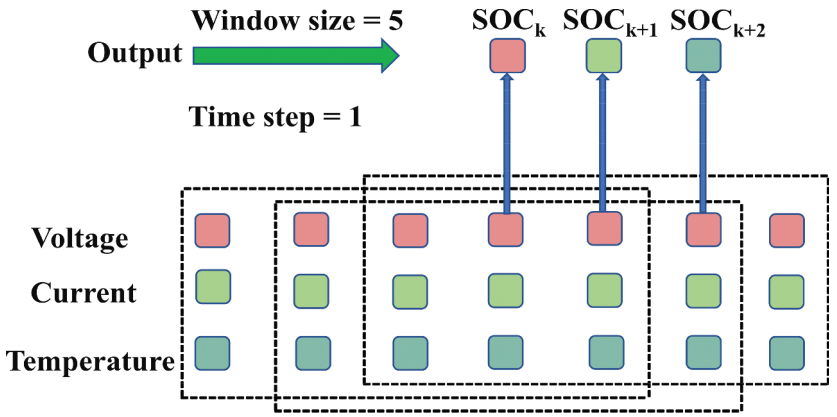

Figure 5. The "multi-time input" structure of the network.

between output and data in the window. All voltages, currents, and temperature measurements within that window are included in the input at time k. SOC_k applies to all data. This approach can increase the estimation accuracy and durability while maximizing the impact of all previous information on the outcomes (Naguib et al. 2021b).

3.3. Model training and hyperparameters tune

The Jupyter Notebook and Google Collab have used programming environments. The Keras library is used to implement the suggested models (Keras: The Python Deep Learning API). With the learning rate set to 0.01, the Adam algorithm is the selected optimizer to update the network weights and biases. All suggested models are trained for 50 epochs. The loss function is the root mean square error and mean squared error. The proposed network architectures, need the selection of different hyperparameter values to improve model accuracy and robustness. These values frequently have a significant impact on performances, if they are not set carefully. For example, an increase in computation time becomes large and costly, when the number of hidden is not selected carefully. Furthermore, the learning rate may be used to get accurate results and prevent overfitting and underfitting, while epochs are reducing the training load of networks (Ren and Du 2023b; Xie et al. 2023). In this article, all the hyperparameters are modified without traversing all possible standards, but rather by roughly setting different values of the parameters so that the training outcomes are within a satisfactory precision range.

3.4. Evaluation standard

The mean absolute error (MAE), mean squared error (MSE), root mean square error (RMSE), and maximum error (MaxError) are used to verify the estimation accuracy of the models calculated by Eq. (14–18).

$$MAE = \frac{1}{N}\sum_{k=1}^{N} \mid SOC_k - SOC_k^{'} \mid \tag{14}$$

$$MSE = \frac{1}{N}\sum_{k=1}^{N} \left(SOC_k - SOC_k^{'}\right)^2 \tag{15}$$

$$RMSE = \sqrt{\frac{1}{N}\sum_{k=1}^{N} \left(SOC_k - SOC_k^{'}\right)^2} \tag{16}$$

$$R^2 = 1 - \frac{\Sigma_k \left(SOC_k^{'} - SOC_k\right)^2}{\Sigma_k \left(SOC_k - \overline{SOC}\right)^2} \tag{17}$$

$$MaxError = max \mid SOC_k - SOC_k^{'} \mid \tag{18}$$

Where "N" number of windows, "SOC_k" actual value, and $SOC_k^{'}$does the proposed network estimate the value. The arithmetic mean of the actual SOC value is $\overline{SOC}$. MAE evaluates how closely estimation is to actual values. The RMSE, on the other hand, indicates the variation of faults and is significantly more sensitive to considerable errors. The R^2 prediction coefficient is calculated as the assessment standard in order to highlight better the models' ability to fit data in this research. The network performs better the closer it is to 1.

3.5. Impact of temperatures on LIBs performance

The efficiency of a battery cell is highly reliant on its temperature; as a result, the operating temperature of the battery cell must constantly be maintained to stay within a specific range of temperature for battery safety, excellent performance, life cycle, and cycle stability (Jin et al. 2021). Therefore, the core problem is creating a battery energy storage technology that uses less energy and can more effectively avoid cell overheating. Operating circumstances, such as operation at high and low temperatures, have an impact on LIBs performance and shorten the battery's lifetime. When the temperature rises, it might result in thermal runaway, and the power and energy of the batteries are almost entirely lost (Divakaran et al. 2020). The variation in the working environment may have a significant impact on SOC estimation. The effect of dynamic load on SOC estimation, particularly under time-varying temperature conditions, has been addressed. The temperature change in the storage battery may inevitably occur during typical electric vehicle performance and will mainly affect SOC measurement (Li et al. 2021).

4. Analysis, simulation results, and performance comparison

In practice, battery loading varies significantly depending on how the battery is being used. For example, the battery-loading behaviors of hybrid vehicles while traveling on highways and in cities differs significantly with temperatures. Temperatures significantly influence the accuracy of SOC estimation. The suggested neural networks are trained based on AI approaches without needing a battery model. In this article, the authors trained the recommended neural network models using LA92 test drive cycle data at −10, 0, 10, 25, and 40°C to investigate the effect of temperature. To

4	25	0.2615	0.0901	0.3003	0.9996	0.6111	351
5	40	0.2892	0.1165	0.3413	0.9995	0.7473	56

analyze the comparison between the applied algorithm and its performances on data inputs with temperatures. Additionally, we examine the comparability of the SOC estimation curves, and the errors of all datasets are uploaded into the standard LSTM, GRU, and CNN models. Models are run multiple times to decide the best parameters, such as optimizers, learning rates, epochs, etc.

Figure 6 shows estimated SOCs with errors using LSTM at different temperatures. It was found that at 25, 40, and 10°C, the LSTM model performed more efficiently, while very poor at −10 and 0°C with maximum error found to be 0.4710 and 0.3322, respectively. The LSTM accuracy outcomes are tabulated in Table 2. The high accuracy was obtained in ambient as well as high temperature. The fluctuations were observed at 0°C, as clearly seen in Figure 6. The zoom inset plot is also plotted in all figures. It might have occurred due to internal battery chemistry, which is very difficult to attribute at low temperatures. It was found that the model worked better with minimal errors, 0.0986 at ambient temperature and about 0.01037 at high temperature. Therefore, based on its maximum error, LSTM was found to be ineffective at low temperatures with this battery data because it is hard to know its internal chemistry at low temperatures.

The GRU model performs faster to train, taking small parameters, which is helpful in systems integration. To upload data into the GRU model to obtain estimates with actual results as tabulated in Table 3. At 10°C, performances of the GRU model are given notable fluctuations and significant errors between the estimated and actual SOC results. As seen in Figure 7, the fluctuations and errors become more effective at a temperature 10°C, which does not meet the accuracy and robustness requirements in the actual operation. It might be attributed that the performance of the GRU at 10°C does not give more accurate estimations. The main factor behind this is the more complicated internal temperature dynamics of lithium-ion batteries, which shows poor performance with variations in temperatures, which makes it considerably more difficult for the suggested network to get meaningful attributes. The GRU estimation performance at 0°C shows the best accuracy, RMSE, and Max error around 0.2569 and 0.4982, respectively. While at −10 and 40°C showing more errors. As a result, since temperatures significantly impact GRU networks, it is impossible to determine battery SOC at various temperatures. The estimated effectiveness of the model network is more precisely investigated using MAE, RMSE, and R^2, as shown in Table 3.

The CNN model of SOC estimation results with errors are shown in Figure 8. The estimated performance under various temperatures is generally satisfactory compared to LSTM and GRU. The SOC estimation performances, such as MAE, MSE, RMSE, $R^{2,,}$ and Max error tabulated in Table 4. The superior performance was gained by CNN at 0 and 10°C, while the performance was weakest at 25 and 40°C. The SOC estimate performance at −10°C is satisfactory compared to the ambient and high temperatures. It is significantly more difficult for the suggested network to gain relevant characteristics since lithium-ion batteries perform poorly and have more complicated internal dynamics at low temperatures. In brief,

the proposed network may easily be expanded to consider the impact of ambient temperature on battery SOC estimates by simply adding temperature as a network input. Overall, the suggested approach may provide a reasonable SOC estimate for various temperatures.

To validate the effectiveness of the proposed SOC estimation models LSTM, GRU, and CNN. CNN shows the best results and the worst performance achieved by GRU. Whereas GRU and LSTM take more training time due to their complex structure and many cell states present in each hidden neuron, CNN requires less time to train the model. This research demonstrates that the suggested network completely satisfies the requirements of practical operation and has excellent accuracy and resilience under various working circumstances. A comparison of different reports based on AI models for SOC estimation performance is tabulated in Table 6. In this comparison, the present work is more accurate in estimating SOC, demonstrating that the proposed models could be promising for more accurate SOC estimation. The computational efficiency (CE) of GRU and CNN method is calculated by using Eq. 19, by taking LSTM actual computational time as reference as shown in Table 5. The highest CE shown by CNN is 66.82% at −10°C, while lowest CE shown by GRU is 1.03% at 0°C.

$$\textit{Computational Efficiency}(\%) = \frac{\text{Reference computational time} - \text{Actual computational time}}{\text{Reference computational time}} \times 100 \qquad (19)$$

5. Conclusions

In EVs, the BMS monitors and regulates battery energy storage systems. Estimating SOC is the most essential function of a BMS. The accurate estimation of SOC ensures the safe and stable operation of LIBs in EVs, therefore ensuring the safety of drivers and vehicles. It is a compulsory task to redress the malfunctioning of batteries and improve battery lifespan. Moreover, it reduces the number of batteries needed in the battery pack, which helps lower costs by preventing LIBs from being overcharged or undercharged. The AI-based advancements have confirmed their acceptability in this domain. This paper proposed the LSTM, GRU, and CNN models for SOC estimation at different temperatures with the test drive cycle datasets. These models have the ability to learn to overcome the complexity and uncertainty during the estimation process. The results demonstrate that CNN models perform superior SOC estimation with RMSE about 0.0043 in approximately 243 seconds, while LSTM gives RMSE about 0.0173 in 456 seconds and GRU revealed 0.3003 in 351 seconds. The total time taken by LSTM, GRU, and CNN to perform all the experiments is 1722, 1471, and 883 in seconds, respectively. The CNN and GRU give results faster approximately 67% and 23% as compared to LSTM. Therefore, CNN is the best among these and saves time, which is very crucial for the BMS to take

decisions earliest. In addition, it has the capability to estimate SOC much more accurately than other models. It can also learn the dynamic behavior of batteries more effectively. This work is expected to be a reference for researchers and industrialists to understand the SOC estimation process with the dynamic behavior of batteries. This proposed work may be extended to the future as:

- The battery pack will be used instead of the individual cells for state estimation on different dynamic loading profiles and temperatures.
- The different AI-based algorithms also will be joined together to contribute toward the advanced battery SOC estimate of the battery packs and verify the effectiveness of the proposed algorithm.
- The state estimate may include State of Health (SOH), Remaining Useful Life (RUL), and End of Life (EOL).

Notes on contributors

Deepak Kumar received his B.Tech. degree in Electrical and Electronics Engineering from Dr. A.P.J. Abdul Kalam Technical University Uttar Pradesh, Lucknow, India, in 2017, and M.Tech. degree in Nanoscience and Technology from the Department of Applied Physics at Delhi Technological University, Delhi, India, in 2021. He is currently pursuing PhD degree at Delhi Technological University, Delhi, India with the Department of Electrical Engineering. He has published two research articles in reputed international/national journals. His research interests include battery technology, energy storage in electric vehicles, and AI-based battery management ystems/battery state estimation.

Dr. M. Rizwan did his post-doctoral research at Virginia Polytechnic Institute and State University, USA. He is presently working as a Professor at the Department of Electrical Engineering, Delhi Technological University, Delhi, India. He has almost 20 years of teaching and research experience. Dr. Rizwan has successfully completed three research projects in the area of renewable energy systems and published and presented more than 175 research papers in reputed international/national journals including IEEE transactions and conference proceedings. Dr. Rizwan has published one book titled Grid Integration of Solar Photovoltaic Systems, CRC Press, (Taylor and Francis Group), 2017, and Edited one book for AIP Publishing, USA. He is the recipient of Raman Fellowships for Post-Doctoral Research for Indian Scholars in USA, DST Start up Grants (Young Scientists) and many more. His area of interest includes soft computing applications in power engineering, renewable energy systems, building energy management, smart grid etc. He is a Sr. Member of IEEE, Life Member of ISTE, Life Member of SSI, Member of International Association of Engineers (IAENG), and many other reputed societies.

Dr. Amrish K Panwar completed his MS degree from Chaudhary Charan Singh (CCS) University, India, and his PhD degree from Indian Institute of Technology (IIT) Roorkee, India in 2005. After completing PhD degree, he has worked as a post-doctoral research associate at the Department of Metallurgical and Materials Engineering, IIT Kharagpur, India. Before joining Delhi Technological University (DTU), he has also worked as senior lecturer in Jaypee University of Engineering and Technology (JUET), India. Presently, he is working as Assistant Professor in the Department of Applied Physics, Delhi Technological University, New Delhi, India. His area of research includes: energy storage and conversion devices (Li+ /Na+ batteries/supercapacitors/solar cells), surface modification, wetting adhesion, and nanocomposites.

Dataset availability statement

Dataset analysis and forecasting have been performed utilizing publicly available data from Mendeley Data.

Declaration

The authors declare that the present research has no financial or personal ties to any individual or group that could unreasonably affect this work. This manuscript is the author's work and does not contain material from other sources. All data measures are accurate and unaltered results, and this work has never been published or submitted to another journal for publication consideration. Also, none of the authors has any financial or scientific conflicts of interest concerning the research described in this manuscript.

ABSTRACT

The main deliberation of this review paper is on metallic catalysts, including Cu-based catalysts, with distinct formulations and compositions, utilized for steam reforming of methanol (SRM). The review critically examines the performance of these catalysts, considering the active components, supports, promoters, and their interactions. Additionally, the review identifies and elucidates the various kinds of reaction mechanisms and routes involved in SRM. This comprehensive analysis provides valuable insights into the progress of well-organized and effective catalysts for SRM. To achieve high yields of H_2, it is crucial to conduct a fundamental study of the role of copper as a component in both mono and multimetallic systems, as well as the nature of support. These factors are essential to understand the catalytic mechanisms involved in the steam reforming of methanol and to develop effective strategies for optimizing hydrogen production. Therefore, a thorough investigation of copper-based catalysts and their interaction with the support material is essential for the development of highly efficient steam reforming processes.

Keywords: methanol reforming; hydrogen production; catalyst reaction scheme

1. Introduction

In the present day, achieving stability between economic evolution, growth, and sustainability while safeguarding the environment poses a monumental challenge to the world. Energy and the environment are intricately linked, and the path toward achieving this balance grows more complex each day. According to a report in 2019 by the International Energy Agency (IEA), a 1% increase in global economic output results in a 0.5% rise in CO_2 emissions annually[1]. In recent decades, there has been a significant focus on using non-carbon renewable sources, such as solar, wind, hydrothermal, and tidal energy, as well as hydrogen energy. However, all of these sources, except hydrogen, experience availability issues throughout the year[2]. Hydrogen is becoming an increasingly popular alternative to traditional energy sources in fuel cells, thanks to its higher energy density and lack of greenhouse gas emissions[3]. Specifically, when it comes to energy sources for transportation, polymer electrolyte membrane fuel cells (PEMFC) are extensively utilized[4]. However, unlike fossil fuels that can be directly extracted from the environment, hydrogen needs to be obtained through different reforming reactions, including steam reforming, auto-thermal reforming, and partial oxidation[5]. Methane is often used as a feedstock for hydrogen generation, but this process has significant

drawbacks when it comes to industrial applications. It can be complex, and there are safety concerns related to hydrogen storage and transportation[6]. The majority of hydrogen production worldwide, particularly for the refinery and chemical industries is achieved through steam reforming or partial oxidation of fossil fuels like naphtha or natural gas. This process is well-established and widely used for various feedstocks, including LPG, methanol, diesel and jet fuel[7].

Currently, natural gas reforming is considered more cost-effective and efficient than steam reforming of methanol (SRM) for the production of H_2. However, relying on natural gas reforming is not a sustainable and environmentally friendly solution in the long term[8]. The process reforming of natural gas involves high temperatures, which results in significant CO_2 production and purification requirements for hydrogen production. This translates into higher assets funds, functional charges, and CO_2 radiations[9]. Byun et al.[10] revealed that the lowest cost for hydrogen production was 2.78 USD per kilogram of hydrogen, achieved with a reactant cost of 100 USD per ton and a cost exponent of 0.6, it remains higher compared to the cost of hydrogen produced through SMR (steam methane reforming), which is 2.30 USD per kilogram. However, the analysis of various scenarios provided valuable insights into the steps necessary to achieve economic feasibility in hydrogen production.

In modern centuries, there has been a growing interest in using methanol reforming as an attractive option for hydrogen production. Methanol has several advantages, including its small sulfur content, higher volumetric energy density, higher hydrogen/carbon ratio of 4:1, and biodegradable properties[11]. In the context of hydrogen extraction, methanol stands out as the preferred choice among other alcohols due to its ability to undergo the process at lower temperatures, typically within the range of 200 °C–300 °C. This is attributed to the absence of C–C bonds in methanol's molecular structure. In contrast, the reforming of ethanol and methane necessitates higher temperatures, around 400 °C and 500 °C, respectively[12].

The demand for methanol has been growing at a compound annual growth rate (CAGR) of 6% since 2014, mainly due to its increasing usage in various industries. Recent studies have shown that 40% of the methanol formed is used in the area of energy region[13]. The reforming technologies for hydrocarbons and alcohols have made it possible to generate hydrogen in situ, thereby overcoming the challenges of hydrogen storage and transportation[12,14]. The US Department of Energy (DOE) has established a goal to achieve hydrogen production at a charge of 4 USD/kg or lower, employing emerging technologies[1]. By 2030, it is projected that the cost of hydrogen extraction will see a further reduction to 1.8 USD/kg. Additionally, hydrogen is expected to fulfill approximately 15% of the global energy demand (GED) during that timeframe[15].

During the steam reforming of methanol (SRM) process, in which methanol is converted into hydrogen and other products, the primary product is hydrogen, along with small amounts of carbon dioxide and CO, unreacted H_2O, and CH_4. However, the generation of CO needs to be restricted, as concentrations higher than 10 ppm can damage the catalyst[16]. Therefore, the design and performance of the catalyst play a critical role. An efficient catalyst should have higher activity and selectivity to yield a higher H_2 production, thereby minimizing CO production. Additionally, the catalyst should be resistant to sintering and have the longest feasible stability[17]. Extensive investigations have been carried out on copper and palladium-based catalysts in the field of steam reforming of methanol (SRM). Among these catalysts, copper-based ones are highly favored for their remarkable activity and selectivity. However, a significant concern associated with copper-based catalysts is their susceptibility to catalytic deactivation caused by thermal sintering[18,19].

The attainment of the catalyst through the reforming reaction is dependent on both the metal component and the support material[20]. Promoters, such as acid oxides or metals of alkaline, are critical in removing unwanted reaction products. To increase the efficiency of the reaction, it is also necessary to understand catalyst deactivation caused by coking or sintering[21,22]. In a study by Song and Ozkan[23], it was proposed

that employing an improved performance reusable catalyst could offer a cost-effective solution for steam reforming of methanol (SRM). The growing interest in the SRM is apparent from the increasing number of publications on the topic each year (as shown in **Figure 1)**.

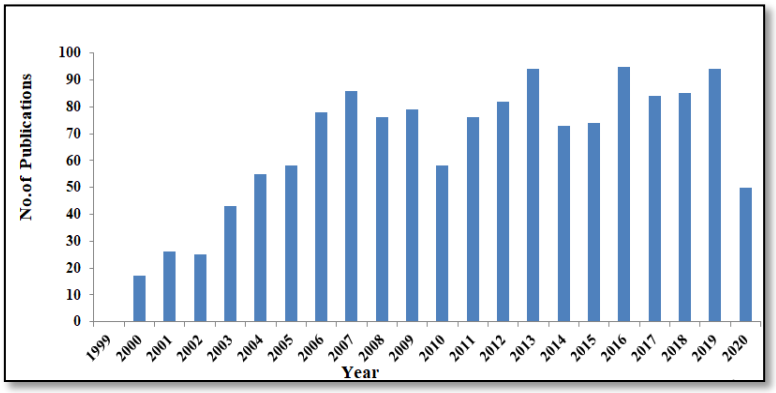

Figure 1. Publications detail on steam reforming of methanol to H_2 production from various databases, modified from Reference [1].

The cost of SRM is impacted by the process of separating hydrogen from the product mixture. Membrane reactors are more efficient than traditional reactors because they allow for the reaction and H_2 separation from CH_4, CO_2, CO, and other known by-products to occur within the same reactor, eliminating the need for additional processing steps. By bypassing the water gas shift (WGS) reaction, membrane reactors are more cost-effective. This is because they can perform both the reaction and separation simultaneously, reducing the cost and time associated with the separation process. This information is supported by research that shows the efficiency and cost-effectiveness of membrane reactors in SRM[24]. Numerous kinds of membrane reactors have been employed for SRM, including fluidized bed membrane reactors (FBMRs), packed bed membrane reactors (PBMRs), micro-porous SiO_2 membranes, and micro membrane reactors[25]. In recent years, research has also focused on disseminated feeding membranes that exhibit selectivity nearby H_2 and CO[26]. This approach has shown promise in enhancing the efficiency and selectivity of hydrogen separation in SRM. These countless varieties of membrane devices have been studied and evaluated, and their effectiveness has been documented in the literature.

Concerning its practical implementation, a study conducted by Pashchenko[27] investigated the utilization of low-grade heat for methanol decomposition. The findings demonstrated that the use of low-grade heat for methanol decomposition can lead to an efficiency improvement of up to 5% compared to utilizing the same heat for steam generation. Furthermore, the study highlighted that the efficiency of a combined cycle increases with higher gas turbine inlet temperatures.

Pashchenko et al.[28] conducted a thermodynamic analysis using the Aspen Hysys platform to evaluate the efficiency of various fuels, including methanol, ethanol, n-butanol, and glycerol, in thermochemical recuperation (TCR) systems. The analysis utilized the Gibbs free energy minimization method and investigated a wide temperature range of 400 K to 900 K, with a steam-to-fuel ratio of 1 and a pressure of 1 bar. The study focused on determining the maximum fuel conversion levels achieved. Notably, specific temperatures were found to yield the highest fuel conversion: 600 K for methanol, 730 K for ethanol, 860 K for n-butanol, and 890 K for glycerol.

Similarly, the study revealed that the efficiency of thermochemical heat recuperation systems is significantly influenced by both the composition of the initial reaction mixture and the process temperature. Notably, the maximum efficiency for steam reforming in these systems varied at different temperatures: 600 K for methanol, 700 K for ethanol, and 900 K for methane. These findings underscore the importance of

carefully considering the specific reaction mixture and process temperature to optimize the efficiency of thermochemical heat recuperation systems[29].

In the concerning of pressure drop analysis, a combination of numerical simulations and experimental investigations was employed to analyze the pressure drop and loss factor in thermochemical recuperators that incorporated catalysts of varying shapes. The reaction space within these recuperators was modeled as a porous packed bed utilizing a $NiAl_2O_3$ catalyst, and the commercial software ANSYS Fluent was utilized for the simulations. A comparison between the experimental and simulation outcomes for pressure drops revealed a strong correlation, with a discrepancy of less than 8%. Furthermore, it was observed that the pressure loss in the packed bed displayed an approximately linear relationship with the bed depth[30].

Using the RBD algorithm (rigid body dynamics), a numerical calculation was performed to investigate the flow characteristics in a realistic computational domain. The results of the analysis indicated that when the pore size is less than 0.5 mm, the flow through the particle-filled porous medium is negligible. On the other hand, when the pore size exceeds 0.5 mm, a substantial flow occurs through the porous elements of the fixed-bed reactor[31].

The main aim of this paper is to offer a thorough and inclusive examination of the recent progressions in hydrogen production utilizing the steam reforming of methanol technique. The study focuses on Cu-based catalysts and analyzes their performance along with the factors affecting their reactivity. Additionally, the literature review covers the classification of SRM, its usefulness as a hydrogen storage medium, and its potential applications.

2. Literature

2.1. Classification of steam reforming of methanol (SRM)

SRM is a chemical process used to produce hydrogen gas by reacting methanol with steam. This process is highly endothermic, meaning it requires a lot of energy to be supplied in the form of heat. SRM is often preferred over other methods of producing hydrogen such as partial oxidation of methanol (POM), oxidative steam reforming of methanol (OSRM), and sorption-enhanced steam methanol-reforming because it results in a higher yield of hydrogen. There are several categories of SRM as shown in **Figure 2**, including thermo-catalytic reforming, photo-catalytic reforming, aqueous phase reforming, and high-temperature reforming. In general, SRM is represented by the following chemical Equation (1). **Figure 2** shows the various kinds of hydrogen production methods from steam reforming of methanol.

$$\text{SRM: } CH_3OH + H_2O \rightarrow CO_2 + 3H_2;\ \Delta H^{o}_{298\,K} = +49.2\left(\frac{kJ}{mol}\right) \quad (1)$$

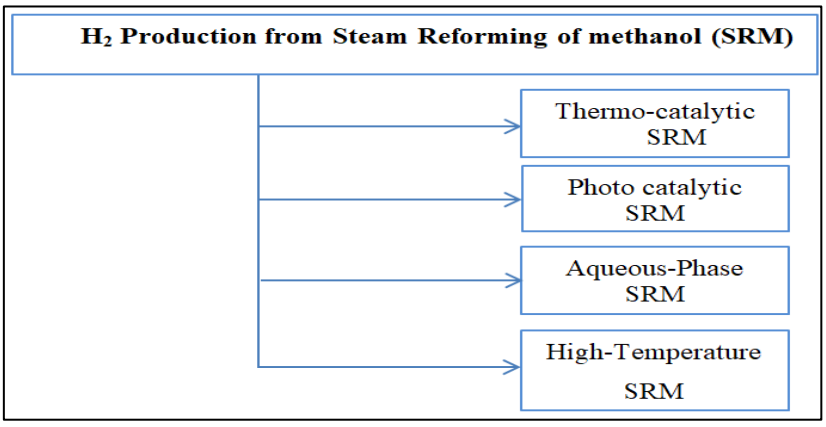

Figure 2. Classification of SRM methods.

2.1.1. Thermo-catalytic SRM

It is a commonly used method in industry for hydrogen production. However, side reactions are a common occurrence, especially when the lower ratio of steam/methanol. These side reactions often include the decomposition of methanol and the WGS reaction, leading to the production of methane, methyl formate, dimethyl ether, and other by-products[32].

$$\text{Dehydration: } 2CH_3OH \rightarrow (CH_3)_2O + H_2O; \Delta H^{o}_{298\,K} = -23\left(\frac{kJ}{mol}\right) \quad (2)$$

$$\text{Methanation: } 2CH_3OH \rightarrow CH_4 + 2H_2 + CO_2; \Delta H^{o}_{298\,K} = -66.9\left(\frac{kJ}{mol}\right) \quad (3)$$

$$\text{Dehydrogenation: } 2CH_3OH \rightarrow HCO_2CH_3 + 2H_2; \Delta H^{o}_{298\,K} = +64.4\left(\frac{kJ}{mol}\right) \quad (4)$$

$$\text{Formaldehyde synthesis: } CH_3OH \rightarrow CH_2O + H_2; \Delta H^{o}_{298\,K} = +84.7\left(\frac{kJ}{mol}\right) \quad (5)$$

$$\text{Carbonation: } CH_3OH \rightarrow C + H_2O + H_2; \Delta H^{o}_{298\,K} = +159.5\left(\frac{kJ}{mol}\right) \quad (6)$$

Wang et al.[33] were involved in a study on the thermodynamic performance of fuel cells via a poly-generation system that incorporated solar, waste heat, fuel cells, and SRM. The simulation results indicated that the system achieved an efficiency of 73.7% during the summer and 51.7% during the winter. In a separate study, Hosseini et al.[34] developed a poly-generation system that utilized a molten carbonate fuel cell (MCFC) system with an SRM, a heat and power cycle, and a methanol generation process using the distillation technique. The system demonstrated the capacity to generate electricity, warm water, and methanol concurrently, resulting in an impressive gross exergy efficiency of 83.7%. Schuller et al.[35] created a new type of heat exchanger reactor specifically for SRM. In their study, it was reported that this reactor employed waste heat from a fuel cell to drive the reforming reaction, leading to the thorough transformation of methanol at a temperature of 180 °C.

2.1.2. Photo catalytic SRM

It is a new type of technology that uses photon energy to reduce the temperature of the reaction. Sun et al.[36] studied SRM by lowering the reaction temperature with photon energy. Through a comparison of process outcomes with and without light, it was found that photon energy promotes the dissociation of formate into CO_2 and H_2. With no evidence of carbon monoxide, the rate of H_2 generation was 50.6 mmol/(g h) at 200 °C and 76.2 mmol/(g h) at 210 °C. Chiarello et al.[37] reported SRM over Pt/TiO_2 retaining in situ diminished entire reflection IR spectroscopy presented that TiO_2 physicochemical were pretentious from Pt nanoparticles.

2.1.3. Aqueous-phase SRM

It is an innovative technology that converts various compounds such as alcohol, sugar, and polyol into H_2 and CO_2 by placing them in an aqueous solution. The utilization of this process is regarded as an environmentally friendly technique for converting biomass into H_2 and CO_2 at lower reaction temperatures[38]. The key factor for the successful aqueous phase of methanol-reforming is the creation of a durable catalyst that can produce high hydrogen yields while minimizing the absorption of alkanes and CO[39]. The hydrogenation process of CO and CO_2 can lead to methane development.

$$CO + 3H_2 \rightarrow CH_4 + H_2O; \Delta H^{o}_{298\,K} = -253.70\left(\frac{kJ}{mol}\right) \quad (7)$$

$$4H_2 + CO_2 \rightarrow CH_4 + 2H_2O; \Delta H^{o}_{298\,K} = -165\left(\frac{kJ}{mol}\right) \quad (8)$$

Davda et al.[40] utilized the catalyst (Pt/Al_2O_3) in their research on ethylene glycol and the methanol aqueous phase reforming. Their findings indicated that hydrogen had maximum activity and selectivity, with nearly 100% efficiency. Similarly, the catalyst $Ni/25\%CeO_2{-}ZrO_2$ was employed in investigating aqueous

phase SRM. The research showcased a methanol conversion rate exceeding 50% and a hydrogen efficiency surpassing 40%[41]. Cortright et al.[42] also reported on the feasibility of H_2 extraction from alcohols at approximately 227 °C via aqueous phase SRM. These studies suggest the potential for efficient hydrogen production through AP-SRM using various catalysts.

2.1.4. High-temperature SRM

This technique explores the utilization of bimetallic catalysts, specifically iron and copper supported on Al_2O_3-Zn-ZrO_2, for the extraction of hydrogen. The investigation revealed that hydrogen extraction without any detectable carbon monoxide could be achieved at a temperature of 500 °C. The catalytic activity was evaluated across a temperature range of 150 °C to 500 °C. The research team observed an intriguing synergy that led to a decrease in particle size and improved reducibility for a bimetallic catalyst with an equal Fe/Cu ratio of 1:1. Furthermore, when the copper content exceeded 75%, the selectivity towards CO was practically eliminated. By conducting DRIFTs analysis, the researchers were able to identify that the existence of Fe_2O_3 as the surface species on the catalyst played a key role in the transformation of produced CO to CO_2. The results of the analysis indicated that Fe_2O_3 acted as an active component in facilitating the chemical transformation of CO into CO_2. These findings suggest the potential for efficient H_2 production using bimetallic catalysts through iron and copper[42,43].

2.2. Chemical hydrides as methanol

Chemical hydrides and metal hydrides share the characteristic of chemically bonding hydrogen, but their properties differ significantly due to the presence of lighter elements in chemical hydrides. Significantly, chemical hydrides exhibit a liquid state under normal conditions, which offers several advantages. It simplifies the transportation and storage of these hydrides and facilitates heat and mass transfer through dehydrogenation and hydrogenation approaches. Some chemical hydrides, including formic acid, methanol, and ammonia are already commonly produced through natural gas and used for purposes beyond hydrogen storage. This pre-existing infrastructure for production, handling, and transport is advantageous. Furthermore, utilizing hydrogen obtained through water electrolysis instead of natural gas reforming for the production of these bulk chemicals can contribute to a reduction in fossil fuel consumption. While certain chemical hydrides have been proposed as substitutes for hydrogen, this article does not aim to compare these fundamentally distinct pathways[44].

Methanol (CH_3OH) exhibits hydrogen storage capacities of 12.5% (wt) and 99 kg/m^3 in terms of gravimetric and volumetric measurements, respectively, making it the simplest alcohol with the potential for hydrogen storage. One of the most widely discussed methods for producing renewable methanol is over-carbon dioxide (CO_2) hydrogenation[45]. There are several ways to release hydrogen from methanol, including through steam reforming where it reacts with water, partial oxidation where it reacts with oxygen, or via methanol thermolysis (decomposition)[46]. Among these methods, steam reforming stands out as advantageous because it yields 3 moles of H_2 per mole of CH_3OH, whereas the other two reactions result in only 2 moles of H_2 per mole of CH_3OH[46,47].

To facilitate the methanol steam reforming, external heating is required due to the endothermic nature of the reaction and the evaporation of water and methanol. Typically, a catalyst (Cu/ZnO/Al_2O_3) is employed at temperatures ranging from 230 °C–330 °C[46]. The production of methanol through the synthesis of CO_2 and hydrogen has reached a commercial stage, and the “George Olah Renewable Methanol Plant” has been operational in Iceland since 2011, making it the world’s first facility of its kind. The same type of catalyst used in conventional natural gas-based development can be used in the CO_2-based process[45]. The reaction to form methanol from CO_2 and hydrogen is exothermic, and temperatures around 220 °C–280 °C and pressures (10–80 bar) are normal reactor conditions. The methanol-water mixture produced from this process can be

used to hydrogen yield directly through the reaction of steam reforming, without the need for the energy-intensive separation of developed methanol and water by distillation[48]. In this scenario, the overall process can be streamlined, resulting in a significant surplus of heat during the synthesis of methanol.

2.3. Utilization of hydrogen production in associated sectors

Hydrogen can be viewed as a feasible substitute fuel for engines originally intended to operate on different fuels due to its broad flammability range, which allows for precise regulation of engine power[49]. Chehade et al.[50] have stated that, although the reactivity of liquids is not a concern, the high density of liquid hydrogen makes it a more desirable option compared to lightweight hydrogen gas. However, due to its compressibility in smaller reservoirs, hydrogen gas offers greater storage capacity[50]. In terms of storage efficiency, high-pressure reservoirs are preferred for storing hydrogen gas over liquid nitrogen because gas molecules can be packed into a smaller space, whereas liquid nitrogen requires refrigeration units and takes up more space in its liquid state. Fuel combustion can only occur in the vaporized or gaseous states, and H_2 can reach its state of gaseous form at a relatively lower temperature. The flashpoint, which is the temperature at which a fuel can ignite in the occurrence of an ignition source, is typically lower than its boiling point[51] However, low temperatures can reduce vaporization, which may result in the fuel flame not lasting without an ignition source. Consequently, it is anticipated that engines utilizing hydrogen as fuel would necessitate less sophisticated ignition and starting equipment in comparison to engines operating on alternative fuel types[52]. Moreover, hydrogen-powered engines can operate effectively in severe conditions. For example, a hydrogen-fueled vehicle was reported to continue functioning even after being stored in lower temperatures for multiple days, without the need for ignition[53]. Furthermore, hydrogen has a unique flammability range, which presents several opportunities for its use in turbine or combustion engines. This is due to the significant disparity between its lower flammability level (LFL) and higher flammability level (HFL)[54].

3. Cu-based catalyst

Copper-based catalysts are widely used in the steam reforming of methanol. To improve their selectivity and prevent deactivation, various methods have been proposed in the literature. Some of these methods involve investigating the configuration, properties, and preparation of the catalyst, including the accumulation of promoters and supports, while others focus on optimizing preparation methods. Furthermore, numerous scientists have underscored the significance of examining the interfacial synergy between supported metal catalysts and the interactions among their constituents. This approach is crucial for acquiring a comprehensive comprehension of the reaction mechanisms and deactivation processes[55].

3.1. Composition and active components

It is widely recognized that $Cu/ZnO/Al_2O_3$ serves as the commercial catalyst for the SRM reaction and the associated water-gas-shift (WGS) process employed in industrial hydrogen production. The catalyst ($Cu/ZnO/Al_2O_3$) is widely recognized as the commercial catalyst used in the SRM reaction and the associated water-gas-shift (WGS) process, which are integral to industrial hydrogen production.

As per prior research papers, copper is typically recognized as the primary energetic ingredient of the metal compound, implying that the catalytic characteristics are sturdily influenced by the chemical properties and structure of copper. Though, it is important to note that higher copper loading does not necessarily result in better activity and selectivity. The performance of the catalyst greatly depends on the synergy with supports and the interaction between various components. ZnO, for instance, is known to enhance the surface catalytic properties of Cu by promoting its reducibility, which plays an essential role play in the process of reforming.

Moreover, the process can be influenced by the acid/base characteristics of ZnO and its capacity to

enhance copper dispersion while inhibiting sintering. Utilizing porous alumina as catalyst support offers the advantage of generating a large surface area, resulting in enhanced copper dispersion, increased loading capacity, and reduced particle size. Furthermore, recent studies have focused extensively on investigating various dopants and support to enhance the overall performance of Cu-based catalysts, leading to promising advancements[56–58].

Fu et al.[59] conducted a study showcasing the effective adsorption of both CO and water through Cu doping of the Fe_3O_4 (111) surface, which in turn facilitated the steam reforming process. Furthermore, recent advancements highlighted the remarkable enhancement in the specific surface area achieved by the 2D Cu-Fe-Al-O nanosheet structure, leading to the creation of additional active sites for metallic Cu[60]. This innovative structure not only contributed to the stability of the catalyst but also enhanced its catalytic activity, showcasing the potential of Cu-Fe composite materials[61].

3.2. Effects of promoters on catalytic activity and selectivity

Copper, as the energetic element, can be easily influenced by various promoters to enhance its catalytic performance. The desirable objectives in producing highly active catalysts are achieving well-dispersed and small copper particles, as well as maintaining stable physicochemical properties. In addition, these promoters can also lead to improved selectivity, which is an added benefit[55]. **Table 1** presents the impact of these promoters on the performance of SRM catalysts. The impact of zirconia as a structural promoter has been studied extensively over the years. Recent research has led to a better understanding of the synergistic effects of zirconia, revealing that it can improve both the stability of the catalyst and the dispersion of the active phase. As a result, this structural promoter has been shown to significantly enhance both the activity and selectivity of SRM[55].

Azenha et al.[62] conducted a study to examine how the SRM behavior is affected by the structure of the ZrO_2 support, specifically comparing the impacts of the monoclinic and cubic forms. The utilization of ZrO_2-monoclinic as a support in CuePd/ZrO_2-monoclinic catalyst resulted in significantly improved metal phase dispersion, leading to a remarkable increase of up to 13 times in activity and a doubling of selectivity compared to the CuePd/ZrO_2-cubic catalyst, as observed in the study. By incorporating zirconia into the conventional CuO/ZnO/Al_2O_3 catalyst, the researchers observed enhanced stability, which was attributed to the presence of surface oxygen sites on zirconia clusters and an improved ability to adsorb methanol. This finding indicates that the addition of zirconia has beneficial effects on the catalyst's performance[63]. The inclusion of zirconium was found to induce microstrain in CuO and ZnO, resulting in a decrease in their crystallite size and limiting their growth. Moreover, Zr-based catalysts exhibited a higher quantity of metallic copper during the reduction process, even at lower temperatures. These observations highlight the influence of zirconium on the structural and chemical properties of the catalyst[64].

Table 1. Promoters effect on various categories of catalyst (Cu-based) for SMR.

Catalyst	T (ºC)	GHSV, LHSV or WHSV (h^{-1})	X_{MeOH} (%)	Activity (mmol/g_{cat}/h)	S_{H2} (%)	S_{CO} (%)	Reference
$Cu_{33}Fe_{19}Al_{15}O_{33}$	240	1760 (g)	94.3	225	100	-	[60]
CuPd/ZrO_2-m	260	2400 (g)[a]	>80	40	87	5	[62]
Cu/ZnO/ZrO_2	250	21,600 (g)[a]	88.6	806.41[b]	75	NA	[64]
$CuMnO_x$	400	12,000 (g)[a]	75	414	-	5	[65]
$CuZn_3GaZr$	275	2200 (g)	75	836	-	0.3	[66]
CueGa/ZnO	320	3600 (g)	96	720	74	NA	[67]
CuO/ZnO/CeO_2/Al_2O_3	260	1000 (g)[a]	98	-	65	NA	[68]
CuO/ZnO/Al_2O_3/ZrO_2/CeO_2	220	10,000 (g)[a]	100	-	75	1	[69]
CueMgO/Al_2O_3	220	2923 (g)[a]	100	-	99.4	<0.15	[70]

Table 1. (*Continued*).

Catalyst	T (ºC)	GHSV, LHSV or WHSV (h^{-1})	X_{MeOH} (%)	Activity (mmol/g_{cat}/h)	S_{H2} (%)	S_{CO} (%)	Reference
$Cu/Ni/Zr/Ce_{0.1}$	330	172 (g)	60	1000	100	NA	[71]
Cu/SiO_2	400	2400 (g)[a]	97	-	72–77	<11	[72]
$CueNi/LaZnAlO_4$	300	20.8 (w)	90	-	>80	<2	[73]
CueFe/ATP	300	3.52 (w)	100	-	98.25	2.55	[74]

The unit for "a" is mL/gcat/h (milliliters per gram of catalyst per hour).
The unit for "b" is mol/molmetal/h (moles per mole of metal per hour).

3.3. Effects of Cu-based catalyst preparation methods

Apart from utilizing various promoters and combinations of active metals, the method of preparation has also been found to significantly impact catalytic performance, a wide range of preparation approaches have been informed via literature for different types of materials. While co-precipitation, sol-gel synthesis, hydrothermal synthesis, and impregnation are commonly used methods, some authors have also proposed novel approaches or modifications to conventional methods to improve the catalytic activity and selectivity of the synthesized materials[50]. Hosseini et al.[75] systematically investigated the effects of the preparation method on the surface area and performance of their materials. They studied ZrO_2/CeO_2 doped $CuO/ZnO/Al_2O_3$ without specifying it as a catalyst.

Investigations have been conducted by researchers to examine the influence of various preparation techniques on factors such as surface area, metal dispersion, and particle size of catalysts containing copper. One method that has received attention is the urea nitrate combustion (UNC) method, which is known for its fast and easy synthesis of nano-catalysts. Several studies have shown that this method can result in catalysts with improved metal dispersion, smaller particle size, and greater surface region, which can lead to enhanced catalytic performance[76]. Yang et al.[77] examined different preparation methods for CuO/CeO_2 catalysts, emphasizing the importance of ceria morphology in influencing catalytic performance. This underscores the importance of selecting appropriate synthesis methods to optimize active site size, dispersion, and morphology to achieve desired properties.

3.4. Catalyst performance by supports

It should also be noted that the quality of the support material plays a crucial role in ensuring the effectiveness and stability of catalysts. Properly designed supports, when combined with specific modification techniques, can lead to the development of catalysts with extremely high surface area and metal dispersion[78,79].

In the study conducted by Tajrishi et al.[78], SBA-15 mesoporous substantial was produced using a hydrothermal arrangement and utilized as a support for Cu-based catalysts. The research findings highlighted that SBA-15 is a highly suitable support material for promoting the dispersion of Cu due to its exceptional stability and maximum surface region. Opting for suitable support materials with a high surface area is vital to enhance the dispersion of active metals. Support materials like MCM-41, SBA-15, carbon nanotubes (CNTs), spinel, and silica possess surface areas nearly ten times larger than those of compound catalysts. A previous study reported that an MCM-41-supported Cu-based catalyst, with a surface area of 662 m^2/g, demonstrated excellent stability and resistance to deactivation[79].

Acetic acid modification of MCM-41 before metal impregnation is effective in reducing particle size, leading to a significant improvement in dispersion and reduction behavior, as demonstrated in previous research[80].

Optimizing the catalytic performance of SRM relies on the careful selection of suitable support material with a high surface-to-volume ratio. This characteristic plays a pivotal role in facilitating the improved

dispersion of active components on the surface of the support. The uniform mesopores, high BET surface area, and exceptional thermal stability of mesoporous molecular sieves like SBA-15 and MCM-41 have contributed to their widespread acceptance[80].

Moreover, the surface area and pore volume of 3D metal foam, felt, and porous ceramics can be modified to suit various catalyst loadings. However, it is imperative to conduct additional investigations into the size and pores distribution, considering the dimensions of reactant molecules and their transport characteristics. An illustration of this is seen in the case of SBA-15, which possesses mesopores with sizes ranging from 3 to 30 nm, making it well-suited for the reforming of larger molecules such as tars. In contrast, traditional microporous catalysts are not suitable for this application[78]. Additionally, the thermal conductivity and permeability of catalysts can be influenced by gradient and cascading structures, ultimately affecting their performance. Therefore, it is important to consider the current application scenarios and not generalize that porosity and higher specific surface zone always lead to improved catalyst performance.

3.5. Catalyst deactivation

Despite exhibiting high catalytic activity, Cu-based catalysts are prone to deactivation due to various factors such as changes in oxidation state, sintering of the catalyst, or deposition of coke[57], as depicted in **Figure 3**. Furthermore, the presence of foreign species such as chloride and sulfur in the feed mixture can lead to the poisoning of the catalyst[81]. The research conducted by Fasanya et al.[82] demonstrated that the selectivity of side reactions was significantly influenced by the ratio of methanol to water. When the feed mixture lacked sufficient water, there was a higher selectivity towards CO and CH_4, and coke formation occurred at temperatures exceeding 300 °C.

Tonelli et al.[83] perceived that the deactivation of Cu-based catalysts can result from two concurrent processes. Firstly, the deposition of carbonate species, which is a reversible phenomenon. Secondly, the sintering of the active phase, which is an irreversible process that is more likely to occur at higher temperatures. The catalytic system, however, can undergo a simple regeneration process using either a 400 °C air flow or an inert flow at the reaction temperature. This regeneration procedure leads to nearly identical initial conversion rates, indicating the effective restoration of catalytic activity.

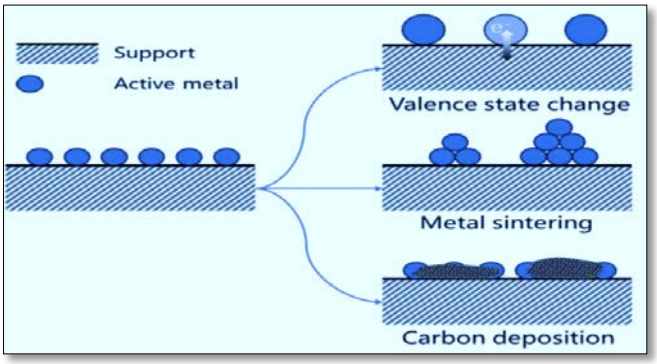

Figure 3. Various kinds of catalysts deactivation[55].

3.6. Reaction mechanism

Extensive research has been conducted on the reaction mechanism of SRM over Cu-based catalysts over a prolonged period. Initially, it was believed that the MD and WGS reactions were responsible for the reaction process[81,84].

$$CH_3OH \leftrightarrow CO + 2H_2 \quad (9)$$

$$CO + H_2O \leftrightarrow 2H_2 + CO_2 \quad (10)$$

Contrary to the initial assumption that the steam reforming of methanol (SRM) reaction is solely driven by the reaction of water gas shift and methanol decomposition, it has been discovered that the resulting product should have a higher concentration of CO, which is not observed as the produced hydrogen is nearly pure. Subsequent investigations have indicated that the steam reforming of methanol (SRM) reaction exhibits a low yield of carbon monoxide (CO) at lower temperatures, which is influenced by factors such as the steam-to-carbon ratio and catalyst properties. Further research suggests the involvement of alternative reaction pathways, including the participation of methoxy species, methyl formate, dioxymethylene, and formate intermediates[85].

Takezawa et al.[86] proposed a potential pathway for the SRM reaction mechanism involving a stepwise dehydrogenation process leading to the establishment of formaldehyde and formic acid.

$$CH_3OH \rightarrow HCHO + H_2 \quad (11)$$

$$HCHO + H_2O \rightarrow HCOOH + H_2 \quad (12)$$

$$HCOOH \rightarrow H_2 + CO_2 \quad (13)$$

The reaction rate may be restricted by the dehydrogenation step of methanol to form formaldehyde[85]. Nevertheless, there is some inconsistency in the explanations for how CO is formed. While Shishido et al.[87] supported a pathway where CO_2 is produced directly and provided evidence for a stepwise dehydrogenation pathway of methanol to form formaldehyde and formic acid, ultimately resulting in the production of H_2 and CO_2. However, there are differing opinions on the origin of CO. Some scientists argue that adsorbed formaldehyde is directly decomposed to generate H_2 and CO, which then participates in the water-gas shift reaction[85].

$$HCHO \rightarrow CO + H_2 \quad (14)$$

It is worth noting that while decomposition occurs at a slower rate compared to reforming, it still needs to be considered in most kinetic models. The endothermic nature of the decomposition reaction has a more significant impact in the presence of water, especially at higher temperatures as predicted by thermodynamics. Another proposed mechanism involves a complex process that includes a methyl formate intermediate[81].

$$2CH_3OH \rightarrow HCOOCH_3 + 2H_2 \quad (15)$$

$$HCOOCH_3 + H_2O \rightarrow CH_3OH + HCOOH \quad (16)$$

The Langmuir-Hinshelwood mechanism proposes that the initial step in methanol conversion involves the breaking of the O–H bond, leading to the formation of surface methoxy species. Subsequently, the methoxy species undergo dehydrogenation to generate formaldehyde[85].

In their work, Frank et al.[88] presented a comprehensive catalytic cycle that encompasses two types of active sites, one responsible for hydrogen adsorption and the other for the adsorption of all other intermediates. Hammoud et al.[89] illustrated a potential pathway, shown in **Figure 4**, for the production of methyl formate. In this process, formaldehyde, produced through dehydrogenation, reacts with a methoxy group. This interaction gives rise to an intermediate, which subsequently decomposes with the involvement of hydroxyl groups, resulting in the formation of methoxy and formate groups. Another pathway involves the dimerization of methoxy groups, leading to the synthesis of methyl formate.

Despite numerous studies, a clear consensus on the kinetics and reaction mechanism of SRM has yet to be reached. However, significant progress has been made in utilizing these studies to develop specialized catalyst formulations. In recent years, the pathway through a methyl formate intermediate has gained widespread acceptance as the most feasible mechanism for SRM.

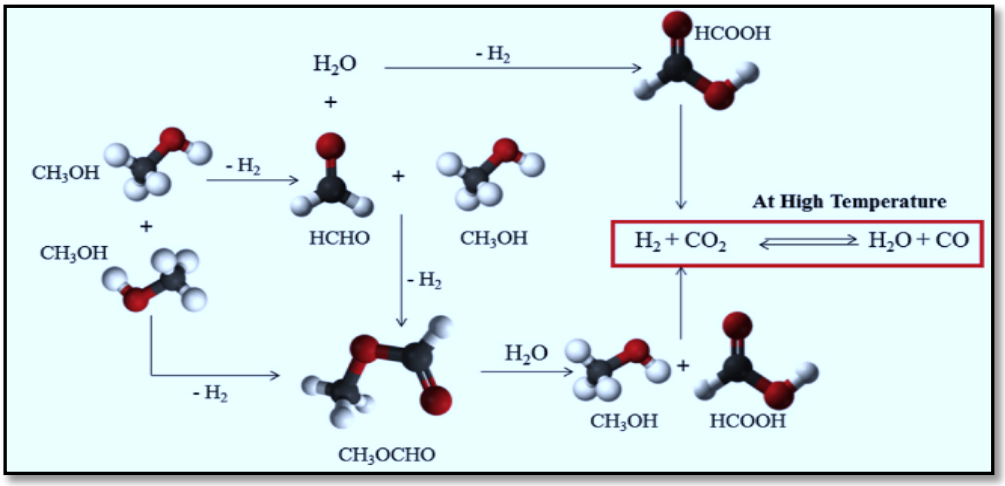

Figure 4. Reaction pathways of steam reforming of methanol[55,89].

4. Future research

The primary hurdle encountered in the SRM process is the deactivation of the catalyst caused by coking or metal sintering. To address this concern, it is crucial to develop and fabricate a catalyst that exhibits, reduced coke formation, enhanced catalytic activity, smaller particle size prolonged stability even distribution of metal particles. These catalyst properties are essential for achieving optimal hydrogen yield at lower temperatures. This requires advanced research focused on developing such catalysts using various promoters and supports. Additionally, reducing the reforming temperature and producing pure hydrogen can make the process more cost-efficient. Advanced materials like CNT (Carbon nanotubes) and SAA (single-atom alloys) can be explored to achieve these objectives, along with amalgamating various reforming reactions to enhance economic viability, for example, by utilizing heat produced through an exothermic reaction for SRM. To achieve high yields of hydrogen, it is of utmost importance to gain a deep understanding of the fundamental role played by copper in both mono and multimetallic systems, as well as the characteristics of the supporting material. The interactions between the metal and the support, specifically the transfer of oxygen from reducible oxides to the metal sites, need to be thoroughly investigated to assess their impact on catalyst performance, selectivity, and stability. Moreover, advanced characterization techniques should be employed to gain insights into the effects of alloying on selectivity in multimetallic catalysts utilizing mixed metal oxides.

5. Conclusion

The diminishing availability of fossil fuels and the growing environmental apprehensions underscore the urgent demand for clean and sustainable alternative energy sources. Hydrogen, being the most ample component on earth, holds great promise as an energy solution due to its superior energy density compared to fossil fuels on a mass basis. However, addressing the cost of production and transportation, improving energy conversion efficiency, ensuring safety, and managing the transition period for energy infrastructure requires in-depth research to develop and examine a comprehensive hydrogen supply-demand network that simultaneously meets economic, efficient, and feasible standards.

The present study undertook a comprehensive review of the literature on various approaches for steam methanol reforming (SRM) in hydrogen production. Based on the analysis conducted, the following conclusions can be drawn from this research investigation.

- Hydrogen production has traditionally depended on conventional sources such as coal, natural gas, and naphtha using steam reforming processes. However, the sustainability of these sources presents a challenge in the present era.
- In upcoming years, hydrogen is projected to have a substantial impact on carbon-neutral and carbon-negative economies. This has spurred extensive research into developing new and environmentally friendly technologies for H_2 production.
- Steam reforming methanol (SRM) has emerged as a highly promising technology that has gained significant attention. This review offers an in-depth analysis of different catalysts, their supports and promoters, the interactions among them, and the effects of various operating conditions on the performance of SRM.
- The analysis of SRM catalysis utilizing different Cu-based catalysts, as well as alternative catalysts, revealed their susceptibility to deactivation caused by coking and sintering.
- Among the Cu catalysts, catalysts (Cu/ZnO) have received significant attention, with the formation of Cu-Zn alloy considered critical for high activity. To enrich the catalytic activity and stability, different kinds of promoters such as ZrO_2, Al_2O_3 and CeO_2 have been utilized.
- The existing literature addresses different types of methanol-reforming reactions, focusing on their application in specific mobile devices powered by internal combustion engines (ICEs) with in-cylinder thermochemical fuel reforming (TFR) processes, solid oxide fuel cells (SOFCs), and polymer electrolyte membrane fuel cells (PEMFCs). The discussions consider the varied temperature requirements and inlet gas compositions associated with each technology.
- The analysis utilized the Gibbs free energy minimization method and investigated a wide temperature range of 400 to 900 K, with a steam-to-fuel ratio of 1 and a pressure of 1 bar. The study focused on determining the maximum fuel conversion levels achieved. Notably, specific temperatures were found to yield the highest fuel conversion: 600 K for methanol, 730 K for ethanol, 860 K for n-butanol, and 890 K for glycerol.
- Future investigations should prioritize achieving a consistent system output and instantaneous hydrogen yield to enhance hydrogen production and utilization.
- It is worth noting that methanol benefits in the reforming process, production, and storage making it a crucial component of the entire hydrogen network.

Abstract: High-rise structures have always fascinated people since the dawn of civilization, and they are unique in many ways, including the consideration of lateral deflections caused by lateral loads. In this paper, an attempt is made to present the results of CFD analysis on 1:100 length scale models of rectangular-shaped buildings with different side ratios, having the same height and same plan area. The study was carried out using the ANSYS CFX package for CFD simulation. Pressure coefficients on each face for different angles of attack are computed. Wind pressure variations on different faces of buildings are presented using contour plots. For the purpose of validation, the result of a regular square-plan shaped building is compared with previously experimental data for similar wind flow conditions. It has been concluded that with a change in side ratio, there is an almost negligible effect on pressure distribution and pressure coefficient on windward walls. However, there is a considerable change in the pressure coefficient on leeward as well as sideward walls. The study also revealed how a change in the angle of attack changes the magnitude of pressure coefficients.

Keywords: Tall building; pressure coefficients; numerical simulation; side ratio; vertical center line.

INTRODUCTION

With the advancement of technology and enormous growth in the population, the need for and design of tall structures with different configurations has been a growing trend. High-rise structures have always fascinated people since the dawn of civilization, and they are unique in many ways, including the consideration of lateral deflections. Wind is a complicated phenomenon in which the motion of an individual particle is so unpredictable that one needs to be concerned about the statistical distribution of velocity rather than just simple averages. The total wind force is equal to the sum of windward pressure and leeward suction, although each has its own local effect. The designers consult appropriate wind load standards such as (AS/NZS 1170.2:2011), (ASCE 7-10), (BS 6399-2:1997), (EN 1991-1-4), (IS-875 Part 3) to estimate the design pressure coefficients and force coefficients for such buildings subjected to wind induced loads. CFD has expanded as a tool to replace wind tunnel testing as it is quicker, less expansive and gives more information and control to designers. CFD for determining wind responses is becoming immensely popular as the analysis saves time in the design process and is hence cheaper and less time-consuming compared to conventional testing. Since the 1960s, several researchers have derived a wealth of useful information by assuming that wind pressure behaves in a static manner. Urbanization in the twentieth and twenty-first centuries stimulated the development of tall buildings, which became taller and taller as demand increased. (Amin & Ahuja, 2013) summarized the outcomes of wind tunnel tests on 1:300 scaled down models of rectangular buildings having the same height and plan area but different side ratios. They concluded that the side ratio of models has a significant impact on the amplitude and distribution of wind pressure on leeward and sidewalls, but only a little impact on windward walls at a 0-degree wind incidence angle. (Revuz et al., 2012) investigated the size of the domain size for conducting CFD in the field of wind engineering. This paper discussed what size of domain to use while using CFD tools for simulation of tall buildings. (Kastner & Dogan, 2019) estimated the time-saving

methodology that is possible along with specific mesh properties to take the lead in the proposed method. In this research study, they proposed a cylindrical meshing for wind simulations. They tried to compare the box-shaped simulation domain with the cylindrical computational domain, and showed that it is recommended to use the box-shaped simulation approach if no annual wind analysis is intended. Franke et al. (2004) reviewed the outcomes from published simulations and attempted to make a recommendation on how to use CFD for wind engineering tasks, focusing on the statistically steady simulation of wind. The results for mean velocities and turbulence in the constructed environment were summarized from statistically steady RANS simulations accessible in the literature, and advice on how to use CWE properly for that purpose was given. Huang and Chen (2007) attempted to evaluate the wind load response and equivalent static wind loads (ESWLs) of high-rise buildings based upon measured synchronic surface pressures in a wind tunnel procedure. They proposed a practical procedure for modelling ESWLs on tall buildings, linking the effect of higher mode contributions. Li et al. (2007) used wind tunnel tests and full-scale field measurements to explore the effect of wind on the Jin Mao Building under strong winds. Mallick et al. (2018) studied the simulation of the wind pressure coefficient on C-shaped building models by means of numerical analysis using ANSYS Fluent and concluded that the pressure on the building was remarkably influenced by the structure geometry, orientation, aspect ratios, and wind angle of attack. Fouad et al. (2018) compared pressure coefficients from ASCE code, Euro code and CFD simulation results for low-rise buildings and concluded that the CFD simulation findings are substantially identical to the experimentally determined values for the walls and leeward side of the roof; however, there is a difference in the results for the windward side of the roof. Kwon & Kareem (2013) investigate the similarities and differences in the wind response of tall buildings based upon major international wind standards such as ASCE, AS/NZ, AIJ, CNS, NBCC, EU, ISO, and IWC and a database-enabled design procedure, Nat-Haz Aerodynamic Loads Database (NALD). (Nagar et al., 2020) investigated H-shaped and square-shaped buildings under isolated as well as interference conditions due to surrounding buildings. They examined the mean pressure coefficient using wind tunnel experiments for various angles of attack of the wind. (Pal et al., 2021) discussed twin square and fish-plan form building models with equal volume for wind-induced mutual interference effects and investigated the maximum efficiency in terms of wind pressure and base shear for both the shapes and concluded for the most efficient condition. Bhattacharyya & Dalui (2018) presented a detailed study on an E-plan-shaped building that is asymmetrical about both the plan axes under wind excitation. The angle of incidence of the wind varied from 0° to 330° at an interval of 30°. Assainar & Dalui (2020) discussed the effectiveness of aerodynamic alterations performed on a pentagonal-plan shaped model using computational fluid dynamics (CFD) simulation. The study focused on evaluating the effectiveness of different corner modifications applied to a pentagon-shaped tall building. Sanyal & Dalui (2020a) investigated the effect of major shape modifications on a Y-plan-shaped building was studied statistically by computational fluid dynamics. Sanyal & Dalui (2020b) studied the wind pressure distribution on a Y-shaped tall building owing to changes in the building side ratio where the length-to-width ratio was altered while the total plan area remained the same for all models. Tominaga et al. (2008) evaluated computational fluid dynamics (CFD) findings for flow around a high-rise building model with a 1:1:2 shape placed within the surface boundary layer using several revised k-models and large eddy simulation (LES).

NUMERICAL ANALYSIS

In this study, rectangular-plan shaped buildings with different side ratios are analyzed by using the ANSYS CFX package for CFD simulation.

Governing Equation

The model's mean flow characteristics are simulated using a κ-ε turbulence model. This model uses two equations by means of two transport equations. For the turbulence model used, instantaneous velocity can be written as the summation of time-averaged mean velocity and a time-varying fluctuating component given in equation (1).

$$u_i = U_i + u_i' \tag{1}$$

where, u_i = instantaneous velocity

U_i = time averaged mean velocity

u_i' = fluctuating component of velocity

As per Reynold's Average Navier Stokes Equation (RANS) equation (2)

$$\frac{\partial}{\partial x_i}(\rho U_i) = 0 \tag{2}$$

where, ρ = density of fluid

and conservation of momentum equation (3)

$$\frac{\partial}{\partial x_j}(\rho U_i U_j) = -\frac{\partial P}{\partial x_i} + \frac{\partial}{\partial x_f}\left[\mu\left(\frac{\partial U_i}{\partial x_j} + \frac{\partial U_f}{\partial x_i}\right)\right] + \frac{\partial}{\partial x_j}\left(-\rho\overline{u_i' u_j'}\right) \tag{3}$$

Building Models

Rectangular building model with different side ratio are considered in this study whose plan shape and elevation are as shown in fig.1 and fig.2 respectively. All the models analyzed are of same plan area 900 m2 and height 90 m modelled on a scale of 1:100 tabulated as in Table 1.

Table 1 Model Dimensions

Modal shape	Prototype Dimension(m)	ANSYS Model Dimension(mm)	Height of Model (mm)	Scale of Model
Square	30*30	300*300	900	1:100
Rectangle-1	36*25	360*250		
Rectangle-2	45*20	450*200		
Rectangle-3	60*15	600*150		

The models are rotated from 0° to 90° at 30° interval. Therefore, attacking wind angles are 0°, 30°, 60°, 90°. This study also validates with wind pressure of an isolated square plan shape, tall building using CFD simulation and compared it with wind effects of conventional plan shape building given in Indian code IS: 875 (Part- 3), 2015.

Domain and Meshing

In the case of high-rise buildings, domain size is mainly governed by the height of the building, such that a large number of cell counts could be formed and many of them used up in the region far away from the wake region. The domain size selected in modelling is defined as per Zidan et al. (2004). The inlet and outlet distances of the domain from the building position are taken as 4H and 15H, respectively. The side aspect and top clearance are also taken as 5H and 8H, where H is the height of the building. The domain configurations are depicted in Fig 3.

10 August 2023 06:50:22

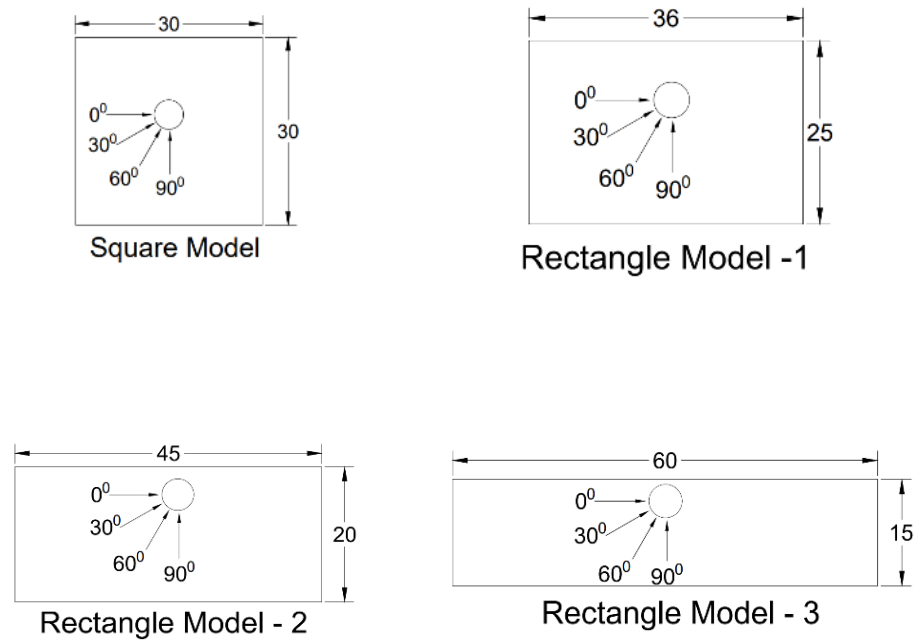

Fig 1. Plan Dimension of Models

.

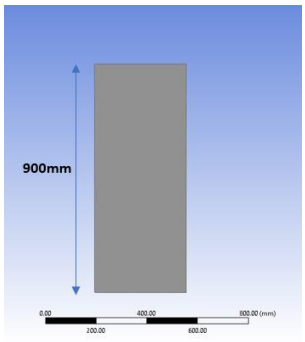

Fig 2. Elevation of Model

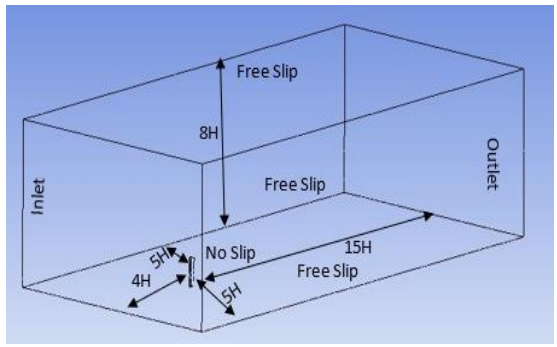

Fig 3. Modelling of Tunnel

The meshing of buildings is in fig. 4, and domain meshing is in fig. 5. Domain meshing is done by tetrahedral mesh elements. Meshing near the buildings is made comparatively finer to enhance the accuracy of the results. The inlet velocity is taken as 10 m/s.

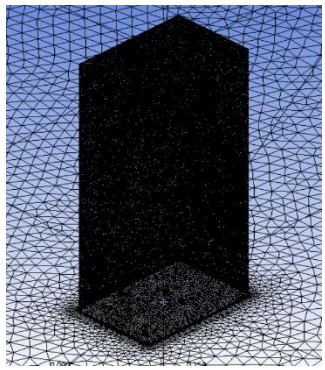

Fig 4. Building Meshing

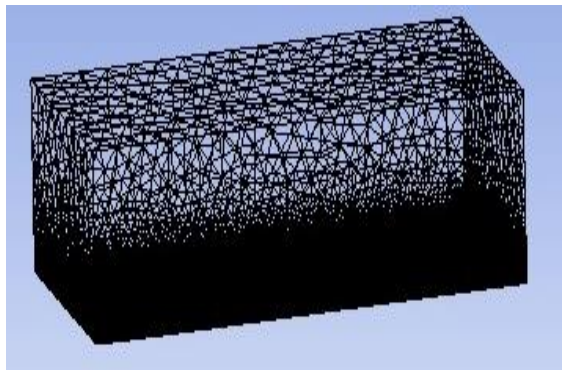

Fig 5. Domain Meshing

Velocity Profile and Turbulent Intensity Profile

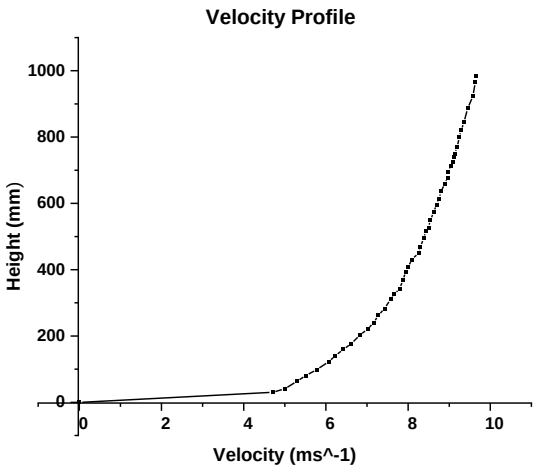

Fig 6. Variation of velocity with height

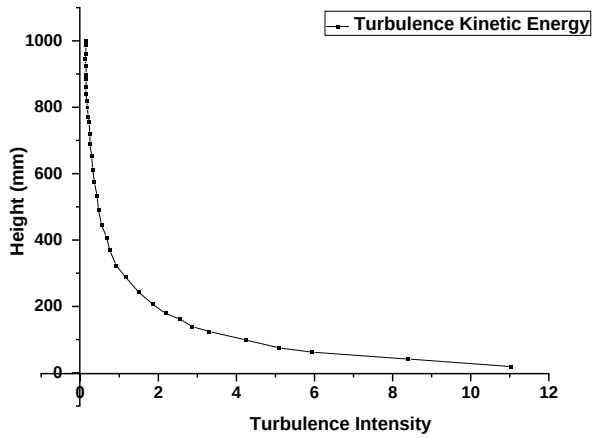

Fig 7. Variation of turbulence intensity with height

The wind profile boundary layer is governed by the power law equation. As per Power's Law, the wind speed profile within the atmospheric boundary layer is given by:

$$\frac{V}{Vo} = \left[\left(\frac{Z}{Zo}\right) \wedge \left(\frac{1}{alpha}\right)\right] \quad (4)$$

Where, V = velocity of wind at height Z

Vo = gradient velocity of wind at reference height Zo

Z = height above ground

Zo = Nominal height of Boundary layer (also called gradient height)

alpha = power law coefficient.

10 August 2023 06:50:22

Validation

The validity of the ANSYS CFX software is validated before beginning the numerical study of the building. For this purpose, a square-plan shaped building with dimensions of 100 mm 100 mm and a height of 500 mm (i.e., aspect ratio of 1:5) is investigated using the k-epsilon model with ANSYS CFX in the domain under uniform wind flow. The ANSYS CFX programme determines the face average values of coefficient of pressure, which are then compared to wind action codes from various regions. The velocity profile in fig. 6 and the turbulent kinetic energy curves so obtained are as shown in fig. 7.

Results and Discussion

Result which are investigated after investigating the wind generated effects are investigated for the building and results are explain in the following section.

Pressure Distribution

As below, pressure distribution for various faces of a building model is represented using contour plots as below:

• The pressure contours for different faces at various angles of incidence depict the pressure distribution on faces and are shown in figures.

• For Model 1, contour plots for various faces showing pressure distribution with different angles of wind incidence have been shown as in fig. 8 to fig. 11.

• Initially, at 0 degree of incidence, Face A shows a positive pressure being the windward face whereas face B, C, and D depicts a negative pressure distribution being the leeward and side wall face of the building.

• As the angle of wind incidence changes, the pressure distribution changed showing negative pressure at face A and face C showing positive pressure at 90-degree wind incidence.

• For Model 2, contour plots for different faces showing pressure distribution with different angles of wind incidence have been shown as in figs. 12 to 15.

Mean Pressure Coefficient:

The mean pressure coefficient '$C_{p\ mean}$' is calculated from the equation (1)

$$C_{p\ mean} = \frac{(p - p_o)}{\frac{1}{2}\rho U_H^2} \quad (5)$$

where p is the pressure at point on surface,

p_o is the reference height static pressure,

ρ is the air density

U_H is mean wind velocity at the building reference height.

The external pressure coefficient is calculated by using the expression,

$$C_{pe} = \frac{p}{0.6 \times V_z^2} \quad (6)$$

The mean pressure coefficient for different faces is evaluated and compared with the standards as shown in fig 24.

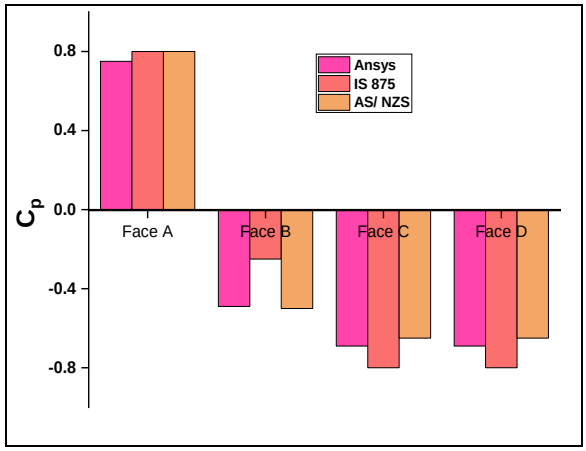

Fig 24. Comparison of mean pressure coefficients on a different face of all model for 0-degree between numerical result and International Standards

Vertical Centreline Pressure Coefficients

The curve in these figures depicts the variation in the pressure coefficient Cp value for various faces as a function of height. Therefore, the face average value of Cp for several models at various angles of incidence is evaluated. The vertical centreline Cp variation with height for Model 1, Model 2, Model 3, and Model 4 is plotted as shown in figs. 25, 26, 27, and 28.

CONCLUSION

The pressure contour and mean pressure coefficients for the rectangular-shape building models for different side ratios at 0^0 ,30^0 ,60^0 and 90^0 wind incidence angles are compared in this paper. The k-ε model is used to simulate the results. The major outcome of this research is as below:

- The effect of side ratios and wind directions on wind pressure distribution and the magnitude of pressure coefficients on rectangular building models is identified by a numerical study measurement of wind pressures on building models.
- The variation of pressure coefficients on the centreline is discussed and plotted graphically.
- The model side ratio has a significant impact on the amplitude and distribution of wind pressure on leeward and sidewalls, but only a little impact on windward walls when the wind incidence angle is zero.
- At 0 degrees of incidence, face A portrays a positive pressure distribution as the building's windward face, whereas faces B, C, and D depict a negative pressure.
- As the angle of incidence changes, the pressure distribution changes, and so does the pressure coefficient. For 30° and 60° angles of incidence, positive pressure distribution at face A becomes slightly less than in the case of 0°, along with suction pressure increase at face D, and a comparable change can be viewed from the pressure coefficient data so obtained as a result of the distribution as the building's leeward and sidewall faces.
- At 90° angle of incidence, face C becomes windward and a similar contour plot pattern as that of face A when the angle of attack was 0° can be seen.
- The present study shows that changes in side ratio have considerably affected the general magnitude of peak pressures and peak suctions in models with constant cross section.

***Abstract*— Artificial intelligence (AI) and its nature have evolved over the period of time. With its rapid growth and application, it has shown many remarkable changes, especially in the identification and diagnosis of various diseases including lung disorders. One such disease is Chronic obstructive pulmonary disease (COPD). COPD is a chronic lung condition that makes breathing difficult. It is characterized by a prolonged airflow blockage that interferes with normal breathing. The high amount of data including various test reports and images sample that can be obtained on the clinical level and seeing the nature of COPD makes this disease an ideal subject that can be uncovered using the help of many AI and ML tools. This review focuses on the application of ML models and AI tools that have played a vital role in suggesting the nature of COPD including the areas where the tools have limitations and the further opportunities where the tools can be improved.**

Keywords—Artificial Intelligence; Machine learning; Deep Learning; Chronic obstructive pulmonary disease; Emphysema; Respiratory disease

I. INTRODUCTION

Chronic obstructive pulmonary disease (COPD) is a steady developing, incurable lung condition marked by a persistent airflow restriction that leads to more widespread illnesses such as respiratory failure and pulmonary heart disease. Prolonged obstruction of the lungs' airways is what leads to COPD. This obstruction has a significant negative impact on the heart's ability to pump blood and on gas exchange, both of which have systemic repercussions. Emphysema, where the pulmonary air sacs get injured, or chronic bronchitis, which causes ongoing airway inflammation, are the two main causes of this illness. In addition to heart failure, bronchiectasis, cardiovascular illnesses, sleep apnea, asthma, frailty, and malnutrition are some serious symptoms in COPD patients, also these patients frequently suffer from other pulmonary and systemic comorbidities [1].

Despite significant efforts, there are still many obstacles in the diagnosis, management, and treatment of this disorder these include the absence of consistent classification criteria for different phenotypes, an unclear understanding of its pathogenesis, and the substantial costs associated with exacerbations. Additionally, COPD carries a high mortality risk. Overcoming these challenges is crucial to improve outcomes for individuals with COPD, necessitating the development of standardized criteria, enhanced understanding of disease mechanisms, cost-effective strategies to manage exacerbations, and interventions to reduce mortality rates.

The way we interpret and analyze complex systems using clinical, imaging, and molecular data has been transformed by artificial intelligence (AI). This led to the growth of various AI applications in different fields, including healthcare. Despite the fact that applied AI is still an emerging concept in numerous disciplines, this has demonstrated intriguing and significant outcomes when used to diagnose various ailments using primary sources of data such as diagnostic images [2].

AI includes machine learning (ML), which uses statistical techniques for self-learning without explicit programming. Machine learning is frequently compared to a "black box," where input goes into one side and a solution is displayed on the other. It is particularly true for neural networks, where data might go through intricate algorithmic transformations involving many layers, and the model may be highly complicated and uncertain to work with.

Recently, a number of AI/ML techniques have been used for COPD, but only a small number have made a substantial impact on clinical practice. In order to use AI/ML tools safely and effectively, it is necessary to summarize current knowledge and suggest future paths in the field of computational biology.

II. ADVANCEMENT OF MEDICINE USING AI

Machine learning can be helpful since it enables important associations to be drawn from data between different pieces of information instead of needing a specific human definition. The ability of a technique based on ML to consider a larger variety of data may result in a more accurate diagnosis. Furthermore, defining the correlations within the dataset will enable a better understanding of the condition. ML is additionally will play a key part in enabling medical professionals to provide better management of diseases in patients, from a scientific or medical perspective [3]. There are many advantages of applying AI, one of them being it makes it easy to observe data such as medical images and tests obtained from underserved areas or remote areas. This helps in the early identification of diseases and to send the

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 02,2023 at 06:45:44 UTC from IEEE Xplore. Restrictions apply.

patient to expert care on time, if necessary, which could redirect the course of the disease's outcome.

Using AI, in 2018 a medical device by US Food and Drug Administration (FDA) was accepted to identify the levels of diabetic retinopathy in patients having diabetes. The device gives a screening conclusion observation that does not require a specialist to evaluate the outcome, making it useful for healthcare professionals that might not typically be taking part in eye care and allowing patients to receive an initial diagnosis and severity determination without having to wait to be referred to specialists.

TABLE I. LIMITATIONS AND ISSUES IN EXISTING MODELS

CRITERIA	DESCRIPTION
Inadequate capability of current procedures	The article states that the current procedures for categorizing COPD patients into phenotypes are insufficient and require additional information
Limited dataset representation	Some studies mentioned in the article had limitations in terms of the percentage of female participants, which could affect the generalizability of the results.
Dependency on specific tests	Some AI/ML models relied on lung function tests to assess hindrance in airflow, but not all patients were able to complete these tests, leading to missing data.
Dataset size and diversity:	The datasets used in some studies were relatively small or limited to specific ranges of COPD severity, which could affect the accuracy and generalizability of the models.
Training time and computational resources:	Certain approaches mentioned in the article required significant training time and computational resources, making them less practical for widespread use.
Scope and additional features:	The applicability of some models was limited to specific contexts, such as hospitalized patients or acute exacerbations of COPD. The article suggests that including additional features in the dataset could enhance the models' scope and performance.

A supporting tool for a clinical conclusion that examines the brain's computed tomography (CT) images for signs of a stroke and alerts a neurovascular expert if a potential large blockage in the vessel is found was approved by the FDA in 2018. Instead of requiring a neurovascular specialist to be notified once a radiologist examines the CT images, the algorithm automatically alerts the specialist while the first-line healthcare professional is performing a regular assessment of the images. Patients thus, receive the best care sooner for an illness where a positive result is highly time-sensitive.

Even so, the healthcare systems have advanced their delivery mechanisms to make sure the secure distribution of drugs to individuals, [4] The various application of ML will necessitate a similar polished network of governing oversight, local norms, and valid framework to assure the safe usage, monitoring and development of AI systems [4]. Additionally, scalable computer infrastructure will be needed to handle the massive volumes of data generated by the use of these models. In order to advance the field and reduce the unfavorable effects of utilizing AI in health care, clinicians, AI researchers, and also developers of AI devices and applications will be required to work together [5]. With the help of these AI technologies, decision-making and operational procedures can be enhanced. Physicians must take a proactive role in modifying clinical practices by using computational tools and contributing to the advancement of clinical AI [5].

AI tools have significant potential in addressing challenges in COPD. They can aid in developing consistent classification criteria by analyzing large datasets, identifying patterns, and enabling accurate and personalized diagnosis and treatment. AI can enhance understanding of COPD pathogenesis by analyzing complex biological data, leading to the identification of therapeutic targets and more effective interventions. AI-powered predictive models help identify individuals at high risk of exacerbations, enabling proactive management and cost reduction. By revolutionizing diagnosis, management, and treatment, AI tools offer personalized approaches, optimized resource allocation, and enhanced decision-making to improve COPD outcomes and reduce mortality rates.

III. ARTIFICIAL INTELLIGENCE BASED APPLICATION OF COPD

A. COPD detection and diagnosis

1) PULMONARY FUNCTION TESTS

Pulmonary function test (PFTs) is thought to be a crucial technique for assessing the respiratory system and for diagnosing disorders such as chronic obstructive pulmonary disease.

In one study, 50 people with varied pulmonary conditions were examined by 120 pulmonologists to determine PFTs patterns. Their analysis was contrasted with a decision tree-based machine learning method which uses general affected individual characteristics and functional parameters as input and the data was trained with 1,430 subjects [6]. The accuracy of pulmonary pattern interpretation among specialists were 74.4%, and the challenge of such a prominent task was reflected in the kappa interrater variability which is 0.67. In terms of diagnosing the appropriate PFT pattern, the automated technique showed 100% and 82% accuracy. These remarkable findings point to the potential of AI as a tool that supports decision making in clinical planning and proceedings.

It has been established that machine learning is extremely efficient in detecting patterns in feature spaces where a high number of dimensions or variables exist, and hence it can help with quicker and more precise diagnostic interpretation of PFT. Topalovic et al. [6] created a ML system that has a general accuracy of 68% for detecting the four most prevalent obstructive diseases: asthma, COPD, neuromuscular disease (NMD), and interstitial lung disease (ILD). The same study was used to demonstrate that when using the usual manual method of interpretation, only 38% of the candidates received the correct diagnosis.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 02,2023 at 06:45:44 UTC from IEEE Xplore. Restrictions apply.

To sum up, automating PFT interpretation with ML has largely solved numerous previous constraints of expert systems. Although it appears promising, more validation is necessary before PFT interpretation software can be used in a clinical context.

2) COMPUTED TOMOGRAPHY

In a set of data, AI systems look for patterns that can be utilized to estimate a clinical result or identify obstructive phenotypes. Automatic pulmonary function test interpretation and differential diagnosis of obstructive lung disorders are both successfully accomplished using ML. CT plays an important role in many areas. It is a modern tool for the diagnosis and evaluation of airway conditions as well as the detection and characterization of emphysema using images.

Convolutional neural networks (CNN) have been among the most effective deep learning architectures in the area of computer vision. A CNN model is made from one input layer, one output layer, and a set of many hidden layers. Every subsequent hidden layer's job is to perform a more detailed computation of the input data to get a better representation with increasing complexity, which is relevant to the categorization's objective [3]. CNN has been employed in the field of obstructive lung disorders to categorize textured patterns in CT images into several categories of emphysema tissue [7]. In an intriguing study, Tajbakhsh et al. [8] used a well-trained CNN model with exact tuning (transfer learning) to diagnose pulmonary embolism.

Positive outcomes have been obtained using CNN to diagnose obstructive patterns in CT scans. But creating a CNN from the start has its own challenges. It needs extensive computational resources, and huge training datasets—which are usually difficult to come by in the medical field—and is frequently affected by overfitting and convergence problems. A promising alternative is the use of a well-trained CNN network model on non-medical datasets of images in combination with the exact tuning of domain-related datasets [9].

B. Artificial intelligence based categorization of COPD

Depending upon indicatory symptoms, increasing exacerbation, and most importantly, the hospitalization history of COPD patients, they are categorized into four phenotypes justified by Global Obstructive Lung Disease Initiative. However, the unjust capability of this procedure is inadequate, which makes an AI/ML-type alliance of extra information which are the results of lung function tests, genome, physiological features, biomarkers, and comorbidities, for accurate categorization of phenotypes, severity evaluation, and therapeutic counseling more useful. In a study, an ML clustering model, named the k-means clustering has already been applied which helps in grouping and categorization of COPD patients into four phenotypes as different clusters. The method was performed on a dataset of 195 patients with medical history, physiological features, postbronchodilator FEV1, and COPD assessment test scores. FEV1 stands for how much air a person can forcefully expel from their lungs in just one second. The spirometer records the volume of air expelled during the first second of exhalation, which represents the FEV1 value. These values help doctors to understand the illness's severity and the development of the condition over time. When referring to the four clusters which are: Cluster (CL) 1, CL 2, CL3, and CL4 are termed as putative asthma overlap, mild, moderate, and severe COPD respectively, all of these clusters help to make different observations, such as Cluster 1 had the higher rate of severe exacerbation, whereas patients from Cluster 4 has forced expiratory volume in one second (FEV1) score of 46.7% of post-bronchodilator, high (17.5) COPD assessment test scores. [10]. However, the output needs to hold up for a longer period (>6 months). Another study performed on COPD patients from different Asian countries compared the data of change in FEV1, modified scale score of Medical Research Council dyspnoea, and St George's Respiratory Questionnaire (SGRQ) score for one year. The study reveals three phenotypes of COPD using hierarchical cluster analysis and factor analysis. Cluster 2 shows a high risk of FEV1 and acute exacerbation, whereas Cluster 1 and Cluster 3 show fever symptoms. Both studies have their own limitation one of them being less percentage of female participants (10%) into consideration. Also, the two clustering techniques (hierarchical clustering and k-means) and based on risk factors and co-occurring conditions, five phenotypes representing a large percentage of COPD patients were identified: weakness, cardiovascular disease, severe hindrance in airflow, anxiety/depression, diabetes, and non-comorbidity and obesity/atopy [11]. Even though the algorithms used in the above-mentioned studies are distinct and have certain limitations, they all reinforce the aim that inspecting various phenotypic categorizations can upgrade individualized diagnosis and medication. For example, if an individual is showing the symptoms of hindrance in airflow, then according to the AI tool the individual will be classified under Cluster 2 which shows that they have a severe condition of COPD which means that it requires immediate medication treatment.

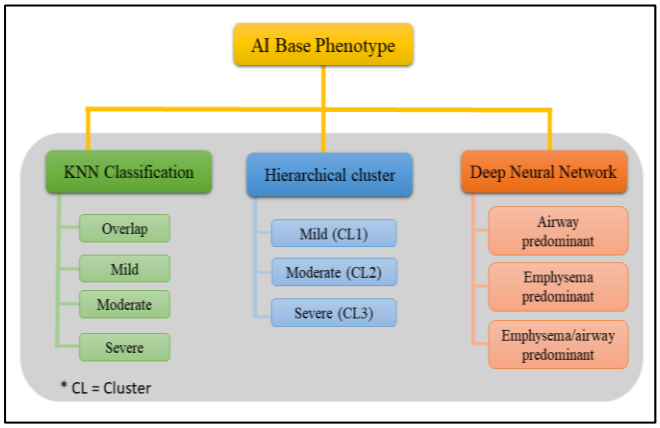

FIG. 1. Phenotype categorization using AI.

For a better understanding of phenotypes and accuracy, a Deep Neural Network model was developed. This model was trained on the 8980 individuals' dataset (COPDGene cohort study) and categorized phenotypes as normal, mixed emphysema/airway, emphysema predominant, and airway predominant. The methods demonstrated high precision of categorization for emphysema/small airway predominant phenotypes with an area under the receiver operating

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 02,2023 at 06:45:44 UTC from IEEE Xplore. Restrictions apply.

characteristic curve (AUC) of 0.91 and emphysema/airway predominant phenotypes with an AUC of 0.80. During the comparison of the data with FEV1 prediction using random forest classification a large amount of data was found missing, since this ML technique was dependent on lung function tests for checking the hindrance of airflow and just a few patients are able to reach the end of the test, so it became a major drawback which needs to be corrected for advances in AI and ML.

Keeping the above problem in mind, an AI tool was developed that showed high accuracy of around 95% to find FEV1 values of COPD veterans (41,689) in the electronic health records (EHRs) [12]. The high accuracy is achieved as the training dataset that was used to train the model matched the model definition. So that's why when the training was done on the model it was able to achieve the desired accuracy within the margin of 70%-90%. Hence the model provided the required accuracy when used on testing data which has a similar categorization as in the training dataset.

Another study using logistic regression and support vector machine (SVM) algorithm-based ML model was used for analyzing the chest CT to assess the pulmonary ventilation function of COPD patients. The method was based on 87 features of an image that was taken and tested on 27 COPD patients; the model gave 87% of accuracy with 0.81 of AUC and validated the patient's COPD condition.[13] The output obtained from the model was satisfying but the dataset was not recorded on a large scale thus the COPD range of patients on which the data were obtained was from moderate to severe, so COPD patients having a condign mild range also need to be included for better analysis. With the advancement of AL/ML a new study was proposed using CNN that is done to observe the chest-CT. The data was collected from the group of regular smokers having COPD, which came from ECLIPSE cohorts and COPDGene to access the mortality, stage, diagnosis, and exacerbation. The data were divided into two phases, one being the training phase with 8,983 COPD smoker patients and another one being the testing phase with 1,672 patients. The output from the testing phase gave a 0.856 c-index value for the identification of COPD with 51.2% of precision for exactly determining the COPD patient's current stage. Moreover, the observations obtained for determining mortality and exacerbation of c-indices are 0.60 and 0.55 for the ECLIPSE cohort as well as 0.72 and 0.64 for the COPDGene cohort [14]. These outcomes show that the CNN model works better on the COPDGene cohort.

The approach used in the study has limited applicability because of its immense training time as well as computational resources. It becomes effortless for evaluating the seriousness of the data that can be obtained from clinical practice. In a study, clinical practice data of hospitalized acute exacerbations of COPD (AECOPD) were used to train an altered decision tree model that analyzes 28 clinical features. The data were taken from 208 patients having mild AECOPD and 202 patients having severe AECOPD. The accuracy obtained from testing the model was about 80.3% which was then used to identify the stage of AECOPD in hospitalized patients [15]. However, in the future other features can also be added to the dataset to improve the scope.

C. Supervision and surveillance of COPD

Readmissions and acute exacerbations may return as a result of airflow restriction and continuous chronic airway sensitivity of COPD. Multiple researchers adapted to new strategies based on ML, that have been shown to manage COPD patients and track the condition more effectively than traditional methods. In particular, 44,929 COPD hospitalizations split into test (30%) and training (70%) sets were examined using machine learning algorithms like deep neural networks and lasso regression. The built models attempted to identify if the patient would be readmitted within the period of 30 days of release in order to demonstrate the better capacity to predict (c-statistic = 0.61) as compared to the conventional techniques. In a similar manner, the medical claims data from COPD patients was mined using different non-deep and deep Machine learning algorithms in an attempt of predicting whether the readmission is happening within thirty days after release. The value 0.653 was found for the optimum AUC for the data depicting the high accuracy of predictions[16]. Decision tree analysis was used in a retrospective study of France to forecast the readmission of 143,006 COPD individuals over the age of 40. The study not only showed that the number of prior admissions was the most significant risk factor for readmission, but it also calculated the expense of readmission in 6 months. The prediction models can be utilized as a guide by physicians, despite the fact that these studies have a number of drawbacks, such as the absence of crucial clinical parameters.

COPD is a chronic, potentially fatal condition marked by a persistent restriction of airflow and ongoing respiratory symptoms. Thus, it is crucial to keep an eye on changes for lung function and avoid long-term airflow restriction. In order to identify those who are most likely to acquire or already have COPD, a machine learning model using random forest has been created utilizing spirometry data collected from 4,167 individuals. FEV1 was the model's primary output, and the threat of airflow limitation (FEV1/forced vital capacity) was its secondary output. This model might be helpful for predicting an individual's risk of hindrance in airflow and for preventing COPD in the initial stage [17].

Due to COPD's irreparability, early diagnosis and identification are essential, Thus, to demonstrate that six models using ML techniques were developed that use the data from the different clinical features and 101 single nucleotide polymorphisms. From the observation, it was found that nine single nucleotide polymorphisms have been shown to be strongly linked to this disorder. The ML models such as logistic regression and K-nearest neighbor classification tend to have a better level of accuracy and precision (81% and 82%, respectively) in the test set, while the algorithm used for building multilayer perceptron classification model is artificial neural network has achieved the maximum sensitivity of 100%. This model is perhaps useful for diagnosing COPD in the early stage despite only including a small number of genes and clinical variables, making up for test results of lung function tests for detection of the disease at its initial stage.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 02,2023 at 06:45:44 UTC from IEEE Xplore. Restrictions apply.

For the early detection of AECOPD patients and the prediction of exacerbation, ML algorithms were utilized to assess functional respiratory imaging [18]. Similar to this, data from 135 AECOPD and 168 control participants' electronic health records were mined using various machine learning methods, such as SVM, k-nearest neighbor, random forest, logistic regression, and naive Bayesian. Additional testing and evaluation for the created models revealed that the SVM approach performed better with an AUC value of 0.90. As a result, ML models particularly the SVM model can aid medical professionals in locating AECOPD patients and making quick conclusions. However, the effectiveness of the models needs to be additionally verified using data from outside sources. Another strategy involved developing a mobile telemedicine system to enhance COPD self-management and quickly identify acute exacerbations in stable COPD patients. The technology may continuously track the clinical data of the registered patients in residence and issue a three-day advance warning for an acute exacerbation[19]. Even though the precision was just 40% and the study only lasted six months, it is still important to look at the advancement of an effective AI driven monitoring and warning mechanism. Every year, the cost of COPD on the world economy rises; this tendency is made worse by the aging of the population. According to estimates, COPD accounts for 56% of yearly healthcare expenses for respiratory disorders in Europe. Three ML algorithms - extreme gradient boosting, random forest, and logistic regression have been employed to evaluate 54 distinct demographic variables and clinical records from 780,295 hospitalizations in order to support vital information regarding health management and to determine and estimate the COPD patient cost in China. Though all ML models demonstrated outstanding predictive effectiveness, the extreme gradient boosting model had the best precision of 71.30% and an AUC value of 0.80, suggesting it could be useful for the predictive strategy for physicians, patients, and other healthcare specialists in progressive nations. Some studies have employed AI technology to determine the probability of COPD patient death because it's one of the most common causes of death in the world. As an example, the data of 3,9000 patients were collected who have COPD ranging from moderate to severe in order to predict death using the random forest classification model the data was observed over chest imaging characteristics and lung function tests. The 6-minute walk test, the ratio of pulmonary artery-to-aorta, and the FEV1 value were the best risk predictors according to the novel model, which demonstrated good predictive accuracy (C-index > 0.7) [20]. As a result, adapting to a new ML model that can detect COPD at its early stage can be helpful to prevent future damage, however, larger exterior population cohorts are required for the validation of the same.

D. Treatment of COPD

AI systems can track, integrate, and evaluate a vast range of heterogeneous clinical data from COPD patients, recommend the best course of action for each patient, and minimize under or over-treatment, brought on by mistakes made by clinicians. In a study, a variety of ML models were created using patient data of 135 individuals having COPD ranging from mild to extreme condition, the data was recorded on 153 prognostic parameters obtained from symptoms, baseline data, and telemonitoring of physiological data. These models include multitask neural network models, ensembles of boosted classifiers, and sparse maximum margin classifiers. The above-mentioned data was collected with the intention of identifying acute exacerbations and directing COPD corticosteroid medication. The best ML model (multitask neural network) demonstrated a greater value of AUC compared to non-ML approaches regardless of the use of chronic exacerbations or corticosteroids (0.73-0.76 vs 0.61-0.67) [21]. However, the model accuracy was measured using cross-validation rather than numerous independent cohorts, indicating the need for additional research.

IV. FUTURE POTENTIAL

Although, there has been significant progress in many areas of managing and understanding COPD, still a lot to be done in the future. The field of personalized medication for COPD is still developing as researchers look for distinctive phenotypes, biomarkers, prognostic indices, etc. that should direct a patient's decision-making process. AI can be used to make this procedure easier. AI can produce models using enormous volumes of data that are not readable to a doctor. The next phases in managing COPD are integrated computer systems with clinically related patient results, multi-scale and specific medical problems such as estimations of mortality, exacerbation risk, screening, and modifying medication depending on risk factors or characteristics of the disease.

AI has many uses one of them is its potential to define the mathematical relationship between real-life data sets. The current way of identification for the stage of COPD phenotype helps in clinical practices. However, all these methods are hypothetical and to solve this issue the image based phenotype can be used in combination with molecular and genetic features that allow us to explore the disease which in turn leads us to new remedies that are less hypothetical [22]. Even though the results obtained from the AI integration can be speculative, they can still be used for the understanding and uncovering of different areas of disease nature. The integration of AI with clinical data has changed perspectives about many diseases and discovered new potentials in the field of diagnosis and treatment of COPD.

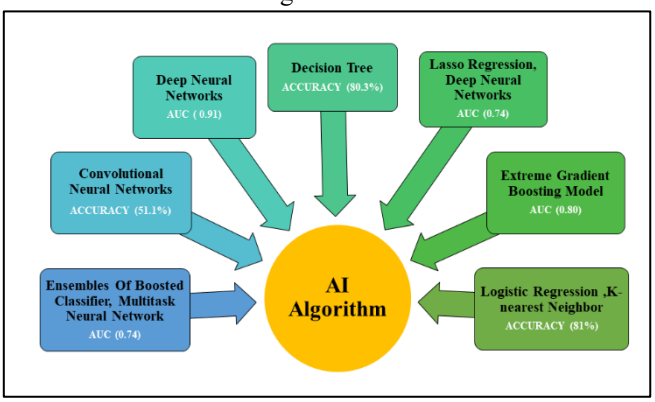

FIG. 2. Machine Learning models with their respective measures.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 02,2023 at 06:45:44 UTC from IEEE Xplore. Restrictions apply.

V. CONCLUSION

Artificial intelligence has gained widespread acceptance in healthcare fields and has begun to significantly dominate the field of respiratory research. AI includes machine learning, which allows computers to learn on their own without explicit programming. This technology is changing the clinical perception regarding imaging and diagnostic data and their use to investigate the causal factors for the progression of severe diseases such as COPD. The grasp of disease trajectories and subtypes can be expanded beyond the existing knowledge of disease's phenotype with the help of a machine learning model which combines biomarker, functional, imaging, and multi-omics data. The paper revolved around different types of data sets and each of them has different nature. Some data have a high male to female ratio others have different levels of symptoms. Each data was trained using different models technique and provided different accuracy results which provide better Interpretability for our datasets hence the model with high accuracy and better Interpretability was pricked through the course of this paper, we discovered and uncovered many areas of AI application in COPD, defined tools and studies for characterization, assessment, and monitoring practices, as well as therapeutic practices.

ACKNOWLEDGMENT

The work was supported and guided by the members of the Department of Biotechnology, Delhi Technological University and hence I am very thankful to them.

***Abstract*—Agriculture is the process of growing crops and raising livestock and cultivating other forms of food. It has been a fundamental activity for human societies throughout history, providing food and other resources necessary for survival. Hence plant diseases can have a significant impact on the economy, particularly in agricultural-dependent countries. Crop yield loss, trade restrictions, increased production costs and reduced agricultural productivity are some of the ways plant diseases can affect the economy. Farmers visually inspect their crops for symptoms of diseases, such as discoloration, spots, wilting, and deformities. Farmers can also use their sense of touch and smell to detect diseases, such as the sticky or slimy feel of plant leaves infected with fungal diseases and the foul smell of rotting or decaying plant material. However, traditional methods of plant disease detection do have limitations. Visual inspection and other traditional methods may not always detect diseases at an early stage, and there is a risk of misdiagnosis. Furthermore, conventional techniques may fail to identify illnesses that are not perceptible to the unaided observation. The other alternatives are the use of Artificial Intelligence(AI) which includes training computers to detect plant diseases using image recognition technology. These AI methods are increasingly being used for plant disease detection because they offer a fast, accurate, and cost-effective way to diagnose plant diseases, which can help prevent crop losses and increase yields. In this article, a Multilayer CNN model, inspired by InceptionNet, is put forward. This model is trained on the "Plant Pathology 2021: FGVC8 dataset". This proposed model is compared with three existing CNN models using RMSprop with Nesterov Momentum Optimizer. The suggested model outperforms other models that are already trained and achieves an accuracy of 92.56% in diagnosing the disease.**

***Index Terms*—Artificial Intelligence (AI), Deep Learning (DL), Convolutional Neural Network (CNN), Plant Disease**

I. Introduction

People all over the world enjoy eating apples, which are among the most common and beloved fruits. They are not only delicious but also packed with many essential nutrients and health benefits. Here are some of the benefits of apples: Nutrient-rich, Good for heart health, boosts immune system, may help regulate blood sugar levels. In general, apples are a flavourful and nutritious fruit that can offer numerous health advantages if eaten as a component of a well-rounded diet. However, there are several diseases that can affect apple plants, some of which are caused by fungi, bacteria, or viruses. These diseases[1] in the plants can be harmful in several ways, both to individual plants and to entire ecosystems. Plant diseases[2] can have significant economic impacts, both in terms of lost productivity for farmers and increased costs for consumers. It can have adverse effects on ecosystem function: and can affect the interactions between plants and other organisms, such as pollinators or herbivores, leading to changes in ecosystem function.

Detecting plant diseases[2] in their early stages is crucial for effective management and control of the disease. Managing apple diseases typically involves a combination of cultural, biological, and chemical control methods, including proper pruning and sanitation, use of disease-resistant varieties, and application of fungicides and bactericides when necessary. Traditionally, plant disease[2] detection involves visual inspection of plants by experienced plant pathologists or farmers. The presence of characteristic symptoms, such as spots, wilting, or deformities, is often used to diagnose the disease. In some cases, laboratory tests may be required to confirm the diagnosis. While these traditional methods are still commonly used for plant disease[2] detection, they can be time-consuming, expensive, and require specialised expertise.

In recent years, new technologies such as remote sensing, AI[3], and biosensors have emerged as promising tools for early and rapid detection of plant diseases[2]. These new approaches offer faster, more accurate, and cost-effective solutions for disease detection and management. The next alternatives are Imaging techniques which have emerged as promising tools for prior detection of plant diseases[2]. They have the potential to revolutionize plant disease[2] detection by offering fast, non-destructive, and cost-effective solutions for prior detection and management of plant diseases. While imaging techniques offer several advantages for plant disease[2] detection, there are also some disadvantages to consider: Imaging equipment can be expensive, and specialized training may be required to use and interpret the images. Imaging techniques may only capture images of small areas of plant tissue, requiring multiple images to be taken to cover larger plants or fields. Environmental elements like lighting or humidity can impact the image quality produced by imaging technologies. ML[4] techniques like Support Vector Machines(SVM)[5] and K-Means Clustering[6] have shown promise in the detection and diagnosis of plant diseases[2]. But it comes with the added

(a) Fire blight
(b) Powdery mildew on leaf
(c) Cedar apple rust infection on the leaf

disadvantage of a complex feature extraction process which reduces the overall efficiency of the system.

On the other hand, we have DL[11] algorithms such as recurrent neural networks (RNNs)[12], CNNs etc. These algorithms are trained on large datasets of plant images to learn the characteristic features of healthy and diseased plants, enabling automated disease detection and classification with high accuracy. DL[11] algorithms can be trained on large datasets of plant images to automatically detect disease[2] symptoms with high accuracy. This can enable faster and more accurate disease detection, particularly in large-scale agricultural settings.

DL[11] algorithms can detect subtle changes in plant tissue that may be difficult for humans or traditional ML[4] algorithms to detect, leading to improved accuracy in disease detection[2]. Overall, We can use DL[11] methods to find and deal with plant diseases[2] before they get worse, with the potential to improve crop yields, reduce pesticide use, and promote sustainable agriculture. While DL[11] techniques offer many advantages for plant disease[2] detection, there are also several challenges that need to be addressed. Plants can vary widely in their morphology and appearance, making it difficult to develop generalized DL[11] models that can detect a wide range of diseases across different plant species. Labelling and annotating large datasets of plant images can be time-consuming and resource-intensive, particularly for rare or emerging plant diseases.

Here, in this study the FGVC8 dataset from the Plant Pathology 2021 Kaggle competition[13], is taken. The FGVC8[13] dataset is a collection of images used for fine-grained visual categorization tasks, which includes the classification and recognition of subordinate categories within a larger category. The apple leaves with unhealthy areas are shown in Fig. 1 and in Fig. 2 which shows the various unhealthy leaves of apple trees. Multilayer CNN model makes it quite simple to identify them. The proposed Multilayer CNN model will be used to identify such apple foliar diseases[1], and the performance will be compared to previously trained models which are based on InceptionNet[14].

Taking inspiration from InceptionNet[14], the proposed Multilayer CNN model is comprised of a Convolution Layer, Batch Layer, Max-Pooling Layer, Flatten Layer, Dense Layer, and Inception Block. The result shows that the proposed model, which is the Multilayer CNN model works very well with RMS Prop with Nesterov momentum Optimizer[14] which is trained on Plant Pathology 2021- FGCV8 Dataset[13]

Fundamentals will be covered in chapter 2. Related work will then be covered in chapter 3 along with the methods that have previously been suggested for identifying PDs. chapter 4 will provide a summary of the proposed work. Data evaluation will be described in chapter 5. Experiments and results will be discussed in chapter 6, followed by the conclusion and future scope in chapter 7 and references in the last section.

II. Background

When identifying a foliar disease[1] in apple leaves from an image, one DL[11] algorithm known as CNNs performs better than other deep learning algorithms, resulting in higher accuracy. A CNN is a sort of deep neural network that is often utilized in computer vision applications such as image and video identification. It is an advanced Neural Network[15]-[17] architecture made specifically or processing data with a grid-like layout, like pictures, by performing a series of convolutional and pooling operations. Convolutional layers, pooling layers, and fully connected layers are the key building blocks of a CNN. By applying different filters to the input image, these layers enhance the accuracy of the model. It can have varying numbers of layers depending on the architecture and complexity of the model. The different layers are the following.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:21:04 UTC from IEEE Xplore. Restrictions apply.

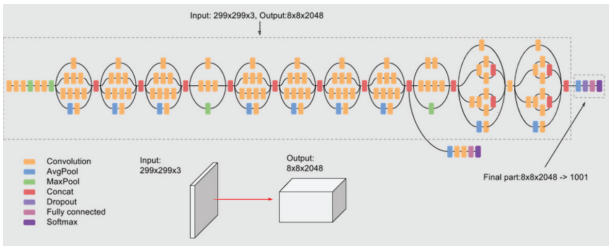

Fig. 3. Architecture of InceptioNet[20]

1) Convolutional layers: The convolutional layer is a key building block in CNNs. It performs a mathematical operation called convolution.
2) Pooling layers: In CNNs, the pooling layer serves as a crucial important block, contributing to dimensionality reduction and feature extraction. Its main function is to reduce the spatial dimensions of the feature maps produced by convolutional layers while retaining the most important feature.
3) Connected layers: The connected layer, also can be called as the dense layer, is a key component in CNNs. It is typically the last layer in the network and is responsible for making the final prediction by mapping the extracted features to a specific class or label.

The filters start as simple features in the lowest layer and become more complex as the layers progress to identify unique features of the input object. In the classification of plant diseases[2], leaf images are utilized because they exhibit signs sooner than rest of the plant, making it easier to detect and diagnose the disease[2] at an early stage. CNNs use features and texture analysis to accomplish this task. The fully connected layer, which uses the flattened vector from the preceding layers as its input, computes the output vector for the CNN. The fully connected layer picks up a set of weights and biases that translate the input vector to the predicted probabilities for each class in the output vector. To enhance the CNN's performance for a given job, the fully connected layer's neuron count can be altered.

Google created a type of neural network[15]–[17] called the InceptionNet[18] for images that applies different types and sizes of filters simultaneously, and merges their results to produce a single result. This helps the network to learn features at different levels of detail and resolution, and makes it more accurate in tasks that involve images. The network has been applied to various problems, such as identifying images, finding objects, and segmenting images. The first version of the network, also called GoogLeNet[19], had 22 layers, including layers for filtering, pooling, and connecting. However, there have been later versions and enhancements of the network that have more layers, such as InceptionV2, InceptionV3, and InceptionV4. These newer versions have up to hundreds of layers and use additional techniques like batch normalization and residual connections to make them better. The architecture of InceptionNet[18] is given in Fig 3.

III. Related Work

In this chapter, we will look at a few of the important researches by other authors. Several DL[11] techniques have been introduced in the past few years.

In the paper, proposed by[21] the DL approach is used which is based on CNN. An available dataset, from PlantVillage[22] with 39 different classes is utilised to train the suggested CNN model. Before training, this dataset undergoes 6 different types of data augmentation methods. This proposed model is compared with transfer learning approaches. It has been concluded that compared to popular transfer learning[23], [24] approaches, data augmentation can improve model performance. With transfer learning, DL[11] models can be built with less training data, less time, and fewer computational costs.

The author of [25] suggested a model that uses transfer learning, called INC-VGG, which merges VGG19[26] and InceptionV3. After the first layers of VGG19 models, three ConvBN layers of size 3X3 were added, followed by two InceptionV3 layers, and in the end a Softmax layer. The suggested model merges two models that are already trained and it outperforms other models that are also trained beforehand.

A multilayer model based on CNN was proposed by [27] to identify tomato diseases present on monitored tomato plants, compared CNN with F-RCNN[28], and used Transfer Learning[23],[24] for disease recognition on tomato plant leaves. Before training, data augmentation is done to increase the dataset size and reduce overfitting. Transfer Learning is used as well. In comparison to F-RCNN[28], the proposed model gives better accuracy.

Author [29] proposed the DenseNet201 model which contains 201 layers. This proposed model is compared with transfer learning approaches. As a result of this proposed model, the vanishing gradient problem has been solved, feature propagation has been improved, feature reuse has been promoted, and the number of parameters has been reduced. Networks with too many connections are less efficient in computation, and are more prone to overfitting.

Author of [30] specifies in his study a technique that has used a model called LeNet[31], which has layers for filtering, activating, pooling, and connecting, to train it on data and find diseases in tomatoes. This model can correctly recognize different kinds of diseases in tomato plants. The model gets the data after it has been augmented. It achieves about 95% of accuracy which is much higher than other models that use CNN or are based on CNN.

The researchers [32] suggested a DCNN that uses Bayesian learning[33] on a residual network. This method combines the strength of Bayesian learning[33] with the speed of residual networks for better performance in finding diseases. This model is trained to find diseases in tomatoes, potatoes, and bell peppers. The process of learning features is effective but it takes a lot of time to compute.

[34]Developed a Deep Siamese CNN. Photos of grape leaves were collected and sorted into four categories. Photographs are taken from the field.The proposed model handles

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:21:04 UTC from IEEE Xplore. Restrictions apply.

the challenge of a small dataset. Although it gives high accuracy, it is not computationally efficient.

[35] studied the AlexNet[36] and GoogLeNet[19] DNN architectures and achieved a classification accuracy of 99.55% on the PlantVillage[22] dataset using 50k sample images over 30 training epochs. Images captured from the farm. This model is prone to overfitting because it uses only 800 leaf images. And also a simple model which uses only three layers.

[37] developed a three-layer CNN system with an average accuracy of 94.9% after 40 epochs of training. The Images are captured from the farm. This study used 800 leaf images of cucumber. This model is prone to overfitting because it uses only 800 leaf images. And also a simple model which uses only three layers.

The article[38] examines the utilization of DL[11] algorithms to identify plant diseases[2] through images. It presents a summary of DL[11] models, datasets, and preprocessing techniques employed to train such models. The article emphasizes the significance of data augmentation, transfer learning[23], [24], and hyperparameter tuning to attain high accuracy in Plant Disease[2] Diagnosis. Additionally, it discusses the obstacles and prospects of using DL-based image analysis in Plant Disease[2] Detection. In general, the article presents a comprehensive summary of the utilization of DL[11] algorithms for image-based Plant Disease[2] Diagnosis. It emphasizes the potential for these algorithms to transform agricultural production by enabling the timely and precise identification of plant diseases[2].

IV. Proposed Methodology

This chapter focuses on the Multilayer CNN model which has been proposed. The first section describes the dataset used in the study, followed by an explanation of the Data Preprocessing in the subsequent section. Finally, the Proposed Model is discussed in the final part of this chapter. It can be seen how the model that has been suggested works in detail in Fig. 4.1.

A. Dataset

One real-world datasets, Plant Pathology 2021: FGCV8[13] has been used to identify a certain disease affecting apple plants. This is a summary of the datasets that have been used.

TABLE I
Distribution of Dataset

Total Images	Training Images	Testing Images
18632	16769	1863

B. Data Acquisition

Data collecting from various sources and conversion to a digital representation is known as data acquisition. It then can be handled by a computer or another electronic device. Overall, data acquisition plays a crucial role in collecting and analyzing data from various sources, allowing for better decision making, process control, and scientific research.

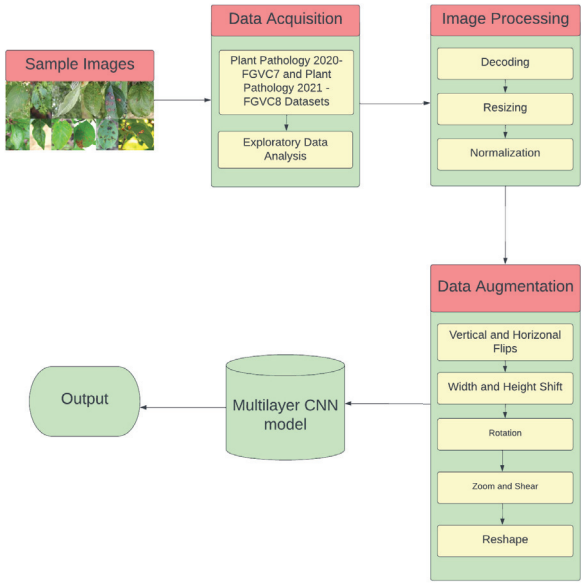

Fig. 4. Graph showing proposed methodology process

C. Image Processing

The editing and analysis of digital pictures fall under the umbrella of the field of image processing. It involves the use of various algorithms to transform, enhance, or extract information from images. Some of the common techniques used in image processing include image filtering, edge detection, image segmentation, image restoration, and feature extraction. These techniques can be used individually or in combination to achieve various image processing goals. In recent years, DL[11] techniques such as CNNs have also been used in image processing, achieving trailblazing results in various image associated tasks such segmentation, and image grouping. It uses various algorithms and techniques to change, improve, or get information from images. These techniques can be used separately or together to achieve different image processing goals. In recent years, DL[11] techniques such as CNNs have also been used in image processing, getting the best results in various tasks related to images such as object detection, segmentation, and image classification.

D. Data Augmentation

It is the process of making a dataset bigger by applying various changes or alterations to the original data. Data augmentation aims to broaden the dataset's diversity, which can make ML[4] models better by preventing overfitting and improving generalization. There are several techniques that can be used for data augmentation, based on the task and the type of data.

E. Proposed Model

A CNN based model called Multilayer CNN is proposed which contains Convolution Layer, Batch Normalization Layer, Max-Pooling Layer, Flatten Layer, Dense Layer,

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:21:04 UTC from IEEE Xplore. Restrictions apply.

Dropout Layer and Inception Block. Here Inception Block is inspired from InceptionNet[14]. And in this proposed architecture, ReLU, LeakyReLU and Softmax activation functions are used. In Table 1, a multilayer CNN architecture is presented. Detailed Explanation of Each Layer is given below:

- Input: Defines the shape of the input tensor, which is (input image, input image, 3) for this model.
- Conv2D: Performs 2D convolution on the input tensor with a specified number of filters (64 in the first layer), kernel size of 3x3, and padding of 'same', which means the output feature maps will have the same spatial dimensions as the input.
- BatchNormalization: It ensures that the mean activation is near to 0 and the activation standard deviation is close to 1. Normalises the outputs of the preceding layer.
- Activation: Applies the ReLU activation function to the output of the previous layer.
- MaxPooling2D: Downsamples the input tensor along the spatial dimensions by taking the maximum value within a specified pool size (default is 2x2) and strides (default is pool size).
- inception_module: A custom layer that applies the inception module that takes the output of the previous layer as input and returns a feature map with increased depth through concatenation of different convolutional filters. inception_module consists of a 1x1 convolution branch, a 3x3 convolution branch, a max pooling, and a 1x1 convolution followed by 5x5 convolution and then 2x2 convolution branch. The output of each branch is concatenated along the channel axis to produce the final output.
- Flatten: Used to transform the 3D output of a convolutional layer into a 1D vector that can be given to a fully connected layer. The Flatten layer basically "flattens" the output of the preceding layer into a long, one-dimensional array of values.
- GlobalAveragePooling2D: Takes the avg. of each feature map in the preceding layer along the spatial dimensions to reduce the tensor to a vector of length equal to the number of filters.
- Dense: A fully connected layer that takes the vector output of the previous layer and applies a specified number of neurons (9216, 4096, 1024, and 128 in this model) with ReLU activation.
- Dropout: Randomly sets a fraction of input units to 0 at each update during training to prevent overfitting. BatchNormalization: Applies batch normalization to the output of the previous layer.
- Dense: A fully connected layer that takes the output of the previous layer and applies a softmax activation to classify the input into one of 4 possible classes(in case of Plant Pathology 2020-FGCV7) or 12 possible classes(in case of Plant Pathology 2021-FGCV8) [as defined by the number of neurons in the output layer].

TABLE II
DETAILED ARCHITECTURE OF MULTILAYER CNN MODEL

F. Optimizer Used

In this suggested work, RMS Prop with Nesterov momentum optimizers[14] is used to test whether the suggested multilayer CNN model works better than the existing models. In order to decrease the loss function, method called RMS Prop Nesterov momentum[14] in DL[11] are used to modify the biases and weights of neural networks during training. The choice of optimizer can have a big impact on the performance of the model, and there are several different optimizers available to pick from.

V. EXPERIMENTAL EVALUATION

This chapter will cover the performance of the proposed model. In this case, the suggested model is evaluated using data from dataset. The Data Evaluation section contains information on these datasets in depth. In this study, the suggested model was trained using the optimizer, and the outcomes were compared. The optimizer has a learning rate[39] setting of 0.01 for learning. further contrasted the outcomes with three previously suggested CNN based algorithms.

A. Performance Matrics

- Accuracy: The degree to which a measurement, computation, or forecast is accurate or precise is referred to as accuracy. To express how precise a prediction or measurement is, we can use a fraction or a percentage.

$$Accuracy = \frac{numberofcorrectpredictions}{totalnumberofpredictions} \quad (1)$$

- Precision: Precision is the percentage of all retrieved occurrences that are relevant.

$$Precision = \frac{NumberofPredictedPositive}{NumberofTotalPositivePredictions} \quad (2)$$

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:21:04 UTC from IEEE Xplore. Restrictions apply.

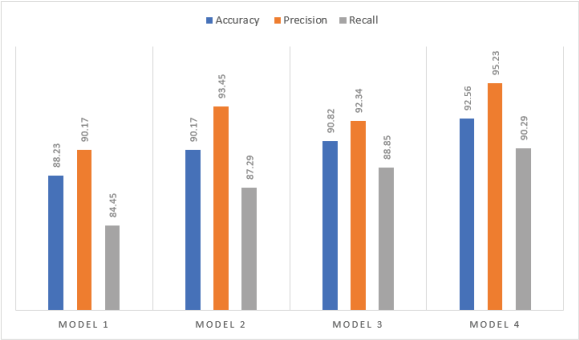

Fig. 5. Comparison of Performance[21], [40], [41]

- Recall: It is the ratio of true positives i.e., positively identified cases to the total of true positives and false negatives i.e., positively recognised cases that were overlooked.

$$Recall = \frac{Truepositives}{Truepositives + Falsenegatives} \quad (3)$$

Accuracy, Precision, and Recall have been used as assessment measures to assess the performance of the proposed approach on the dataset. Additionally, the performance of the proposed model has been compared using the optimizer, namely RMSprop with Nesterov Momentum[14] with 3 existing models.

The model is trained on the dataset for 50 epochs using the RMSprop with Nesterov Momentum Optimizer[14]. The model with the best accuracy (0.9256), precision (0.9523), recall (0.9029), and least loss (0.2543) is this one.

A Bar chart has been shown in the Fig. 5 which compares the performance of the proposed model with the other existing CNN-based models[21], [40], [41] using the same optimizer[14].

VI. Conclusion

CNNs have already shown great promise in the field of plant disease detection and diagnosis. However, there are several potential areas for future development and application of CNNs in this field. Prior to usage, the entire dataset is divided into two subsets: the training dataset and the test dataset. The split is performed at a ratio of 18:2, which corresponds to 90% and 10% of the dataset, respectively. The proposed model has proven to give a better performance of 92.56% than the existing models hence the proposed model can be applied for better performance. Overall, the proposed model has the capability to reorganize the field of plant disease detection and management by providing accurate, efficient, and early detection of diseases, which can help in maintaining crop health and improving agricultural productivity.

Abstract - This research study intends to predict the stock price movement of a set of stocks using the Geometric Brownian Motion and optimize the portfolio built from selected stocks using Feed Forward [1] Neural Network. The onset of the current global pandemic has led to major negative implications for the overall economy and personal financial situations. With many people losing jobs, getting reduced salaries, and exhausting their savings, they have started to invest heavily. The Securities and Exchange Board of India (SEBI) reports that there were 4.9 million new Demat accounts opened in the fiscal year 2020, which was the biggest in at least ten years. Thus, the study of the Stock Exchange is very relevant to the current times. We shall explain the importance of learning about investing in the Stock Market and derive an efficient model to make real-time predictions of a stock price and build an optimized portfolio. In the finance sector, portfolio optimization is a critical responsibility. The goal of portfolio optimization is to increase return on investment while lowering portfolio risk. Due to its capacity to understand intricate correlations between input and output variables, feed-forward neural networks have been successfully used to solve portfolio optimization issues. We explore the research on portfolio optimization using feed-forward neural networks in this paper.

Keywords - Feed Forward Neural Network, Deep Learning, Portfolio Optimization, Geometric Brownian Motion, Stock Market, Machine Learning

I. Introduction

The market trend is the broad direction that the stock is heading in, according to Motilal Oswal Financial Services, a well-known supplier of financial services listed on both the NSE and BSE. Depending on whether the market is bullish or bearish, the trends shift upwards or downwards. Share market trend analysis or equity market trend analysis is the process of looking at current patterns in order to predict future trends. Although there is a lot of data used in this share market trend analysis process, no one can predict the trends with absolute certainty of 100%. Thus, different firms and institutes uses various methods to create future prediction such as chart analysis, technical analysis, and Stock parameters such as Return on Equity (ROE), Price-to-Earning Ratio (PE Ratio), etc to predict the future prices of a particular Stock/Sector.

There are two approaches to reducing risk when making stock investment decisions: gathering the most recent stock market information and diversifying your investments. Investment diversification is the distribution of capital among a number of businesses through the creation of a stock portfolio. A portfolio is a collection of assets that investors own, including both tangible and intangible assets. By building a portfolio of investments, investors can lower their risk of losing money on profits from investments made in the capital market due to stock price volatility. As indicated in the papers, there are several studies on the impact of portfolio optimization on stock prices.

On the capital market, fluctuating stock prices are constantly represented by uncertain stock price movements. The current stock price, which represents the price of the stock in the past, and the market's response to corporate news both affect how the stock price moves, claims the efficient market theory. Stock prices are thought of as random variables, and everyday stock price fluctuations on the capital market are seen as random movements.

One of the major issues in finance is portfolio optimisation. The goal of portfolio optimisation is to distribute the portfolio weights in order to maximise return on investment while lowering portfolio risk. Mean-variance optimisation is one of the traditional portfolio optimisation strategies that is based on the premise that returns have a normal distribution. This presumption might not hold true in reality, and the resulting portfolio might underperform. Due to its capacity to understand intricate correlations between input and output variables, feedforward neural networks have been successfully used to solve portfolio optimisation issues.

The scope of this paper is to conduct a price analysis to predict the movement of future price of selected stocks via application of the Geometric Brownian Motion as the basis of

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:36:29 UTC from IEEE Xplore. Restrictions apply.

the analysis and further use it to build an optimized portfolio for favorable returns.

II. Related Works

[1]"Feed-forward neural networks" by Bebis and Georgiopoulos (1994) introduces the concept of feed-forward neural networks, which are artificial neural networks where the information flows in only one direction, from the input layer to the output layer. The article discusses the structure and functioning of these networks, highlighting their ability to model complex relationships and solve various computational problems. Additionally, it explores the potential applications of feed-forward neural networks in diverse fields such as pattern recognition, signal processing, and control systems. The authors provide insights into the advantages and limitations of this neural network architecture, paving the way for further research and development in the field.

[2]Fama (1995) presents the concept of random walks in stock market prices, which suggests that future stock price movements cannot be reliably predicted based on past price patterns or information. The article explores the implications of this theory for the efficient market hypothesis (EMH) and financial analysis. It discusses how the notion of random walks challenges the traditional methods of technical analysis and fundamental analysis used in stock market forecasting. By examining empirical evidence and market trends, Fama provides valuable insights into the efficiency of stock markets and the role of random price movements, contributing to the understanding of market dynamics and the development of investment strategies.

[3]Telser (1959) proposes a theory of speculation that establishes a relationship between profitability and stability in financial markets. The article argues that speculation serves a vital role in maintaining market stability by aligning prices with fundamental values. Telser introduces the concept of the stabilizing speculation premium, which compensates speculators for their contribution to market stability. By analyzing the interplay between speculative behavior, profitability, and market equilibrium, the author highlights the importance of speculation in reducing price fluctuations and promoting market efficiency. Telser's theory provides a theoretical framework for understanding the dynamics of speculation and its impact on financial markets, offering valuable insights for policymakers and market participants.

[4]Lu, Li, Wang, and Qin (2021) propose a novel method called CNN-BiLSTM-AM for stock price prediction. The approach combines convolutional neural networks (CNNs), bidirectional long short-term memory (BiLSTM) networks, and an attention mechanism (AM) to capture temporal patterns and extract relevant features from historical stock price data. The article describes the architecture and training process of the proposed model, highlighting its ability to capture both short-term and long-term dependencies in the stock market data. The authors present experimental results demonstrating the superior predictive performance of CNN-BiLSTM-AM compared to other traditional and deep learning-based approaches. The findings contribute to the field of stock price prediction and offer insights into the potential of combining different neural network architectures for enhanced forecasting accuracy.

[5]"Louis Bachelier's Theory of Speculation" by Bachelier (2011) provides an in-depth overview of Louis Bachelier's pioneering work on the theory of speculation, which laid the foundation for modern mathematical finance. The article delves into Bachelier's groundbreaking doctoral thesis, "Théorie de la Spéculation," in which he introduced stochastic calculus and developed a mathematical framework to model and analyze stock price movements. Bachelier's work, published in 1900, anticipated future advancements in option pricing, risk management, and quantitative finance. The article discusses the historical significance of Bachelier's theory and its impact on subsequent research and practical applications in the field of finance, cementing his legacy as one of the pioneers of modern financial theory.

[6]Kim and Han (2000) present a genetic algorithm-based approach for feature discretization in artificial neural networks to predict stock price indexes. The article focuses on the preprocessing step of feature discretization, which transforms continuous input variables into discrete values. By employing genetic algorithms, the authors aim to find an optimal set of discretization thresholds that maximize the predictive performance of the neural network model. The article provides a detailed description of the proposed approach, including the encoding of discretization thresholds, fitness evaluation, and the genetic operators used in the optimization process. Experimental results demonstrate the effectiveness of the genetic algorithm-based feature discretization in improving the accuracy of stock price index prediction models, offering valuable insights into feature engineering techniques for financial forecasting tasks.

[7]Reddy and Clinton (2016) investigate the use of geometric Brownian motion (GBM) to simulate stock prices, with a particular focus on Australian companies. The article explores the application of GBM, a stochastic process that assumes the logarithmic returns of a stock follow a normal distribution with constant mean and variance, in modeling stock price dynamics. Reddy and Clinton analyze historical stock price data of various Australian companies and estimate the parameters of GBM to simulate future stock price movements. The findings shed light on the limitations and assumptions of GBM as a modeling tool, providing insights into the accuracy and applicability of this approach for stock price simulation in the Australian market context.

[8]Ma, Han, and Wang (2021) propose a portfolio optimization framework that incorporates return prediction using deep learning and machine learning techniques. The article addresses the challenge of constructing optimal investment portfolios by integrating return prediction models into the portfolio optimization process. The authors introduce a hybrid model that combines deep learning algorithms, such as long short-term memory (LSTM) networks and convolutional neural networks (CNNs), with traditional machine learning

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:36:29 UTC from IEEE Xplore. Restrictions apply.

methods. The integrated model aims to capture the complex relationships and nonlinearities in financial data to enhance return prediction accuracy. By incorporating the predicted returns into a portfolio optimization algorithm, the authors demonstrate improved risk-adjusted performance compared to traditional approaches. The research contributes to the field of portfolio management by leveraging the power of deep learning and machine learning for enhanced investment decision-making.

[9]Huang, Miao, and Wang (2019) analyze the potential impact of saving China's stock market, examining various factors and policies influencing its stability and growth. The article investigates the challenges faced by the Chinese stock market and explores potential solutions to improve its performance. The authors discuss the role of government interventions, regulatory policies, and investor sentiment in shaping the dynamics of the Chinese stock market. By examining the economic and financial factors influencing stock market stability, the article provides insights into the potential strategies to enhance the resilience and efficiency of the Chinese stock market, which is of significant interest given its size and importance in the global financial landscape.

[10]Jiang (2021) provides an overview of recent progress in applying deep learning techniques to stock market prediction, highlighting advancements and challenges in this area. The article discusses various deep learning architectures, including convolutional neural networks (CNNs), recurrent neural networks (RNNs), and generative adversarial networks (GANs), that have been used for stock market forecasting. It explores the utilization of alternative data sources, such as social media sentiment, news articles, and macroeconomic indicators, in combination with deep learning models to improve prediction accuracy. The article also addresses challenges such as data scarcity, model interpretability, and model robustness in the context of deep learning-based stock market prediction. The comprehensive overview of recent developments provides researchers and practitioners with valuable insights into the state-of-the-art techniques and potential future directions in this field. [11]Pang, Zhou, Wang, Lin, and Chang (2020) propose an innovative neural network approach for stock market prediction. The article introduces a hybrid model that combines a convolutional neural network (CNN) and a long short-term memory (LSTM) network to capture both spatial and temporal dependencies in stock market data. The CNN-LSTM model is designed to extract meaningful features from historical stock price sequences and predict future price movements. The authors provide a detailed description of the model architecture, including the convolutional layers, LSTM layers, and the fusion mechanism between the two networks. Experimental results demonstrate the effectiveness of the proposed approach in predicting stock market trends and outperforming traditional time series forecasting models. The research contributes to the field by offering a novel neural network-based approach for stock market prediction that integrates both spatial and temporal information.

[12]Hiransha, Gopalakrishnan, Menon, and Soman (2018) employ deep learning models to predict the National Stock Exchange (NSE) stock market in India. The article explores the application of deep learning techniques, including convolutional neural networks (CNNs) and recurrent neural networks (RNNs), in modeling and predicting stock market movements. The authors preprocess the financial data and train the deep learning models using historical stock price and trading volume data. The article provides insights into the performance and accuracy of the deep learning models in forecasting the NSE stock market, highlighting the potential of these models for predicting financial market trends. The findings contribute to the understanding of deep learning applications in stock market prediction and provide practical implications for investors and financial analysts in the Indian stock market context.

[13]Mukherjee, Sadhukhan, Sarkar, Roy, and De (2023) investigate the use of various deep learning algorithms for stock market prediction, comparing their performance and analyzing the underlying mechanisms. The article explores popular deep learning architectures such as convolutional neural networks (CNNs), long short-term memory (LSTM) networks, and hybrid models in the context of stock market forecasting. The authors conduct experiments using historical stock price data and evaluate the prediction accuracy of different deep learning algorithms. They analyze the strengths and limitations of each approach, considering factors such as model complexity, interpretability, and computational efficiency. The research provides valuable insights into the selection and optimization of deep learning models for stock market prediction, offering guidance for researchers and practitioners in the field.

[14]Mintarya, Halim, Angie, Achmad, and Kurniawan (2023) conduct a systematic literature review on machine learning approaches in stock market prediction. The article synthesizes and analyzes existing research on the application of machine learning techniques for stock market forecasting. The authors identify common machine learning algorithms used in this domain, such as support vector machines (SVM), random forests, and neural networks. They examine the datasets, features, and evaluation metrics employed in different studies. The review provides an overview of the strengths and limitations of machine learning approaches in stock market prediction, highlights trends, and identifies potential areas for future research. The comprehensive review contributes to the understanding of the current state of machine learning in stock market prediction and serves as a valuable resource for researchers and practitioners interested in this field.

[15]Brătian, Acu, Mihaiu, and Șerban (2022) analyze the behavior of stock indexes under geometric Brownian motion (GBM) and investigate the relationship between financial market uncertainty and non-crisis as well as financial crisis scenarios. The article explores the application of GBM, a widely used stochastic process in finance, to model the dynamics of stock indexes. The authors simulate stock price movements using GBM and analyze the impact of different levels of market uncertainty on the behavior of stock indexes

III. Objective

Our aim is to conduct a price analysis for multiple stocks listed on the NSE, which in our case are City Union Bank, Spicejet, Astrazeneca Pharma, Wockhardt, jubilant pharmova, Tata Motors, ITC, HDFC , Ultratech Cements and Sun Pharmaceuticals using the Geometric Brownian Motion. We will analyze the Stock price for a time frame using the programming language Python. We will first pre-process the data (clean the data and remove all values unnecessary for the scope of this analysis) and then implement the Geometric Brownian Motion Model to conduct a comparative analysis of the stock prices. Then we will implement Feed Forward [1] Neural Network implemented with a single hidden layer using the programming language Python to create an optimized portfolio out of stocks with better returns.

IV. Brownian Motion

More than just the flow of particles out of a liquid, Brownian motion has been applied mathematically as well.
A standard Wiener process also referred to as standard Brownian is a stochastic process.

$$W_t(t >= 0); \tag{1}$$

which represents, a family of random variables W_t , defined on a similar probability space (Ω,F,P)) and indexed by non-negative real values t, having properties as following:

- W_o = 0
- The function t $\rightarrow W_t$ is continuous in t, with probability 1,
- The increments of the process $W_t, t \geq 0$ are stationary and independent.
- The distribution of the increment $W_{(t+s)}$ - W_s is normal(0,t).

Independent increments refer to the property that for each choice of real numbers which are non-negative,

$$0 \leq x1 < y1 \leq x2 < y2 \leq \ldots \leq xn < yn < \infty, \tag{2}$$

the random variables represented by the increments

$$W_{y1}–W_{x1}, W_{y2}–W_{x2}, ..., W_{yn}–W_{xn} \tag{3}$$

are independent jointly;
By stationary increments, it is meant that for any

$$0 < x, y < \infty \tag{4}$$

the increment's distribution $W_{y+x}–W_x$ should follow the same distribution as $W_t–W_0 = W_t$.

V. Geometric Brownian Motion

'Brownian Motion' can have negative values, making it dubious to use it directly to simulate stock prices among other things.Consequently, we use the 'Geometric Brownian Motion', a non-negative variant of Brownian Motion:
S(t), which can be defined as

$$S(t) = S0 * e^{X(t)} \tag{5}$$

Where,

$$X(t) = \sigma * B(t) + \mu * t \tag{6}$$

is Brownian Motion which has drift as well as volatility.

$$S(0) = S_o > 0 \tag{7}$$

represents the initial value.
To determine the Brownian Motion, logarithms are used;

$$X(t) = ln[S(t)/S_o] = ln[S(t)) - ln(S_o]. \tag{8}$$

$$\ln(S(t)) = \ln(S_o) + X(t) \tag{9}$$

is normal with mean: μ*t + ln(S_0), and variance: $\sigma^2 * t$; hence, S(t) has a log-normal distribution for every t.
OR

$$S_{pred} = S_o * e^{(drift+diffusion)} \tag{10}$$

Where,
So: The closing price of the beginning time point
Drift: the longer-term trend in stock prices is shown.
Diffusion/Volatility: reflects shorter-term fluctuations

Two components make up GBM: a definite component and an uncertain component. A specific/definite component reflects the return on the stock over a limited period of time and is also referred to as the stock's drift. The uncertain component is a stochastic process that depicts the randomness of the stock price with a component of random volatility and a component of stock market volatility.

A. Drift

- The longer-term trend in stock values can be seen in drift. As you can see in the expression above, drift is a constant value that may be applied to a certain time point's stock price (t-1) if we assume there is no random shock.
- Stock prices will gradually increase if the drift is favorable or decrease if the drift is unfavorable as long as there is no sudden shock. We can see that because drift is applied using the exponential function, stock prices can never reach zero.

B. Volatility/Diffusion

- Diffusion reflects transient changes. We multiply the sigma by the random value z(k) to determine the diffusion component.
- Several stock price prediction scenarios can be created thanks to the diffusion component. The component of drift is constant.It limits the number of scenarios we can create, but the diffusion component, which uses the Wiener process to create independent, stationary, and evenly spaced random shocks, allows us to create as many scenarios as we want.
- Therefore, we must add the effects of both components when making a prediction for the time point (k) while

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:36:29 UTC from IEEE Xplore. Restrictions apply.

taking into account the stock price at the time point (k-1). We can make a prediction about what will happen at time point (k) using the combined total effect.
- We could always predict the stock price at the following time point if there was only the drift component, but the diffusion component disturbs up this smoothness by injecting random shock. As a result, neither a steady upward trend nor a downward trend in stock prices can be seen. .

The GBM model assumes that stock returns are normally distributed and that stock prices follow a log-normal distribution.
The model is based on three parameters:

- the price of stock at the current time (S_o)
- the expected rate of return (μ), and
- the volatility (σ) of the stock.

The following equation is what the GBM model predicts the stock price will follow:

$$dS = \mu S dt + \sigma S dW \tag{11}$$

where dW is a Wiener process or Brownian motion, dS represents the shift in stock's price, dt represents the change in time, μ symbolizes the expected rate of return and σ is used to represent volatility.

VI. Feed Forward Neural Network

A variant of Artificial Neural Network (ANN) called as Feed-Forward Neural Network (FFNN) only permits data to move from the initial input layer towards the output layer.The output layer creates the finished product after getting the input data. In order to retrieve pertinent information between the input and output layers, the hidden layers execute computations on the input data.

Every neuron in a layer of a feed-forward neural network is connected to every other layer below it, but there exist no connections between layers that are higher or lower or within the same layer. While each neuron comprising the input layer represents a feature of the input data, each neuron comprising of the output layer generates a prediction or classification based on the input data.

Each neuron in the feed-forward neural network is given weights and biases, which are changed during training to reduce the difference in the discrepancy between the anticipated and actual production. The biases and weights govern the threshold for neuron activity and the strength of the connection between neurons, respectively. Classification, regression, and pattern recognition are just a few of the tasks that feed-forward neural networks are capable of. Gradient descent-based algorithms can efficiently train them, and they are easy to implement. However, they might not be appropriate for difficult tasks that call for a lot of data or have a lot of fluctuation in the input data.

VII. Feed Forward Neural Network with Single Hidden Layer

A feed-forward neural network with one hidden layer is an Artificial Neural Network (ANN) comprising an input layer, a hidden layer, and an output layer. Data is first received by the input layer, then processed by the hidden layer, and finally produced by the output layer.

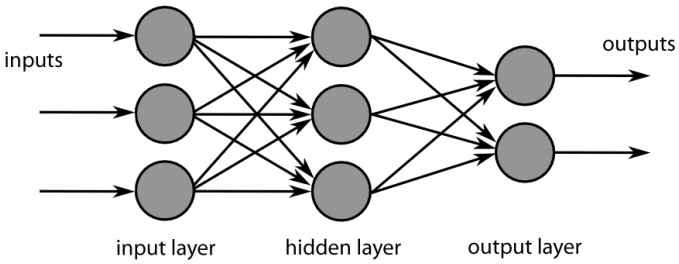

Fig.1 FFNN with single hidden layer

The circles in the above diagram stand in for individual neurons, while the lines joining them stand in for their connections. Three neurons form the input layer, the middle section of four neurons makes up the hidden layer, and the output layer is comprised of the two neurons.
The input layer receives the data as input, and the output is given to the hidden layer. The hidden layer in a feedforward neural network is significant as it extracts important features, enables non-linear mapping, processes information, facilitates generalization, and determines the network's capacity to learn and represent complex relationships. It acts as a feature extractor, transforming input data into abstract representations. The non-linear transformations in the hidden layer allow the network to capture complex patterns. It serves as a computational unit that processes information and helps the network generalize from training data to unseen examples. The number of neurons and layers in the hidden layer affects the network's capacity and expressiveness. The output is then created by the hidden layer by performing a linear combination of the inputs along with the application of an activation function, such as the sigmoid function. The output layer then receives this output and creates the network's final output.

Instead of a step function a single-layer neural network can compute a continuous output. The 'logistic function' is a well-liked choice.

$$f(x) = \frac{1}{1 + e^{-x}} \tag{12}$$

By making this decision, the single-layer network is changed into a model that is exactly like the logistic regression model, a popular statistical modeling technique. The logistic function is a member of a group of mathematical operations known as sigmoid functions because of the way their S-shaped graphs resemble the Greek letter Sigma in lowercase. Owing to the fact that the derivative of this function is continuous, it can be applied in backpropagation. An additional reason to choose

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:36:29 UTC from IEEE Xplore. Restrictions apply.

this function was that it is straightforward to calculate its derivative

$$f'(x) = f(x)(1 - f(x)) \tag{13}$$

VIII. Data

To ensure the accuracy and relevance of our research paper on the stock market, we obtained access to reliable stock prices and related information from the National Stock Exchange (NSE) website. We used the yfinance package to analyze data on the stocks of Sun Pharmaceutical Industries, Spice Jet, Jubilant Pharmova, ITC Ltd, HDFC, City Union Bank, AstraZeneca Pharma India Limited, Wockhardt Limited, Tata Motors Limited, and UltraTech Cement Limited. These companies represent a diverse range of industries and sectors. For instance, Sun Pharmaceutical Industries is a prominent Indian pharmaceutical company, while Spice Jet is a well-known Indian airline company. AstraZeneca Pharma India Limited is a multinational pharmaceutical firm with a focus on the discovery, production, and research of novel medications. A well-known public sector bank in India, City Union Bank provides a variety of financial goods and services. An Indian pharmaceutical company called Wockhardt Limited produces and sells a wide variety of medical supplies. Commercial and passenger cars are produced by the Indian multinational automobile manufacturer Tata Motors Limited. UltraTech Cement Limited is an Indian cement company that manufactures and markets various types of cement and building materials. By analyzing stock prices and other pertinent data, we aim to gain valuable insights into market trends and investor behavior. The collection of data from the NSE website via yfinance constitutes a critical step towards conducting a comprehensive and insightful research paper on the stock market.

IX. Methodology

We have followed a step-wise approach which begins with understanding our data set and what it is composed of. We first import consolidated CSV files separately containing the stock prices of the mentioned stocks for the period 17th March 2020 to 17th March 2023 from a database of NSE India using finance in the programming language Python. We further removed the columns that were unnecessary for our analysis. As the next step, we create a model to implement the Geometric Brownian motion and create visualizations to compare the results. Having done that, we choose a set of stocks with better returns as predicted by GBM for the creation of an optimized portfolio. We implement Feed Forward Neural Network with a single hidden layer using the programming language Python on the Google Colab platform. We import Stock price data of the selected stocks for the last 10 years to train the model. Further, to compare the returns, we implement visualizations.

X. Application of GBM Model

The Model for implementing the Geometric Brownian Motion has been created using Python as the Programming Language and executed on the platform Google Colab. The parameters used for the application of model are:

1) T - Total Time period for prediction
2) dt - Incremental time period between two consecutive closing prices,in our case it is 1 day
3) N - Number of time points in the prediction time horizon, N = T/dt
4) t - The time progression in our model is displayed in an array. We can measure time by counting the number of time points that have passed, just like on a time ticker.
5) μ - The average return of the stock prices over the historical period we are predicting.
6) σ - The returns from previous stock prices' standard deviation.
7) b - We introduce randomization to our model using an array. Contains a random number drawn from the normal distribution of the standard distribution for each relevant predicted time point. The random shocks will be added by these random numbers.
8) W - From the time point at the starting (So) to another time point, values of the stock will change according to the Brownian path.
9) S_o - The closing price of the beginning time point, in our case it is the Closing price of day 0

For analysis, we take the array of returns;

$$R_t = (S_t - S_{(t-1)})/S_{t-1} \tag{14}$$

R_t: Stock return at time t
S_t : the value of a stock at time t
$S_{(t-1)}$: Cost of a stock on the previous day (t–1)

Now, for calculation of μ and σ:
μ = mean of return of the stock prices
σ= standard deviation of return of stock prices
We calculated the expected rate of return (μ) and volatility(σ) using the 80% of data from 17/03/2020 to 17/03/2023 split into 80:20 ratio, and use it to forecast the stock movement for the remaining 20% of data.

$$drift = \mu - 1/2\sigma^2 t \tag{15}$$

We compare the stocks using mean return during the Forecast period.

XI. Outcomes of GBM Modelling

The simulation results of the Geometric Brownian Motion model for the Indian stocks suggest that the model can provide reasonable predictions of the future prices of these stocks in the Indian market. The model accurately captured the general trend of the stock prices over time and showed that the prices tend to fluctuate around the mean with a certain level of volatility, which is a common phenomenon in the Indian stock market.

These charts compare the Forecasted value vs the Actual value for these stocks: Here in the figure, the Blue Line represents the Forecasted values of the GBM model over time

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:36:29 UTC from IEEE Xplore. Restrictions apply.

and the orange line shows the actual fluctuation in the stock prices.

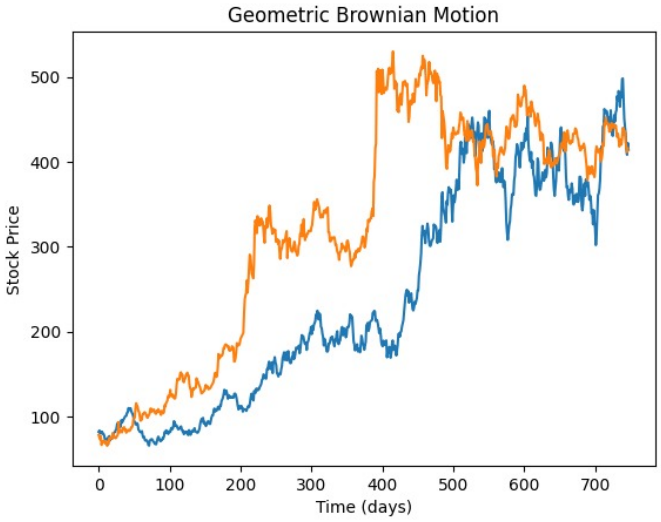

Fig.9 Tata Motors Stock price prediction

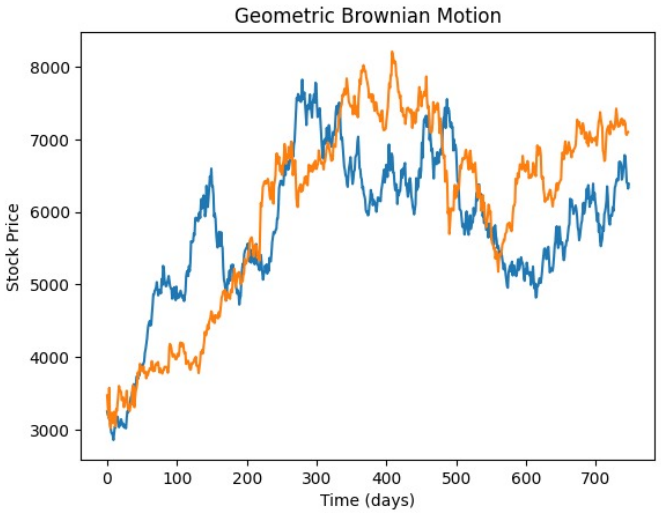

Fig.10 Ultratech Cements Stock price prediction

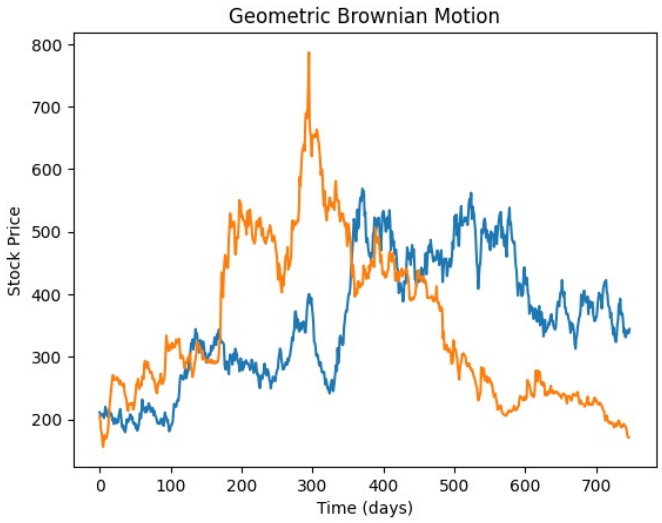

Fig.11 Wockhardt Ltd. Stock price prediction

We now compare the expected return on stocks through predicted values over a period of six months:

S No.	Stock	Return
1	SUNPHARMA	0.003378
2	City Union Bank	-0.001497
3	SPICEJET	0.002355
4	Astrazeneca	0.000542
5	Wockhardt	0.002105
6	Jubilant Pharmova	0.004663
7	TATA Motors	0.000608
8	ITC	0.001397
9	HDFC	0.000794
10	Ultratech Cements	0.001279

XII. Application of Feed Forward Neural Network

We start with selecting our data and then we calculate the daily returns. We define the inputs for the neural networks. We then split out the entire data into a ratio of 80:20 Then we create our training and testing data. After defining the structure of our model we start training the model. We use mean square error as a validation method to notably find out the loss and the error.

XIII. Outcomes of Portfolio Optimization using Feed Forward Neural Network

We trained the model using a large data set of historical stock market data and observed that the training loss consistently decreased during the initial training period. However, after the 20th epoch, the training loss reduction rate slowed down significantly, indicating that the model had reached a certain level of optimization.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:36:29 UTC from IEEE Xplore. Restrictions apply.

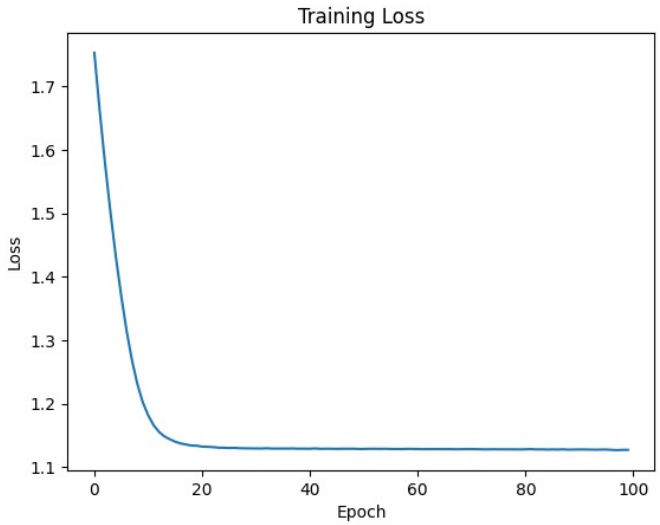

Fig.12 Training Loss

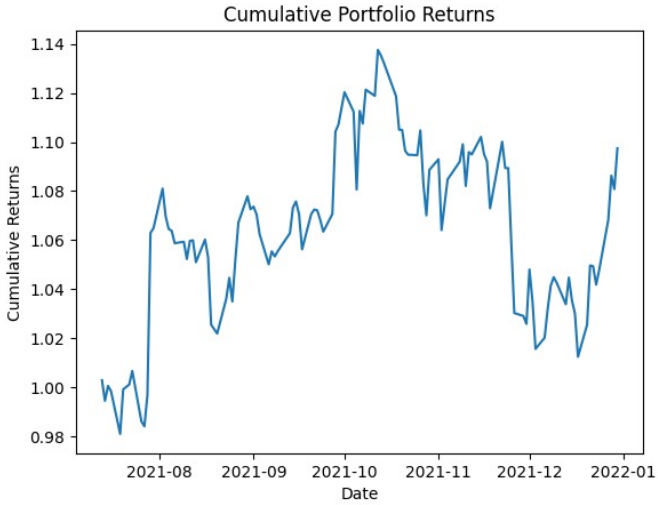

Fig.13 Cumulative Portfolio Returns

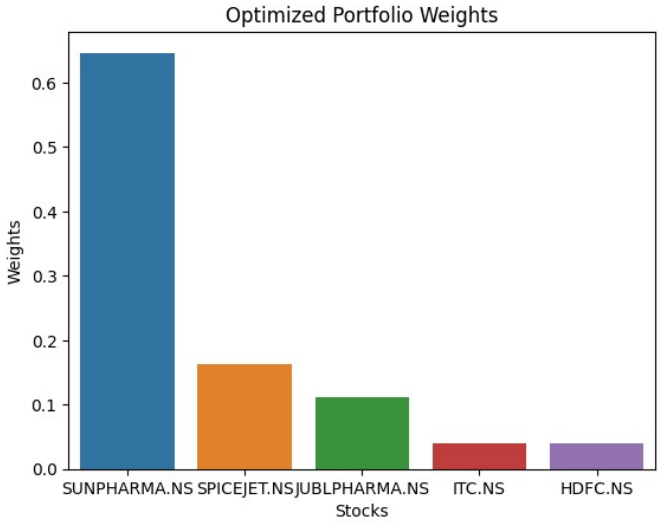
Optimized portfolio Weights as calculated using Feed Forward Neural Network with a single hidden Layer after training the model is:



Optimized Portfolio Weights

S No.	Stock	Optimized Weight
1	SUNPHARMA	0.6283615
2	SPICEJET	0.17370817
3	JUBILPHARMA	0.11454658
4	ITC	0.04296229
5	HDFC	0.04042152

XIV. Conclusion and Future Work

The model performs well only when the following conditions pertaining to the stock prices are satisfied:

- The businesses are still operating, and their stock prices are stable over time and in terms of value.
- Because stocks show the pattern of a Markov process, it is only possible to predict future prices using the current stock price.
- A stock's proportional return has a log-normal distribution.
- A stock's continually compounding return is typically distributed.
- The presence of such mathematical constraints limits the application and generalization of the GBM model in the actual Stock investment and/or trade analysis.

Through our analysis we can conclude if the above conditions are met, then the GBM model for stock simulation can be used to predict the future prices of the selected Stock.
However, the model also had some limitations in accurately predicting the exact prices of the stocks, particularly during periods of high volatility. Overall, the results of this study suggest that the GBM model can be a useful tool for predicting the future prices of Indian stocks in the Indian market, but it should be used in conjunction with other forecasting techniques for more accurate predictions.

In addition to the findings discussed above, our study also employed a portfolio optimization technique using a feed-forward neural network on the five stocks selected out of the ten. The results showed that the neural network approach

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:36:29 UTC from IEEE Xplore. Restrictions apply.

outperformed the GBM model in predicting future stock prices and generating maximum returns on investment. Furthermore, the portfolio optimization technique allowed us to identify the best possible combination of stocks to invest in for maximizing returns. Therefore, our study suggests that a combination of the GBM model and portfolio optimization techniques, such as neural networks, can be a powerful tool for Stock Trading or Swing trades.

Abstract Yamuna River Delhi stretch is a leading source of water supply to Delhi. The river stretch is a receptacle of urban liquid waste of human interference from domestic and industrial fields and conduces to the most contaminant reach of the country. The present study used multivariate techniques to represent the spatiotemporal water quality variations and interpreted a large hourly complex dataset (March 2021–February 2022) obtained from two real-time monitoring stations situated upstream and downstream of this reach. Eleven water quality parameters were assessed, and Box Whisker plots were drawn monthly basis. The increased concentrations of conductivity, BOD, COD, TOC, NH4, and low DO downstream indicated the influence of outfalling drains and diffused sources contributing pollutants into the river stretch. A higher BOD, COD, and TOC concentration was observed downstream in monsoon attributed to the organic substance in surface runoff. FA and PCA were implemented in the standardized data set to reveal the correlation between the water parameter. For upstream, turbidity, TOC, COD, and TSS have strongly positively loaded for factor 1 for all the seasons except monsoon. For downstream. TOC and COD contributed strongly positive load except in winter. The study reveals that the urban river flows with agricultural and surface runoff: industrial and domestic wastewater with organic and inorganic substances. This present study is a novel approach to assessing spatial and temporal variation of an urban reach for the current geomorphological conditions with real-time data.

Keywords Water quality variations · Urban river reach · Box Whisker plot · Principal component analysis · Factor analysis

1 Introduction

Rivers are the most sensitive natural resources as they carry domestic, industrial, and agricultural runoff from the large watershed (Zhang et al., 2009). The river conditions rely on natural and anthropogenic activities such as precipitation, erosion, municipal waste, land use pattern, urbanization, industrialization, agricultural flow, and mining (Yilma et al., 2019). The combined effect of these activities deteriorates the surface water bodies, which need (Wang et al., 2013) appropriate management options. Vegetation, topography, geological characteristics of the

catchment area, seasonal variation of the precipitation levels, surface runoff, ground surface interaction, interception, and abstraction promote the water quality parameter of a water body (Avtar et al., 2013). The spatiotemporal assessment of river water quality requires regular and continuous monitoring programs to estimate and maintain (Singh et al., 2004). This monitoring leads to the creation of vast and complex data matrices composed of many physicochemical constituents, which are challenging to interpret and conclude (Bonansea et al., 2018; Singh et al., 2004). A reliable river quality assessment framework is required to minimize the impacts of pollutants and protect a river's ecological health and sustainable expansion (Arora & Keshari, 2021). Nowadays, principal component analysis (PCA), and factor analysis (FA), are widely accustomed to assess river characteristics by simplifying complex data and removing spare information, and keeping valuable information (Bonansea et al., 2018).

Multivariate statistical techniques create a matrix from acquired data to assess relation, likeness, and unlikeness (Singh et al., 2004) among the constituents and their origin (Achieng et al., 2017). The PCA and CA (Cluster Analysis) help to distinguish potential pollutant sources affecting water resources and provide a unique understanding of the relationship between different pollutants (Singh et al., 2020; Wang et al., 2013). These methods are essential to verifying spatiotemporal variation generated by various natural and manmade factors (Shrestha & Kazama, 2007; Vega et al., 1998). PCA/FA is used to assess river quality, identify pollutant sources, and as a tool for water resource management (Atakoglu & Yalcin, 2022; Dehghanzadeh et al., 2015). PCA reduces the dimensionality of factors and keeps all related information of corresponding constituents (Singh et al., 2004). Achieng et al. (2017) deployed multivariate statistics to interpret the seasonal variation of the Sosiani River, Kenya, and evaluated the effects of anthropogenic activities. FA explained the specific contamination sources in the Karstic region (Calijuri et al., 2012). The hydrogeochemical influences and anthropogenic activities on groundwater were assessed for the Ken-Betwa River (Avtar et al., 2013). Setia et al. (2021) investigated the Sutlej River water quality and concluded the presence of ions in transboundary regions with the help of multivariate techniques PCA/FA and CA successfully evaluated the spatial variations in river quality and identified hidden contributors of contaminants in the Songhua River (Wang et al., 2013). Bu et al. (2010) applied multivariate statistics to appraise the Jinshui River quality in China and classified the sites with 22 variables into three clusters. They extricated five factors revealing 90.01% of the total variance by identifying the sources for watershed management. A case study of the Nakdong River, Korea, with multivariate tools, revealed that manmade activities controlled the river quality (Venkatramanan et al., 2014). Singh et al. (2020) examined the relationship between physicochemical variables with pollution index and PCA to assess pollutant sources suggesting management procedures for Kali River, India. PCA/FA, DA (discriminant analysis), and multiple regression analysis are used to reduce complex data sets and identify the factors and sources of pollutants for the high-low flow conditions of the Melen River, Turkey (Koklu et al., 2010). Githaiga et al. (2021) applied water pollution evaluation indices to assess heavy metals' water quality, concentration, and health risks. They also used PCA and CA to deduce the sources of these metals. PCA and CA were used no and locations of monitoring stations for the Lis River (Vieira et al., 2012). Bonansea et al. (2018) estimated the reservoir water quality for eleven sampling sites of two reservoirs in Argentina. In contrast, cluster analysis grouped samples into three clusters, and PCA/FA shows the existence of five. PCA explained the groundwater quality of Guwahati City of Assam and determined that rock weathering is the primary factor for the pollution of groundwater (Hinge et al., 2022). Artificial activities were established by using PCA and Pearson's correlation for the Marreco River (Priya & Arulraj, 2011).

The present study applied PCA, FA, and Box Whisker plots for analyzing the real-time dataset of the urban reach of the Yamuna River, Delhi, India. This stretch has been turned into a sewage drain due to tremendous anthropogenic pressure aggravating the pollution load (Upadhyay et al., 2011). The stretch between Wazirabad to Okhla gets massive pollutant input from eighteen major drains comprising domestic sewage and industrial effluent from different clusters of Delhi (CPCB, 2012). Khullar and Singh (2022) assessed water quality with a deep learning method for the Palla, which is upstream of the Delhi reach, Arora and Keshari (2021) used a pattern recognition method to assess the river stretch

with the five years data for the year 2006–2010 for seven parameters. Sharma and Kansal (2011) evaluated the water quality index for the monthly data of 1999–2009 for BOD (Biochemical Oxygen demand) and DO (Dissolved Oxygen). The objectives of the present study were to evaluate the spatiotemporal variations of eleven physiochemical water quality parameters from the large one-year hourly datasets (March 2021–February 2022) for the upstream and downstream of the Yamuna River Delhi stretch. The study revealed the hidden factors describing the large data sets and impacts of probable water pollutant sources. The present study assessed the variation of water quality parameters for current geomorphological and meteorological conditions to administrate a sustainable water quality management commencement. This study is a novel approach to assessing spatial and temporal variation upstream and downstream of an urban reach for real-time data sets.

2 Materials and Methodology

2.1 Study Area

Originating from Yamunotri, located at the coordinates 31° 01′ N and 78° 46′ E (CPCB, 2006), Yamuna River, the lengthiest tributary of the Ganges, travels 1376 km and joins the Ganga River at PrayagRaj. Before entering Delhi, it covers 348 km from its origin. The Yamuna River enters Delhi 1.5 km upstream of Palla village, travels 48 km to reach Okhla, and leaves at Jaitpur downstream of Okhla village(Upadhyay et al., 2011). The urban reach of the Yamuna, Delhi, is located between Wazirabad (28°49′24.39″N and 28°31′50.99″ N) and Okhla (77°13′39.92″ E and 77°20′36.8″ E), flowing 22 km long (CPCB, 2006). Figure 1(a) shows the Delhi reach of the Yamuna River from Wazirabad (ST1) to Okhla (ST2), which receives untreated and partially treated wastewater from 16 main drains shown in Fig. 1(b) carrying domestic sewage and industrial effluents. One of the largest drains, Shadra Drain, outfalls downstream of the Okhla barrage (CPCB, 2012), is excluded from this study. The reach from Palla to Wazirabad, for the considerable flow, the water contains adequate DO and low BOD (Arora & Keshari, 2021). After Wazirabad, scarce fresh water is available due to the water abstraction at Wazirabad for the water supply of Delhi. The outfalling drains generate 3393 MLD of wastewater with 229 TPD BOD loads per day (CPCB, 2012). Low flow and outfalling wastewater with high organic and nutrient loads cause the river conditions to degrade (Mandal et al., 2010). The wastewater from Hindon also disposes of upstream of Okhla (Arora & Keshari, 2021). Delhi is in a subtropical zone with the highest temperature of around 45 ºC and an average temperature of 32ºC. During winter lowest temperature is 2ºC, and the average is 12ºC. Monsoon approaches late June and ends in mid-September. For Delhi, rainfall is highest (234 mm) in August and contributes 32% of annual rainfall (715 mm) (Rana et al., 2012). Hence, dilution is higher during the monsoon period. The data were collected from two Real-Time Water Quality Monitoring Stations (RTWQMS) of the Delhi Pollution Control Committee (DPCC) upstream of the Wazirabad (ST1) barrage and upstream of the Okhla (ST2) barrage.

2.2 Data Used and Methodology

The present study collected data from the Real-Time Water Quality Monitoring Stations (RTWQMS) of the Delhi Pollution Control Committee (DPCC) at Wazirabad and Okhla. These RTQWMSs use S::CAN water monitoring technologies. UV Spectro::lyser is used to determine TSS (total suspended solids), turbidity, BOD (biochemical oxygen demand), COD (chemical oxygen demand), TOC (total organic carbon), and NO3-N (nitrate-nitrogen). Ammino::lyser Eco is used to measure Ammonia. pH::lyser is used to monitor pH and Temperature. The data has been collected from ST1 (Wazirabad) (6085 hourly observations) and ST2 (Okhla) (25,540 no observations at 15-min intervals). The observation period was March 2021 to February 2022 with current geomorphological conditions. The parameters analyzed were DO, BOD, COD, pH, water temperature, conductivity, turbidity, ammonium-nitrogen (NH4), nitrate nitrogen (NH3), total suspended solids (TSS), and total organic carbon (TOC). Hourly data had been used for multivariate analysis and extracted valuable information. Collected data were subdivided monthly to evaluate the average monthly water quality variations by Box Whisker plots. For PCA/FA, complex datasets were divided into four subdivisions – summer, monsoon, post-monsoon, and winter. Box Whisker plots

(b)

Fig. 1 **(a** & **b)** Yamuna River at Delhi with a line diagram showing monitoring stations (ST1 and ST2) and a line diagram showing respective drain positions (Source: DPCC)

were used to interpret the temporal and spatial variation in 11 parameters. Significant parameters have introduced a classification for further assessment. The data sets were subdivided monthly basis, and Box Whisker plots were drawn for each parameter and both stations to interpret the spatiotemporal variations of parameters, which are shown in Figs. 2 and 3.

The PCA is a data-minimizing method (Singh et al., 2020). It gives details of the most crucial constituents explaining the variability of data sets (Singh et al., 2004). PCA reshapes the indigenous variables into a lower set (Vega et al., 1998) and can be expressed as (Bu et al., 2010)

$$z_{ij} = a_{i1}x_{1j} + a_{i2}x_{2j} + \cdots + a_{im}x_{mj} \quad (1)$$

where z and a are component score and loading, respectively, x = observed variables quantity. i = constituent no, j = sample no, m = total no of variables. FA was computed using varimax rotation generating factors. PCA is included in FA, and FA is dominating tool to lower the dimensionality of the data matrix with a high no of related variables (Singh et al., 2004). The PCs are extracted from the cross-product data matrix and help to explain the disintegration of multiple parameters by obtaining eigenvalues and eigenvectors. Varifactors or factors obtained after rotating Varimax rotation distributes Principal components (PCs) loading by maximizing the dispersion and minimizing the number of co-efficient. This tool extracts latent information and discriminates parameters with a large load. The PCs are used for varimax rotation and generate varifactors (VFs), including hypothetical, latent, and unobservable values, to gather the details (Helena et al., 2000). FA simplifies the data structure coming from PCs and decreases the contribution of low-significant observations (Bu et al., 2010).

$$z_{ij} = a_{f1}f_{i1} + a_{f2}f_{i2} + \cdots + a_{fm}f_{mi} + e_{fi} \quad (2)$$

where z = observed variables, a and e are factor loading and score, e = residual term associated with error and other variations, i = sample no, m = no of factor.

For PCA/FA, water quality datasets were arranged into four main seasons: Summer, monsoon, post-monsoon, and winter. The data were standardized to classify correctly for the higher difference in data dimension (Liu et al., 2003). Standardization makes variables dimensionless to enhance their influence with different variances by eliminating the different measurement units (Singh et al., 2004). PCA was applied, and the variance, covariance, loading, and score were calculated. All the computations were performed using Excle2019, SPSS 20.0, and Origin Pro-2022.

3 Results

The water quality data for 11 parameters were collected from March 2021 to February 2022. For ST1, the dataset for May was not available. Tables 1 and 2 show the mean values of eleven water quality parameters on monthly basis Data were analyzed for spatial and temporal variations, and Box Whisker plots are shown in Figs. 2 and 3. For ST1, the mean DO varied between 4.64 and 12.8 mg/l. Whereas for ST2, it varied from 1.62 to 5.43 mg/l. BOD varied from (1.37 ± 1.34) mg/l to (6.65 ± 0.8) mg/l for ST1. A higher value was observed during the monsoon (July). Whereas for ST2, BOD was varied from (7.24 ± 6.75) mg/l to (25.98 ± 13.9) mg/l. During the monsoon, high BOD might be caused for the decaying of organic substances and vegetation in the river water from surface runoff (Gadhia et al., 2013). COD observed (8.15 ± 3.5) mg/l in August and (64.09 ± 88.7) mg/l in April at Wazirabad (ST1). At Okhla (ST2), COD fluctuated from (52.13 ± 6.1) mg/l to (158.02 ± 219.9) mg/l. The conductivity varied from (351.35 ± 99.47) µS/cm to (1181.92 ± 197.48) µS/cm at ST1, whereas the parameter varied from (548.55 ± 34.7) µS/cm to (1575.71 ± 234.65) µS/cm at ST2. The values for pH were found within the range for both stations. For ST1 mean pH varied from (7.22 ± 0.44) s.u. to (7.99 ± 0.5) s.u., and for ST2, pH varied from (6.0949 ± 0.3971) s.u. to (7.97 ± 0.2926) s.u. The median pH is around 7.5 t0 8, describing the river outfalls with wastewater-neutralizing water (Arora & Keshari, 2021). The mean temperature of river water was from (13.99 ± 1.1)°C to (33.9 ± 0.58)°C and (15.23 ± 0.96)°C to (30.06 ± 1.05)°C for ST1 and ST2, respectively. A high mean turbidity concentration was observed in monsoon (733.88 ± 489.4) NTU at ST1 and (239.85 ± 26.43) NTU in winter at ST2. NH4 varied from 0.02 to 1.2 mg/l for ST1, whereas 8.39 to 59.11 mg/l for ST2. Turbidity varied from 10.38 to 733.88 NTU for ST1. PCA/ FA is shown in Figs. 4,

5, and 6. Factors and their variances are shown in Tables 3, 4, 5, and 6. At ST1, DO concentration was high in December (12.84 ± 2.96) mg/l. At ST2, DO was found high in September (4.98 ± 4.47) mg/l.

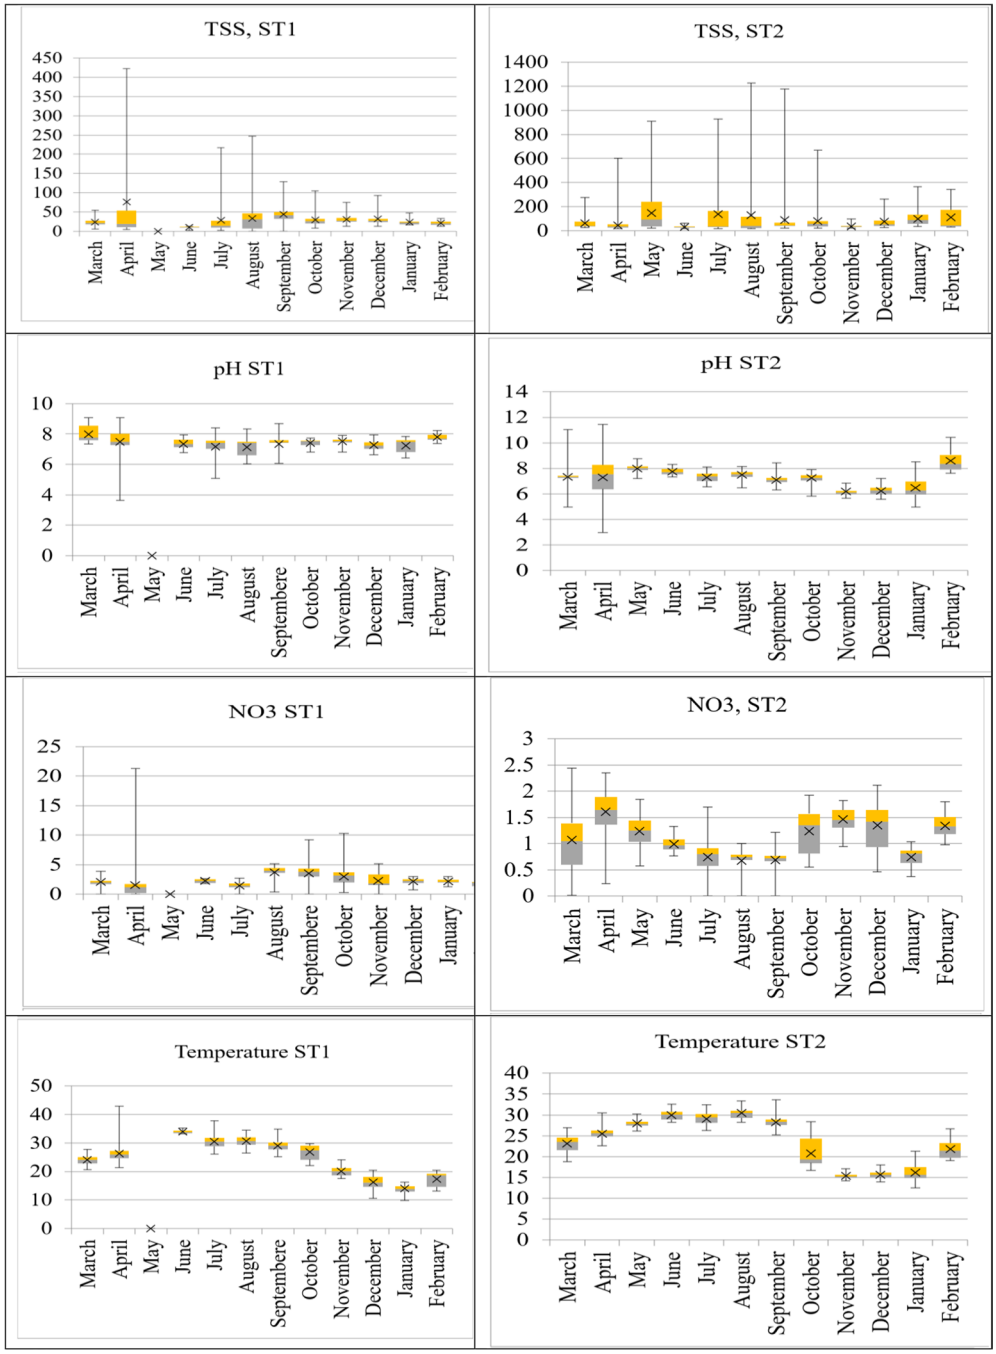

Fig. 3 Box Whisker plots for spatial/temporal variations such as TSS, NH_4, NO_3, and TOC are in mg/l, pH (s.u.), temperature (°C), and turbidity (NTU)

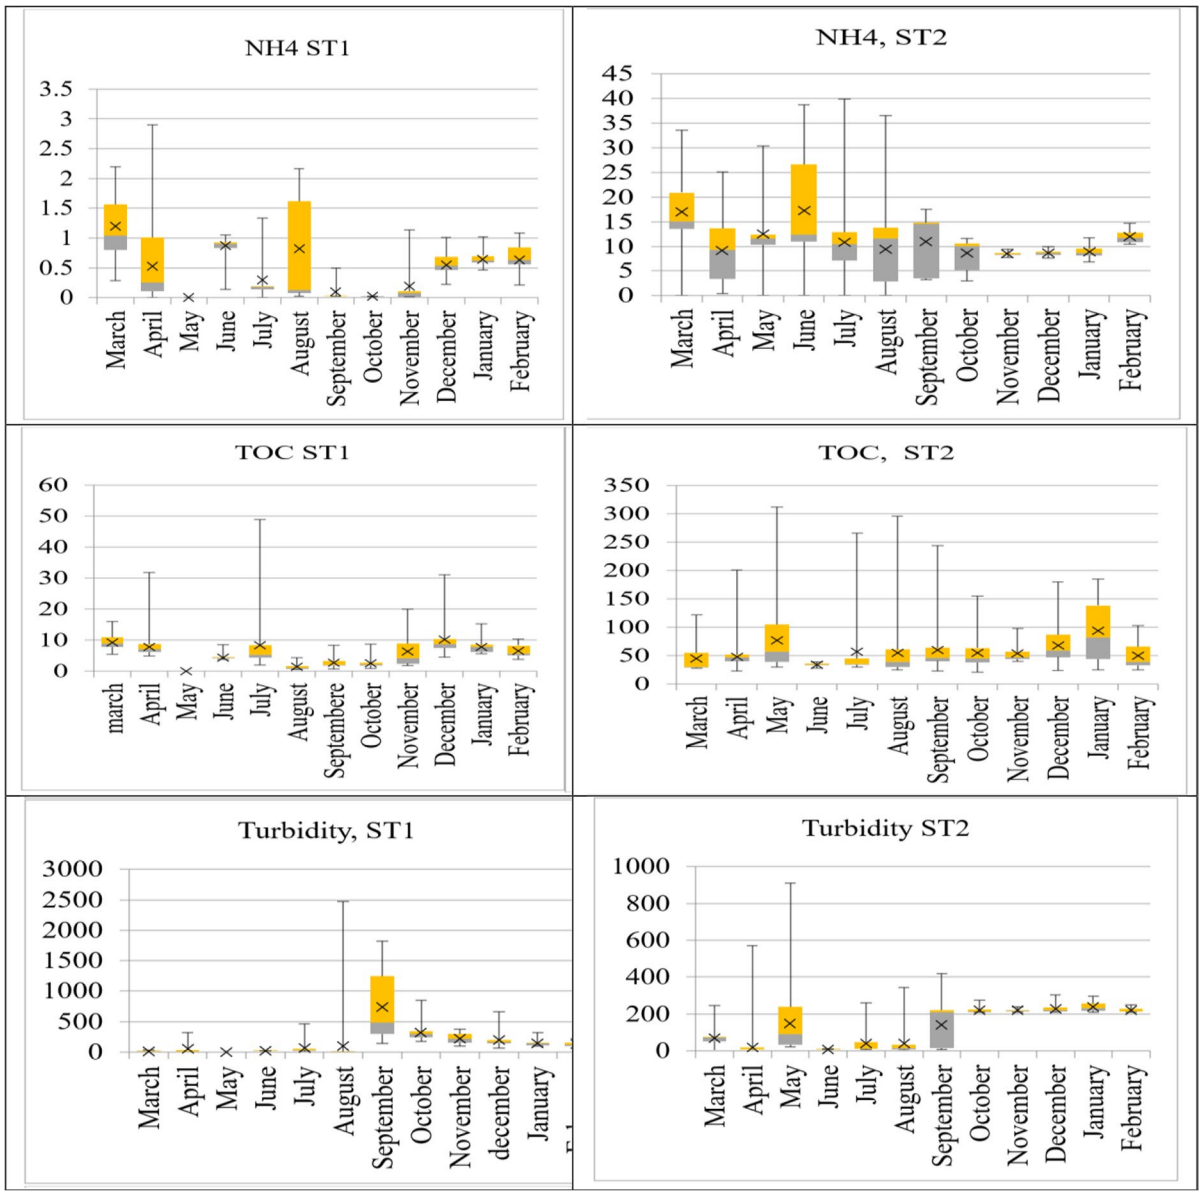

Fig. 3 (continued)

Maximum COD found during monsoon (Fig. 2). TSS is measured in fine clay, silt, microorganisms like plankton, and organic and inorganic substances. TSS value was high in lean summer flow (76.95 ± 1) mg/l and (147.5 ± 138.6) mg/l for ST1 and ST2, respectively.

For ST1, in summer, four PCs with eigenvalues > 1 explain about 84% of the whole variance in the data. The first PC counted 41% of the combined variance and appeared in positive correspondence with COD, turbidity, TSS, and TOC. The second PC that contained 22.3% of the aggregated variance and positive loading were conductivity, NO3, pH, and DO. Factor 3 had a strong negative relation with temperature. BOD had moderate loading in factor 2. For ST2, summer season, PCs were four with 80% of the aggregated variance, and PC1 had 35% of the variance. Factors were determined, and factor 1 was strongly correlated with TOC, COD, and TSS. Factor

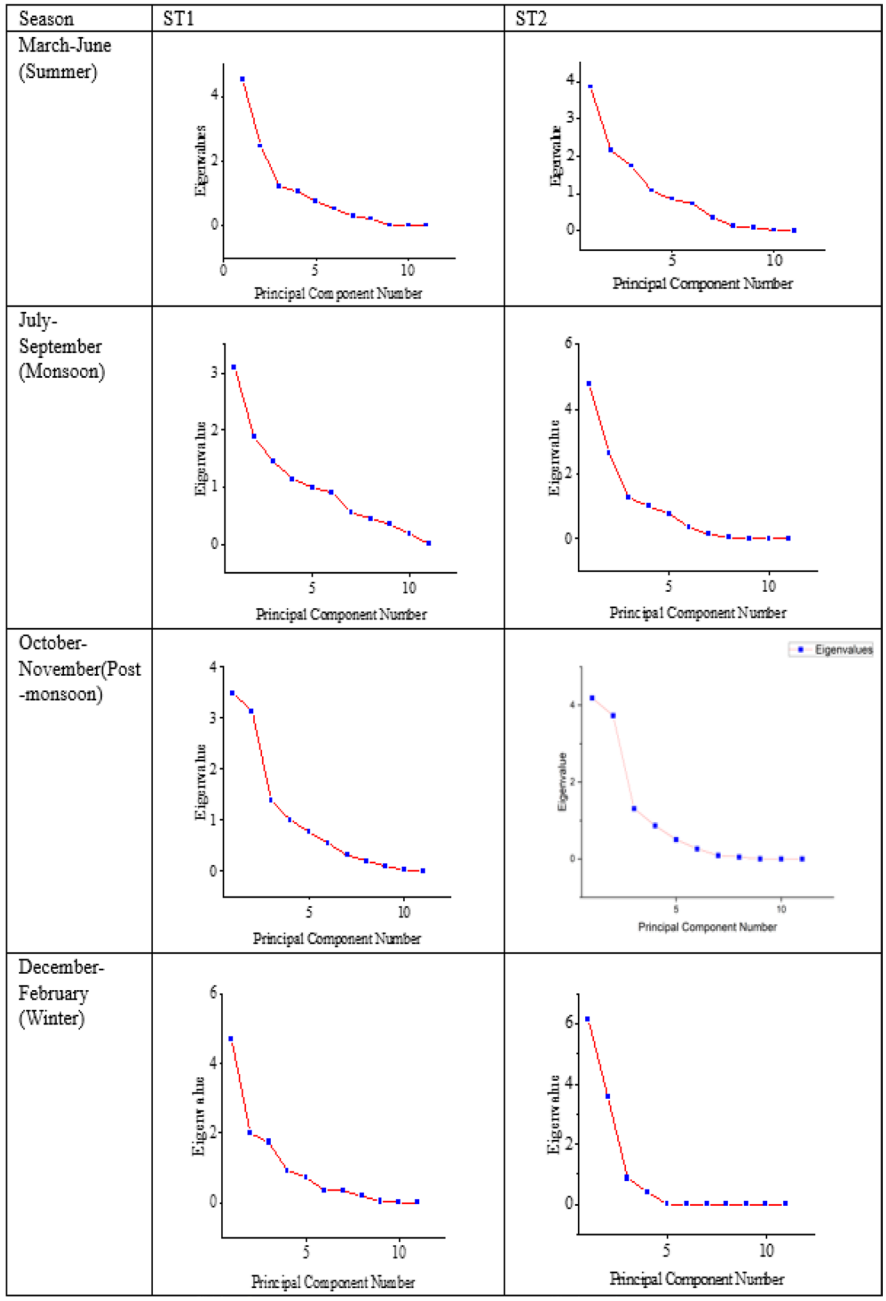

Fig. 4 Scree plots for determining principal components of four seasons

2, factor 3, and factor 4 were correlated with conductivity, NH4, and NO3, respectively. Factor 3 was strongly negatively related to pH. For monsoon, PCs were 4 for the ST1 with a variance of 68%, with PC1 28.2% variance. TOC, COD, and TSS were strongly correlated with PC1. Factor 1 was strongly related to TOC and COD, moderate loading with TSS, and very low negative turbidity loading. For ST2, 3 PCs were obtained for the monsoon period with a 78.8% whole variance. For monsoon, TOC and COD were strongly related to factor 1 at ST1. For factor 2 and factor 3 NH4 and turbidity were strongly related. At ST2, for factor 1 TSS, COD, and TOC were positively related while NO3 was negatively strongly related. For factor 2, pH, conductivity, and temperature were strongly related and for factor 3, BOD was strongly related.

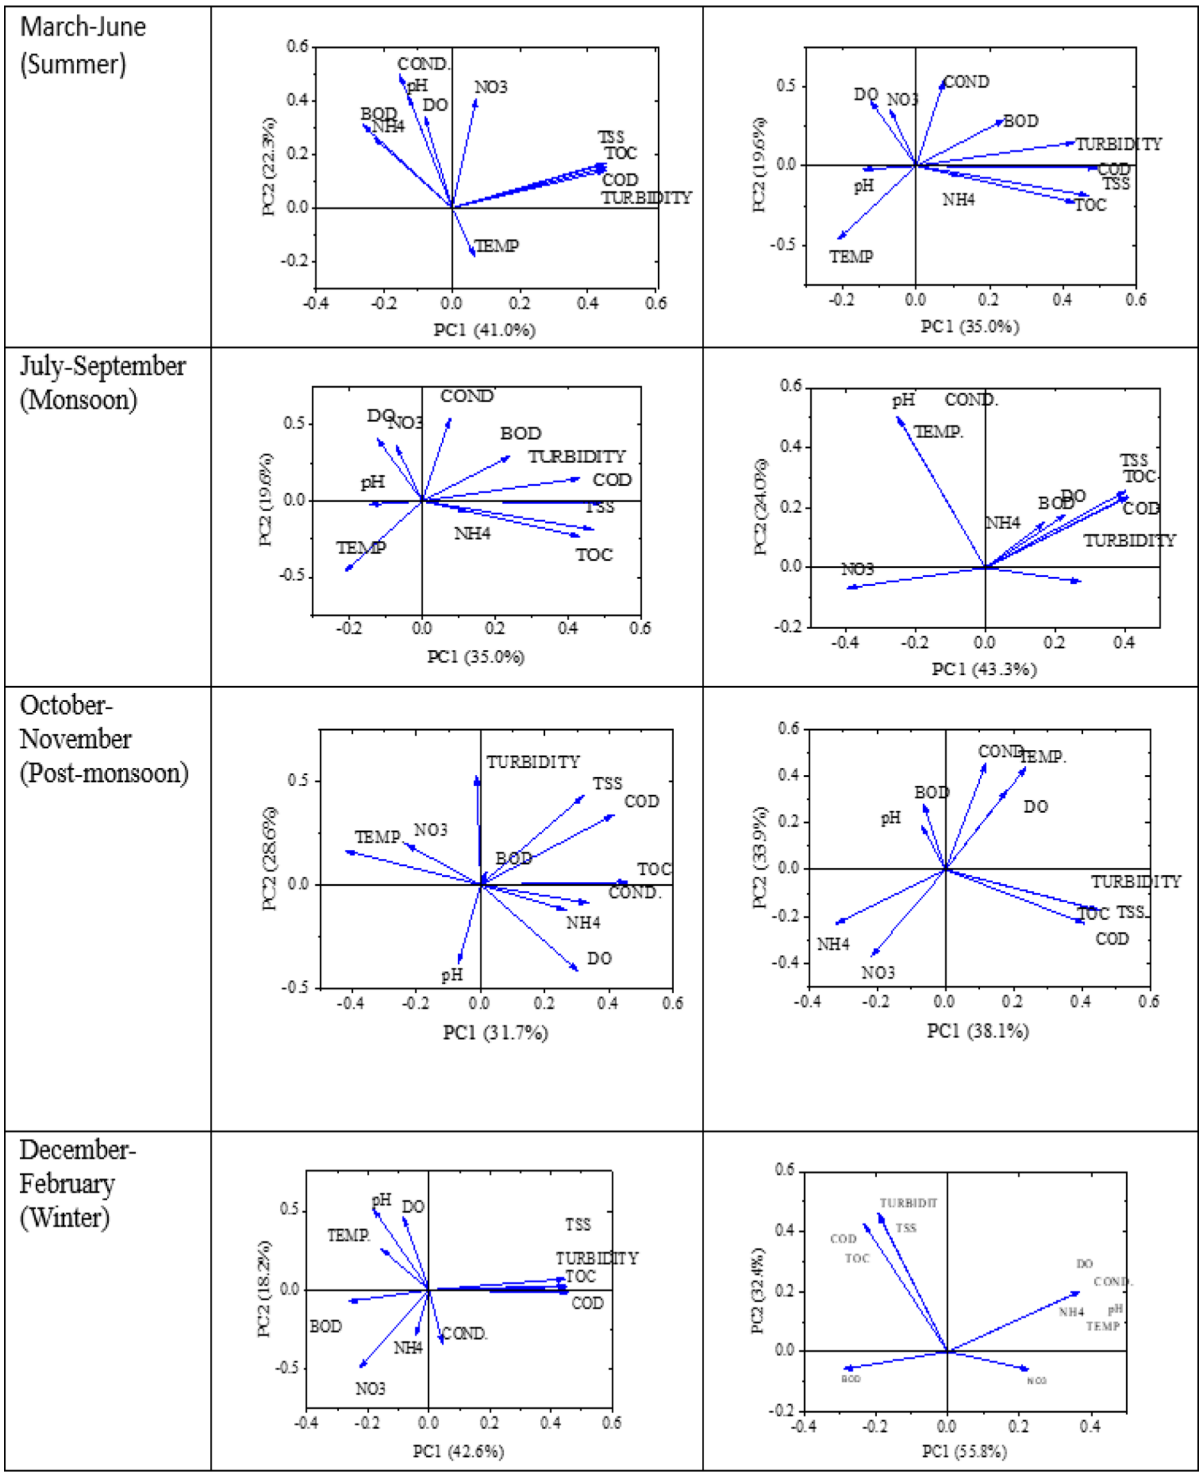

Fig. 5 Loading diagram for principal components (PCs)

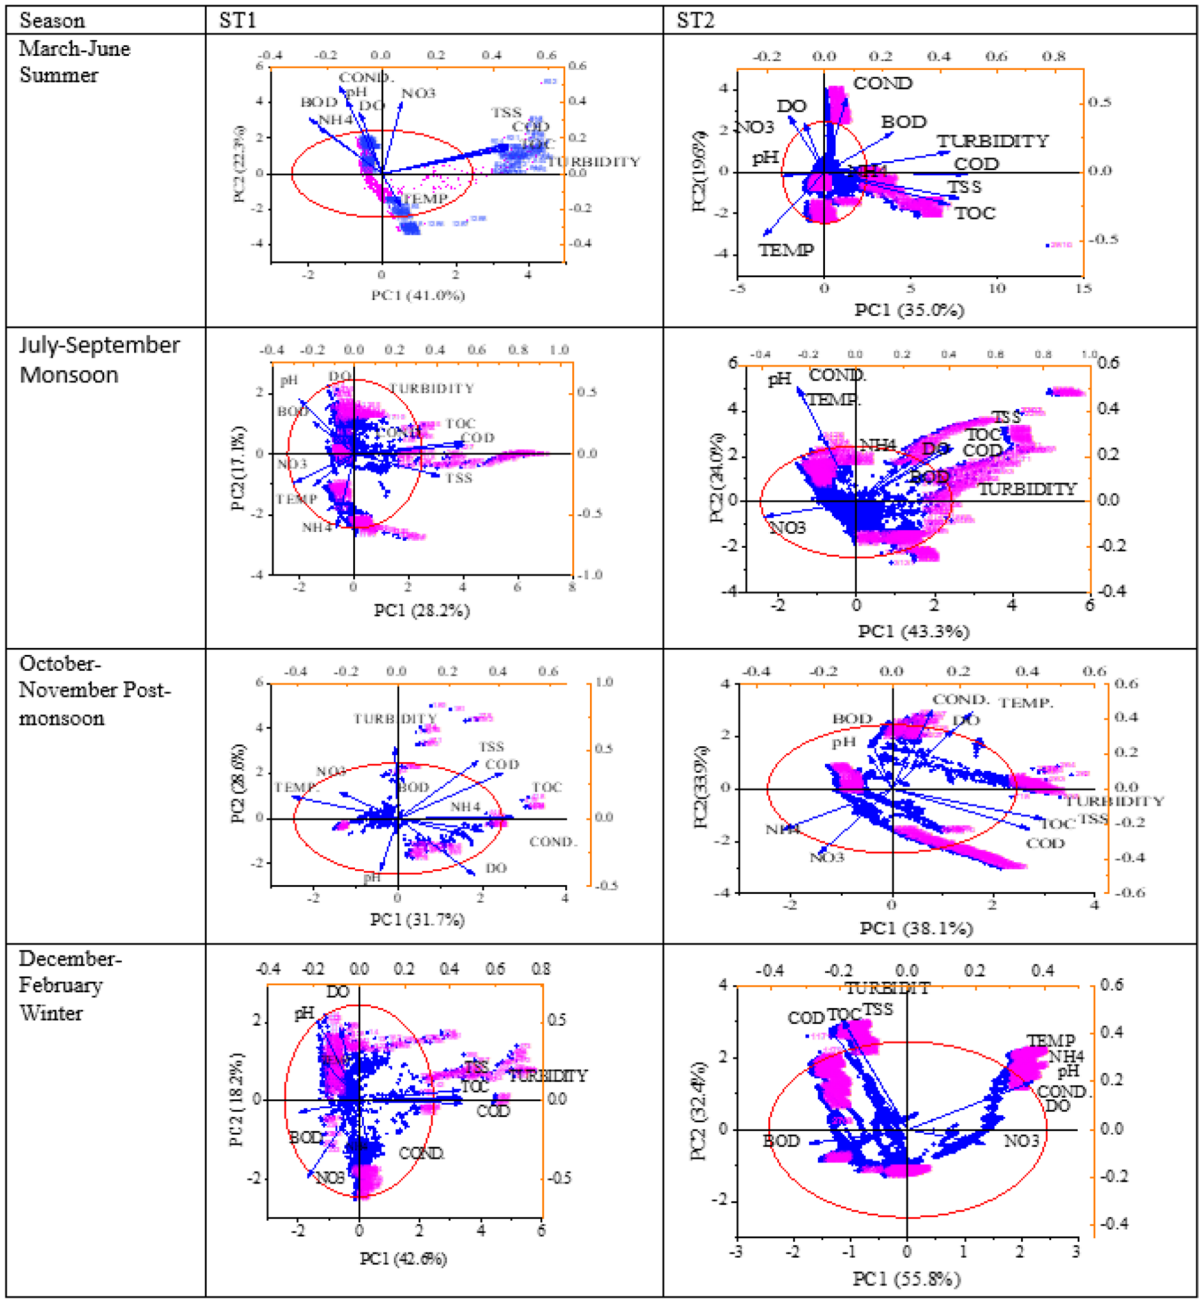

Fig. 6 Biplot for principal components (PCs)

For post-monsoon, ST1 had four PCS with a total variance of 82%. Factor 1 was positively related to Turbidity, COD, and TSS. Factor 2 was strongly positively related to conductivity and moderately related to NH4. Factor 3 was strongly negatively related to NO3 and factor 4 was strongly positively related to BOD. AT ST2, factor 1 was strongly related to turbidity, TOC, COD, and TSS. Factor 2 was strongly related to conductivity and temperature while moderately related to DO. Whereas, factor 3 was strongly related to pH. For winter, at ST1, factor 1 had a positive strong correlation with turbidity, TOC, COD,

4 Discussions

The data assessment observed that DO concentration varied sharply among the two stations, revealing that substantial oxygen-consuming pollutants were discharged through the sixteen main drains (Fig. 1) (Mandal et al., 2010). At ST1, DO concentration was found high in December. It might be due to the water's low temperature and high inflow volume, as DO is inversely related to temperature (Water Science School, 2018). Whereas, at ST2, DO concentration was found high in September due to the integrated effect of high wind speed and freshwater mixing due to rainfall (Das et al., 1997). DO is an indicative parameter for the fitness of an aquatic ecosystem, the metabolism, and the respiration of aquatic organisms (Gadhia et al., 2013). At Wazirabad, the minimum DO was adequate to sustain lives. However, at the ST2, the minimum DO was observed as nil for most of the year (Arora & Keshari, 2021). High BOD and COD were observed during some periods of monsoon. The monsoon brought runoff from agricultural fields, raising the nutrient concentration (Gadhia et al., 2013). The high COD load is caused by surface runoff, indicating organic pollution caused by non-point sources. (Joseph and Srivastava (1993) concluded that higher BOD observed during the monsoon period indicated high demands of oxygen required for life process support. Clark, 1986, also stated that higher organic load experienced in monsoon caused higher BOD levels. Due to continuous rainfall, soil erosion and surface runoff with non-point pollutants are attributed to additional organic waste load in the river water and increased BOD level (Odokuma & Okpokwasili, 1997). The large value of BOD and COD indicated the presence of organic–inorganic chemicals (Arora & Keshari, 2021). Furthermore, it clearly stated the presence of high oxygen-demanding pollutants from both fixed and diffused sources. The chemical oxygen demand was high in the monsoon. Since BOD and COD are highly related, the causes for BOD and COD being high during the monsoon accounted for unchanged. Industrial effluents carried high COD resulting in high values of oxygen-demanding chemicals in river water (Gadhia et al., 2013). The summer season showed a higher conductivity range might occur due to the lower flow available in the river during summer (Gadhia et al., 2013). The conductivity value decreased during the monsoon at both stations. It might be a high volume of water from the upstream end due to rainfall. In the monsoon, river water gets diluted due to the increasing volume of water (Izonfuo & Bariweni, 2010). Higher values of TSS at ST2 indicated wastewater outfall with substances increasing TDS. During the monsoon, a low TSS value was observed for both points. TSS can be changed by changing the pH, which causes precipitated solutes and affects solubility (Gadhia et al., 2013). pH was observed higher in the summer and low in the monsoon. Variations in pH values are attributed to factors like dilution of water (Rajasegar, 2003), reduction of temperature, decaying of organic substances, and degradation of carbon dioxide (CO2) during photosynthesis through reduction of bicarbonate (Izonfuo & Bariweni, 2010). The higher conductivity, BOD, COD, and low DO express the outfalling point

sources and diffused sources contributing pollutants into the river stretch (Arora & Keshari, 2021). Two locations did not show significant temperature variation revealing the outfalling drains did not contribute to high-temperature wastewater (Arora & Keshari, 2021). Maximum turbidity was found in the pre-monsoon period (Fig. 3). Turbidity in water shows the presence of suspended matter like silts, clay, plankton, and other microorganisms, organic and inorganic substances. NO3 concentration was high during monsoon at ST1 and could be due to organic substances discharged from the surroundings (Das et al., 1997). NH4 level was low during the same period. The cause may be the oxidation of ammonia to nitrite and nitrate (Rajasegar, 2003). Figure 3 shows that the availability of sufficient flow due to rainfall reduces the ammonia concentration in river water (Arora & Keshari, 2021). A high variation of ammonia concentration was observed between the two locations, and it concluded that the river got discharged with a high volume of nutrient-rich wastewater. TOC concentration was low in the monsoon period due to sufficient flow and high in the summer season at Wazirabad. A higher concentration of TOC was observed at Okhla during the monsoon, attributed to the presence of the organic substance in surface runoff. For PCA/FA total dataset has been divided into four seasons for both locations: summer, monsoon, post-monsoon, and winter. The PCA reduces the dimension of data keeping information unchanged and identifying the eigenvector and eigenvalue (Arora & Keshari, 2021). Scree plots (Fig. 4) were used to determine the principal components for each dataset to perceive the data structure (Vega et al., 1998). The PCs were selected from scree plots with eigenvalues of more than one. Loadings of PCs and actual variables are shown in Fig. 5. The biplot provides correlation and impact of different parameters with PCs shown in Fig. 6 for multiple locations. A new set of factors were defined by rotating the PC's axis. New factors introduced involving primarily a subset of original variables without overlapping each other and independent groups shown in Fig. 7.

FA and PCA were used for the standardized data for correlating the structural designs of the water parameter and identifying the parameters with influence on factors. The first PC showed positive correspondence with COD, turbidity, TSS, and TOC for ST1. The factor loaded with TSS indicates that the runoff originated from a field of high solids and waste (Singh et al., 2004). The scree plot was used to select the no of PCs with an eigenvalue greater than 1 (Vega et al., 1998). FA further examined the values of PCs and identified the factors that participated more clearly. Liu et al. (2003) explained the factor loading as strong (>0.75), moderate ($0.75-0.50$), and weak ($0.50-0.30$), correlating to absolute loading. Four factors identified with 84% of the variance, TOC, Turbidity, COD, and TSS, were strong loading with factor 1. The excessive loading of these parameters might be due to low flow, erosive process, presence of microorganisms, and huge suspended organic and inorganic substances from upstream (Fan et al., 2010). NO_3 and conductivity were correlated with factor 2, and Factor 4 strongly correlated with DO and pH. The strong relationship between NO3 and conductivity might be due to high agricultural runoff (Ogwueleka, 2015). Factor 3 had a strong negative correlation with temperature. BOD had moderate loading in factor 2, indicating an excessive loading of dissolved organic matter added from urban runoff carrying nutrients with high oxygen demand (Pati et al., 2014). For ST2, summer season, PCs were four with 80% of the aggregated variance, and PC1 had 35% of the variance. Factor 1 strongly correlated with TOC, COD, and TSS. These factors loading indicated that domestic wastewater, industrial discharges, and agricultural runoff had strongly affected the water quality.

For monsoon, TOC, COD, and TSS were strongly related to PC1 at ST1. It revealed that compared to the summer season, in monsoon, sufficient water flow was available in the location, which reduced the turbidity and TSS. However, organic and inorganic substances with a high oxygen demand were attributed. Factor 2 and factor 3 were strongly loaded with NH4 and turbidity, respectively. Factor 4 was not strongly correlated with any variables, and moderate loading with BOD indicated the presence of moderate oxygen-demanding organic substances PC1 with 43.3% variability positively correlated with TSS, TOC, and COD, indicating domestic, industrial, and surface runoff with a high volume of organic and inorganic substances, microorganisms, and fine materials (Akbal et al., 2011).

For post-monsoon, ST1 had four PCs with 82% of the total variance. Factor 1 loading revealed low flow conditions with high turbidity, TSS, and COD. Whereas, factor 2 was strongly loaded with conductivity and moderate loading with NH_4. The reasons

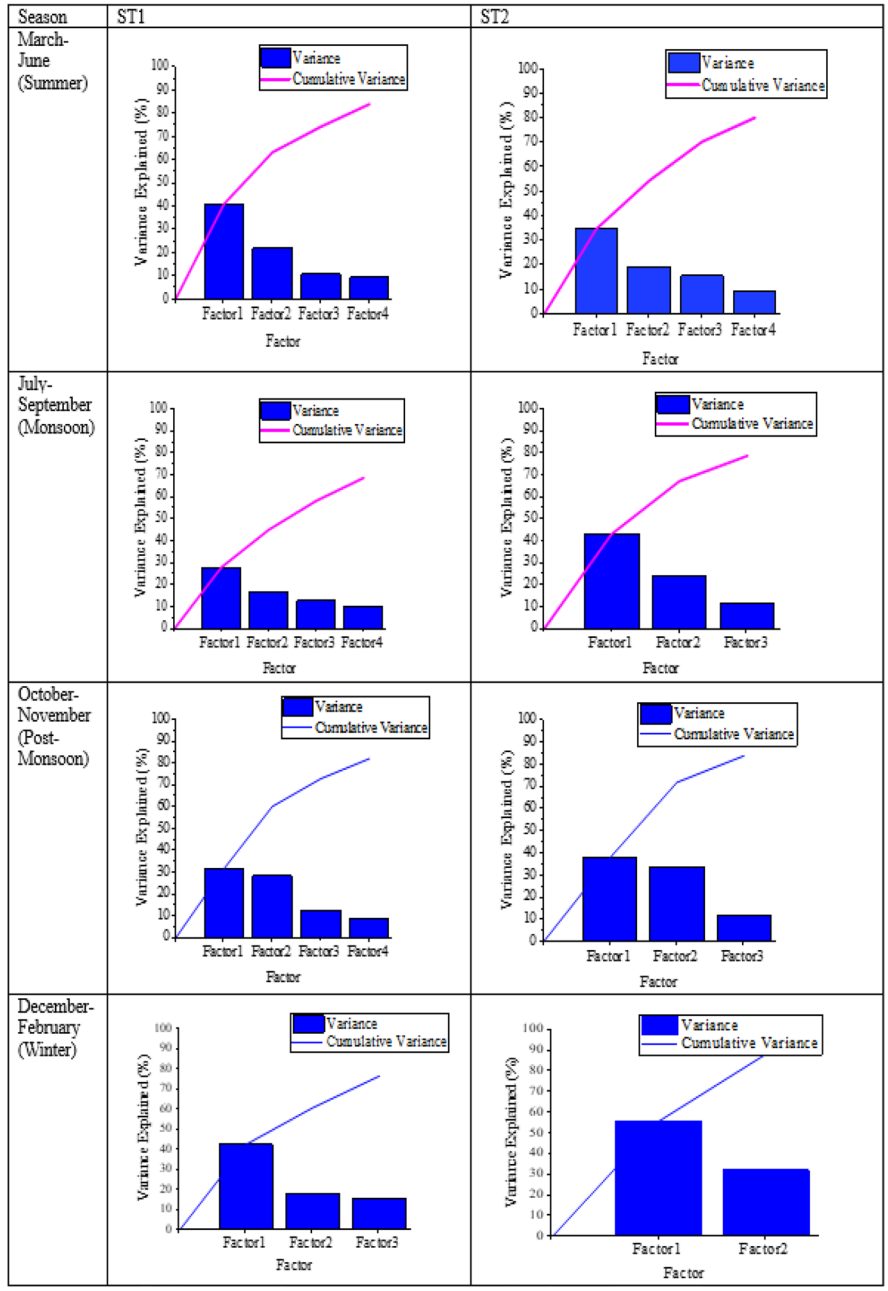

Fig. 7 Variances for factors

could be upstream flow with agricultural runoff with high nutrients, Factor 3 had strong negative loading of NO_3, and Factor 4 had strong positive loading of BOD. For ST2, three PCs with 83.9% variance and DO had strongly positive loading in factor 2. For winter, ST1. 76.5% of total variance with 46.2%variance in PC1. For ST2, PCs were two with 86.2% of the total variance, and PC1 had the 55% of the variance. For Factor 1, intense positive loading was Turbidity, TOC, COD, and TSS, indicating 55% of total variance with anthropogenic sources of pollution. Factor 2 showed a high positive relation with DO, temperature, and conductivity, explaining the physical characteristics of the river. This element illustrated that DO in water depends on temperature (Bu et al., 2010). However, significant loading of BOD and COD

revealed that partially treated and untreated wastewater discharged into the river contained pollutants.

In contrast, the strong loading of TKN and NH4 indicate the transfer of excess nutrient from industrial effluent and agricultural runoff (Singh et al., 2020). Negative loading of pH and DO also indicate contamination with industrial effluents forming anaerobic conditions with high pH and low oxygen. The wastewater carrying industrial effluent and domestic sewage is outfalling throughout the length between ST1 and ST2. The factor analysis of the Yamuna River reveals anthropogenic pollution sources and a high volume of organic and inorganic substances demanding a large amount of oxygen, hence undergoing an anaerobic fermentation process forming ammonia and other organic acids(Singh et al., 2004).

5 Conclusions

This study used PCA/FA and Box Whisker plots to predict seasonal variations of river quality parameters upstream and downstream of the Yamuna River Delhi stretch. The methods were used to reduce the data set and assisted in extracting and establishing the significant constituents/ sources accountable for the changeability of water quality parameters at two monitoring locations. The spatiotemporal variations revealed that the downstream water quality is severely poor throughout the year due to the point and diffused sources of pollution. Although there was sufficient flow in the monsoon, the water quality was not maintained to the standard due to surface runoff with excessive oxygen-demanding organic and inorganic substances. In contrast, upstream water quality is less polluted. However, high turbidity, COD, NO_3, and conductivity described the river flowing with nutrients, high microorganisms, and inorganic substances. The results obtained from factor analyses supported the box whisker plots. The principal component analysis was applied for four seasons to observe the correlation and variability among different parameters. The varifactors from factor analysis specified that upstream water is less polluted with organic substances than downstream water. Downstream water is polluted with organic and inorganic substances from drains (untreated/ partially treated domestic and industrial wastewater) and monsoon surface runoff with highly demanding oxygen substances. The study emphasizes that reducing pollutants from different sources can improve this river's reach and management of the ecosystem. Also, regular monitoring systems are required to sustain the aquatic ecosystem.

Acknowledgements The authors are thankful to Real-Time Water Quality Monitoring Stations at Wazirabad and Okhla, Delhi Pollution Control Committee for providing data. The authors are grateful to the reviewers for giving their valuable time and suggestions to improve the quality of the study.

Author Contribution NV has completed the research work under the supervision of GS and NA. The manuscript was written by NV and critically reviewed by GS and NA. All authors read and approved the manuscript.

Data Availability The dataset analyzed during the present study is available in RTWQMS, Delhi.

***Abstract*—Multimodal aspect-based sentiment recognition (MABSR) is a recently developed task in sentiment recognition that tries to assess the sentiment associated with text and image pairings by generally extracting the polarity terms from the pairs. Both the pipeline and the unified transformer based technique, which employs the cross-attention only mechanism, have been widely utilized in recent works. However, the alignment between text and picture is not openly and reliably included in these approaches. There is still a minimum threshold of aligned image-text pairings needed for supervised fine-tuning of said universal transformers for MABSR. Motivated by this observation and inspired by the various attention-only mechanisms, we analyze MABSR and propose an attention-free encoder-based transformer architecture. Dual attention-free based backbone encoder models with cross-modal symmetry are utilized in this work. To improve cross-modal performance, we include two new subtasks: aspect-only extraction and polarity feature representation alignment. This motivates both encoders to provide more precise depictions of multiple modalities.**

Keywords—Multimodal Aspect Based Sentiment Recognition (MABSR), Multi-task learning, Attention-free encoders, Cross-Modal Fusion.

I. INTRODUCTION

Multimodal aspect-based sentiment recognition (MABSR) refers to the analysis of sentiments along with the extraction of the aspect terms within multiple modalities. Our immersive awareness allows us to see the environment in many different ways, including via sight, sound, touch, and taste. In most cases, one aspect of a multimodal experience will correlate with another. Images, for instance, typically have tags and explanatory text attached to them, and vice versa to better communicate the speaker's primary objective. Communication via social media posts has become increasingly multimodal i.e., via text and visual content due to the ubiquitous accessibility of cell devices with digital cameras. One must be able to understand these multimodal attributes jointly to effectively utilize the existing approaches.

Fig 1 (a) shows an example: *That boy Fellaini, what a talent in MMA; maybe dirty elbowing shithouse of a footballer though!* An ideal system is anticipated to yield three aspect-sentiment pairs from this sentence and image, i.e., (*Fellaini*, positive), (*MMA*, neutral) and (*footballer*, negative). Firstly, if the input is using text modality only at the inference step, the model tends to predict (*Fellaini*, neutral) and (*MMA,* positive*)*. When the visual modality is also included, the context of the text tends to be neutral.

Fig 1. Two examples of Aspect Based Multi-Modal Sentiment Recognition.

Fig 1 (b) shows another example: *Former top John McCain aide says he'd back Hillary Clinton over Donald Trump*. It is difficult to infer from the textual modality only about the polarity sentiment of the three personas in context of the sentence.

Many former studies have tried a variety of ways to merge the acquired representations of both modalities as the final classification features. To establish a text-image fusion and generate vision-aware-context and vice versa, researchers have utilized various techniques, however the image-text pairings convey distinct types of information as there is not an equal proportion of knowledge in each modality. With the gradients from the text modality tending to dominate over a weaker modality in terms of information, it will be challenging to train the model. Estimating the attention distribution superficially makes encoding explicit cross-modal information challenging.

Key Contributions:

- For the task of MABSR, we present a dual-encoder technique that incorporates cross-modal information. Instead of extracting ROI features, the MLP-Mixer [1] architecture is utilized, which tokenizes the visual input by dividing it into a series of patches. The textual and visual modalities were encoded using FNet [2] and, MLP-Mixer [1] which are both initialized from pre-trained checkpoints. We used a multitask learning framework comprising a few subtasks and these are — aspect-only extraction, polarity feature integration and co-attention fusion to fuse the acquired information.

- To evaluate the efficacy of proposed framework, we utilised two comparable data sets, Twitter-2015 and Twitter-2017, which mainly contain social media opinions. The empirical results demonstrate that the proposed framework for MABSR task surpasses both the current unimodal and multimodal approaches at lower compute and more efficient memory requirements. Further evaluation of the effects on various subtasks revealed that each subtask plays an indispensable role in performance enhancement.

The remaining work is organised as follows: Section II presents former related studies on the MABSR task, Section III describes the methodology employed and further implementation details. Section IV discussed the experimental results, and the conclusion is summarised in Section V.

A. Unimodal Aspect-Based Sentiment Recognition

1) Based on Textual Content

Aspect-based sentiment recognition (ABSR) is a branch of sentiment analysis that aims to identify polarity towards specific aspects in a given context. [3]; [4]; [7] were among the early works which explored ABSR. They proposed various techniques such as utilizing sentiment lexicons, syntactic patterns, and word embeddings for target-dependent sentiment classification via recurrent neural networks due to its ability to extract semantic features from texts.

Recent studies have also focused on deep learning models that utilize attention mechanisms to dynamically assign weights to relevant aspects and corresponding sentiment expressions. [6] proposed an LSTM based approach; [7] introduced an 'Interactive Attention Network (IAN)' that incorporated attention mechanisms. Memory networks, have also been explored for fine-grained opinion mining. [8] proposed a 'Target-Sensitive Memory Network (TSMN)' that employs a hierarchical memory mechanism for targeted storage and retrieval of aspect-specific sentiment information. [9] proposed a 'Latent Opinion model' that integrates a latent opinion variable into the sentiment recognition framework. [10] discussed a GCM-IAN model that incorporated granular computing to enhance the interpretability of parameters.

Additonally, transformer-based architectures have also shown superior performance in various NLP tasks, [11] proposed a BERT-based approach that utilizes a self-attention mechanism that integrates field-specific expertise through refinement of the pre-trained model. Although the above proposed models have shown promise, challenges in sentiment recognition still persist i.e. detecting sarcasm and irony in abundance of shifting trends to image supported text simply is a challenging task for current models due to the need for a nuanced understanding of context and social cues.

2) Based on Visual Content

Visual sentiment recognition (VSR) is also a research area that belongs to a broader range of sentiment recognition tasks. The objective is to comprehend human viewpoints, and stances via visual media, such as pictures and videos. A prevalent method for VSR entails examining facial expressions. [12]; [13]; [14] suggested a deep network in which domain features are transferred to perform well on smaller datasets with greater accuracy. [15] utilised skip-gram and autoencoders for enhanced VSR feature learning. Another approach would be to focus on localized features, [16]; [17] proposed an attention mechanism that captures fine-grained information by attending to local image regions. [18] proposed predicting visual sentiments through the automatic discovery of affective regions. Additionally, [19] proposed a 'context-dependent sentiment recognition method' which employed text and visual elements to convey a videos' sentiment. As the field continues to develop, one of the major challenges hindering progress is the absence of large-scale accurately labelled datasets. The other is the need for more robust and interpretable models that can capture complex relationships.

B. Multimodal Aspect Based Sentiment Recognition

Aspect-based multimodal sentiment recognition seeks to classify the sentiment conveyed in a text or image by examining its various aspects [20]; [21] conducted early experiments in the field, the latter proposed 'Convolutional Multiple Kernel Learning (MKL)' approach that aims to determine the optimal kernel for each modality. [22] discussed 'word-level fusion and reinforcement learning-based' approach for sentiment recognition. [23] proposed MultiSentiNet, a deep semantic network that utilized a combination of LSTM and CNN networks for feature extraction.

Further studies for MABSR were conducted by [24]; [25] as they studied a 'multi-interactive memory network' to encode text and image information. [26] utilised a gated attention mechanism; [27] proposed utilizing 'attention capsule extraction' via a fusion network with entity-level classification for the text and their corresponding images. Researchers have also investigated the utilization of pre-trained large language [11] and vision models for MABSR as [28] introduced VL-BERT and [29] proposed UNITER i.e. both architectures simultaneously learns visual and textual representations and can be fine-tuned for MABSR task.

Existing approaches typically consist of two pipeline subtasks: 1) multimodal aspect term retrieval; 2) sentiment classification. The former aims at recognizing all aspect terms from sequences, whereas the latter attempts to categorize each identified aspect term with its associated sentiment. However, the pipeline approach disregards the inherent connection between the two tasks and is susceptible to information loss. Mixing diverse modalities to boost performance is logical, but overcoming the noise and conflicts across such modalities proves difficult.

III. Proposed Methodology

Fig. 2 shows the overview of our proposed methodology. We define the above problem as a token classification task in terms of polarity and corresponding aspects. In the following subsections, we first introduce our separate input representations and their encoders as feature extractors for both modalities, followed by the details of our cross-modal feature alignment and subsequent subtasks involved.

A. Image Representation

For visual modality, unlike many existing transformer [30] derivatives, we employ MLP-Mixer to extract spatial features from an input image. The input image is first sliced into a sequence of patches $s = [\, s_1, s_2, \ldots\ldots, s_I]$ $where\ s \in R^{I\times(P^2\times C)}$, P^2 is the resolution per patch, C is the number of color channels, and $I = \mathbb{H} \times \mathbb{W} \,/\, P^2$ is the resulting number of non-overlapping patches [1]. Each patch is then flattened and prefixed with a special token, i.e., [*CLS*], followed by a simple linear projection $S \in R^{(P^2\times C)\times d_h}$. The resulting patch embeddings $S_{emb} \in R^{I\times d_h}$ can be formulated as, $S_{emb} = [\, s_1 S, s_2 S, \ldots\ldots, s_I S]$ where d_h is the dimensionality. Our vision encoder does not need position embeddings.

B. Text Representation

For textual modality, we first tokenize the input text by the Unigram Tokenizer [31] utilized in the FNet model to obtain a sequence of tokens embeddings $\bar{t} \in R^{(L+1)\times d_h}$ with a word embedding matrix $T \in R^{L\times|\bar{g}|}$ as follows, $\bar{T} = \left[\, t_{[CLS]}, t_1 T, t_2 T, \ldots\ldots, t_L T, t_{[SEP]}\right] + T^{pos}$ where $T^{pos} \in R^{(L+1)\times d_h}$, $|\bar{g}|$ represent the position embeddings, and the number of the vocabulary items respectively. Here, the $[CLS]$ and $[SEP]$ tokens correspond to the classification and end-of-sequence tokens in the text encoder. No supplementary embeddings were applied to the input text modality, as it did not yield any improvement to the empirical results.

C. Encoders

Both Fnet and MLP-Mixer are constructed from a series of layers of stacked transformer-like mechanism blocks, which provided behaviour of mixing tokens without requiring the attention mechanism. Fnet replaces the general self-attention sublayer [30] within former Transformer architecture with a Fourier sublayer, which applies a 2-D discrete fourier transform (DFT) (from Eq. 1) to its input token embeddings across sequences of length F_{seq} and hidden dimension, d_h.

$$X_K = \sum_{l=0}^{L-1} x_l e^{-(\frac{2\pi i}{L})lk}, 0 \le k \le L-1 \quad (1)$$

$$y = \Re(F_{seq}(F_{d_h}(x))) \quad (2)$$

Here $\Re$ is the real part of the extracted composite output.

$$\tilde{z}^{(n)} = LayerNorm\left(DFT\ Mixer\ (Z^{n-1})\right) + Z^{n-1} \quad (3)$$

$$Z^n = LayerNorm\left(MLP\ (\tilde{z}^{(n)})\right) + Z^{n-1} \quad (4)$$

Similarly, MLP-Mixer replaces the self-attention block responsible for mixing features between different spatial locations with two identical sized MLP blocks.

The former is responsible for token-mixing and the latter is responsible for channel-mixing. The final MLP layer in either encoders comprises of two dense layers with a GELU non-linear activation. Before both the token mixing modules and final MLP block, layer normalization (LayerNorm) was applied respectively for both FNet or MLP-Mixer mechanism (from Eq 4; Eq. 6). The token mixer block represents either Fast Fourier Transform approach from FNet or all fully connected MLP layer approach from MLP-Mixer (from Eq. 3; Eq.5).

$$\tilde{z}^n = TokenMixer\left(LayerNorm\ (z^{(n-1)})\right) + z^{(n-1)} \quad (5)$$

$$z^n = ChannelMixer\left(LayerNorm\ (\tilde{z}^{(n)})\right) + \tilde{z}^{(n)} \quad (6)$$

The final output of our encoders are hidden representations $Z_s^{(N)} = [\hat{s}_1, \hat{s}_2, \ldots\ldots, \hat{s}_I]$ and $Z_T^N = [\hat{t}_1, \hat{t}_2, \ldots\ldots, \hat{t}_L]$ (Eq. 7a; 7b) at the L-th layer, which is last in our case. It is used as input for multi-task learning and the final extraction. For all the experiments, the parameters of FNet and MLP-Mixer were respectively initialized from pretrained *fnet-base* and *mixer-b16-224-in21k* checkpoints. The hidden size d_h is 768, the number of encoders layers, N is 12, Patch Size, P is 14, and final MLP layer hidden dimension is 3072.

D. Cross-Modal Fusion:

With the goal of aligning the characteristics of both the visual and language modalities, we propose a cross-modal fusion layer to train both the image and language encoders for the final extraction. Our approach involves two subtasks: aspect-only extraction and co-attention exchange with polarity feature alignment.

1) Text extraction:

The textual representation received from text encoder i.e.

$$Z_T^N = \left[\hat{t}_{[CLS]}, \hat{t}_1, \hat{t}_2, \ldots\ldots, \hat{t}_L, \hat{t}_{[SEP]}\right] \quad (8)$$

was input to a dense layer with softmax activation to estimate auxiliary tags for the tokens, defined as,

$$\hat{y}_n = Softmax(w^t \hat{t}_n + b^t) \quad (9)$$

where $w^t \in \mathbb{R}^{K\times dh}$ and $b^t \in \mathbb{R}^K$ are trainable parameters, and K are the number of the prospective tags for either subtask. Given a training dataset of {x(j), y(j)}, the loss function used is Dice Loss proposed in [32],

$$L^{DL} = \frac{1}{J\times N} \sum_j^{j\in\{0,1,2\}} \sum_i \left[1 - \frac{2p_{ij}\, y_{ij} + \gamma}{p_{ij}^2 + y_{ij}^2 + \gamma}\right] \quad (10)$$

The BIO schema was utilised for token classification. We employed 3 tags, *I-ASP, O, B-ASP* for subtask 1 and a reduced set of 5 tags, specifically *I, O, B-POS, B-NEU, and B-NEG*, as opposed to the previous usage of 7 tags for subtask 2 and 3. For instance, the pattern of {*B-NEG, I-NEG*} can be compressed to {*B-NEG, I*}, trimming the number of

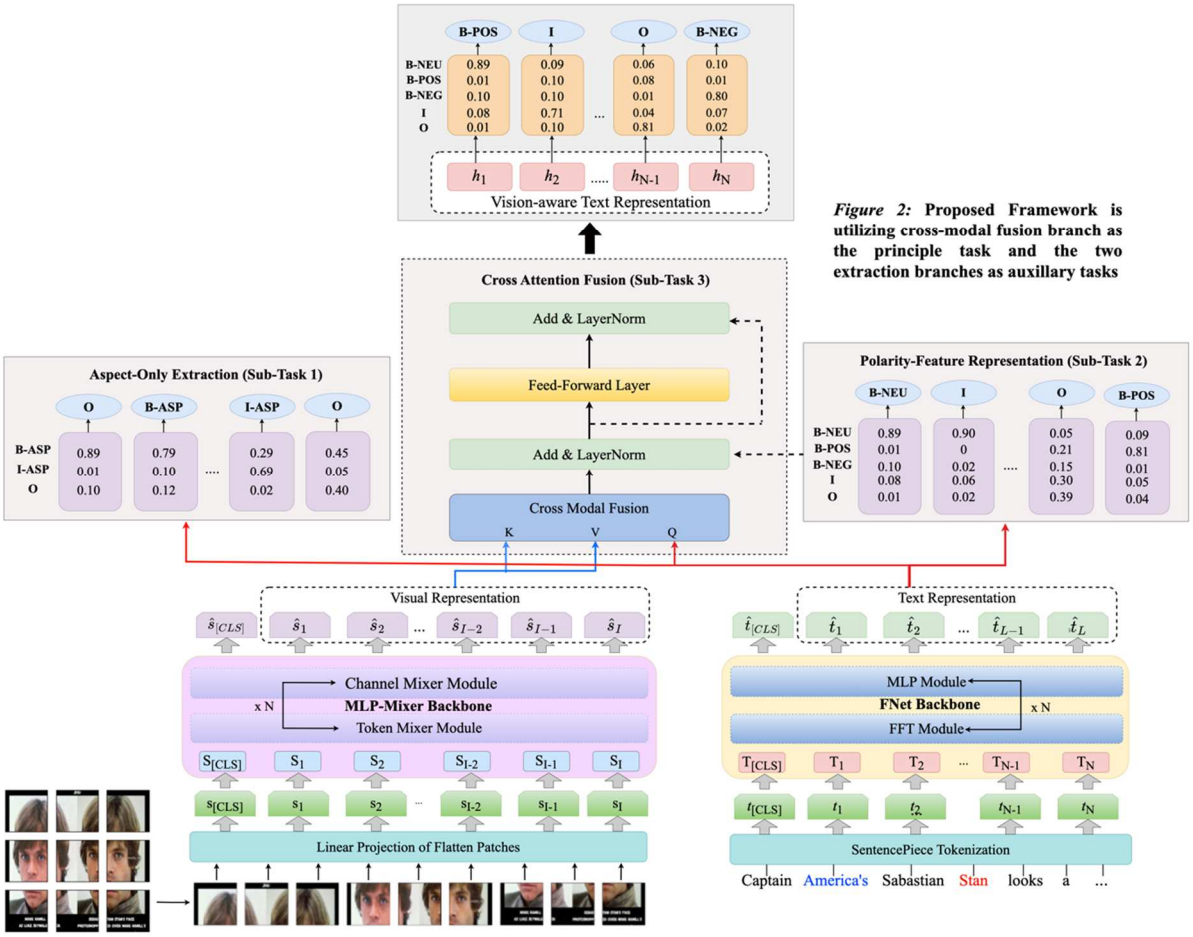

Figure 2: **Proposed Framework is utilizing cross-modal fusion branch as the principle task and the two extraction branches as auxillary tasks**

Fig. 2. Proposed Framework

classes K. This can reduce the overall forecasting error resulting from the classes K in the task.

E. Vision-aware Text Extraction:

After further investigation, multi-headed cross-attention was applied to integrate the textual and visual features where the text representation (from eq. 8) is regarded as the query, while the image representation (from eq. 7a) was utilised as the key and the value,

$$Atte_u\left(\mathcal{Z}_T^{(N)}, \mathcal{Z}_S^{(N)}, \mathcal{Z}_S^{(N)}\right) = softmax\left(\frac{\left(W_Q^U \mathcal{Z}_T^{(N)}\right)\left(W_K^U \mathcal{Z}_T^{(N)}\right)}{\sqrt{d_h/_u}}\right)\left(\left(W_V^U \mathcal{Z}_S^{(N)}\right)\right) \quad (11)$$

where $W_Q^U \in \mathbb{R}^{d_h/u \times L}$ and $\{W_K^U \quad W_V^U\} \in \mathbb{R}^{d_h/u \times I}$ are matrices of the query, key and value [30]. With multi-headed cross-fusion, the final representation of vision-aware text extraction $\bar{p} = [p_1, p_2, \ldots, p_n]$ can be formulated as,

$$\bar{p} = W^p[Atte_1, Atte_2, \ldots, Atte_u]^T \quad (12)$$

where $W^p \in R^{d_h \times d_h}$ refer to the parameter matrix for the multi-headed cross fusion. By passing a fully connected dense layer and two-layer normalization with two skip connections, the resulting representation is formulated as $\hat{p} = [\hat{p}_1, \hat{p}_2, \ldots, \hat{p}_L]$. The skip connections incorporated the text-based representation to maintain a compatible size of representation. Different from the aspect or polarity-only extraction subtasks, the output layer uses CRF Score [33] estimation as input to our loss function which is the negative log-probability of the ground truth label,

$$L^{CRF} = -\frac{1}{J}\sum_{j=1}^{J}\left(s\left(x^{(j)}, y^{(j)}\right) - logadd_{y' \in Y_x^{(j)}} e^{s\left(x^j, y'^{(j)}\right)}\right)$$

where L^{CRF} $(Eq.\,13)$ is the CRF loss and $s\left(x^{(j)}, y^{(j)}\right)$ is the estimated CRF score. The main purpose is to integrate the three subtasks into a cohesive whole, as outlined below,

$$L = L^{CRF} + \theta L_1^{DL} + \delta L_2^{DL} \quad (14)$$

where θ and δ are hyper-parameters that regulate the impact of individual subtasks. The output of solely vision-aware context extraction ($\theta = 0$, $\delta = 1$) was utilised for inference.

IV. Experimental Results:

A. Datasets and its brief description and statistics:

To evaluate the performance of our proposed attention-free dual encoders with cross-modal fusion, we utilized two MABSR benchmark datasets, mainly consisting of reviews on Twitter. These datasets are Twitter-2015 and Twitter-2017 provided by [34]; [35]. These were annotated with the sentiment for each aspect and can be accessed from —

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:42:43 UTC from IEEE Xplore. Restrictions apply.

https://github.com/jefferyYu/TomBERT. An aspect is deemed correctly identified only when the aspect term and its polarity match the ground-truth aspect term as well as polarity. We evaluated our approach on the precision, recall, and micro F1-score metrics.

Table 1: Statistical characteristics of respective dataset.

Datasets	Positive Aspects	Negative Aspects	Neutral Aspects	Total Aspects
Twitter-15	1548	630	3169	5347
Twitter-17	2516	728	2728	5972

B. Implementation details

The Hyperparameters were fine-tuned through grid-search based on validation set performance in all experiments. The hidden size d_h is 768 for the visual and language encoders. The cross-modal fusion module has 8 heads. The AdamW optimizer was utilised to update all trainable parameters with a primary learning rate of $1e^{-4}$ and warmup of 0.1. The max length and batch size were set to 80 and 64 limited by the GPU (Nvidia P100 with 16 GB VRAM), respectively. For training, we leveraged an early stopping strategy with a patience of 15 to 25 epochs to avoid overfitting. Both θ and δ belonged to the prospective set of {0.2, 0.8, 0.3, 0.7, 1.0}.

C. Results

Table 2 and **Table 3** llustrate the experimental results for the task of MABSC. **Fig. 3** gives the comparision of our proposed framework with the previous state of the art approaches for both the datasets. The empirical results for both Twitter-15 and Twitter-17 datasets including comparative analysis with [36]; [25]; [27]; [37]; [38].

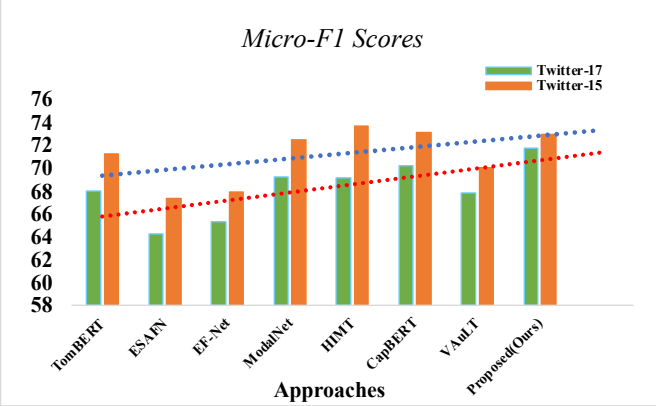

Fig. 3. Comparitive graphical analysis with previous cutting-edge methods using F1 score metric.

V. Conclusion

This work proposes a dual-encoder mechanism with cross-modal fusion for encoding text-image features into the representations for MABSR tasks. A multitask learning architecture containing three subtasks was applied to coalesce both text and image modalities. Empirical experiments demonstrate the effectiveness of the proposed framework improved the performance for MABSR tasks verified via Twitter-2015 and Twitter-2017 datasets. In addition, future work can extend the proposed framework to more multi-modal tasks, such as multi-modal machine reading comprehension and affective computing.

***Abstract*—Electronic Health Records (EHR) is a technology that enables users to monitor their medical data. Over several healthcare organizations, it maintains computerized records. Enterprise-wide data exchanges and other networking exchanges and technologies are used to exchange records. People today demand fast access to their medical records. The privacy and security of patient medical records are a concern because the health industry has rapid access to data. Thus, a blockchain-based solution can help to solve this problem. A blockchain network is used in healthcare to store and distribute health information amongst hospitals, diagnostic laboratories, pharmaceutical firms, and physicians. This study uses Blockchain Technology (BT) to analyze electronic healthcare data management. Insightful analysis of patient data is made possible by such a technology, which medical institutions can utilize. After an analysis of the survey of the relevant literature, a comparison of the many earlier studies is presented. Encryption, the keyword (KW) search, server and user verifiability, storage integrity, and dynamic updates are all aspects that have been compared. After examining. the author Tan et al., (2022) agrees with all the key features such as server-side verifiability, encryption, KW search, user-side verifiability, storage integrity, and dynamic updating**

***Keywords*— Blockchain, EHR, Medical records, Personal Health Record (PHR)**

I. INTRODUCTION

Healthcare providers, administrators, and researchers increasingly rely on Electronic Health Records (EHRs), which are computerized compilations of healthcare operations and assessments. [1]. Structured and unstructured data are both present in electronic health records [2]. Diagnoses, medications, and test values are all examples of the types of structured data found in EHRs. However, examples of unstructured data include clinical documentation such as notes, and discharge summaries created by healthcare professionals. When doctors enter their notes on a patient's condition into an electronic health record (EHR), they do it in free text. Electronic health record (EHR) adoption has skyrocketed in recent years. It has risen drastically in the US, going from 10% to almost 96% in just ten years. The sum is up by well over 85 percent [3]. The same pattern holds true for Australia's GP offices, major hospitals, and medical service providers [4,5]. The widespread use of EHRs has resulted in a data volume large enough to be classified as "Big Data," which includes the processing and use of the vast amounts of information stored in EHRs. There is a need to invent technological devices that can organize, evaluate, and recognize patterns within this information because the ability of the human intellect to analyze, understand, and interpret information is limited. The next phase in creating an EHR ecosystem is to conduct an analysis of data on EHRs big data, which includes the implementation of information mining and processing of natural language techniques. To deal with the explosion of free-form text in the medical field, researchers have turned increasingly to cutting-edge Machine Learning (ML) methods [6,7]. Many medical and healthcare contexts [8] include the diagnosis of heart disease and other cardiovascular issues [9]. Blockchain is an exciting new technology with the potential to revolutionize healthcare data administration by enabling greater data efficiency and ensuring trust [10-15]. Decentralized storage, transparency, data integrity, verification, data access flexibility, connectivity, and security are remarkable and built-in properties that allow BT to employ extensively in the healthcare industry [16-17]. The healthcare systems possible by BT are shown in Figure 1 [18-19].

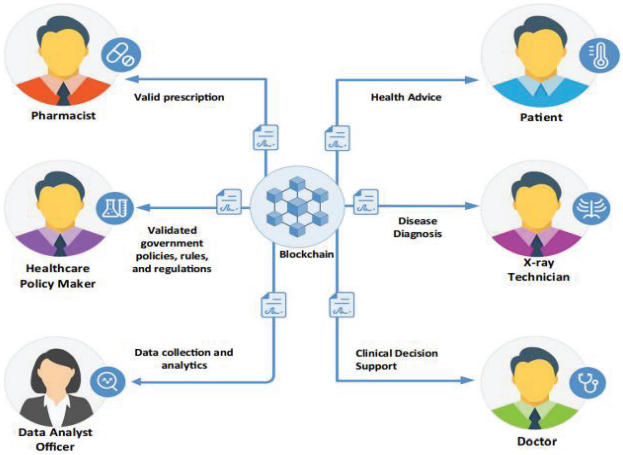

Fig. 1. Blockchain-enabled healthcare systems [20].

Blockchain data management systems are instead addressing the integration of data silos. Despite several recognized eHealth interoperability strategies, health record data is still compartmentalized inside hospitals [21]. Interoperability worldwide is not yet a reality, even if the size of these silos expands (to include the whole European continent or the United States, for example) [22]. In such a case, the use of BT can aid in establishing sharing practices to solve the obstacles of data dissemination [23]. New possibilities for everyday health data management and for patients to easily access and exchange health data are

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:20:29 UTC from IEEE Xplore. Restrictions apply.

opening up due to developments in EHR collecting, patient data privacy protection policies, and cloud healthcare data storage (Table 1).

PHR data management	Hearthy	Spain
	Medcredits	USA
	MyClinic	UK

Note: EMR: Electronic Medical Record, PHR: Personal Health Record.

The rest of this work is structured as follows. The authors provide a comparison table and a literature review of surveys in Section 2. The authors offer a comparative literature review analysis with the graph in Section 3. Finally, they stated the conclusions in Section 4.

A. Blockchain-based Management Applications

Opportunities for better health data management and easier patient access to and sharing of health data have arisen with developments in EHR, patient data privacy protection policies, and cloud healthcare data storage [25].

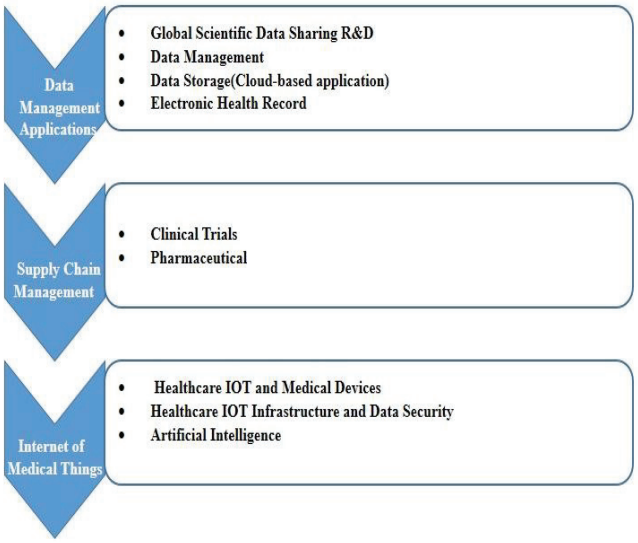

Fig. 2. Healthcare blockchain applications [26].

Applications of BT in healthcare are shown in Figure 2. BT can tackle these crucial challenges robustly and efficiently, which is particularly important in the healthcare industry, which relies heavily on secure data storage and transactions and the management of their seamless integration.

TABLE II. THE POTENTIAL OF BT IN THE MEDICAL INDUSTRY [27].

Applications	Summary
EHR	The digital EHR stored on the distributed ledger of a permitted blockchain maintains its integrity without the need for any intermediaries from the moment data is generated until it is retrieved.
Clinical Research	Blockchain provides a trustless, immutable structure for sharing data in clinical trials. It allows investigators to communicate data with one another in a safe environment.
Medical Fraud Detection	As a distributed ledger that cannot be altered once recorded, blockchain facilitates fraud detection and prevents unauthorized duplicates or alteration of transactions.
Pharmaceutical Industry and Research	Blockchain's sophisticated tracking capabilities are used in the pharmaceutical industry to maintain tabs on the whole supply chain, ensuring that pharmaceutical counterfeiting and theft are prevented at every level.

The seven stages of the blockchain-based healthcare data management process are shown in Figure 3. Data management, data sharing, data storage (such as cloud-based apps), and EHR are all examples of applications built on BT that will be covered in further depth below. Data Management, data sharing, data storage (such as cloud-based apps), and EHR are all examples of applications built on BT that will be covered in further depth below.

1) Data Management

The fact that many businesses, particularly healthcare institutions, are data-driven and that the amount of data created now and in the future, thanks to technologies like the IoT, is rising exponentially, there are persistent breaches of data security and privacy [28]. Therefore, many institutions' credibility and financial resources have been severely damaged. Health data users should be separated into categories based on their functions, with access controlled according to the level of authorization granted to each category. BT can be employed to guarantee such access is secure and discreet.

2) Electronic Health Record

Paper-based medical records are cumbersome because they need accurate tracking of a patient's health condition over time [29]. Also, they are vulnerable to inaccurate information, which can lead to inappropriate treatment of patients. The development of Information Technology (IT) allowed for the implementation of EHRs, significantly reducing the need for such initiatives. Access to EHR enables medical practices to increase treatment quality [30]. Additionally, EHR allows for improved disease management and higher levels of preventative treatment. The digital

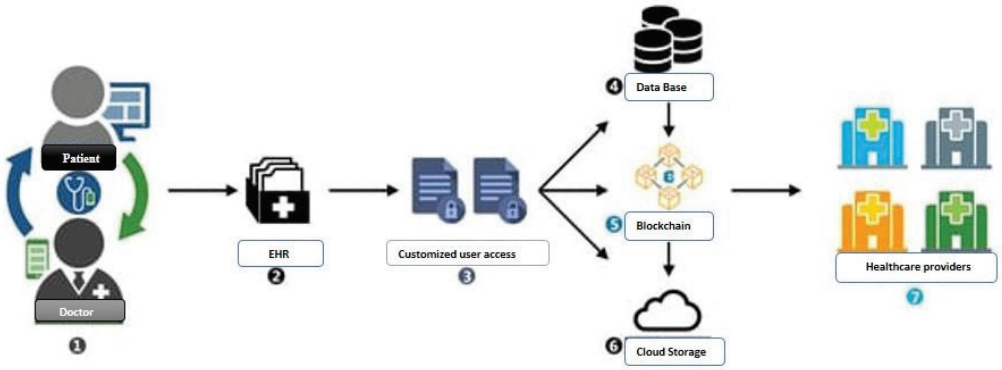

Fig. 3. Blockchain-based healthcare data management [26].

record also enables improved decision-support features and enhanced teamwork among medical professionals. Consequently, its importance is becoming more widely acknowledged in the medical field [31].

II. LITERATURE REVIEW

In this section, the author studies about the previous research work based on electronic healthcare records (EHR) management using blockchain technologies (BT).

Tan et al., (2022) [32] investigate using BT with smart contract implementations to build a decentralized, verifiable, and unchangeable database. The suggested approach allows for immutable storage, real-time changes to EHR, and the protection of patient privacy when using an outsourced service. The authors evaluate the proposed method against current options in terms of performance and safety. The findings show that the suggested method is feasible and meets the necessary functional and security criteria.

Al Asad et al., (2021) [33] developed a permissioned blockchain using proof of authority (PoA) technology to provide confidentiality, permission sharing, and efficient distributed healthcare record administration. Furthermore, discussed the benefits of using de facto standards like Fast Health Interoperable Resources (FHIR) to facilitate the meaningful exchange of healthcare information among all parties involved and the significance of managing medical records in an interoperable manner. The study relies on simulated PoA use to learn about the performance of such a consensus process while using BT for safe information exchange.

Chelladurai et al., (2021) [34] established smart contracts on the blockchain to traditionally meet the needs of patients, doctors, and healthcare professionals. The proposed system introduces health models on the decentralized blockchain, such as immutable patient log creation using the Modified Merkle Tree data structure to store and quickly retrieve health records, medical record updates, health information exchange between providers, and viewership contracts. Many studies have been conducted to test the efficacy of the suggested system. The suggested system's performance regarding resources, transactions per second, and latency has been assessed using qualitative and quantitative indicators.

Abbas et al., (2023) [35] proposed the current Electronic Healthcare System and the primary constraints of current systems are their lack of scalability and privacy; thus, the purpose of this study is to define alternate approaches for achieving scalability, usability, and data protection in the healthcare system. It is essential in the healthcare field to provide complete, up-to-date patient records. Instant availability of patient records for improving efficiency and coordination is another quality that helps academics to think about effective EHR systems. The proposed model implementation makes use of blockchain-sharing technology, hyper-ledger protocols, and Proof-of-Authority.

Rathee et al., (2020) [36] establish a foundation for the safety of healthcare multimedia data using BT by producing a hash for each piece of information, allowing users throughout the network to be alerted to any unauthorized changes to data or medication. Simulation improvements are attributable to the usage of Blockchain have been used to confirm the findings, which show an 86% success rate in the face of product drop ratio, wormhole attack, falsification attack, and probabilistic authentication.

Anitha et al., (2023) [37] proposed Statistical Package for The Social Sciences (SPSS) to have a profound effect in many fields, including healthcare. The study of its potential uses in fields other than finance has been ongoing for some time. The author within the domain of health information technology is always struggling to stay up with the latest discoveries in the field because study in this area is still relatively new but increasing at a rapid rate. This paper includes findings from a survey of ongoing research into the potential medical applications of blockchain technology and an examination of the factors influencing the development of blockchain within the healthcare sector. The analysis reveals that multiple studies have proposed various applications for blockchain technology in the medical field. Even Nevertheless, there is a lack of prototypes implementations or studies that evaluate the efficacy of the stated use cases. The study expands our understanding of the current state of blockchain applications in the healthcare sector, including their potential benefits and limitations, and suggests directions for future investigation. Therefore, further study is required to fully comprehend, describe, and assess blockchain's potential benefits and drawbacks in the medical field. The primary objective of this study is to discover the elements that affect blockchain. Discriminant analysis and then path analysis has been employed in SPSS for analysis.

Gosh et al., (2023) [38] established the applications of this technology while also drawing attention to the challenges and potential areas for future blockchain study in the field of healthcare. An in-depth exploration of the

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:20:29 UTC from IEEE Xplore. Restrictions apply.

blockchain and its capabilities serves as the paper's initial section. The remainder of the study is devoted to a comprehensive literature assessment of those articles chosen to represent the state of the art in a blockchain-based healthcare system research. Then, the answers offered by blockchain technology in healthcare systems and its primary areas of use are highlighted. The paper concludes with a discussion of its limitations, problems, and potential future research areas.

Lee et al., (2019) [39] introduce the SHARE Chain, a standardized architecture for sharing that includes two components designed to address interoperability and reliability concerns. First, it makes data more trustworthy by relying on a Blockchain registry's immutability; second, it establishes a Consortium Blockchain Network whereby only verified institutions can exchange information. The second enhancement is enhanced compatibility with healthcare data exchange standards through Quick Healthcare Interoperability Resources and Cross-Enterprise Document Sharing.

Wang et al., (2019) [40] suggest a novel method for exchanging individual health records that uses BT to prove the authenticity of the shared data. The novel system employs searching attribute-based encryption and symmetric encryption to safeguard privacy, keyword search, and fine-grained access control while exchanging personal health data. Moreover, the new scheme utilizes blockchain to maintain scheme keys, removing the potential for a single failure point associated with centralized key management. Lastly, the investigation of security threats and performance benchmarks confirm the safety and practicality of the method.

Wang et al., (2018) [41] employed attribute-based encryption (ABE)and Identity-based encryption (IBE) to protect sensitive patient information, while identity-based signatures (IBS) can be used to authenticate online transactions. Authors offer a new cryptographic primitive termed combined attribute-based/identity-based encryption and signature (C-AB/IB-ES) that combines the features of ABE, IBE, and IBS into a single system. It greatly reduces the complexity of system management and eliminates the requirement for additional cryptographic systems to provide different degrees of security. Table 3 indicates the comparison table of the literature of review.

TABLE III. COMPARISON OF LITERATURE OF REVIEW

Authors	Outcomes
Tan et al., (2022) [32]	The findings show that the suggested method is feasible and meets the necessary functional and security criteria.
Al Asad et al., (2021) [33]	It has been shown that proof of authority is superior to more conventional mining as a consensus method.
Chelladurai et al., (2021) [34]	The experimental findings demonstrate that BT reduces latency in the proposed network and increases throughput and performance using fewer resources.
Abbas et al., (2023) [35]	The proposed model implementation makes use of the blockchain sharing technology, hyper-ledger protocols, and Proof-of-Authority.
Rathee et al., (2020) [36]	The suggested technique outstrips the state-of-the-art by a factor of 86% in experimental analysis against unlawful actions carried out by malicious IoT devices such as the over products drop ratio, wormhole attack, falsification attack, and probabilistic authentication situations.
Anitha et al., (2023) [37]	The primary objective of this study is to discover the elements that affect blockchain. Discriminant analysis and then path analysis have been employed in SPSS for analysis.
Gosh et al., (2023) [38]	The solution offered by blockchain technology in healthcare systems and its primary areas of use are highlighted. The paper concludes with a discussion of its limitations, problems, and potential future research areas.
Lee et al., (2019) [39]	Compared and examined with comparable explore in various criteria (On/Off-chain, Identity, Interoperability, Patient-centered), where the suggested solutions meet all but one of the requirements.
Wang et al., (2019) [40]	The technique is secure and practically viable via performance assessment and security analysis.
Wang et al., (2018) [41]	The proposed models protect the privacy and authenticity of patient information. The authors conclude with a sample application in the health insurance industry.

III. PERFORMANCE EVALUTION

In this section, the author compares all the literature survey papers based on EHR encryption efficiency comparison and feature comparison.

A. EHR Encryption efficiency comparison

The time required for encryption is compared in Figure 4 for the [40] and [41] systems as well as the [32] scheme. The y-axis displays the encryption time in seconds (s), while the x-axis displays the file size in kilobytes (KB). To ensure that

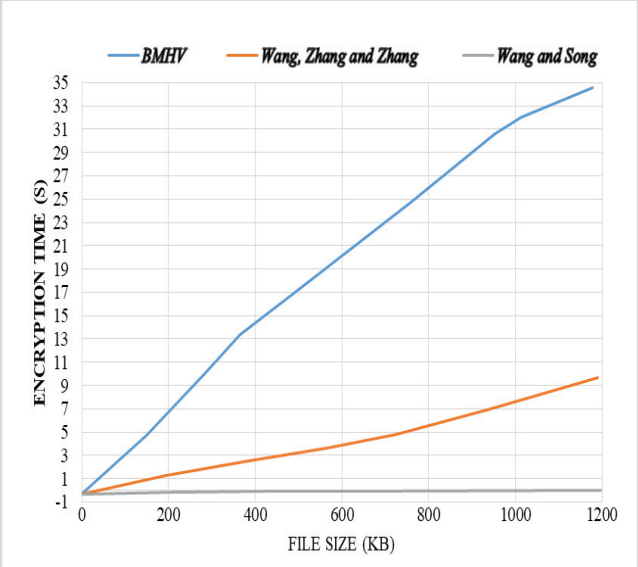

Fig. 4. Encryption efficiency comparison [32]

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:20:29 UTC from IEEE Xplore. Restrictions apply.

the analysis of the exact file sizes utilized in the two approaches above is accurate, the size of the file subject used for the comparison is restricted to 1200 kilobytes (1.2 MB). The results show that BHMV's encryption algorithm is more effective than the alternatives studied. In other words, the encryption time scales better with file size than the competing approaches. BMHV's suggested method is future-proof and feasible, providing a quicker overall encryption performance that can be used in the system's massive EHR storage and sharing infrastructure.

B. Features comparison of schemes

Features including server-side verifiability, encryption, KW search, user-side verifiability, storage integrity, and dynamic updating are all compared and contrasted in Table 4. These systems rely entirely on blockchain for security, which is inadequate for keeping information private. Comparing the two, it is clear that author [32] supports all the essential characteristics, whereas author [33] supports all the features apart from storage integrity. Similarly, the author supports all major features [40] except dynamic updates.

TABLE IV. MAJOR ASPECTS OF BLOCKCHAIN-BASED HEALTHCARE MANAGEMENT SYSTEMS (SUPPORTED = ✓; UNSUPPORTED = ✗).

Authors	Encryption	KW Search	Server-side Verifiability	User-side Verifiability	Storage Integrity	Dynamic Update
Wang et al., (2018) [41]	✓	✓	✗	✗	✓	✗
Wang et al., (2019) [40]	✓	✓	✓	✓	✓	✗
Lee et al., (2019) [39]	✗	✓	✗	✗	✓	✗
Al Asad et al., (2021) [33]	✗	✗	✗	✗	✓	✗
Chelladurai et al., (2021) [34]	✗	✗	✗	✗	✓	✓
Tan et al., (2022) [32]	✓	✓	✓	✓	✓	✓

IV. CONCLUSION AND FUTURE SCOPE

An EHR is software that stores and organizes a person's medical history. Several medical facilities' records are stored in its database. Emerging technologies like blockchain are being used to provide novel solutions across industries, including healthcare. The healthcare industry uses a blockchain to store and transfer patient data across labs, pharmacies, clinics, hospitals, and doctors' offices.

The medical industry is one where BT can be employed to detect serious and perhaps life-threatening errors properly. In this study, authors examine the use of BT for managing EHR. Medical facilities can benefit from this technology since it facilitates a deeper study of patient information. After an examination of the relevant literature, it draws parallels between different studies. Encryption, KW search, server and user verifiability, storage integrity, and dynamic updates are all features that have been compared and contrasted. Comparing the two, it is clear that author [32] supports all the essential characteristics, whereas author [33] supports all the features apart from storage integrity. Similarly, the author supports all major features [40] except dynamic updates.

Important for patients and necessary for any subsequent treatment, particular rules for the electronic storage of patient data, medical supplies, equipment, and materials utilized, etc., should be created in the future. Then, it's necessary to specify which data can be encrypted and stored publicly through permissionless blockchains and which can be encrypted and stored privately, with access restricted to approved network members.

***Abstract*— A current fed ZCS-ZVS push-pull converter has been analyzed and designed for renewable energy conversion applications. The topology maintains both zero current switching (ZCS) and (ZVS) on leading and trailing edges owing to the resonance between the trapped capacitor and the leakage inductance of the HF transformer, resulting in a near sinusoidal waveform at the primary of the HF transformer. The voltage spike across the power devices are suppressed effectively enabling the selection of low-voltage, low cost power devices. The proposed converter no auxiliary circuit is involved and since all the switches are ground referred, non-isolated driver with single power supply can be employed. A comprehensive study of 500 W highly efficient push pull converter and design of the proposed converter including steady-state and transient analysis has been reported.**

Keywords—Push Pull, ZCS, ZVS, Trapped Capacitor, Current fed DC-DC converter

I. INTRODUCTION

In light of the scarcity of fossil fuels and concerns regarding climate change, interest in renewable energy has grown considerably in recent years. As a sustainable way to satisfy our energy demands, renewable energy sources, help lowering of greenhouse gas emissions thereby reducing the effects of climate change. Solar energy being abundant and closest to the loading point, but struggle with intermittency issues and generally yield low output voltages, and thus require step-up dc-dc converters having high conversion ratio with low input current ripple for its effective utilization for off grid and grid connected application [1][8]. High efficiency, low EMI, low weight, lower cost, high power density, extended lifetime, among are major factors for design considerations of charging infrastructure for EV loads for off grid applications, where charging station is required to be supported by PV fed generation to charge intermediate batteries[9].

DC-DC converters can be either isolated or non-isolated, however, the isolated converters with High-frequency (HF) transformer are chosen over non-isolated topologies because of their advantages in galvanic isolation, low ripple contents, enhanced regulation, flexible output voltage, and provide multiple output at different levels with ease. Electrical isolation between the input and output reduces the risk of electrical shock and protect the delicate components against ground events, and electrical noise.

Current-fed converters are considered front runner in various step-up dc-dc converters applicable to PV fed system. These converters naturally come with smaller input current pulsations and due to pre-boosting paving the advantage of a lower transformer turns ratio compared to voltage-fed converters with output voltage clamping, risks of HF transformer getting saturated reduced largely and there are no duty cycle loss issues. Therefore, for low-voltage input renewable energy conversion applications, current-fed DC–DC converters are preferable over voltage-fed versions [2].

The most common topologies for isolated current-fed step-up DC-DC converters employ flyback, half-bridge, full-bridge, and push-pull (PP) architectures. For galvanic isolation initially line frequency (50–60 Hz) transformers [3] are employed, although dependable and simple, its large size and weight is major impediment. Flyback converter falter on account of large losses and significant voltage drop as the step up voltage output increases. On the other hand; compared to the PP or full-bridge converter configuration, the half-bridge converter configuration falls short for high step up application since it requires twice the turn ratio of the comparable high-frequency transformer. Features like simple circuitry, fewer power switches, reduced conduction losses, high step up voltage conversion ratio, better transformer utilization makes the PP converter more suitable as compared to full bridge configurations. Owing to utilization of the leakage inductor of the HF transformer as integrated magnetic solution, the power density is increased drastically for energy transfer in current-fed topologies [3].

Traditional current-fed push-pull converters have a number of disadvantages, including high-voltage spikes across switches resulting from the resonance between the switching loop parasitic capacitor and the leakage inductance of the HF transformer, and high switching losses due to the hard-switching operation of the primary switches. Passive snubbers, energy recovery circuits, and active clamp snubbers are reported in the literature [3] to provide protection against high spikes on the switches. Active-clamp snubbers are favourably utilized as their auxiliary circuit may not only suppressed the voltage spikes but also assisted in zero voltage switching (ZVS) thereby showing high efficiency hence, paving the way for increase in the switching frequency and reduction of the converter size[4]. For further effective remediation, numerous enhanced topologies with zero-voltage switching (ZVS) [3], zero–current switching (ZCS)[4], and voltage spike clamping and suppression [4] are suggested in literature. The resonant push-pull converters, which use the circuit parasitic, or resonant tank to help with zero-voltage switching (ZVS) or zero-current switching (ZCS) for primary switches, is also reported [5].These methods achieve a high conversion efficiency while reducing the switching loss drastically.

A new simple active-clamped ZCS-ZVS current-fed push–pull DC–DC converter for PV applications is proposed. The proposed converter includes a current-fed push–pull circuit with a trapped clamping capacitor, one HF transformer, a rectifier with fast-recovery SIC diodes and a capacitive filter to output power to 380V DC bus. Both ZCS and ZVS on leading and trailing edges are attained owing to the resonance

between the trapped capacitor and the leakage inductance of the HF transformer, resulting in a near sinusoidal waveform at the primary of the HF transformer. The voltage spike across the power devices are suppressed effectively enabling the selection of low-voltage, low cost power devices. In the proposed converter no auxiliary circuit is involved and since all the switches are ground referred, non-isolated driver with single power supply can be employed with very simple control. The power range of the proposed converter is 3 KW. A 500 W scaled down model was implemented in this paper. Figure 1 Block diagram of the architecture of the renewable energy conversion system. The paper briefly analysis and design the key characteristics and simulation results are discussed thereby demonstrating the capabilities of the converter in terms of boosting the voltage with desired power at high efficiency while undergoing ZCS-ZVS operations.

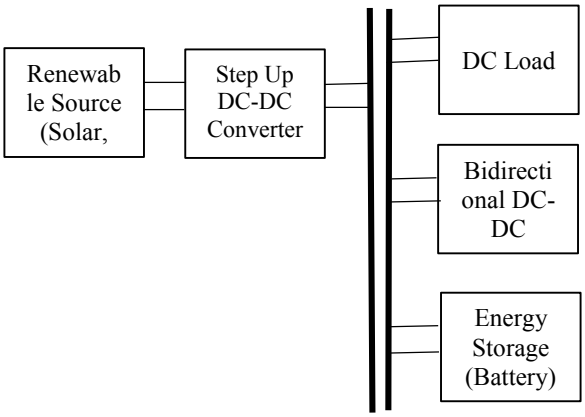

Fig. 1 Architecture of renewable energy conversion system

II. System Configuration

The proposed converter configuration employs an active clamped ZCS-ZVS operation of the 500W current fed push pull converter as shown in Figure 2. The converter operates on low voltage DC bus duly fed by MPPT charge controller having voltage of 48V. The new configuration employ 2 blocking diodes with a trapped clamping capacitor on the primary side of conventional push pull converter which enable the configuration to achieve ZCS-ZVS operation of the switches. The output side of the HF transformer is assumed connected with fast recovery SIC diodes to formulate a DC bus having output voltage 380V with a capacitive filter.

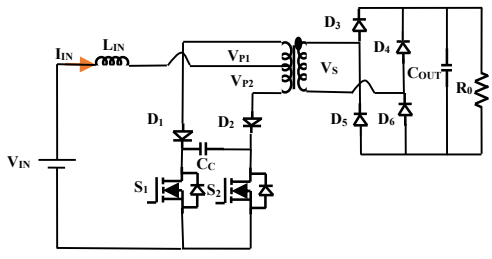

Fig. 2 Schematic of Proposed Converter

III. Modes of Operation

The proposed naturally clamped ZCS-ZVS Push Pull converter's steady-state operation and analysis, together with pertinent mathematical equations and assumptions, is summarized in this section. The resonant tank for the ZCS functioning of the primary switches is composed of an trapped capacitor C_C and transformer leakage inductance L_{Leakge}. The gating signals of the switches have a duty cycle D that is larger than 50% and are 180 °phase-shifted. Figure 3 shows the waveforms under steady conditions. The analysis was completed for the first half cycle, the intervals were repeated for the second half cycle with the other symmetrical devices conducting. Figure 4 shows analogous circuits that represent the various operating modes of the converter.

The quantities and ratings of components as well as the theoretical converter performance can be determined using analytical equations that were generated.

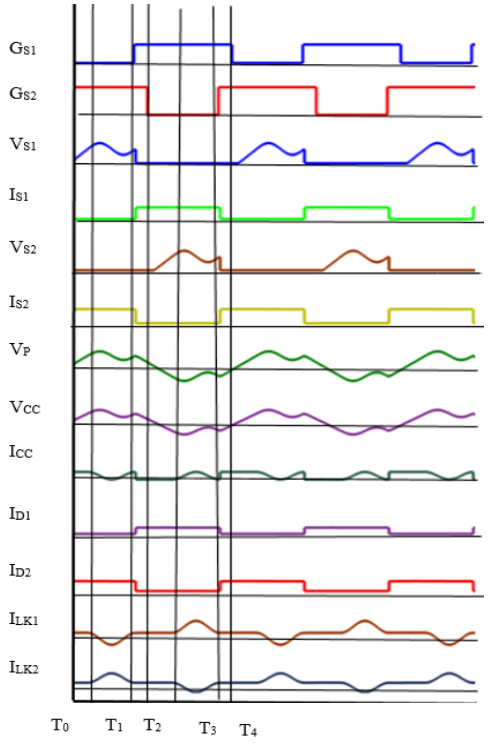

Fig. 3 Switching pulses and steady state waveforms

A. Interval 1 (Fig. 4(a): T0< t < T1')

In this interval the primary side switch S_2 is conducting and diode D_3 and D_6 of secondary side Rectifier Bridge are conducting. Constant current I_{IN} flows through $L_{Leakage1}$ and $L_{Lekage2}$ .Switch S_2 carries the entire input current. The trapped capacitor's voltage ($V_{C\ trapped}$) is clamped at $2V_{P1}$.

$$V_{P1} = V_{P2}$$

$$V_{IN} = V_L + V_{P1}$$
$$V_{IN} = V_L - V_{P2} + V_{CC}$$
$$V_{P1} = \frac{V_{C\ trapped}}{2}$$
$$V_L = V_{IN} - \frac{V_{c\ trapped}}{2}$$

$$V_{C\ trapped} = 2V_{P1}$$

B. Interval 2 (Fig. 4(a): T1' < t < T1)

The clamping capacitor starts discharging through the path: Clamping capacitor via Diode D_1 via S_1 parasitic capacitor to achieve ZCS and ZVS. Current through $L_{Leakage1}$

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:55:16 UTC from IEEE Xplore. Restrictions apply.

starts decreasing sinusoidaly and current through $L_{Leakage2}$ starts increasing sinusoidaly.

C. *Interval 3 (Fig. 4(b): T1< t < T2)*

Switch S_1 is turned ON and all the primary side switches conduct simultaneously during this interval. The current through S_2 decreases and current through S_1 increases. The input current gets distributed in both primary leakage inductors due to the presence of clamping capacitor. Polarity across the capacitor got interchanged which signifies that the capacitor starts discharging which is supported by previous mode. Therefore ZCS-ZVS for switch S1 (turning ON) and S2 (turning OFF) gets achieved.

D. *Interval 4 (Fig. 4(c): T2< t <T2')*

At T_2 the switch S_2 gets turned OFF and only S_1 is conducting diode D_5 and D_4 of secondary side Rectifier Bridge are conducting. Constant current Iin flows through $L_{Leakage1}$ and $L_{Leakage2}$ .Switch S_2 carries the entire input current. The trapped capacitor's voltage ($V_{C\ trapped}$) is clamped at $-2V_{P1}$.

E. *Interval 5 (Fig. 4(c): T2' <t<T3)*

At T2' current through $L_{Leakage1}$ starts increasing sinusoidaly and current through $L_{Leakage2}$ starts decreasing sinusoidaly and trapped capacitor Cc starts charging until it reaches its maximum value.

$$V_{P1} = V_{P2}$$
$$V_{IN} = -V_L - V_{P1} + V_{CC}$$
$$V_{P1} = \frac{V_{C\ trapped}}{2}$$
$$V_L = \frac{V_{c\ trapped}}{2} - V_{IN}$$
$$V_{C\ trapped} = 2V_{P1}$$

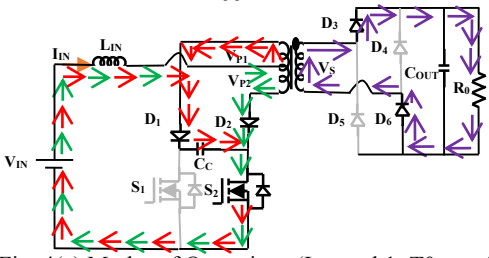

Fig. 4(a) Modes of Operations (Interval 1: T0< t < T1)

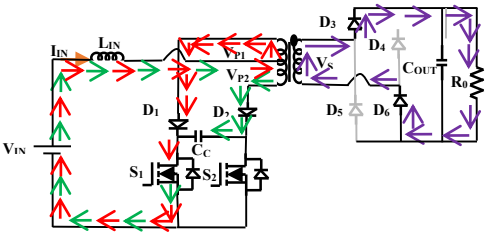

Fig. 4(b) Modes of Operations (Interval 1: T1< t < T2)

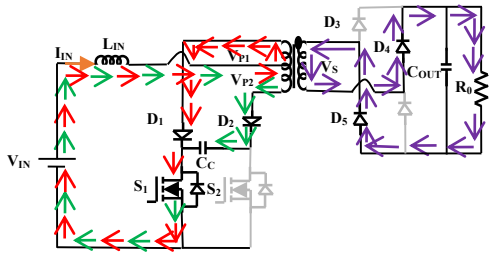

Fig. 4(c) Modes of Operations (Interval 1: T2< t < T3)

IV. System Analysis

This work explains the analysis of the current fed push-pull converter shown in Figure 2. The notable characteristics of this converter include high efficiency, ZVS ,ZCS and a low switching surge. In addition, the inductor's series connection with the input power source results in the suppression of backward noise and high immunity against external noise. Two operating modes are analysed in this study: the first when the switch S_1 or S_2 is ON, and the other when both switches S_1 and S_2 are ON. Second, the effects of the transformer's leakage inductance and trapped capacitor were discussed in detail. The formulation of differential equations that reflect the low-frequency behaviour of the resonant converter is the initial step in the analytical process. Differential equations are derived in this analysis, and a few analytical expressions are explained. Calculations of the static and dynamic properties are also discussed. Our mathematical model considers the effects of the inductance of the transformer and trapped capacitor. Resistances against parasites were disregarded. Diodes are considered ideal for the analysis.

$V_{IN}(t)$: Input Voltage
$V_{GS1}(t), V_{GS2}(t)$: Gate to Source Voltage of Mosfet Switch S_1 and S_2 respectively
$V_{C\ trapped}(t)$: Voltage across trapped capacitor
$I_{IN}(t)$: Input inductor current
$I_{OUT}(t)$: Output current
$V_{OUT}(t)$: Output Voltage
L_{TF}: Total leakage inductance of transformer's primary

A. *State 1:Either S_1 or S_2 is on.*

The circuit equations in this interval are:

$$V_{IN} = L\frac{di}{dt} + \frac{d\emptyset}{dt} \quad (1)$$

Where ∅ is linkage flux associated with primary winding of the transformer

$$I_{C\ trapped} = C_{trapped}\frac{dV_{C\ trapped}}{dt} \quad (2)$$

$$(I_{IN} - I_{C\ trapped}) - I_{C\ trapped} - nI_{OUT} = \frac{\emptyset}{L_{TF}} \quad (3)$$

$$V_{C\ trapped} = 2\frac{d\emptyset}{dt} \quad (4)$$

$$C_{OUT}\frac{dV_{OUT}}{dt} + \frac{V_{OUT}}{R} = I_{OUT} \quad (5)$$

Where n is turns ratio of transformer $n = \frac{N_2}{N_1}$
Equation (3) represents the relation of transformers magnetizing current and linkage flux.
By using Laplace transform technique to solve (1) to (5) we get:

$$\emptyset(t) = \emptyset(0) + A\left(t - \frac{\sin w_0 t}{w_0}\right) + \frac{B}{w_0}(1 - \cos w_0 t)$$

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:55:16 UTC from IEEE Xplore. Restrictions apply.

$$I_{IN}(t) = I_{IN}(0) + \frac{V_{IN}(t)}{L} - \frac{A}{L}\left(t - \frac{\sin w_0 t}{w_0}\right) - \frac{B}{w_0 L}(1 - \cos w_0 t)$$

$$V_{OUT}(t) = V_{OUT}(0)\left(1 - \frac{t}{C_{OUT}R} - \frac{t^2}{2C_{OUT}}\right) + \frac{I_{OUT}(0)t}{C_{OUT}} - \frac{nAC_{OUT}R^2}{1 + (w_0 C_{OUT}R)^2}\left[1 - \frac{t}{C_{OUT}R} - \frac{{w_0}^2 t^2}{2} - \cos w_0 t + \frac{\sin w_0 t}{w_0 C_{OUT}R}\right] + \frac{nBC_{OUT}R^2}{1 + (w_0 C_{OUT}R)^2}\left[\frac{1}{w_0 C_{OUT}R} + w_0 t - \frac{\cos w_0 t}{w_0 C_{OUT}R} - \sin w_0 t\right]$$

$$V_{C\ trapped}(t) = 2A(1 - \cos w_0 t) + 2B \sin w_0 t \qquad (6)$$

Where, $\emptyset(0)$, $I_{IN}(0)$, $V_{OUT}(0)$, $I_{OUT}(0)$ are initial values in this interval and the resonance frequency w_0 and parameters A and B are:

$$w_0 = \frac{1}{2}\sqrt{\frac{1}{C_{trapped}}\left(\frac{1}{L} + \frac{1}{L_{TF}}\right)}$$

$$A = \frac{V_{IN} + nV_{OUT}L}{4{w_0}^2 L C_{trapped}}$$

$$B = \frac{I_{IN}(0) - nI_{OUT}(0) - \frac{\emptyset(0)}{L_{TF}}}{4w_0 C_{trapped}}$$

This state shifts to next state when the resonance voltage $V_{C\ trapped}$ reaches to zero.

B. State 2: When S_1 and S_2 are on.

The circuit equations in this interval are:

$$V_{IN} = L\frac{di}{dt}$$

$$C_{OUT}\frac{dV_{OUT}}{dt} + \frac{V_{OUT}}{R} = 0$$

Using Laplace transform

$$\emptyset(t) = \emptyset(t1)$$

$$I_{IN}(t) = \frac{V_{IN}}{L}(t - t_1)$$

$$V_{OUT}(t) = V_{OUT}(t_1)\left(1 - \frac{t - t_1}{C_{OUT}R}\right)$$

Where t_1 is the time when both switches S_1 and S_2 are ON Putting the differentiation in the above differential equations and to be zero static characteristics are derived.

$$2\emptyset = A\left(t - \frac{\sin w_0 t}{w_0}\right) + \frac{B}{w_0}(1 - \cos w_0 t)$$

$$V_{IN}T_S = A\left(t - \frac{\sin w_0 t}{w_0}\right) + \frac{B}{w_0}(1 - \cos w_0 t)$$

$$V_{OUT}T_S = nA\left(t - \frac{\sin w_0 t}{w_0}\right) + \frac{nB}{w_0}(1 - \cos w_0 t)$$

Where $\emptyset$ is linkage is flux and T_S is the switching period of the converter operation

Above equations yields the following results:

$$|\emptyset| = \frac{1}{2}V_{IN}T_S$$

$$V_{OUT} = nV_{IN}$$

Maximum value $V_{C\ trapped\ ,max}$ of the resonance voltage is derived from (6) as follows:

$$V_{C\ trapped\ ,max} = 2A + 2\sqrt{A^2 + B^2}$$

V. PERFORMANCE ANALYSIS

The circuit of the proposed active clamped ZCS-ZVS push pull converter is implemented in MATLAB Simulink to verify the theoretical analysis. The converter is tested with a 48V DC input voltage with a 100 kHz switching frequency. 380V and 500W are the specified output voltage and power, respectively. The Duty D at the specified input voltage is obtained as 0.58. The leakage inductance $L_{Leakage1}$ and $L_{Leakage2}$ of the transformer T, which has no air gaps, is 2 µH. By using a boost inductor L_{IN} of 500 µH, the maximum ripple current ΔI_{IN}, max is set to 0.3 A at D 0.58. Two blocking diodes with a trapped capacitor C_C has been added on the primary side of conventional push pull converter to achieve ZCS- ZVS. The voltage across the trapped capacitor is chosen from the circuit analysis presented in section IV above. The critical simulation parameters are listed in the Table I.

TABLE I. SIMULATION PARAMETERS

Parameter	Values
Input voltage	48 V
Output voltage	380 V
Output power	500 W
Switching frequency	100 kHz
Turns Ratio	1: 1: 4.3
Leakage inductance ($L_{Leakage1}$and $L_{Leakage2}$)	2 μH
Inductance of boost inductor	500 μH
Trapped capacitor	50 nF
Output capacitor	470 μF

Figure 5 displays the output current and voltage waveforms measured at a 48 V input and a 500 W load condition. Figure 5 shows that due to the presence of capacitive output filter the maximum output voltage ripple is 0.5V.Due to the boost inductor's presence at the input, the maximum ripple current seen in Figure 6 input current waveform is restricted to 10.04 A. In addition to the gating signals for switches S_1 and S_2, Figure 7 shows the waveforms of the current and drain-source voltage for S_1 and S_2, respectively. Both ZCS-ZVS are obtained for switches S_1 and S_2, respectively, as shown in Figure 7 which eliminates the switching conduction losses hence increasing efficiency. Current is at 0 A before switches S_1, S_2 turn off, ensuring the ZCS turn off of both switches. Figure 8, respectively, shows the waveforms of the trapped capacitor voltage and the primary voltages (V_{P1} and V_{P2}) of the transformer. Resonance on the primary side of the transformer causes a voltage

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:55:16 UTC from IEEE Xplore. Restrictions apply.

waveform with a sinusoidal shape at the primary. It is clear that the trapped capacitor voltage is double the primary voltages of the transformer, as determined in the analytical section. As a result of the inclusion of quick recovery SIC diodes on the output side, the secondary voltage waveform of the transformer in Figure 9 is more like a sinusoidal waveform.

A. Comparison of Proposed Converter and the Existing Topologies

Table II compares the efficiency, primary voltage waveform shape, clamping state, soft-switching, and quantity of ground-referred switches and gate drivers of three distinct Push Pull converter topologies [6][7]. The suggested converter contains fewer active power devices than the topologies in [6] and [7], as shown. The proposed converter has the maximum efficiency when compared to the converters in [6] and [7].The resonance at the primary side of the transformer causes the primary voltage to be sinusoidal, unlike in these two converters .As all switches are ground referenced, the circuit design is made simpler and fewer isolation gate drivers are needed. As compared to topology in [7] number of clamping capacitor required is less. In contrast to existing topologies, the suggested converter can provide ZCS-ZVS both operation for both switches that are present at primary.

TABLE II. COMPARITIVE ANALYSIS

Parameters	**Topology**		
	Conventional Push Pull [6]	Modified Push Pull [7]	Proposed Push Pull
Efficiency	High	Higher	Highest
Transformer Primary Voltage	Square	Quasi square	Sinusoidal
Clamping	NO	YES	YES
ZVS/ZCS	NO	ZCS	BOTH
Ground Referred Switches	Yes	NO	Yes
Gate Driver Required	1	2	1
Clamping Capacitor Required	0	2	1

The switch current and drain to source voltage waveforms of the three topologies are compared in Figure 10. Along with high voltage conversion ratio, the voltage stress on the switches is low due to the ZVS and ZCS operations of both the primary side switches as shown in figure 10.The proposed converter has no voltage spike during switching as compared to topologies presented in [6] and [7] as shown in Figure 10. Also switch drain to source voltage in the presented converter is sinusoidal in shape as compared to other two topologies [6][7]. Figure 12 represents the comparison between transformer's primary voltages for all three topologies. The proposed converter features a sinusoidal waveform at the transformer primary, which results in reduced losses in the transformer and less leakage flux, further leading to greater converter efficiency, as compared to topologies presented in [6] and [7] depicted in figure 12. Figure 11 represents the comparison between transformer's secondary voltages for all three topologies The fast recovery SIC diodes present at the secondary side of the converter, gives the proposed converter a sinusoidal-like waveform at the transformer secondary as

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:55:16 UTC from IEEE Xplore. Restrictions apply.

compared to topologies presented in [6] and [7] shown in figure 11.

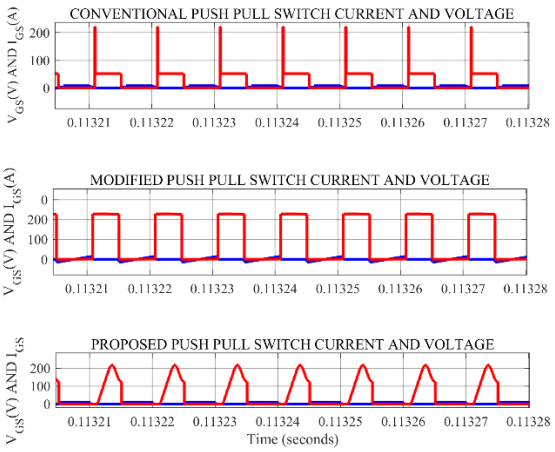

Fig. 10 Comparative waveform of drain to source voltage and current for three topologies

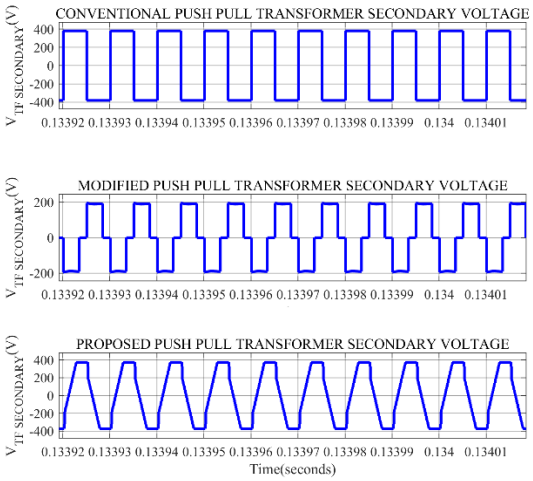

Fig. 11 Comparative waveform of transformer secondary voltage for three topologies

VI. Conclusion

The active clamped ZCS-ZVS resonant push–pull converter has been proposed. The analysis, design and simulation results for the proposed converter have been presented. High voltage conversion ratio, reduced switch conduction loss, and other features of the typical current-fed push-pull converter are all preserved in the proposed converter. Moreover, the proposed converter outperforms all other examined topologies with an efficiency of 97.135. In particular, the ripple current of the boost inductor is extremely low at the duty ratio around 0.58. The proposed converter is suitable for the high step-up converter in fuel cells and solar cell applications due to features like soft switching, sinusoidal shape voltage waveform at the transformer primary, and sinusoidal secondary voltage of the transformer due to fast recovery SIC diode, and single gate requirement.

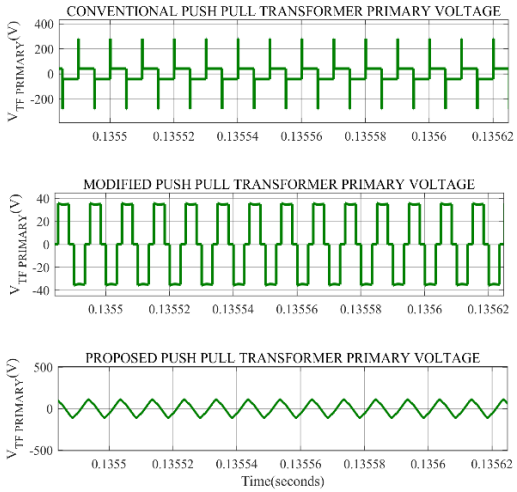

Fig. 12 Comparative waveform of transformer primary voltage for three topologies

***Abstract*—In today's world, online news has become an integral and important part of the daily lives of millions of beings. With every day gone by, an increasing number of people have begun to rely on various websites for their daily dose of information. Due to the ever increasing popularity of these sources, the scope of spreading misinformation has also risen to a great extent. Rumors and biased news can spread like wildfire, thus undermining the credibility of news articles and causing trust in the media to dwindle. This recent surge in false information on social media has prompted extensive research in the field of online fake news detection. Hence, there is a need for efficient yet accurate fake news detection models which can be made accessible to everyone. In this research, we have explored the use of pre-trained distilled variants of the BERT model to identify fake news and rumors from actual online news. We compared the results before and after combining two smaller pre-trained BERT models into a single architecture with other approaches to see how well distilled models are able to learn the key features required to distinguish fake news from real. Results show that these smaller variants were comparable to the related work in terms of accuracy while still being efficient, compact, and easier to train.**

***Index Terms*—ake News Detection, Deep Learning, Natural Language Processing, BERT, Pre-trained Language Modelake News Detection, Deep Learning, Natural Language Processing, BERT, Pre-trained Language ModelF**

I. Introduction

Fake news and the media's stance have always been a matter of concern for societies, as they have the potential to incite political unrest and could generate panic among the masses. The COVID-19 pandemic has only exacerbated the problem, as there has been an overabundance of misinformation and fake news about the virus circulating on social media platforms. With the advent of social media, fake news has become more rampant and has the potential to spread at an alarming rate, leading to what is now known as an "infodemic."

To manage the spread of such misinformation, we need tools that can derive linguistic, sentimental, emotional, and other characteristics from different news articles. In this regard, transformer-based bi-directional models like BERT have shown impressive results. However, the computational requirements of BERT are quite high, making it difficult to use in applications that require real-time processing. In order to address this issue, smaller variants of BERT have been developed, such as BERT-small and BERT-tiny. These models have been shown to be computationally efficient while still maintaining a high level of accuracy. BERT forms the basis of this research, along with its computationally efficient counterparts such as BERT-small and BERT-tiny, both of which will be explored throughout the course of the study, along with their multi-model variants, in order to analyze online fake news, by applying transfer learning.

II. Related Works

Numerous approaches have been explored to handle the task of online news analysis, ranging from the detection of fake news to news sentiment analysis.

The authors of [1] proposed a multi-task model for fake news detection named FDML. This was based primarily on two observations i.e., a few topics may have a higher percentage of fake news, and some writers may have greater intentions to publish fake news. The FDML was claimed to be one of the first works that integrated the task of fake news detection along with classifying the news topics too.

In [2], Julio CS et al. experimented with a wide range of news article attributes such as textual features, news source features, environmental features, etc., and then further used the same with different classifiers, with XGBoost & Random Forest showing superlative performance.

Kai et al. in [3] focused on a broad understanding of fake news detection and its characterizations based on social theories and psychology, along with analyzing existing algorithms from data mining's viewpoint.

In [4], the authors made use of a model known as FNDNet, which makes use of a deep neural network's several hidden layers in order to learn the distinctive attributes of classification of fake news. This proposed model achieved a whopping

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:11:03 UTC from IEEE Xplore. Restrictions apply.

accuracy of over 98% on the Kaggle fake news dataset, and the results were validated using various performance parameters.

The authors of [5] made use of the Naive Bayes Classifier so that they could differentiate between fake and real news. This describes in detail how the process of spam filtering goes about and the features associated with it. On the Buzzfeed news dataset, the model displayed an accuracy of 75%.

III. Methodology

A. Transformers

A major chunk of the learning systems up until recently processed natural language using gated RNNs (for example, LSTM & GRU) which are made for processing sequential input. These designs made an important addition of the attention layers to their architecture after inculcating the attention mechanism for better understanding the relationships between the sequence's components and then weighing them in accordance with their significance to the model [8, 9]. Transformers have mostly replaced the prior sequence models in recent times because of their superior performance in tasks related to Natural Language Processing. The attention mechanism is capable of satisfying the RNN's predicted learning performance, so transformers make use of the same methodology [10]. One of the most promising and latest transformer models is the BERT, which is pre-trained on a large amount of unlabeled data for two purposes [11]:

- Masked language modeling: In a particular sentence or phrase, around 15% of the words are hidden (or masked) so that the model can forecast them based on word context. It should be emphasized that BERT is a bidirectional model, which means that it uses both pre-word and post-word content to predict, in contrast to earlier Transformer models like the GPT. Additionally, both left-to-right and right-to-left languages can use BERT with equal effectiveness, which signifies that it does not rely on the direction of the language.
- Next sentence prediction: As the name suggests, whenever a pair of sentences is given, the model should be capable of predicting if the second sentence follows the first one or not.

The pre-trained model needs fine-tuning in order to be used in downstream activities. The same can be done by applying it to task-specific data, keeping the architecture and weight same as before. Only after the task's intended output is met do we add the output layers. We initially start with the model parameters from the pre-training part when fine-tuning the model. All model parameters are then adjusted simultaneously.

B. Transfer Learning

Deep learning needs an abundance of data to learn and train from, but our access to rumors and false news is quite constrained. This presents a fundamental problem for employing deep neural networks on fake news, because of the limited amount of resources. The majority of the fake news datasets that have been developed to date are either a few hundred or a few thousand rows in size, which makes them unsuitable for training complicated neural networks with many parameters [12, 13]. Transfer learning has been employed in recent studies to solve this issue. In transfer learning, a model, called generally as the pre-trained model, is first trained on a sizable quantity of generic data, usually extracted from the internet. Then, using labeled data for a particular task that shares some knowledge with the core model, the pre-trained model is enhanced [14]. This kind of learning is recently being inculcated in NLP, after being used for several years in image processing methods.

Typically, the pre-training procedure is used to create a language model for transfer learning in Natural Language Processing. A Language models' main task is to anticipate the text's next word or phrase. Language models contain two key characteristics: Firstly, they can be taught on unlabeled data, giving them access to a tonne of data for a thorough learning process. Secondly, a language model which is well-trained may provide us with a thorough knowledge of the semantics and structure of the language, later which becomes crucial for a number of tasks.

C. Distillation

Due to their enormous size, training large-sized models like BERT might take much more time, ranging from a few hours to even days. Additionally, you can discover that running them on small devices would result in significant memory and time expenditures due to today's constantly improving performances.

Distillation can be summarized as an act of teaching a tiny student model to closely resemble a bigger instructor model. Distillation is pretty useful when we intend to migrate a model to less powerful hardware, like a smartphone or a tiny laptop, because distilled models are more efficient and take up less space.

D. Smaller BERT Variants

Two smaller versions of BERT, called BERT-Tiny and BERT-Small, have been developed to address the issue of limited computational resources. These models are easier and faster to train than the original BERT model, as they have fewer parameters as compared to the 110M parameters present in the original model, while still maintaining a high level of accuracy. BERT-Tiny is a miniature version of the original BERT model, with only 2 layers and 128 hidden units per layer. BERT-Tiny is suitable for small-scale NLP tasks that do not require a large amount of computational power.

BERT-Small is a slightly larger version of BERT-Tiny, with 4 layers and 512 hidden units per layer, making it a good choice for medium-scale NLP tasks. BERT-Small is also faster and more efficient than the original BERT model, while still achieving comparable accuracy. BERT-Tiny and BERT-Small, together with the other variations, were proposed in "Well-Read Students Learn Better: On the Importance of Pre-training Compact Models", and then were ported to "Generalization in NLI: Ways (Not) To Go Beyond Simple Heuristics" [18,19].

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:11:03 UTC from IEEE Xplore. Restrictions apply.

We used the BERT-Tiny and BERT-Small models from the Hugging Face transformer library [22].

E. Dual Model Architecture

The main idea behind the proposed dual model architecture is to train two BERT variants jointly on a single task, with each model having different parameters and being initialized randomly. This approach not only allows for the use of smaller, more efficient models but also leverages the complementary strengths of the two models to improve classification accuracy.

We have utilized Dual BERT-Tiny and Dual BERT-Small, which are specifically designed to be computationally efficient and require less memory compared to larger models, while still delivering good performance on various natural language processing tasks. Inputs are encoded as 2 tuples of matrices (token, mask, sequence ids), one for each input. The first model receives the news headlines while the second one receives the body of the news article or a brief textual description. The output layers of both transformers were then concatenated and passed through a fully connected layer to obtain the final output, which was used for fake news classification.

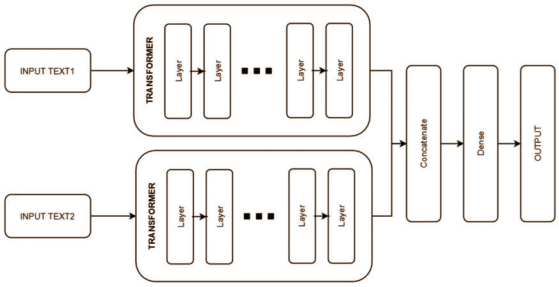

Fig. 1. Architecture of Dual BERT variant

IV. Experiments and Evaluation

A. Dataset

FNC-1 was introduced as a dataset for stance detection and it consists of labeled pairs of a headline text and a body text, which can be either from the same news article or from two different articles. These pairs are labeled as agree (the body text and the headline are consistent), disagree (the body text and the headline are not consistent), discuss (the body text discusses the same subject as the headline, but it is neutral), and unrelated (the headline discussed is different than the body content). The dataset's headlines are all written in the form of statements and contain 25413 samples in the test set and 49972 in the training set.

B. Evaluation Metrics

To evaluate the performance of our models, we consider some of the widely used metrics: accuracy, precision, recall, and F1 score. The number of correctly predicted positive classes by the model is denoted by True Positive (TP), while the number of correctly predicted negative classes is represented by True Negative (TN). False Positive (FP) represents the number of positive classes classified as false by the model, and False Negative (FN) refers to the number of negative classes classified as true by the model.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{1}$$

$$Precision = \frac{TP}{TP + FP} \tag{2}$$

$$Recall = \frac{TP}{TP + FN} \tag{3}$$

$$F1\ score = \frac{2 * Precision * Recall}{Precision + Recall} \tag{4}$$

C. Training parameters

To address the class imbalance in the training dataset, we used focal loss as the loss function and assigned more weights to classes such as *agree*, *disagree*, and *discuss* based on their distribution [21]. During the initial phase of training, the pre-trained layers in Dual BERT-Tiny and Dual BERT-Small models were locked, and then unlocked once the validation loss started to stabilize. This approach allowed the models to better adapt to the specific task of fake news classification while preventing the integrity of the pre-trained weights.

D. Results

We compared our result with the top 4 submissions of teams who participated in the FNC-1 challenge, which are shown in the first half of Table-1, resulting in Athene [28] having the highest accuracy. Per class accuracy is shown in columns 3-6 in % while the second column shows the overall accuracy. The BERT-Tiny and BERT-Small were able to give an accuracy of 85.25%, and 90.11% respectively, and the Dual BERT-Tiny and Dual BERT-Small gave an accuracy of 82.79% and 79.96% respectively on the test set. Table-2 shows precision, recall, and F1-score in % for each class obtained using the BERT-Small model.

TABLE I
Results on FNC-1 Test Dataset

Method	Accuracy	Per Class Accuracy			
		Unrelated	Discuss	Agree	Disagree
SOLAT in the SWEN [27]	89.08	98.70	76.18	58.50	1.86
Athene [28]	89.50	**99.25**	80.89	44.72	9.47
UCL Machine Reading [29]	88.46	97.90	**81.38**	44.04	6.60
Chips Ahoy! [30]	88.01	98.98	70.29	55.96	0.28
BERT-Tiny	85.25	96.19	69.65	45.14	6.89
Dual BERT-Tiny	82.79	93.28	69.85	41.25	3.01
BERT-Small	**90.11**	98.95	76.28	**65.53**	**12.91**
Dual BERT-Small	79.96	92.14	59.21	38.62	5.16

Conclusion and Future Works

In this research, we first addressed the need for an efficient mechanism to differentiate online fake news from real, authentic news. We then explored the use of deep transformer-based bi-directional models for the analysis of online fake news, which showed impressive results across the FNC-1 dataset.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:11:03 UTC from IEEE Xplore. Restrictions apply.

TABLE II
BERT-SMALL RESULTS ON FNC-1 TEST DATASET

Stance	Precision	Recall	F1-score
unrelated	97.98	98.95	98.47
discuss	80.00	76.28	78.10
agree	52.66	65.53	58.39
disagree	34.88	12.91	18.85

Our findings suggest that comparatively smaller pre-trained models such as BERT-Tiny and BERT-Small, when coupled with appropriate loss functions, can deliver great results when used for fake news detection while also being more efficient and faster to train.

Moving forward, further exploration of linguistic, sentimental, emotional, and other characteristics of online news could lead to even better results when combined with fake and real news labels. By analyzing these additional characteristics, we can improve our understanding of the nature of fake news and develop more accurate and effective detection methods. Additionally, the effectiveness of the proposed method could be tested on other datasets and in different languages to evaluate its generalizability. Overall, the findings of this study have important implications for the detection and prevention of fake news, which is a critical issue in today's digital world.

***Abstract*—It has become clear that fake news is dangerous. Identifying fake news is a crucial step towards preserving the virtue and prosperity of society. Social media's rising popularity has led to an increase in the spread of false information. There aren't enough frameworks in place to deal with misleading news. There are many low-cost online news sources and it's an easy access via social media. These are the reasons why there's a spread of fake news. News Content is the only reason for the present fake news detection algorithms, also users' previous posts or activities provide a lot of insights about their views on news and have a significant effect on false news identification. The proposed research seeks to investigate several machine learning approaches for the analysis and identification of false news. In order to identify the spread of fake news on social media, we compare various widely used machine learning methods, such as Naive Bayes and Multi Layer Perceptron Classifiers, in this study. In this work, using solely text data, we develop a number of machine learning methods using the WELFake dataset.**

***Index Terms*—fake news detection, machine learning, text analysis, naive bayes, multi layer perceptron**

I. Introduction

Nowadays, social media networks are the most popular way to distribute thousands of pieces of news, whether they are public or private. Content on social media is simple to obtain, share, and remark on. There is a danger of getting exposed to false information which is purposefully wrong or contains inaccurate information in order to support a certain political or economic objective as it is simpler for users or readers to share their particular opinions. Furthermore, false information typically spreads more quickly, deeply, and widely on social media.

In the past year, fake news detection in social media has drawn a lot of attention from academic and professional circles. Social media networks have identified numerous web pages and misinformation and have devoted resources to the job. A fake news detection method aims to identify and investigate various types of potentially misleading news. The analysis of prior real and fake news samples is used to predict the likelihood that a given piece of news content is being intentionally misleading.

A notable obstacle to this algorithmic method and resolving this natural language processing issue is the lack of news examples that are available as corpora for training the model. The various false news models that already existed were context-specific. There is a dearth of a suitable paradigm for classifying the different kinds of deceptions that can happen when working with written data. This study looks at various techniques and kinds of deception that can be found when working with online news material, weighing the benefits and drawbacks of predictive modeling. It offers an algorithmic method for resolving the specified issue.

We used the WELFake dataset, which consists of 72,134 news stories, 35,028 of which are true and 37,106 of which are false. In order to avoid over-fitting of classifiers and to give more text data for better ML training, authors combined four well-known news datasets (Kaggle, McIntire, Reuters, and BuzzFeed Politics). The four columns in this dataset are Serial number (beginning at 0), Title (about the text news headline), Text (about the news substance), and Label (0 = fake, 1 = authentic). Just 72134 of the 78098 data elements in the csv file are accessible according to the data frame.

The primary goal of this study is to minimise and decrease the spread of false information on social media platforms. It is more practical for the consumer when the virtual site is secure. In this research, we'll attempt to put some methods into practise to see how well the algorithms performs at detecting authenticity. We think it will aid in the identification of rumours and have a transformative effect on the veracity of social media news. Additionally, it will stop people from trusting anything they read or see on social media.

II. Related Works

Akshay Jain and Amey Kasbe conducted a research study in which they evaluated the accuracy of various machine learning algorithms for making predictions. They tested models such as

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:13:33 UTC from IEEE Xplore. Restrictions apply.

bounded decision trees, gradient boosting, and support vector machines, using an unreliable probability threshold. The study found that these models achieved an accuracy ranging between 0.85 to 0.91.[1]

In their study, Farzana Islam and her colleagues utilized the Naïve Bayes classifier algorithm method to categorize deceptive news, employing both count vectorization and TF-IDF vectorization as feature extraction methods. They applied this technique to two open source fake news datasets available on various sources[2].

Zongru Shao and Pranav Bharadwaj conducted experiments on the fake news dataset available on Kaggle.com, utilizing RNN, , a random forest classifiers and a Naïve Bayes classifier. They employed various feature extraction techniques, including Quadgram, Bigram, Trigram, and GloVe[3].

Castillo et al. used a different and more logical approach in their research. They identified positive and negative keywords and hashtags to identify the legitimacy of the news[4].Karimi and Tang introduced a novel technique to detect fabricated news, which relies on HDSF more commonly known as Hierarchical Discourse-level Structure. It is a hierarchical structure. In this algorithm, features of both authentic and fake news documents are pulled out automatically. The researchers evaluated this approach on five datasets [5].

Z Khanam et al used feature selection and processing of attributes to apply machine learning models like SVM, Logistic regression, KNN, XGBoost and obtained the accuracy of 0.92 using SVM model on the dataset imported from Kaggle[6].

Veronica Perez-Rosas used different models, including the decision tree, naive Bayes algorithms and clustering were employed to differentiate between Twitter spam senders. On average, the models were able to identify spammers with an accuracy of 0.70 and fraudsters with an accuracy of 0.712. However, the models exhibited a low level of intermediate precision in distinguishing spammers from non-spam accounts[7].

Their study assumes that Fake news detection is an application of predictive analysis that involves three stages: cleaning/processing, feature extraction, and classification or categorising. A hybrid classification model designed specifically for identifying counterfeit news was used in this study. The classification approach involved a combination of random forests and KNN. Metrics like accuracy, precision and recall for the proposed models were calculated, and the results showed an improvement of up to 8 percent using a hybrid model for fake news detection[8].

Alim Al Ayub Ahmed and team in their research tried to identify which models can and can not be used for fake news classification and the steps to implement them[9]. Fahim Belal Mahmud and team applied models like SVM, LR, Random forest using the spacey and BERT techniques and using four GNN vaiants : GAT,GraphSAGE, GCN, and GIN.[10]

III. METHODOLOGY

This study utilized a three-stage approach for its methods. In the first stage, the raw dataset underwent pre-processing which involved filtering and various data cleaning techniques to extract semantic features. A stopword filter was implemented to remove prepositions and categorize the data. The second stage involved the conversion of text based features into binary vectors through numerical techniques. The final stage utilized both machine learning and deep learning algorithms like Naive Bayes, Random Forest, XGB Classifier to create partitions within the dataset. The same methodology is shown through figure 1.

A. The Pre-processing Stage

Data preprocessing involves the cleaning and transformation of unstructured data, such as text, to prepare it for analysis. Text mining is a common approach to this task, but it can be challenging due to the presence of impurities like HTML tags, single characters, numbers, apostrophes and unwanted symbols. In this study, we applied the stopwords removal method to clean and preprocess a classified dataset. Stopword removal is a widely used data filtering technique in information retrieval and text classification. It involves eliminating certain common words like: ”the, in, a, an, with”, that have little impact on the categorization of data.

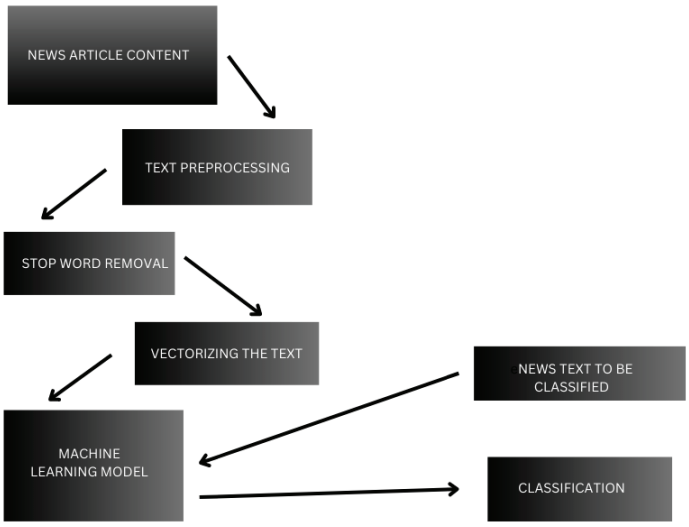

Fig. 1. Structure of this Paper

B. The Extract Features Stage

In this technique we use a method to convert the textual data to binary vectors 0 and 1 to make it convenient to train the classification algorithms. New vectors are created from each new entry in the sample text file. Vectors can be created using multiple techniques mentioned below:

1. TF-IDF vectorizer: The term frequency-inverse document frequency (TF-IDF) vectorizer is one of the most common method for the first stage i.e Feature Extraction. This technique involves two stages, with the first stage calculating the term frequency (TF), and the second stage computing the inverse document frequency (IDF).

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:13:33 UTC from IEEE Xplore. Restrictions apply.

Term Frequency = (Number of times the term appears in a document) / (Total number of terms in the document)

Inverse Document Frequency = log(Total number of documents / Number of documents with the term)

2. N-gram level vectorizer: An n-gram level vectorizer is a technique used in natural language processing (NLP) to convert text data into numerical vectors that can be used for machine learning. N-grams are contiguous sequences of n words from a given text, and the vectorizer creates a feature matrix with the frequency count of each n-gram in the text. This approach captures the contextual information of the text, making it useful for various NLP tasks like sentiment analysis and text classification. N-gram level vectorizers are customizable and can generate feature matrices with different levels of granularity.

3. Character level vectorizer: A character-level vectorizer is a technique used in natural language processing to convert text data into numerical vectors by considering each character in the text as a separate feature. This approach captures the underlying structure and patterns of the text at a granular level and is useful for tasks such as language modeling and text generation.

C. The Classifiers Stage

The following Machine learning and deep learning algorithms were used in this study: Gaussian Naive Bayes, Bernoulli Naive Bayes, Multilayer Perceptron, Random Forest Classifier, XGBoost Classifier.

- **Gaussian Naive Bayes** is a classification algorithm that use Bayes' theorem and assumes that features are independent and normally distributed. It estimates the mean and variance of the input features for each class to compute the probability of each class given the input features. Using these estimations, the system then computes the likelihood of each feature value given the class. It derives the joint probability of the input feature vector given the class by multiplying the likelihoods for each feature. Finally, given the input feature vector, it computes the posterior probability of each class and selects the class with the highest probability as the predicted class.
- **Bernoulli Naive Bayes** is based on the assumption that the features are binary or boolean values. It estimates the likelihood of each feature for each class to compute the probability of each class given the supplied features. Using these probabilities, the algorithm then computes the likelihood of the input feature vector given the class. It derives the joint probability of the input feature vector given the class by multiplying the likelihoods for each feature. Finally, given the input feature vector, it computes the posterior probability of each class and selects the class with the highest probability as the predicted class. Bernoulli Naive Bayes is a text classification method in which the features indicate the presence or absence of specific words in a document.
- **MLP (Multilayer Perceptron) Classifier** is an artificial neural network that is commonly utilized for supervised learning tasks such as classification. It comprises of several layers of interconnected nodes, where each node carries out a weighted sum of its inputs and applies an activation function to generate its output. MLPs are extensively used in various applications such as image recognition, speech recognition, and natural language processing. They have the ability to learn intricate non-linear connections between inputs and outputs and can be trained using the backpropagation algorithm.
- **Random Forest Classifier** is an ensemble learning technique that enhances the accuracy and consistency of predictions by combining multiple decision trees. It creates numerous decision trees during training and then determines the class by identifying the mode of the predicted classes by individual trees. Random Forests have the capability to handle large datasets with high dimensionality and learn non-linear relationships between input features and output classes. They are commonly used in fields such as finance, medicine, and e-commerce for various applications like fraud detection, disease diagnosis, and customer segmentation. Moreover, Random Forests provide feature importance scores that can be used for data interpretation and feature selection.
- **XGBoost (Extreme Gradient Boosting) Classifier** algorithm is a robust machine learning technique that is extensively used for supervised learning problems like classification and regression. It is a highly optimized implementation of the gradient boosting algorithm, which uses a combination of multiple decision trees to enhance the accuracy and efficiency of predictions. XGBoost applies a gradient descent algorithm to optimize the objective function and prune the decision trees to avoid overfitting. This algorithm can handle missing values and feature interactions, and it supports parallel processing to expedite model training. XGBoost is utilized in various fields such as finance, healthcare, and marketing for tasks like credit risk assessment, disease diagnosis, and customer churn prediction.

D. Results

The primary objective of this project is to perform a comprehensive analysis of the news data contained in the WELFake dataset, which is available on the Kaggle website. Our analysis involves the use of six distinct algorithms, namely:

- Bernoulli Naive Bayes
- MLPClassifier
- Gaussian Naive Bayes
- Random Forest Classifier
- XGBoost

These algorithms are chosen due to their proven effectiveness in the data driven field like data analysis and machine learning.

We conduct our analysis by first importing the dataset into the Anaconda platform and then executing the algorithm codes in Python. The cognitive learning library is used

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:13:33 UTC from IEEE Xplore. Restrictions apply.

to automatically generate a confusion matrix, which we use to visualize the results of our analysis. Additionally, performace was measured based on the calculated value of accuracy of each algorithm.

The confusion matrix and accuracy scores for each of the six algorithms used in the analysis are presented below. As can be seen, the XGBoost algorithm outperforms all the others with a high accuracy score of 94%, while the Gaussian Naive Bayes algorithm has the lowest accuracy score of 74%. The results obtained from our analysis provide valuable insights into the usefulness of different algorithms for detecting fake and deceptive news and can be used to inform future research in this area.

TABLE I
RESULTS

Model	*Accuracy(Train)*	*Accuracy(Test)*	*CV Score Mean(Train)*
GaussianNB	1.00	0.74	0.72
BernoulliNB	0.91	0.86	0.85
MLPClassifier	1.00	0.92	0.90
RandomForest	1.00	0.89	0.89
XGBClassifier	1.00	0.94	0.95

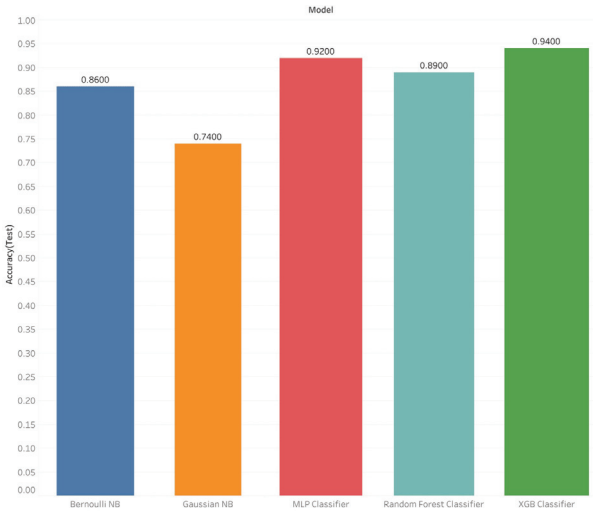

Fig. 7. Accuracy Scores

regarding textual content. The paper aims to provide a comprehensive analysis of previous studies and advancements in the field, and to conduct a comparative analysis on the WELFake dataset available on Kaggle.com. The main objective of the study is to determine the accuracy of various algorithms in classifying news as either real or fake. To achieve this, five different algorithms were applied to the dataset: GaussianNB, BernoulliNB, MLPClassifier, RandomForestClassifier, and XGBClassifier.

The findings of the study indicate that XGBClassifier exhibited the highest accuracy, while GaussianNB demonstrated the lowest accuracy among the tested algorithms. However, the study's results are limited due to the use of only one dataset, and there is significant potential for further research and development of new algorithms to expand the classification beyond textual content to non-textual media such as fake images or videos.

In conclusion, the study underscores the importance of developing effective algorithms to combat the proliferation of fake news on the internet. The use of advanced algorithms in conjunction with human oversight can significantly improve the accuracy and reliability of news classification, thereby reducing the impact of fake news on society.

Abstract. This research paper explores the vulnerabilities of the lightweight block cipher SPECK 32/64 through the application of differential analysis and deep learning techniques. The primary objectives of the study are to investigate the cipher's weaknesses and to compare the effectiveness of ResNet as used by Aron Gohr at Crypto2019 and DenseNet . The methodology involves conducting an analysis of differential characteristics to identify potential weaknesses in the cipher's structure. Experimental results and analysis demonstrate the efficacy of both approaches in compromising the security of SPECK 32/64.

Keywords: Differential Cryptanalysis, Deep Learning, Speck, ResNet, DenseNet

1 Introduction

Cryptography is the technique of converting data into an incomprehensible form known as cipher text. It is done by using mathematical principles and algorithms. This crucial sector ensures the security and privacy of modern digital communications and data storage. Throughout history, critical information ranging from military communications[1] to commercial transactions[2] have been protected via cryptographic processes.

Over the centuries, cryptography has been an art practised by many who have invented techniques to meet some of the information security requirements. The previous two decades have seen the field evolve from an art to a science[3].

Data secrecy,integrity and authenticity are the main goals of cryptography. Confidentiality ensures that only authorised personnel may access the information. Integrity ensures that the data is unchanged throughout transmission or storage. Authentication makes sure that only reliable sources are sharing information

With the aid of encryption algorithms[4], cryptography secures data and communication. This is achieved by converting plaintext into ciphertext, a form

that cannot be deciphered. On the other side, Cryptanalysis is the science of analysing cryptographic systems to find vulnerabilities. These weaknesses can be exploited to obtain the original plaintext or encryption keys. Lightweight block ciphers serve a critical role in cryptography in situations where computational resources are constrained. These ciphers' low computational and memory overhead makes them ideal for secure, effective encryption[5].

The study of decrypting cryptographic methods, or cryptanalysis, is a crucial area for maintaining the security of encryption systems. It involves investigating the mathematical features and design choices to find the flaws in the cipher . Understanding these flaws allows cryptanalysts to create more successful attacks. This helps in increasing the security of the cryptographic systems.

Numerous fields, including cryptanalysis[6], have seen the emergence of machine learning and deep learning as highly effective tools. These methods make use of the models' computational capabilities. They can automatically identify patterns, detect features, and generate predictions.Machine learning techniques can be used in the context of cryptanalysis as well[7]. It can be used to analyse and categorise cryptographic data, such as ciphertexts, plaintexts, or encryption keys.

Deep learning, a branch of machine learning, has achieved outstanding results in a number of fields. Ranging from speech recognition[8], computer vision[9] to natural language processing[10]. Deep neural networks are able to learn complex data representations and identify deep correlations.
In this paper, we investigate the use of deep learning methods, more specifically DenseNet and ResNet. They are used for differential cryptanalysis on the lightweight block cipher SPECK 32/64. We intend to compare the effectiveness of ResNet and DenseNet. It ultimately helps us in understanding of the security of the SPECK 32/64 cipher by utilising the expressive potential of deep neural networks.

2 SPECK 32/64 Overview

SPECK is a lightweight block cipher developed by the National Security Agency (NSA). It was a part of the Lightweight Cryptography Project of the NSA. Here, the term "lightweight" refers to cryptographic algorithms that are designed for efficient operation and low resource consumption.

This qualifies them for usage in environments with limited resources such as Internet of Things devices[11], wireless sensor networks[12], and embedded systems[13].

The SPECK family consists of a variety of block and key sizes. The block is made up of 2 words, and is of the form $2n$. Here, n is the size of the word which may be 16, 24, 32, 48 or 64 bits. The key size(k) is mn bits. The key contains 2,3 or 4 words depending on the variant. Hence, the SPECK family is of the form

SPECK 2n/mn and has ten variants. We use SPECK 32/64 in our work, which denotes 2 words of 16-bits each and 4 keys of 16-bits each as well.

The SPECK family cipher is made up of a Feistel network structure[14]. In this network, the input block is split into two equally sized halves. Encryption rounds are then performed on these halves using a subkey. A different subkey is derived for each round. The number of rounds differ in each variant of the family.

The round function of SPECK 32/64 uses a range of bitwise operations for its cryptographic operations. It includes rotation, XOR, and modular addition, to induce confusion and diffusion features, assuring the security of the cipher.

2.1 Round Function

Speck's round function is very simple.It is an ARX structure, which means it is made out of the fundamental functions of modular addition (mod 2^k), bitwise rotation, and bitwise addition. They are denoted by $\boxplus$, $\gg$ and $\oplus$ respectively. SPECK n/m represents Speck with n bit block size and m bit key size. It produces the next round state $(\mathbf{L_{i+1}}, \mathbf{R_{i+1}})$ with an input k-bit subkey $\mathbf{K}$ and the current cipher state consisting of two k-bit words $(\mathbf{L_i}, \mathbf{R_i})$. The algorithm is as follows:

$$\mathbf{L_{i+1}} = ((\mathbf{L_i} \gg \alpha) \boxplus \mathbf{R_i}) \oplus \mathbf{K}$$

$$\mathbf{R_{i+1}} = (\mathbf{R_i} \ll \beta) \oplus \mathbf{L_{i_i+1}}$$

The values of α and β are constant: $(\alpha = 7, \beta = 2)$ for Speck32/64 and $(\alpha = 8, \beta = 3)$ for other members of the Speck family. The cipher text output is generated by applying the round function on the plain text input for 22 rounds in the case of Speck 32/64. However, we refer to round reduced speck in this paper. The key used in each round is generated from a master key by applying a key schedule. The key schedule depends on the member of the Speck family, we refer to Beaulieu et al[15] in this paper for the key scheduling.

3 ResNet and DenseNet Architectures

3.1 ResNet

ResNet or Residual Network is a powerful deep learning architecture first published by Kaiming[16]. Resnet is intended to address the issue of disappearing gradients[17] in very deep neural networks. It does so, by incorporating residual connections[18] or skip connections, which enable the building of deeper and more precise models.

ResNet is composed of many residual blocks or towers that are layered on top of each other and contain a sequence of convolutions and a skip connection. The skip connection is added to a block's output and then passed on to the following block. This helps in reducing the vanishing gradient problem and allows for better model training. Figure 2 depicts the working of a skip connection.

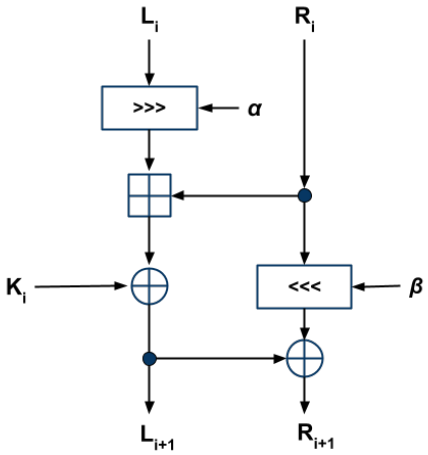

Fig. 1: General round of Speck

ResNet Structure The ResNet structure used in this work is the one used by Gohr in 2019[19]. It consists of a residual tower of depth ten, having a two layer convolutional network. The convolutional network has 32 filters.

First, Convolution is applied followed by a Batch normalization[20] for faster and stable training . It is followed by a Rectified Linear Unit layer[21] which introduces Non-linearity to the model. Then a skip/jump connection at the end adds the output of the final rectifier layer of the block to the convolutional block's input and forwards the result to the next block.

The initial layer is a bit-sliced 1 Dimensional Convolution with 32 output channels, which is followed by Batch normalization. Finally, a Rectified Linear Unit is applied to the preceding layer's output. The final result is a $32x16$ matrix that is fed into the depth-10 Residual Tower.

Finally, the data is flattened and transmitted to the prediction layer. This final layer consists of two densely linked hidden layers of 64 units each, followed by batch normalization, a Rectified Linear unit, and sigmoid activation for a single output head.

3.2 DenseNet

DenseNet is made up of Dense blocks and transition layers. DenseNet, which stands for "Densely Connected Networks" is a deep learning architecture designed by Gao Huang et al. originally published in their paper[22] in 2017.

DenseNet, like ResNet, aims to solve the vanishing gradient problem by maximising feature reuse. DenseNet introduces dense connections between layers and

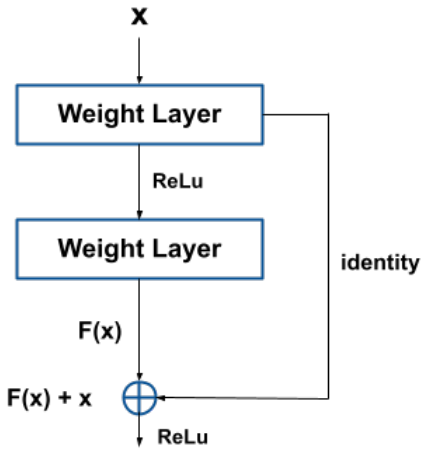

Fig. 2: Skip Connection

blocks as opposed to traditional neural networks, which connect layers sequentially. Unlike ResNet, which utilises an additive approach of adding previous layer output to subsequent layers, DenseNet uses all past outputs as input for future layers. As a result, each layer is directly linked to all the following layers.

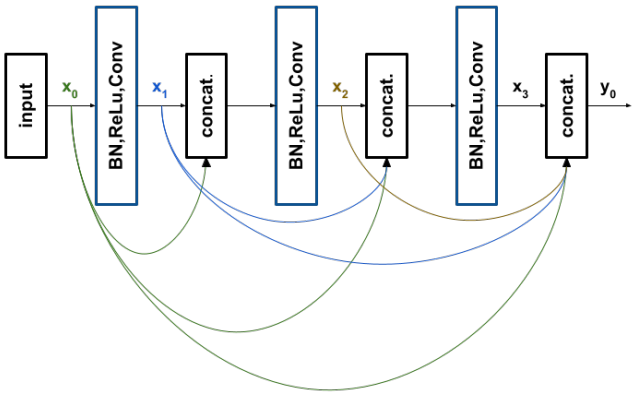

Fig. 3: Dense Connection

DenseNet Structure The first layer, like the one in the Resnet model, is a bit-sliced 1 Dimensional Convolution with 32 output channels.It is followed by

Batch normalisation, and lastly a Rectified Linear Unit is applied to the output of the preceding layer. The resulting 32x16 matrix is passed into the Dense Network.

DenseNet is made up of Dense blocks and transition blocks.The dense block has a depth-8 and is made up of two layers of 1D-convolution, Batch normalisation, and a Rectified linear unit layer. The convolution layer is made up of 64 filters and a kernel with a size of 3.Finally, the output is concatenated with the layer's input and handed on to the next layer.This occurs eight times since the depth is eight.

To restrict the amount of feature maps and minimise spatial dimensions, transition layers are inserted between dense blocks. The transition layer is made up of 1D convolution with 32 filters, batch normalisation, a ReLu layer, and 1D average pooling. The transition layer's output is subsequently passed on to the following dense block.

The dense block and transition layers are now merged with a depth of 2. This indicates alternating dense block and transition layer, followed by a final dense block. The final result is an overall structure of three dense blocks and two transition layers.

Finally, the data is flattened and transmitted to the prediction layer. This prediction layer consists of two dense hidden layers of 64 units each, followed by batch normalisation, Rectified linear unit, and sigmoid activation, similar to ResNet.

3.3 Input Data

Input data: Input consists of a pair of cipher texts (C_0, C_1). They are transformed into a 4x16 matrix with each row consisting of a word of the ciphertext. This way the data consists of four 16-bit words and therefore the input layer has 64 units. This input data is then passed into the ResNet and DenseNet architecture.

4 Experimental Setup and Methodology

4.1 Data Generation

The data generation methodology used is similar to the one used by Aron Gohr in 2019. A random number generator is used to create evenly distributed keys K_i and plain text pairings P_i with the input difference $\Delta = 0x0040/0000$, along with a vector of binary-valued real/random labels Y_i. If Y_i is set(=1), the plain text pair P_i is encrypted for $\mathbf{k}$ rounds to create training or validation data for k-round Speck, and if not, the second plain text in the pair is changed to a newly created random plain text. This way we have cipher texts belonging to 2 classes: Chosen Input difference ($\mathbf{Y} = 1$) and random input difference ($\mathbf{Y} = 0$). As a result we have 10^6 samples for our dataset for training and validation.

4.2 Training and Testing Procedure:

The data set of 10^6 samples is used for training in batches of 5000 and run for 20 epochs as opposed to 200 epochs by Gohr .
Mean Square Error (MSE)[23] loss is used with L2 weights regularization using the Adam algorithm[24] for optimization. This is a down scaled version of Gohr's experiment in which he used 10^7 samples for training for 200 epochs.

Testing data also contains a set of 10^6 samples with 2 classes. One of the chosen input difference and the other of random input difference. Table 1. provides the list of hyper-paramaters used in training with their values.

Hyper-parameters	**values**
Sample Size	10^6
Batch Size	5000
Epochs	20
Encryption Rounds	5,6,7,8
Optimizer	Adam
Loss function	MSE loss
Cyclic Learning Rate	0.002-0.0001

Table 1: Hyper-parameters for training of model

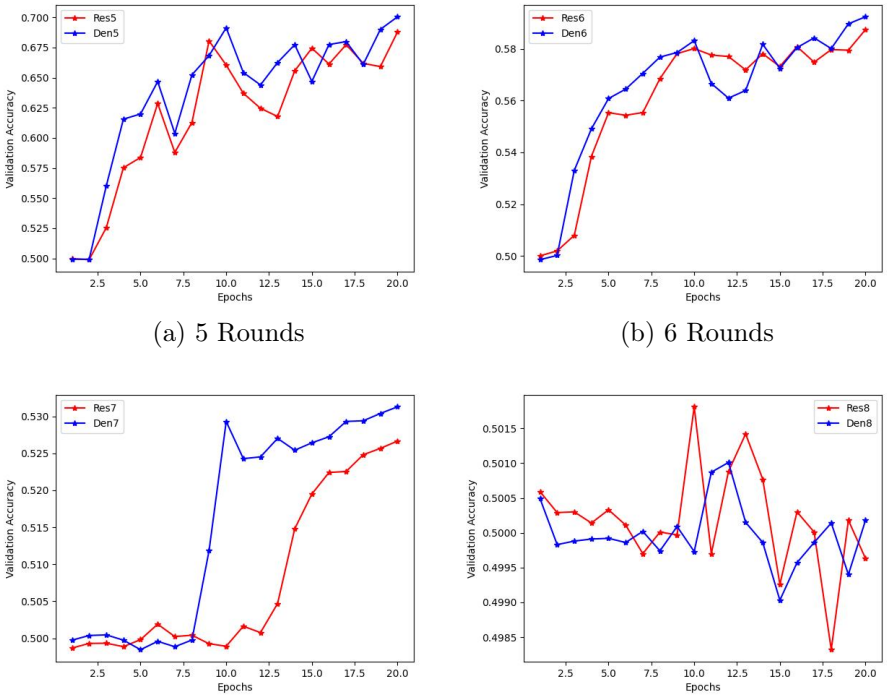
5 Results and Analysis:

In this section, we present the findings of our experiments on the differential cryptanalysis of the round reduced (rounds 5,6,7,8) SPECK 32/64 lightweight block cipher using the ResNet and DenseNet architectures. R5, R6, R7 & R8 refers to the ResNet architecture for rounds 5, 6, 7 and 8 respectively, and similarly D5, D6, D7 & D8 refers to the DenseNet architecture. Table 2 depicts the training and validation accuracy for both the models.

Rounds	**R (ResNet)**		**D (DenseNet)**	
	Training	Validation	Training	Validation
5	0.9332	0.6779	0.9309	**0.7005**
6	0.7952	0.5874	0.7917	**0.5923**
7	0.6096	0.5267	0.6053	**0.5313**
8	0.5012	0.4996	0.4998	0.5002

Table 2: Training and Validation accuracy for ResNet and DenseNet models

The DenseNet model achieved slightly better validation accuracy than the ResNet model for rounds 5, 6 and 7. For round 8, both the models failed to give a prominent result since the models could not learn an accurate pattern. Figure 4 below shows the comparison of accuracy for both the models.



(a) 5 Rounds (b) 6 Rounds

(c) 7 Rounds (d) 8 Rounds

Fig. 4: Validation Accuracy comparison

6 Conclusions

In this paper, we compared the ResNet and DenseNet architectures for differential cryptanalysis of the SPECK 32/64 lightweight block cipher. Our analysis attempted to evaluate their accuracy in deciphering the cipher's complicated differential behaviour.

According to our findings, the DenseNet architecture outperforms the ResNet architecture marginally. DenseNet achieved slightly higher predictions of ciphertext differences in the context of differential cryptanalysis. However, neither model produced a satisfactory result for an 8-round (or higher rounds) encryption cipher.

As of now, this work does not include a key retrieval approach. At last, our findings highlight the importance of architecture selection in differential crypt-

analysis. The observed accuracy improvements of DenseNet support its use in scenarios requiring lightweight block cipher analysis.

Abstract— There are several applications for the crucial colour quantization process in the disciplines of graphics and image processing. The majority of quantization methods are built on data clustering algorithms. Hard c-means (k-means) clustering methods have recently been found to be effective in this field. Other investigations came to similar conclusions with the fuzzy c-means approach and Self-Organizing Maps (SOM). The three different clustering techniques weren't explicitly compared in any of these experiments, which is interesting. In this study, we develop quick and accurate variations of the hard and fuzzy c-means algorithms coupled with SOM and a variety of starting strategies, and then compare the resulting quantizers on a wide range of images. The findings show that images produced by K-means and SOM had a little lower PSNR value than those produced by the fuzzy c-means algorithm. Due to their widespread use in this sector, along with Hierarchical clustering and Density Based-Spatial Clustering of Applications with Noise (DBSCAN), we have picked FCM, K-means, and SOM for comparison. Although we haven't discussed about hierarchical clustering and DBSCAN because they are space and time costly algorithms.

Keywords—Fuzzy C Means (FCM), Self-Organizing Maps(SOM)

I. INTRODUCTION

Over the past two decades, true-color photographs have proliferated. There may be hundreds of thousands of colours in a typical true-color image, making it difficult to display, store, transmit, process, and analyse such an image. A finite number of discrete levels are used to approximate the continuous colour space of an image during the quantization process. The quantization inaccuracies introduced by this approximation, however, can cause apparent artifacts and a decline in image quality.

Image quantization, therefore, aims to reduce quantization mistakes while maintaining the visual quality of the image. Because it lowers the image's storage and transmission needs, image quantization is a crucial step in the processing of images. The division of an image into a range of distinct colours or shades of grey is known as quantization. Clustering techniques are frequently used for this, which classify the image's pixels into clusters based on how similar they are.

Three widely utilized clustering methods that have been extensively employed for picture quantization include fuzzy C-Means, k-means, and self-organizing maps. Over the years, a number of picture quantization techniques—from straightforward uniform quantization to cutting-edge ones based on machine learning—have been developed. Depending on the exact application and the required trade-off between image quality and storage/bandwidth needs, each approach has pros and cons. To achieve the ideal balance between image quality and resource efficiency, it is essential to choose a suitable image quantization method.

According to experimental findings, fuzzy c-means only marginally outperforms other purpose-built colour quantization systems while rapid fuzzy clustering algorithms yield quantization results that are on par with the full classical fuzzy c-means technique. In this study, we review various colour quantization methods. We demonstrate that colour quantization, where colour cluster boundaries are not well specified, is a situation in which the fuzzy membership paradigm is particularly well suited.

We provide a thorough analysis of picture quantization methods and assess the compression efficiency of the quantized images. To do this, we drew on a number of libraries, including numpy, matplotlib, pillow, OpenCV, sklearn, and minisom.

After picture quantization, we compared the compressed image sizes and determined the PSNR value to categorise the three algorithms.

II. K MEANS CLUSTERING

An unsupervised algorithm called K-Means places each pixel in a single cluster based on how near it is to the centroid. K-Means is computationally efficient and provides good results for images with high contrast. When we have unlabeled data—data without clearly defined categories or groups—the algorithm is applied. The K-means algorithm consists of two sections. After identifying the k centroid, each point is subsequently relocated to the cluster that has the closest centroid to the relevant data point.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:21:29 UTC from IEEE Xplore. Restrictions apply.

The Euclidean distance is used to determine which centroid is nearest. After grouping is complete, it updates each cluster's centroid and calculates a new Euclidean distance between each centre. The cluster points with the shortest Euclidean distance are assigned to each data point based on that centroid. The centroid and members (member objects) of each cluster in the partition serve as unique identifiers. The centroid of each cluster is the location from which all of the elements in the cluster are separated by the least amount of distance. The overall distance between every object and every cluster's centroid is decreased. K-Means may, however, yield subpar results for photos with low contrast or intricate texture patterns. Grayscale and coloured images can be quantized using K-Means.

Consider an image with an x-y resolution that needs to be grouped into several groups. The following is the k-means clustering algorithm.:

1. Set the cluster's centre randomly and initialize k value.
2. Find the Euclidean distance (d) between the centre of the image and each individual pixel using the formulae shown below.

$$d = || p(x,y) - C_k || \quad (1)$$

$$d = \sqrt{(x - C_x)^2 + (y - C_y)^2} \quad (2)$$

where,
p(x,y) = point with co-ordinate (x,y).
x = x component of pixel.
y = y component of pixel.
Cx = x component of cluster centroid.
Cy = y component of cluster centroid.

3. Determine the closest location for each pixel's centre depending on the distance d.
4. Once all of the pixels have been assigned, recalculate the new location of the centre using the relation given below.

$$C_k = \frac{1}{k} \sum_{y \in C_k} \sum_{x \in C_k} p(x,y) \quad (3)$$

where,
p(x,y) = pixel with components (x,y).
x = x component of pixel.
y = y component of pixel.
Ck = cluster centroid.
K = number of clusters

5. Till the tolerance or error value is reached, keep going with the process.
6. Utilise the grouped pixels to generate new images.

III. Fuzzy C Means Clustering

An algorithm for clustering called fuzzy c-means (FCM) divides a dataset into a predetermined number of clusters. The soft clustering technique Fuzzy C-Means (FCM) divides each pixel into numerous clusters according to the degree of membership. FCM has been widely used in image processing because it is computationally efficient and provides better results than traditional hard clustering algorithms like K-Means. FCM can be used to quantize both grayscale and color images. However, FCM has some limitations, such as sensitivity to initialization, and it can produce noisy results in images with low contrast.

The algorithm involves the following step:
1. Initialization: Determine the quantity of clusters, then initialise the cluster centroids at random.

2. Assigning Membership Values: Assign each data point a membership value indicating the degree of belongingness to each cluster. The membership values are computed using the following equation:

$$U_{ij} = \frac{1}{\sum_{k=1}^{C} (\frac{d_{ij}}{d_{ik}})^{2/(m-1)}} \quad (4)$$

where
U_{ij} = *membership value of data point 'i' to cluster 'j'*
d_{ij} = *distance between data point 'i' and cluster centroid 'j'*
d_{ik} = *distance between data point 'i' and cluster centroid 'k'*
c = *total number of clusters*
m = *parameter that regulates how fuzzy the clustering is.*

3. Updating Cluster Centroids: Update the cluster centroids using the membership values. The updated centroids are created using the weighted average of the data points, where the weight is the membership value of each data point.

4. Repeat Steps 2-3 until convergence: Iterate the assigning membership values and updating cluster centroids until the membership values converge to a stable solution.

IV. Self Organizing Maps

SOM is a clustering algorithm for neural networks that converts high-dimensional input data to a grid of low-dimensional neurons. SOM can disclose the image's underlying structure while preserving the topology of the input space. As a result, it is frequently utilised in image processing. SOM is particularly useful for color image quantization because it can capture the color distribution of the image. However, SOM is computationally intensive and requires a large amount of memory for training.
The following is the step-by-step procedure of the SOM algorithm:

1. The SOM grid, which comprises of a collection of neurons arranged in a 2D or 3D grid form, should be initialised.
2. Randomly initialize the weight vectors of each neuron in the grid to a small random value.
3. Select an input data point from the dataset.
4. Locate the neuron in the grid whose weight vector is closest to the input data point. The Best Matching Unit (BMU) is the name given to this neuron.
5. Use the following formula to adjust the BMU and its surrounding neurons' weights in the grid:

$$W_{ij} = W_{ij} + \alpha(t) * (X_{ik} - W_{ij}(old)) \quad (5)$$

where

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:21:29 UTC from IEEE Xplore. Restrictions apply.

W_{ij} = weight vector of neuron i,j
X_{ik} = input data point
$\alpha(t)$ = learning rate at time t
$h(C_i, C_{bmu})$ = neighborhood function that determines the influence of the BMU on the neighboring neurons,
C_i, and C_{bmu} = coordinates of neuron i,j and the BMU, respectively.

6. Repeat steps 3-5 for a fixed number of iterations or until convergence is reached.
7. Use the trained SOM grid to cluster the input data points based on the similarity of their weight vectors.

The SOM algorithm can reduce high-dimensional data to a lower-dimensional space while maintaining the input space's structure, making it particularly helpful for data visualization. Additionally, SOMs can be used for feature extraction and data compression tasks by using the weight vectors of the neurons as feature representations of the input data.

V. Implementation Methodology

Python has been used to build the self-organizing maps, fuzzy C-means, and K-means algorithms. The image datatype is handled by the packages Pillow, OpenCV, and matplotlib. For picture compression, we utilised "https://compressjpeg.com/".
1.Read image using an image library like OpenCV, Pillow.
2.Transform image into dataset containing data about pixels.
3.Train the algorithm using the dataset.
4. Assign colours to the pixels based on the centroid closest to them to form the quantized image.
5.Transform the dataset to a new image.

RESULT ANALYSIS FACTOR

PSNR: In order to assess how well a picture may be represented, the peak signal-to-noise ratio (PSNR) compares the maximum power of a picture to the maximum power of corrupting noise. To determine a picture's PSNR, it's critical to contrast it with the clearest, most ideal image possible.

$$PSNR = 10\log_{10}\left(\frac{(L-1)^2}{MSE}\right) = 20\log_{10}\left(\frac{(L-1)}{RMSE}\right) \quad (6)$$

Here,
L = number of maximum possible intensity levels in an image, with 0 being the smallest intensity level.
MSE (mean squared error), is described as follows:

$$MSE = \frac{1}{mn}\sum_{i=0}^{m-1}\sum_{j=0}^{n-1}(O(i,j) - D(i,j))^2 \quad (7)$$

where ,
O = original image's matrix data.
The matrix data of deteriorated photographs is represented by D.
m = count of rows of pixel
i = index of the row inside the image.
n = count of columns of pixel
j = index of that column inside the image.
RMSE = Root mean squared error.

Compression size and Percentage: Comparison of the size of the images before compression and after compression and the percentage reduction according to their relative original images is also a factor to be considered for classifying image quantization algorithms.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:21:29 UTC from IEEE Xplore. Restrictions apply.

FCM will give more better images than K-means because of its soft clustering nature which doesn't not allow colour changes to occur suddenly in the quantized image.

Comparison of images before and after compression

VI. Results

The outcomes demonstrate that both algorithms generated high-quality images. However, in terms of execution time and computational complexity, the Fuzzy C-Means approach surpassed K-means. Fuzzy C-Means had a lower computational complexity than the K-means technique. Although the PSNR values for the two methods were similar, the Fuzzy C-Means approach outperformed the K-means technique by a little margin.

Time Complexity:

Time Complexity of all three algorithms depends upon different factors like image size, number of clusters, implementation of algorithm and hardware. But in general terms we can say that: -

K-means (least number of iterations) > FCM (number of iterations greater than K-means) > SOM (number of iterations greater than K-means and FCM both).

.

VII. Conclusion

In this paper, we compared three popular clustering algorithms, Fuzzy C-Means, K-Means, and Self-Organizing Maps, for image quantization. PSNR value of all three algorithms was almost the same, but fuzzy c means had slightly higher value than the rest. The effectiveness of these algorithms depends on the characteristics of the image being quantized. The compression size of the quantized images was reduced significantly in all three cases, while k means showing images rather greater in size than the other two algorithms.

Photo 1:

Original Compressed Image (106.92 kB) > K means quantized compressed image (101.2 kB) > Fuzzy C means quantized compressed image (71.44 kB) > SOM quantized compressed image (76.6 kB)

Photo 2:

Original Compressed Image (25.08 kB) > K means quantized compressed image (26.28 kB) > Fuzzy C means quantized compressed image (19.71 kB) > SOM quantized compressed image (10.71 kB). As a result, the clustering algorithm selection should be based on the particular needs of the image processing application.

In this work, we explore the parameter constraints of two dark energy models, namely the Modified Chaplygin-Jacobi gas (MCJG) and Modified Chaplygin-Abel gas (MCAG), within the context of $f(T)$ gravity model in a non-flat Friedmann-Lemaître-Robertson-Walker (FLRW) Universe. The Universe is assumed to be composed of three main components: radiation, dark matter, and dark energy. Our investigation involves comparing the equation of state for the MCJG and MCAG dark energy models with the equation of state derived from the $f(T)$ gravity model. To derive constraints for the dark energy and $f(T)$ gravity models, we use recent astronomical datasets, including $H(z)$ data, type Ia supernovae observations, Gamma Ray Bursts data, quasar data, and Baryon Acoustic Oscillation (BAO) measurements. These datasets serve as valuable sources of information to understand the behavior and properties of the Universe on cosmic scales. We present the reduced Hubble parameter in terms of observable parameters such as Ω_{r0} (density parameter of radiation), Ω_{m0} (density parameter of dark matter), Ω_{k0} (density parameter associated with spatial curvature), Ω_{CJ0} (density parameter of Modified Chaplygin-Jacobi gas), Ω_{CA0} (density parameter of Modified Chaplygin-Abel gas), and H_0 (present value of the Hubble parameter). We explore the cosmological evolution through various cosmic diagnostic parameters, including the deceleration parameter, Om diagnostic, and statefinder diagnostic pair $\{r, s\}$. These diagnostic parameters offer valuable insights into the expansion dynamics and the nature of dark energy in the Universe. We have also assessed the viability of the models using the information criteria. By comparing the results with the standard ΛCDM model, we have gained insights into the feasibility of our proposed models. Our aim is to shed light on the nature of dark energy and its connection to the $f(T)$ gravity model, and ultimately gain a deeper understanding of the underlying mechanisms driving the accelerated expansion of our Universe.

I. INTRODUCTION

Over the course of last decade numerous astronomical observations have been carried out to investigate the compatibility of theoretical cosmological models. Recent observations of the type Ia supernova (SNIa)[1–3], Baryon Acoustic Oscillation (BAO)[4, 5], cosmic microwave background (CMB)[6], WMAP [7, 8] have confirmed the most astounding result of modern cosmology that not only our Universe is expanding but it is passing through an era of accelerated expansion. Now, the standard Big Bang cosmology was unable to resolve this 'cosmic puzzle'; so the possible existence of some exotic matter, acclaimed as Dark Energy (DE), with a unique characteristic of negative pressure, has emerged which would obey $\rho + 3p < 0$ as the Friedmann equation reads

$$\frac{\ddot{a}}{a} = -\frac{4\pi G}{3}(\rho + 3p) \tag{1}$$

and $\ddot{a} > 0$ for accelerated expansion. At first ΛCDM model was considered as the 'best fit'[9, 10], but fine-tuning problem and the coincidence problem could not be explained with this model [11–13]. To resolve these severe issues

* himanshuch1729@gmail.com

¶ gmustafa3828@gmail.com

theorists suggested for modification of Einsteins field equations in two ways. One approach is the correction of the matter field that yields various dynamical dark energy models with varying equation of state such as quintessence, tachyon, k-essence, fermionic field, phantom, Chaplygin gas, DBI essenec[13, 14] etc. In search of a befitting candidate for DE, Chaplygin[15] originated a model called Chaplygin gas (CG), defined with a simple equation of state

$$p = -\frac{B}{\rho} \tag{2}$$

where B is considered as positive constant. This model unified dark matter and DE because it acts as dust-like matter at early stage and cosmological constant at later time. But one backdrop of this model is that it can not explain the era of the structure formation in the Universe [16, 17]. In this regard, the pure CG model is generalized to the generalized Chaplygin gas (GCG) model [18] with equation of state

$$p = -\frac{B}{\rho^{\alpha}}, \quad \text{with} \quad 0 < \alpha \leq 1. \tag{3}$$

In Ref.[19, 20] Benaoum proposed Modified Chaplygin Gas (MCG) model that obeys the EoS

$$p = A\rho - \frac{B}{\rho^{\alpha}} \tag{4}$$

where $A, B > 0$ and $0 \leq \alpha \leq 1$. For $A = 1/3$, the model exhibits a radiation era when assuming a minuscule scale factor. On the other hand, with an infinitely large scale factor, it acts as the ΛCDM model. In an intermediate stage, it behaves as pressure-less dust. Further along, the EoS was revised to derive other extensions like variable CG[21], variable modified CG[22], generalized cosmic Chaplygin gas (GCCG), the new variable modified Chaplygin gas (NVMCG)[23], viscous CG[24] etc. For better synchronization of the models to the observational data, constraints on different parameters of CG and MCG were investigated[25–30]. Using Jacobi's elliptic function, Villanueva formulated generalized Chaplygin-Jacobi gas correlated with the generalized Chaplygin scalar field[31–33] which can describe the inflationary stage and confronted the measurement recently released by the Planck 2015 data. Following that, Debnath derived the equation of states for Modified Chaplygin-Abel gas and Modified Chaplygin-Jacobi gas and explored the models' compatibility with observational data using AIC, BIC, and DIC model selection tools[34]. Accretion phenomena of Modified Chaplygin-Jacobi Gas and Modified Chaplygin-Abel Gas models into Schwarzschild Black Hole have been studied in ref [35] .

Another approach to explain the cosmic acceleration of the Universe is constructing gravitational modifications in the geometric part of the Einsteins field equations so that the additional degree(s) of freedom can act as a driving force in the accelerated expansion [36]. Mostly modified gravity theories are formed by extending the Einstein-Hilbert action i.e. by curvature formulation. Some of the widely used examples are $f(R)$ gravity [37, 38]; $f(G)$ gravity[39]; Horava-Lifshitz gravity[40]; Lovelock gravity[41] etc. Another suitable approach to gravitational modification is the extension of the action of equivalent torsional formulation of General Relativity (GR). The simplest modification is $f(T)$ gravity [42–44], developed from the Teleparallel Equivalent of General Relativity (TEGR) [45–50], where T is the Torsion scalar. The characteristic difference between TEGR with GR is that the Lagrangian of TEGR contains a curvature-less Weitzenbock connection whereas GR has a torsion-less Levi-Civita connection. The desirability of $f(T)$ gravity model over $f(R)$ gravity is the second-order field equation in contrast with fourth-order field equations in $f(R)$ gravity. In teleparallelism, torsion is formed from the product of the first derivatives of the tetrad having no second derivative terms. Thus the Lagrangian can simply be extended by just adding a function $f(T)$. Both the inflation phase [51–54] and acceleration phase[55–57] of the Universe have been studied under the framework of $f(T)$ gravity. As $f(T)$ gravity incorporates an unknown function, the viability of the model remains questionable from theoretical and observational perspectives depending on the function chosen. Using Monte-Carlo analysis, $f(T)$ gravity models have been investigated already[58]. Constraining the free parameters have been executed with data sources like Pantheon Supernovae sample[59], redshift-space distribution measurements [59] or solar system data[60]. Previous works in this domain have suggested that DE coupled with a modified gravity field can present fascinating results. For example, Jamil et al answered the cosmic coincidence problem by working on MCG in loop quantum gravity[61]. Park pointed out that additional terms like a^{-4}, a^{-2} contained in Friedmann equation in Horava-Lifshitz gravity can be responsible for cosmic acceleration[62]. Many other gravity theories like Chern-Simons gravity[63], Galileon gravity[64], Einstein-Aether gravity[65], Brans-Dicke theory[66], were combined with MCG to determine the observational constraints on the parameters. Motivated by this line of work, here we will review the observational

constraints of MCJG and MCAG parameters with association of various $f(T)$ gravity models. The free parameters of the $f(T)$ models have also been constrained with the help of different combinations of current observational data.

The flow of work of this paper is as follows: the basic equations of $f(T)$ gravity models is described in section II. In section III the viable $f(T)$ gravity model is presented. Section IV is devoted to investigate the constraints of the model parameters using various observational dataset comprising of $H(z)$, Pantheon, Gamma Ray Bursts, quasars, and BAO measurements. Comparison of observational and theoretical predictions of model parameters are done via $H(z)$ measurements and distance modulus $\mu(z)$ in section V. For cosmographic analysis the deceleration parameter, jerk parameter are derived in section VI. The statefinder diagnostic OM diagnostic are analyzed graphically in section VII and VIII respectively. In section IX, we present the information criteria for both the models. Finally in section X, the results are summarized and the main conclusion is exposed.

II. BASIC EQUATIONS IN $f(T)$ GRAVITY

One of the most intriguing generalization of Einstein's general relativity in the context of explanation of the observed cosmic acceleration of the Universe is the $f(T)$ theories of gravity. Originally teleparallelism was introduced by Einstein in the process of unification of gravity and electromagnetism. Unlike the General theory of Relativity that uses the torsionless Levi-Civita connection, this theory exploits the curvatureless Weitzenb¨ock connection that has only torsion. The geometry of a non-flat Friedmann-Lemaître-Robertson-Walker (FLRW) model of the Universe is described by the metric

$$ds^2 = -dt^2 + a^2(t)\left[\frac{dr^2}{1-kr^2} + r^2\left(d\theta^2 + sin^2\theta d\phi^2\right)\right] \tag{5}$$

where $a(t)$ is the scale factor and $k(= 0, -1, +1)$ is the curvature scalar which represents flat $(k = 0)$, open $(k = 1)$, and closed $(k = -1)$ model of the Universe. The relation of orthonormal tetrad components $\mathbf{e_A}(\mathbf{x}^\mu)$ relate and the metric is

$$g_{\mu\nu} = \eta_{AB} e^A_\mu(x) e^B_\nu(x), \tag{6}$$

where $\mathbf{e_A}(\mathbf{x}^\mu) = \mathbf{e}^\mathbf{A}_\mu \partial_\mu$, the indices A, B run over 0, 1, 2, 3 for the tangent space of the manifold, the coordinate indices on the manifold μ, ν take values 0, 1, 2, 3 and i, j are the spatial indices. In this formalism the torsion tensor takes the form

$$T^\lambda_{\mu\nu} = \Gamma^{\mathbf{W}^\lambda}_{\nu\mu} - \Gamma^{\mathbf{W}^\lambda}_{\mu\nu} = e^\lambda_A(\partial_\mu e^A_\nu - \partial_\nu e^A_\mu). \tag{7}$$

The contorsion tensor reads

$$K^{\mu\nu}_\rho = -\frac{1}{2}(T^{\mu\nu}_\rho - T^{\nu\mu}_\rho - T^{\mu\nu}_\rho) \tag{8}$$

From torsion tensor and contorsion tensor a new quantity is defined

$$S^{\mu\nu}_\rho = \frac{1}{2}(K^{\mu\nu}_\rho + \delta^\mu_\rho T^{\alpha\nu}_\alpha - \delta^\nu_\rho T^{\alpha\mu}_\alpha) \tag{9}$$

The Lagrangian of the Telepaarallel gravity is the torsion scalar T defined as follows

$$T = S^{\mu\nu}_\rho T^\rho_{\mu\nu}. \tag{10}$$

Following the footsteps of $f(R)$ gravity, $f(T)$ gravity is formed by extending the torsion scalar T to $T + f(T)$ where $f(T)$ is a differentiable function of T. The action for $f(T)$ gravity can be written as[43, 44, 67, 68]

$$S = \frac{1}{16\pi G}\int d^4x\sqrt{-g}\,[T + f(T) + \mathcal{L}_m] \tag{11}$$

where $\mathcal{L}_m$ is denoted as the Lagrangian for matter content. TEGR model is retrieved as $f(T) \to 0$. It exhibits the ΛCDM model as $f(T)$ approaches a constant value Λ.

In $f(T)$ gravity, the Friedmann equations are written for non-flat FLRW Universe [69, 70]

$$\left(H^2+\frac{k}{a^2}\right)+2H^2f'(T)+\frac{f(T)}{6}=\frac{8\pi G}{3}\,\rho \tag{12}$$

$$\left(\dot{H}-\frac{k}{a^2}\right)\left(1+f'(T)+12H^2f''(T)\right)=-4\pi G(\rho+p) \tag{13}$$

where, $H=\dot{a}/a$ is the Hubble parameter and the torsion scalar $T=-6\left(H^2+\frac{k}{a^2}\right)$ with prime and dot denote the derivatives w.r.t. T and t respectively. We assume that the total energy density and pressure of the fluid that fills the Universe are ρ and p, respectively. So the energy conservation equation takes the form

$$\dot{\rho}+3H(\rho+p)=0 \tag{14}$$

We start with the prediction that the Universe is composed of matter content comprising radiation, dark matter (DM), and dark energy (DE). So, ρ and p consist of densities and pressures of radiation, DM and DE. So $\rho=\rho_r+\rho_m+\rho_d$ and $p=p_r+p_m+p_d$. Now assume that radiation, DM, and DE follow the conservation equation separately so that

$$\dot{\rho}_r+3H(\rho_r+p_r)=0, \tag{15}$$

$$\dot{\rho}_m+3H(\rho_m+p_m)=0 \tag{16}$$

and

$$\dot{\rho}_d+3H(\rho_d+p_d)=0 \tag{17}$$

The relation between energy density and pressure for radiation is, $p_r=\frac{1}{3}\rho_r$. Solving equation (15) we obtain $\rho_r=\rho_{r0}a^{-4}$. Since pressure for the DM can be considered negligible (i.e., $p_m=0$), equation (16) gives $\rho_m=\rho_{m0}a^{-3}$.
• **MCJG :** Now consider the DE in the form of modified Chaplygin-Jacobi gas (MCJG) whose equation of state is given by [71]

$$p_d=[(2K-1)(1+A)-1]\rho_d-\frac{KB}{\rho_d^{\alpha}}+\frac{(1-K)(1+A)^2}{B}\,\rho_d^{2+\alpha} \tag{18}$$

where $K\in[0,1]$, $\alpha\in[0,1]$, $A(>0)$ and $B(>0)$ are constants. Putting the above expression in (17), we obtain

$$\rho_d^{1+\alpha}=\frac{B}{1+A}\left[\frac{A_s+(1-A_s)(1+z)^{3(1+\alpha)(1+A)}}{KA_s-(1-K)(1-A_s)(1+z)^{3(1+\alpha)(1+A)}}\right] \tag{19}$$

where A_s is constant satisfying $1-K<A_s<1$. So the present value of the energy density is $\rho_{CJ0}^{1+\alpha}=\frac{B}{(1+A)[KA_s-(1-K)(1-A_s)]}$.
If the DE of the Universe obeys the MCJG equation of state (1), then using the equation (19), the equation (12) reduces to the following equation for $E(z)$ as

$$\begin{aligned}E^2(z)=\Omega_{r0}(1+z)^4+\Omega_{m0}(1+z)^3-\Omega_{k0}(1+z)^2+\Omega_{CJ0}[KA_s-(1-K)(1-A_s)]^{\frac{1}{1+\alpha}}\\ \times\left[\frac{A_s+(1-A_s)(1+z)^{3(1+\alpha)(1+A)}}{KA_s-(1-K)(1-A_s)(1+z)^{3(1+\alpha)(1+A)}}\right]^{\frac{1}{1+\alpha}}-2f'(T)-\frac{f(T)}{6H_0^2}\end{aligned} \tag{20}$$

where we have defined the normalized Hubble parameter $E(z)=\frac{H(z)}{H_0}$ and the dimensionless density parameters $\Omega_{r0}=\frac{8\pi G\rho_{r0}}{3H_0^2}$, $\Omega_{m0}=\frac{8\pi G\rho_{m0}}{3H_0^2}$, $\Omega_{k0}=\frac{k}{H_0^2}$ and $\Omega_{CJ0}=\frac{8\pi G\rho_{CJ0}}{3H_0^2}$. Putting $z=0$ in the above equation, we obtain

$\Omega_{r0}+\Omega_{m0}-\Omega_{k0}+\Omega_{CJ0}-2f'(T_0)-\frac{f(T_0)}{6H_0^2}=1$ where $T_0=-6H_0^2\,(1+\Omega_{k0})$.

• **MCAG :** Next, we consider the DE in the form of modified Chaplygin-Abel gas (MCJG) whose equation of state is given by [71]

$$p_d=[(b^2+2c^2)(1+A)-1]\rho_d-\frac{c^2B}{\rho_d^{\alpha}}-\frac{(b^2+c^2)(1+A)^2}{B}\;\rho_d^{2+\alpha} \tag{21}$$

where $b,c\in\mathbb{R}$. Putting the above expression in (17), we obtain

$$\rho_d^{1+\alpha}=\frac{c^2B}{1+A}\left[\frac{B_s+(1-B_s)(1+z)^{3b^2(1+\alpha)(1+A)}}{c^2B_s+(b^2+c^2)(1-B_s)(1+z)^{3b^2(1+\alpha)(1+A)}}\right] \tag{22}$$

where B_s is a constant satisfying $0<B_s<1$. So the present value of the energy density is $\rho_{CA0}^{1+\alpha}=\frac{c^2B}{(1+A)[c^2B_s+(b^2+c^2)(1-B_s)]}$.

If the DE of the Universe obeys the MCAG equation of state (2), then using the equation (22), the equation (12) reduces to the following equation for $E(z)$ as

$$\begin{aligned}E^2(z)=\Omega_{r0}(1+z)^4+\Omega_{m0}(1+z)^3-\Omega_{k0}(1+z)^2+\Omega_{CA0}[c^2B_s+(b^2+c^2)(1-B_s)]^{\frac{1}{1+\alpha}}\\ \times\left[\frac{B_s+(1-B_s)(1+z)^{3b^2(1+\alpha)(1+A)}}{c^2B_s+(b^2+c^2)(1-B_s)(1+z)^{3b^2(1+\alpha)(1+A)}}\right]^{\frac{1}{1+\alpha}}-2f'(T)-\frac{f(T)}{6H_0^2}\end{aligned} \tag{23}$$

where the dimensionless density parameter $\Omega_{CA0}=\frac{8\pi G\rho_{CA0}}{3H_0^2}$. Putting $z=0$ in the above equation, we obtain $\Omega_{r0}+\Omega_{m0}-\Omega_{k0}+\Omega_{CA0}-2f'(T_0)-\frac{f(T_0)}{6H_0^2}=1$.

III. VIABLE $f(T)$ MODEL

Theoretically, the function $f(T)$ can be elected independently; but in practice it should be chosen in accordance with the fact the divergence from TEGR should be very small. Keeping that in mind, various feasible models were proposed over the years. Bengochea and Ferraro have introduced the power-law model characterized by [43]:

$$f(T)=\beta(-T)^{\gamma} \tag{24}$$

where β and γ are the two model parameters. For $\beta=0$, spatially flat Friedmann equation is recovered. To attain accelerated expansion from this model, the restriction $\gamma<1$ need to be imposed.

• **MCJG:** From equation (20), we obtain

$$\begin{aligned}E^2(z)+6\beta H_0^2\left[E^2(z)+\Omega_{k0}(1+z)^2-2\gamma\right]\left[E^2(z)+\Omega_{k0}(1+z)^2\right]^{\gamma-1}\\ =\Omega_{r0}(1+z)^4+\Omega_{m0}(1+z)^3-\Omega_{k0}(1+z)^2+\Omega_{CJ0}[KA_s-(1-K)(1-A_s)]^{\frac{1}{1+\alpha}}\\ \times\left[\frac{A_s+(1-A_s)(1+z)^{3(1+\alpha)(1+A)}}{KA_s-(1-K)(1-A_s)(1+z)^{3(1+\alpha)(1+A)}}\right]^{\frac{1}{1+\alpha}}\end{aligned} \tag{25}$$

with $\Omega_{r0}+\Omega_{m0}-\Omega_{k0}+\Omega_{CJ0}=1+6\beta H_0^2(1+\Omega_{k0}-2\gamma)(1+\Omega_{k0})^{\gamma-1}$.

• **MCAG:** From equation (23), we obtain

$$\begin{aligned}E^2(z)+6\beta H_0^2\left[E^2(z)+\Omega_{k0}(1+z)^2-2\gamma\right]\left[E^2(z)+\Omega_{k0}(1+z)^2\right]^{\gamma-1}\\ =\Omega_{r0}(1+z)^4+\Omega_{m0}(1+z)^3-\Omega_{k0}(1+z)^2+\Omega_{CA0}[c^2B_s+(b^2+c^2)(1-B_s)]^{\frac{1}{1+\alpha}}\\ \times\left[\frac{B_s+(1-B_s)(1+z)^{3b^2(1+\alpha)(1+A)}}{c^2B_s+(b^2+c^2)(1-B_s)(1+z)^{3b^2(1+\alpha)(1+A)}}\right]^{\frac{1}{1+\alpha}}\end{aligned} \tag{26}$$

with $\Omega_{r0} + \Omega_{m0} - \Omega_{k0} + \Omega_{CA0} = 1 + 6\beta H_0^2(1 + \Omega_{k0} - 2\gamma)(1 + \Omega_{k0})^{\gamma-1}$.

IV. DATA ANALYSIS

In this section, we will perform a comprehensive comparison between the predictions of the Modified Chaplygin-Abel gas (MCAG) and Modified Chaplygin-Jacobi gas (MCJG) models with observational data. Our objective is to understand the constraints placed on these models by utilizing different distinct datasets: the $H(z)$ dataset, the ype Ia supernova, Gamma Ray Bursts (GRBs), quasa (Q) , Baryon Acoustic Oscillation (BAO). By comparing the model predictions with these cosmological data sets, We aim to determine the best-fit values for free parameters of each model. In our analysis, we will also incorporate the present-day value of the Hubble function H_0 to provide a robust estimation of the model parameters. To achieve this, we adopt a rigorous and widely-used approach based on Bayesian statistics. This statistical technique involves the use of likelihood functions to quantify the agreement between the model predictions and the observational data. By applying the Markov Chain Monte Carlo (MCMC) method within the Bayesian framework, we can efficiently explore the parameter space and sample the probability distributions of each parameters. The Bayesian approach offers several advantages, including the ability to include prior information or constraints from previous studies and to handle uncertainties in the model and observational data. By employing this method, we can obtain robust constraints on the parameters of the MCAG and MCJG models and gain valuable insights into their viability in explaining the observed cosmological phenomena. The statistical analysis will allow us to determine the regions in parameter space where the models are consistent with the data and, consequently, provide valuable guidance for understanding the nature of dark energy and its role in the expansion of the Universe.

A. Methodology

Markov Chain Monte Carlo (MCMC) methods have become indispensable tools in cosmology for exploring parameter spaces and estimating uncertainties. In the field of cosmology, MCMC techniques offer a powerful approach to sampling from high-dimensional posterior distributions, enabling us to infer cosmological parameters and understand the underlying models. MCMC algorithms have proven particularly valuable for fitting theoretical models to observed data, such as cosmic microwave background measurements, large-scale structure surveys, and type Ia supernova data. By comparing model predictions to observational data, MCMC methods allow us to constrain parameter values and quantify their uncertainties. The MCMC process involves constructing a Markov chain, where each point represents a specific set of parameter values. These values are randomly generated based on a proposal distribution and accepted or rejected based on the likelihood of the data given the model and prior information. Through iterations, the Markov chain converges to the target posterior distribution, providing samples that represent parameter estimates. The strength of MCMC lies in its ability to efficiently explore complex parameter spaces, even in the presence of multimodal or degenerate likelihood surfaces. By generating a large number of samples from the posterior distribution, we can estimate parameter uncertainties, derive credible intervals, and assess model goodness of fit. In cosmology, MCMC techniques have been extensively employed to investigate various topics, including the properties of dark matter and dark energy, inflationary models, primordial power spectra, and cosmological parameters like the Hubble constant, matter density, and dark energy equation of state.

B. Data Discription

1. $H(z)$ measurements

In our analysis, we have utilized the Hubble expansion rate data to impose more stringent constraints on our Dark Energy (DE) models. The Hubble expansion rate, denoted by $H(z)$, describes how the Universe's expansion rate changes with cosmic time or redshift, and it is a critical parameter for understanding the evolution of the cosmos. We can derive $H(z)$ data through two main methods: the clustering of galaxies and quasars by measuring the Baryon Acoustic Oscillations (BAO) in the radial direction [72], or the differential age method, which expresses the Hubble parameter as follows:

$$H(z) = -\frac{1}{1+z}\frac{dz}{dt}, \tag{27}$$

where $\frac{dz}{dt}$ can be inferred from the redshift difference Δz and the age difference Δt between two passively evolving galaxies [73]. For the current analysis, we have employed a compilation of 36 data points of the Hubble parameter, which are presented in table II of the reference [74]. Each data point in the compilation is associated with its corresponding reference. To quantify the agreement between the model predictions and the observed values of $H(z)$, we utilize the $\chi^2_{H(z)}$ statistic, given by:

$$\chi^2_{H(z)} = \sum_{i=1}^{36} \frac{\left[H_{\rm th}\left(z_i\right) - H_{\rm obs}\left(z_i\right)\right]^2}{\sigma^2_{H(z_i)}}, \tag{28}$$

where $H_{\rm th}$ represents the model predictions, $H_{\rm obs}$ represents the measured values, and $\sigma_{H(z_i)}$ is the standard deviation associated with each data point at redshift z_i.

2. *The type Ia supernova dataset*

The study of Type Ia supernovae (SNIa) has played a crucial role in our understanding of cosmic accelerated expansion. SNIa has proven to be one of the most efficient methods for investigating the nature of dark energy, which remains one of the most intriguing and mysterious phenomena in cosmology. Over the past few years, a wealth of supernova data has been collected, providing valuable insights into the expansion of the Universe [75–80]. The recent release of a comprehensive dataset comprising 1701 SNIa observations is a significant milestone in this field. These observations span an extensive redshift range from $0.001 < z < 2.3.$, allowing researchers to explore the Universe's expansion history over a broad cosmic time scale. SNIa are exceptionally luminous astronomical events, and they are considered to be nearly perfect standard candles. This unique property makes them valuable tools for measuring relative distances using the distance modulus. The distance modulus relates the intrinsic brightness of the supernova to its observed apparent brightness, enabling scientists to calculate precise distances to distant objects and thus probe the expansion rate of the Universe at different epochs. The chi-square values of the SNIa dataset are given by

$$\chi^2_{Pantheon+} = \vec{D}^T \,.\, \mathbf{C}^{-1}_{Pantheon+} \,.\, \vec{D}, \tag{29}$$

where $\mathbf{C}_{Pantheon+}$ is the covariance matrix provided with the Pantheon+ data, including both statistical and systematic uncertainties. and

$$\vec{D} = m_{Bi} - M - \mu_{\rm model}, \tag{30}$$

where m_{Bi} and M denote the apparent, and the absolute magnitudes of SNIa, respectively. Furthermore, $\mu_{\rm model}$ denotes the corresponding distance modulus as predicted by an assumed cosmological model, and defined as

$$\mu_{\rm model}\left(z_i\right) = 5\log_{10}\frac{D_L(z_i)}{(H_0/c)Mpc} + 25, \tag{31}$$

where H_0 is the current value of the Hubble rate, and D_L is the luminosity distance, expressed, for a flat homogeneous and isotropic FLRW Universe, as follows

$$D_L(z) = (1+z)H_0\int_0^z \frac{dz'}{H\left(z'\right)}. \tag{32}$$

Unlike the Pantheon sample, the degeneracy between the absolute magnitude M and H_0 is broken in the Pantheon+ dataset, due to the rewriting of the vector $\vec{D}$, appearing in Eq. (29), in terms of the distance moduli of SNIa in the Cepheid hosts, which allows to constrain M independently via the relations

$$\vec{D}'_i = \begin{cases} m_{Bi} - M - \mu_i^{\rm Ceph} & i \in \text{ Cepheid hosts} \\ m_{Bi} - M - \mu_{\rm model}\ (z_i) & \text{otherwise }, \end{cases} \tag{33}$$

where $\mu_i^{\rm Ceph}$ stands for the distance modulus corresponding to the Cepheid host of the $i^{\rm th}$ SNIa, measured independently with Cepheid calibrators. Therefore, Eq. (29) can be rewritten as

$$\chi^2_{SN} = \vec{D'}^T \cdot \mathbf{C}^{-1}_{\rm Pantheon+} \cdot \vec{D'} \tag{34}$$

We also have involve 162 Gamma Ray Bursts (GRBs) ranging in the redshift from 1.44 to 8.1 [81]. GRBs are incredibly bright and short-lived events, making them observable even from the farthest reaches of the visible Universe. In addition to the GRBs, We also included 24 observations of compact radio quasars [82]. These quasars were found in the redshift range of 0.46 to 2.76 and were identified through a survey of 613 ultra-compact radio sources at GHz frequencies using Very Long Baseline Interferometry (VLBI). Both GRBs and compact radio quasars are essential objects in cosmology. GRBs, being among the most luminous events in the Universe, provide valuable information about the distant regions of the cosmos. On the other hand, compact radio quasars offer insights into the properties of active galactic nuclei and their evolution over cosmic time. The combination of these datasets, along with other cosmological probes like Type Ia supernovae, allows us to gain a deeper understanding of the expansion history and the nature of dark energy.

3. Baryon Acoustic Oscillations (BAO)

We have used 17 BAO data points (please see table 1 of this work [83]) measures from [83]) measures from [84–95] a whole catalog of BAO (333) measurements have been selected because considering the whole catalog of BAO might result in significant inaccuracy because of data correlations; hence, a representative subset to minimize errors. Transverse BAO experiments produce measurements. of $D_H(z)/r_d = c/H(z)r_d$ with a comoving angular diameter distance.[96, 97].

$$D_M = \frac{c}{H_0} S_k \left(\int_0^z \frac{dz'}{E\left(z'\right)} \right), \tag{35}$$

where

$$S_k(x) = \begin{cases} \frac{1}{\sqrt{\Omega_k}} \sinh\left(\sqrt{\Omega_k} x\right) & \text{if} \quad \Omega_k > 0 \\ x & \text{if} \quad \Omega_k = 0 \\ \frac{1}{\sqrt{-\Omega_k}} \sin\left(\sqrt{-\Omega_k} x\right) & \text{if} \quad \Omega_k < 0. \end{cases} \tag{36}$$

We also consider the angular diameter distance $D_A = D_M/(1+z)$ and the $D_V(z)/r_d$. This corresponds to the combination of the BAO peaked coordinates and the sound horizon r_d at the drag epoch. Furthermore, we could immediately derive "line-of-sight" (or "radial") observations from the Hubble parameter.

$$D_V(z) \equiv \left[z D_H(z) D_M^2(z) \right]^{1/3}. \tag{37}$$

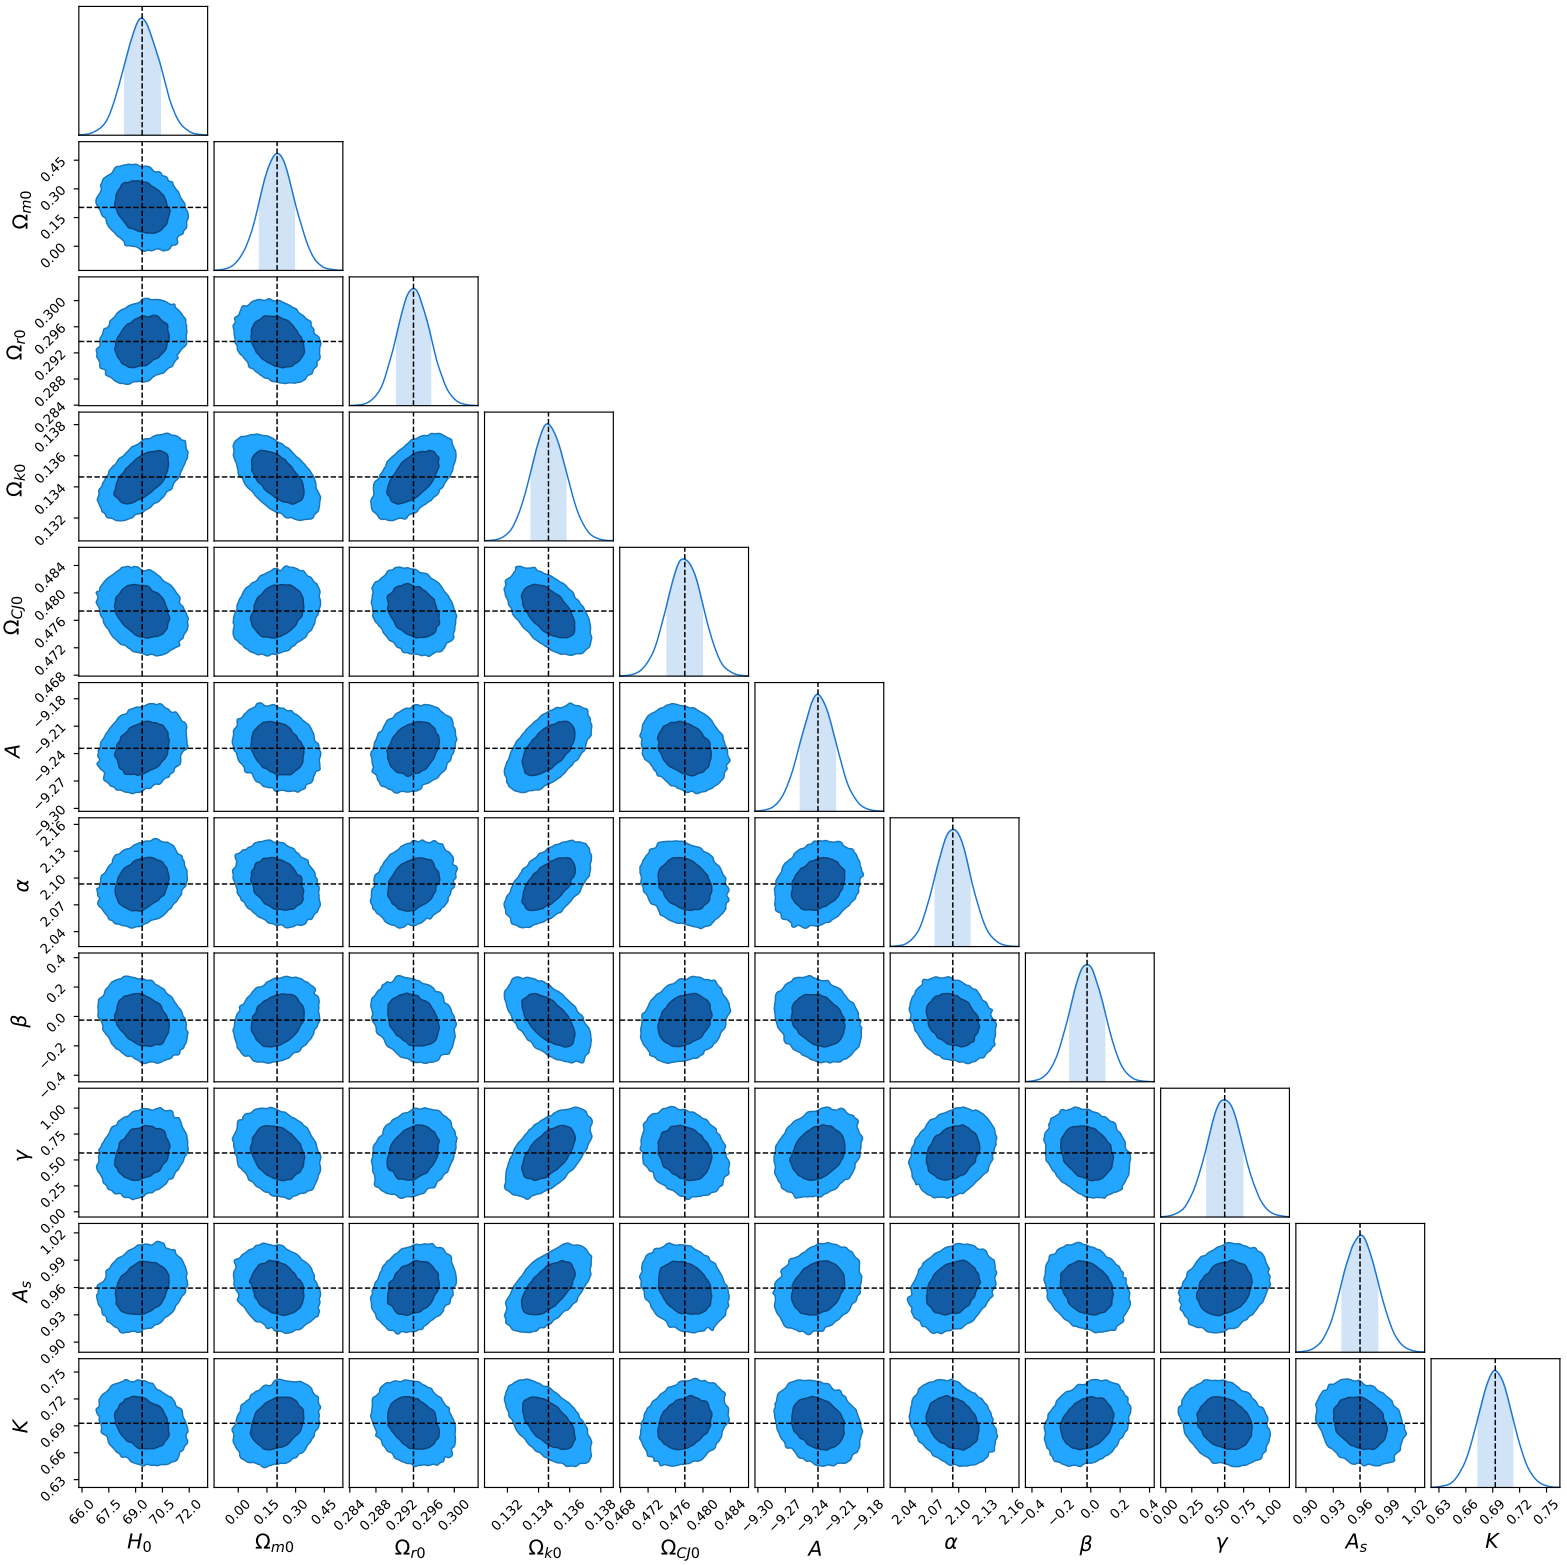

FIG. 1. The above figure shows the MCMC confidence contours at 1σ and 2σ of MCJG Model

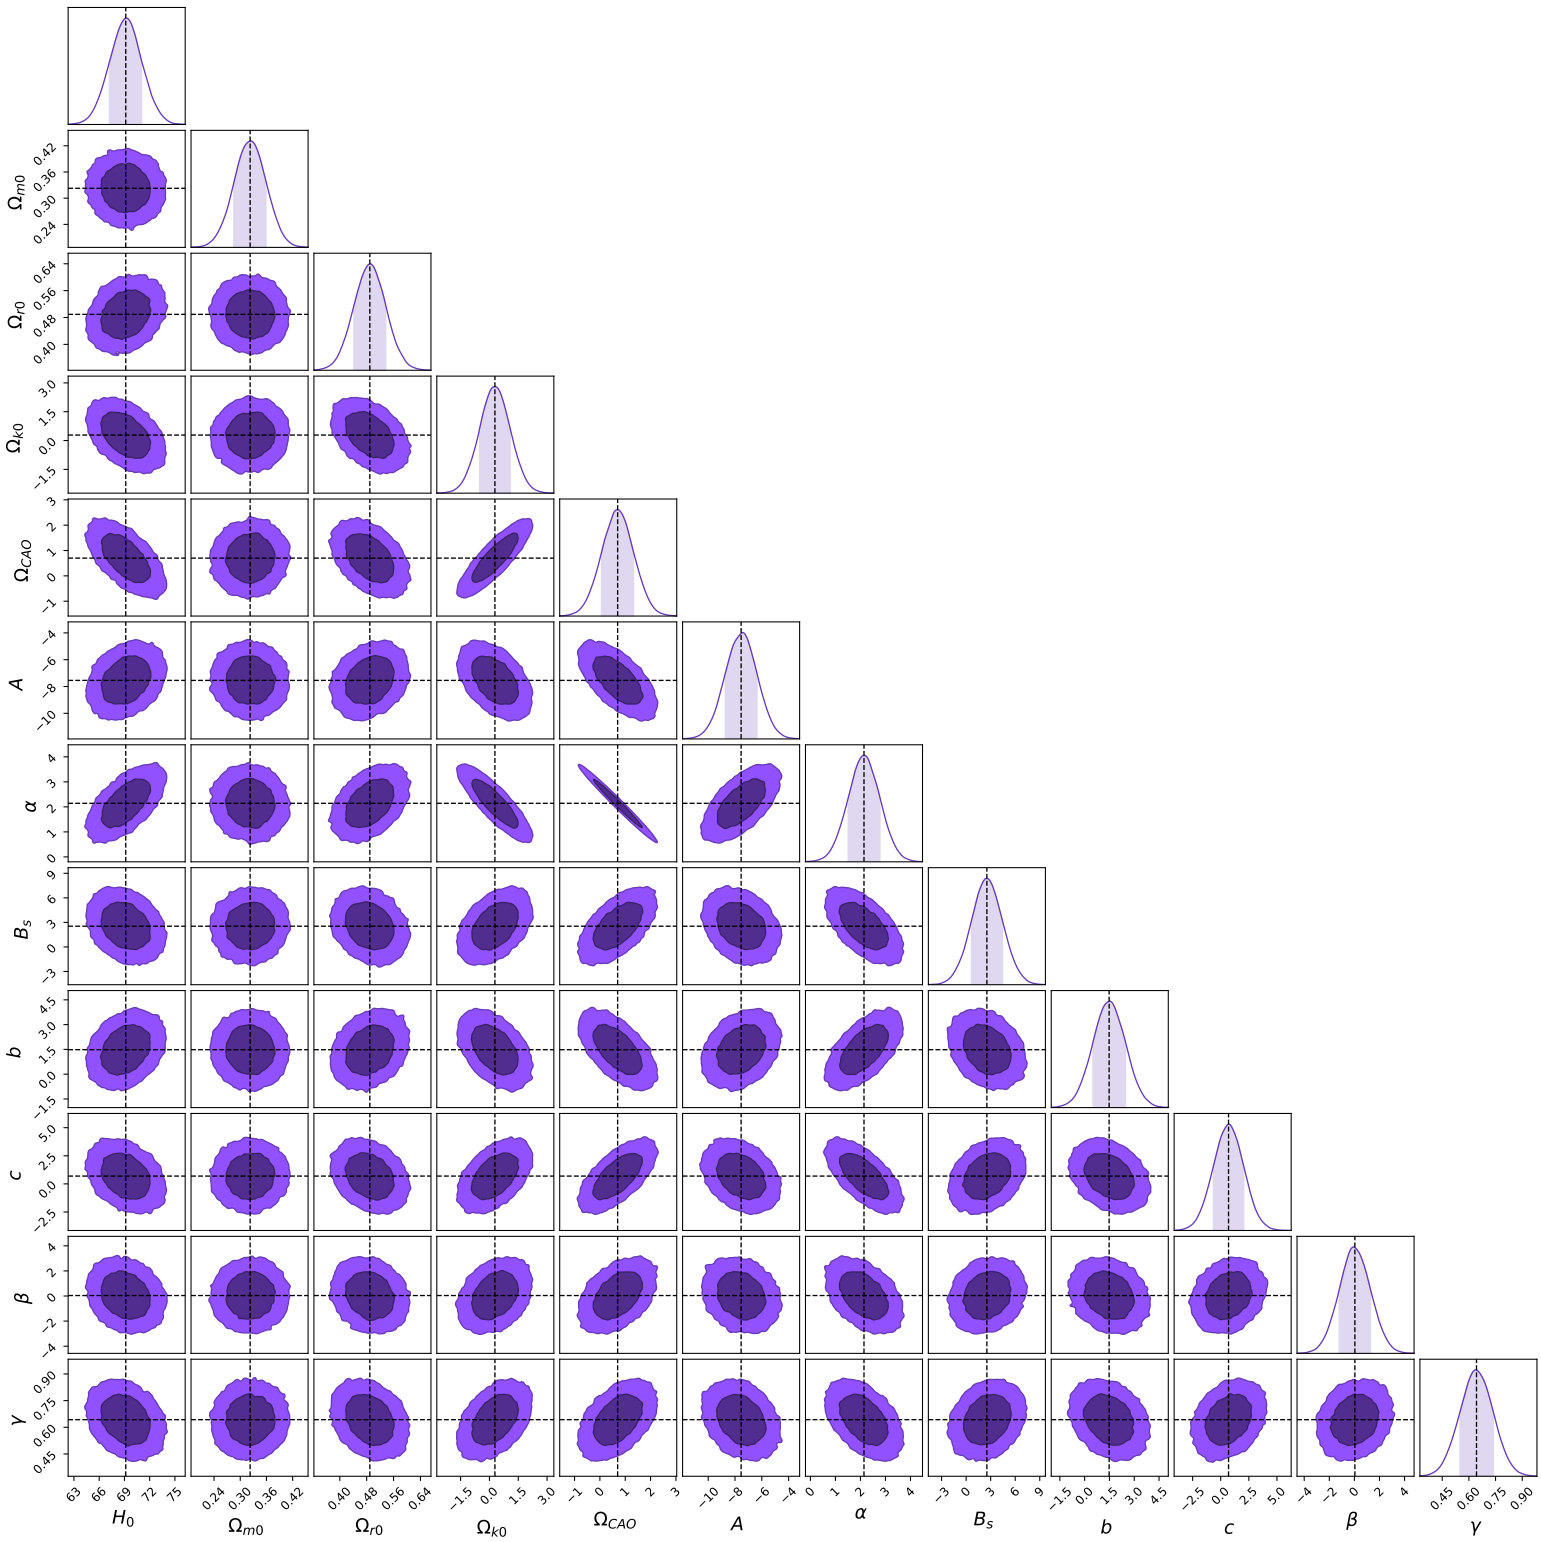

FIG. 2. The above figure shows the MCMC confidence contours at 1σ and 2σ of MCAG Model

V. OBSERVATIONAL AND THEORETICAL COMPARISONS OF THE HUBBLE FUNCTION AND DISTANCE MODULUS FUNCTION

After obtaining the best-fit values for the model parameters of the MCJG and MCAG Models, it is crucial to compare these models with the widely accepted ΛCDM model, which has demonstrated remarkable consistency with various observational datasets. The ΛCDM model is considered a robust framework for describing the evolution of the Universe and serves as a reference point for assessing the viability and reliability of alternative models. By comparing MCJG and MCAG Models with the ΛCDM model, we can investigate the deviations and discrepancies between the two and gain insights into the unique features and behaviors of MCJG and MCAG Models. This comparative analysis allows us to examine how MCJG and MCAG Models differ from the ΛCDM model in terms of the expansion rate, matter content, and overall dynamics of the Universe. Analyzing the deviations between MCJG and MCAG Models and the ΛCDM model provides valuable information about the strengths and limitations of MCJG and MCAG Models. It helps us understand the specific aspects of MCJG and MCAG Models that introduce variations compared to the well-established ΛCDM framework. By identifying these deviations, we can gain insights into the potential implications of MCJG and MCAG Models for our understanding of the Universe and explore novel cosmological dynamics and characteristics. Furthermore, the comparison with the ΛCDM model allows us to assess the goodness-of-fit of MCJG and MCAG Models to observational data. By evaluating the level of agreement between MCJG and MCAG Models models and the ΛCDM framework, we can determine the validity and reliability of MCJG and MCAG Models in light of the available observational constraints.

A. Comparison of MCJG and MCAG with Hubble Measurements

To evaluate the agreement between MCJG and MCAG models with observational data, we compared their predictions to the Hubble data, alongside the well-established ΛCDM model. The results are presented in Fig:- 3 and Fig:- 4. The figures clearly show that both MCJG and MCAG models fit the Hubble data quite well. The data points obtained from observations match very well with the predictions of our models, indicating that both models accurately explain how the Universe is expanding. The fact that both MCJG and MCAG models match the Hubble data provides strong support for their viability and indicates that they capture essential aspects of cosmic expansion. These findings demonstrate the satisfactory agreement of both models with the Hubble data, underscoring their potential to provide meaningful insights into the dynamics and evolution of the Universe within the framework of our proposed models. Such a positive outcome reinforces the credibility and significance of our research and its ability to contribute to a better understanding of the Universe's evolution.

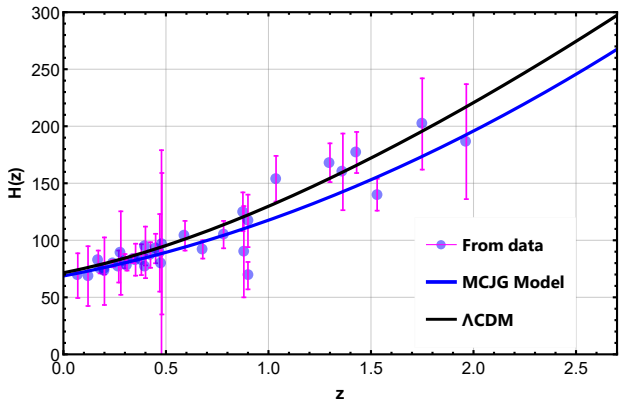

FIG. 3. The figure shows that the theoretical curve of the Hubble function $H(z)$ of MCJG Model shown in blue line and ΛCDM model shown in black line with $\Omega_{m0} = 0.3$ and $\Omega_\Lambda = 0.7$ against the 36 Hubble measurements are shown in blue dots wit their corresponding error bars in purple line.

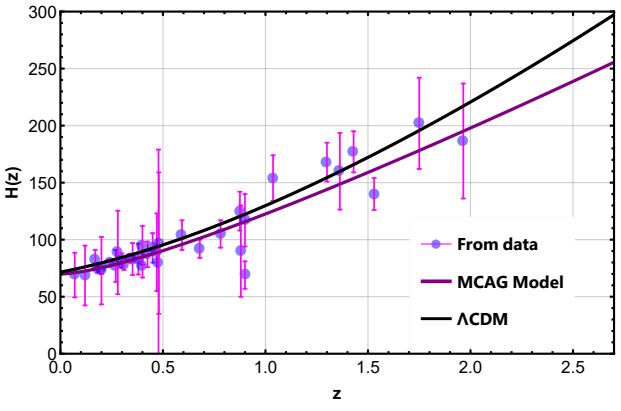

FIG. 4. The figure shows that the theoretical curve of the Hubble function $H(z)$ of MCAG Model shown in purple line and ΛCDM model shown in black line with $\Omega_{m0} = 0.3$ and $\Omega_\Lambda = 0.7$, against 36 $H(z)$ datasetsthe 36 Hubble measurements are shown in blue dots wit their corresponding error bars in purple line.

B. Comparison of MCJG and MCAG with type Ia supernova

In this analysis, we have compared two distance modulus functions, labeled as MCJG and MCAG, with the type Ia supernova dataset, which consists of 1701 data points, as well as the standard ΛCDM model. The comparison results are illustrated in Fig:- 5 and Fig:- 6. These figures shows that both MCJG and MCAG provide an excellent fit to the type Ia supernova dataset and the ΛCDM model. This means that our models closely match the observed distance measurements, and they are consistent with the data we have collected. This comparison with real observational data provides strong support for the validity and trustworthiness of our models in explaining the phenomena we observe in the Universe. It gives us confidence that both MCJG and MCAG accurately represent the expansion history of the Universe, as indicated by the type Ia supernova dataset.

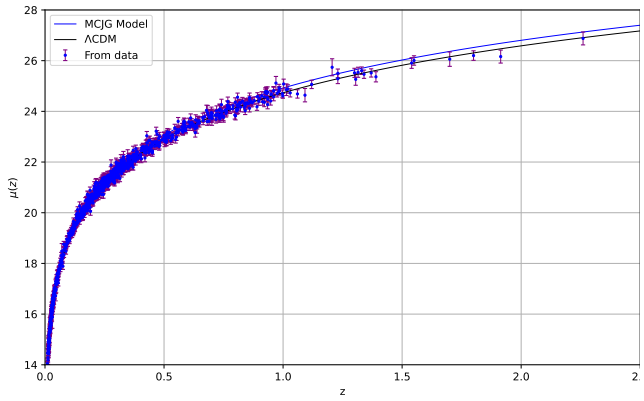

FIG. 5. Theoretical curve of distance modulus $\mu(z)$ of the MCJG is shown in blue line and the ΛCDM model is shown in the black line with $\Omega_{m0} = 0.3$ and $\Omega_\Lambda = 0.7$, against type Ia supernova data are shown in blue dots with their corresponding errors bars shown in purple.

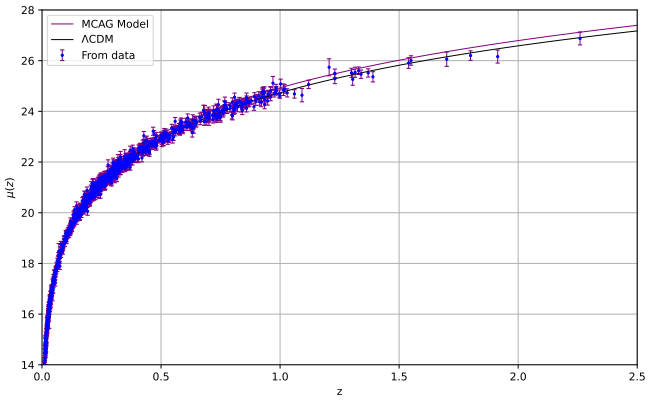

FIG. 6. Theoretical curve of distance modulus $\mu(z)$ of the MCAG is shown in purple line and the ΛCDM model is shown in the black line with $\Omega_{m0} = 0.3$ and $\Omega_\Lambda = 0.7$, against type Ia supernova data are shown in blue dots with their corresponding errors bars shown in purple.

C. Relative difference between MCJG and MCAG with ΛCDM

We have examined the relative difference between MCAJG and MCAG, and the standard ΛCDM paradigm. These comparisons are visualized in Fig:- 7 and Fig:- 8. The figures reveal interesting insights regarding the performance of the typical ΛCDM model and the two alternative models for different redshifts. Specifically, for redshifts z less than 1, all three models demonstrate very similar behavior, indicating a close agreement in their predictions. However, as we move to higher redshifts ($z > 1$), discrepancies begin to emerge between the two alternative models and the ΛCDM model. The differences become more pronounced as the redshift increases. This suggests that at higher redshifts, the alternative models deviate from the predictions of the ΛCDM model.

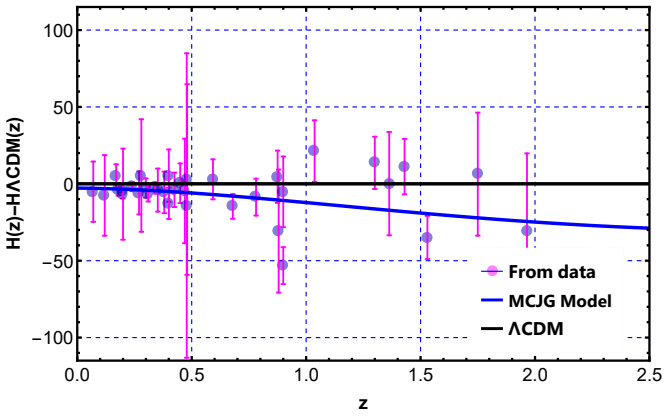

FIG. 7. The variation of the difference between MCJG shown in the blue line, and the ΛCDM model shown in the black line with $\Omega_{m0} = 0.3$ and $\Omega_\Lambda = 0.7$, as a function of the redshift z against the 36 Hubble measurements are shown in blue dots with their corresponding error bars shown in purple line.

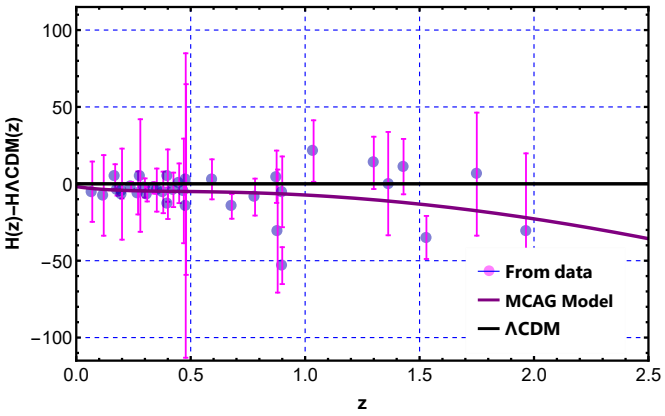

FIG. 8. The variation of the difference between MCAG shown in the purple line, and the ΛCDM model shown in the black line with $\Omega_{m0} = 0.3$ and $\Omega_\Lambda = 0.7$, as a function of the redshift z against the 36 Hubble measurements are shown in blue dots with their corresponding error bars shown in purple line.

VI. GEOMETRICAL DYNAMICS OF THE MODELS

A. Cosmographic analysis

Cosmography parameters [98–100] provide a valuable framework for analyzing and comparing theoretical cosmological models with observational data. They offer a comprehensive set of quantities that describe the expansion history of the Universe and can be used to test the consistency of different cosmological models. The cosmography approach is based on a Taylor expansion of the scale factor, which represents the size of the Universe, around a reference redshift or time. By expanding the scale factor up to a certain order, we can obtain a series of cosmography parameters that capture important aspects of the cosmic evolution. These parameters are derived from observables such as the Hubble parameter and its derivatives. Some of the commonly used cosmography parameters include the Hubble parameter ($H(z)$), deceleration parameter ($q(z)$), jerk parameter ($j(z)$), and snap parameter ($s(z)$), among others. These parameters can be derived from the expansion history of the Universe and provide a quantitative description of its behavior. They allow us to extract meaningful information about the underlying cosmological model and compare it with observational data.

1. *deceleration parameter*

The deceleration parameter is a fundamental cosmological quantity that describes the rate at which the expansion of the Universe is slowing down or speeding up. It provides valuable insights into the dynamics of the cosmic expansion and plays a crucial role in understanding the past and future behavior of the Universe. In the context of Friedmann-Robertson-Walker cosmology, the deceleration parameter, denoted as $q(z)$, is defined as the negative ratio of the second derivative of the scale factor $a(t)$ to its first derivative, normalized by the square of the Hubble parameter $H(z)$:

$$q(z) = -\frac{a''(t)}{a(t)H(t)^2} \tag{38}$$

Here, $a(t)$ represents the scale factor of the Universe, which describes how the distances between galaxies change with time, and $H(t)$ is the Hubble parameter, which characterizes the expansion rate of the Universe at a given time. The deceleration parameter $q(z)$ determines the behavior of the cosmic expansion. If $q(z) < 0$, the Universe is experiencing accelerated expansion, indicating that the expansion rate is increasing over time. Conversely, if $q(z) > 0$, the Universe is undergoing decelerated expansion, with the expansion rate decreasing over time. Studying the deceleration parameter is essential for understanding the evolution of the Universe and the influence of different components such as matter, radiation, or dark energy on its expansion dynamics. References such as [101–105] have

employed the deceleration parameter to analyze and explain the evolutionary phases of the Universe in different cosmological models.

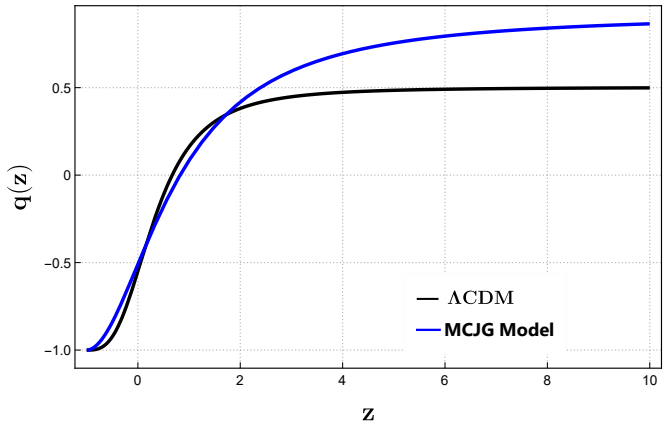

FIG. 9. Evolution of deceleration parameter with respect to the redshift of MCJG Model.

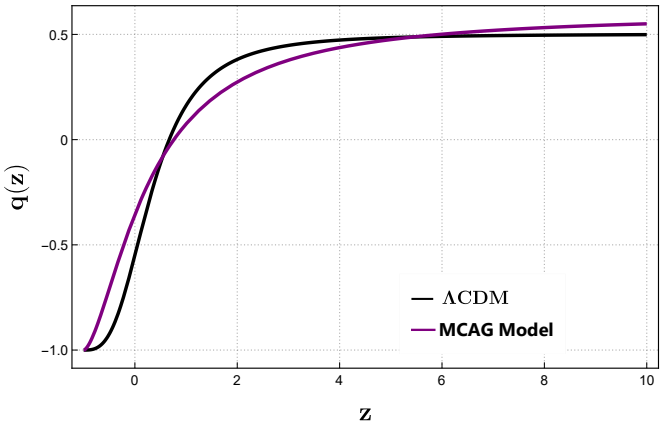

FIG. 10. Evolution of deceleration parameter with respect to the redshift of MCAG Model.

2. Jerk parameter

The concept of jerk parameters in cosmology provides valuable insights into the dynamics of the Universe and the nature of dark energy. Jerk parameters offer novel diagnostics for dark energy, allowing us to study the higher derivatives of the scale factor and explore deviations from the standard cosmological model. In cosmology, the dimensionless jerk parameter, sometimes referred to as jolt, extends the standard cosmological parameters, such as the scale factor $a(t)$ and the deceleration parameter q. It arises from the fourth term of a Taylor series expansion of the scale factor around a reference time t_0. Mathematically, it can be expressed as:

$$\frac{a(t)}{a_0} = 1 + H_0(t-t_0) - \frac{1}{2}q_0H_0^2(t-t_0)^2 + \frac{1}{6}j_0H_0^3(t-t_0)^3 + O\left[(t-t_0)^4\right], \tag{39}$$

where the subscript 0 denotes the present values. The jerk parameter j characterizes the third-order derivative of the expansion factor with respect to cosmic time and offers an absolute measure to explore departures from the standard ΛCDM model. It can be expressed as:

$$j = \frac{1}{a}\frac{d^3a}{d\tau^3}\left[\frac{1}{a}\frac{da}{d\tau}\right]^{-3} = q(2q+1) + (1+z)\frac{dq}{dz}, \tag{40}$$

where τ represents the cosmic time and z is the redshift. This expression provides a direct way to determine the jerk parameter by relating it to the deceleration parameter q and its derivative with respect to redshift. The jerk parameter is a valuable diagnostic tool in cosmology as it helps determine the most suitable candidate for the physical interpretation of cosmic dynamics, particularly in relation to dark energy models. Different values of the jerk parameter offer insights into the correlation between various dark energy proposals and standard Universe models. In the flat ΛCDM model, the jerk parameter takes the value $j = 1$. Deviations from this value indicate departures from the standard model and provide a way to explore transitions between different phases of cosmic acceleration.

3. snap parameter

The snap parameter is a measure of the fifth time derivative of the expansion factor in cosmology. It is a dimensionless quantity that provides information about the curvature of the Universe and the dynamics of its expansion. The snap parameter is associated with the term in the Taylor expansion of the expansion factor beyond the third order. In the context of the Taylor expansion of the expansion factor, the snap parameter represents the fourth-order

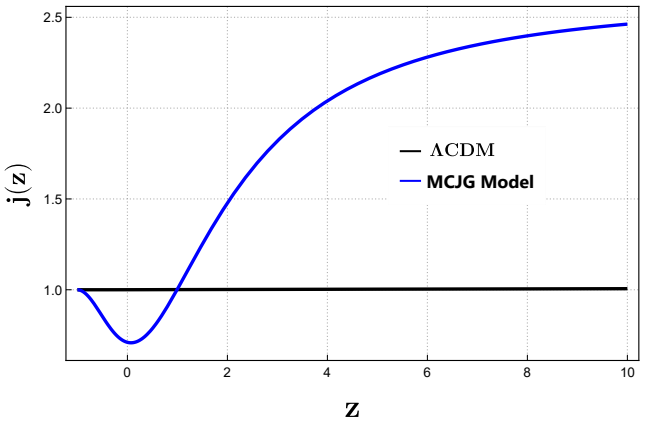

FIG. 11. Evolution of jerk parameter with respect to the redshift of MCJG Model.

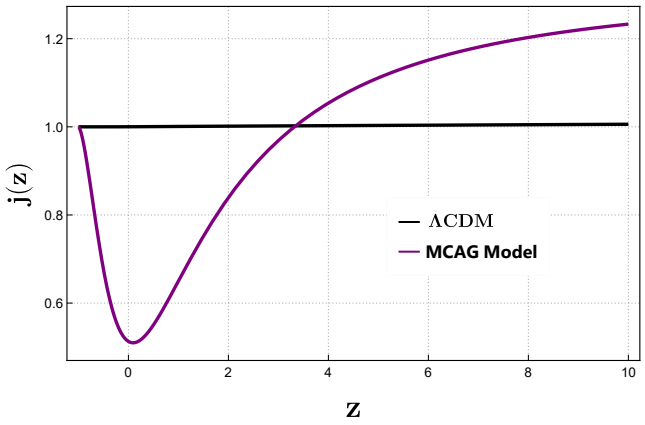

FIG. 12. Evolution of jerk parameter with respect to the redshift of MCAG Model.

term. The expansion factor is expressed as a series expansion around a reference time t_0, with the snap parameter denoted as s_0. The expansion factor can be written as:

$$\frac{a(t)}{a_0} = 1 + H_0(t-t_0) - \frac{1}{2}q_0H_0^2(t-t_0)^2 + \frac{1}{6}j_0H_0^3(t-t_0)^3 + \frac{1}{24}s_0H_0^4(t-t_0)^4 + O\left[(t-t_0)^5\right] \tag{41}$$

Here, $a(t)$ represents the expansion factor at time t, a_0 is the expansion factor at the reference time t_0, H_0 is the present-day Hubble constant, q_0 is the deceleration parameter, j_0 is the jounce parameter (related to the snap parameter), and s_0 is the snap parameter. The higher-order terms beyond the fourth order are neglected in this expansion. The snap parameter s can also be expressed in terms of the deceleration parameter q and the jounce parameter j as:

$$s = \frac{1}{a}\frac{d^4a}{d\tau^4}\left[\frac{1}{a}\frac{da}{d\tau}\right]^{-4} = \frac{j-1}{3\left(q-\frac{1}{2}\right)} \tag{42}$$

For the flat ΛCDM model, where $j = 1$, the snap parameter simplifies to $s = -(2+3q)$. In this case, the deviation of the quantity $\frac{ds}{dq}$ from -3 quantifies how the cosmic evolution diverges from the dynamics predicted by the ΛCDM model.

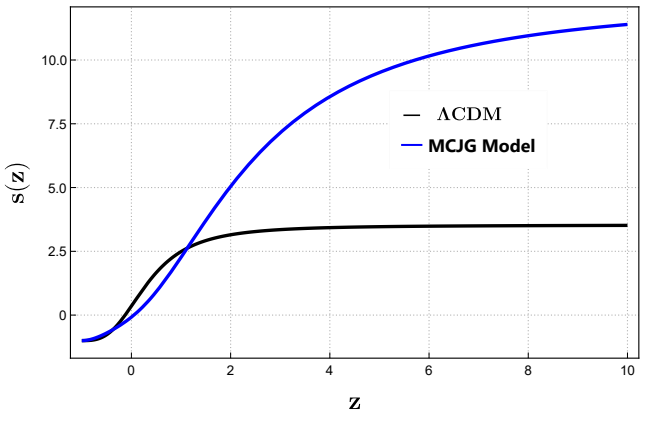

FIG. 13. Evolution of snap parameter with respect to the redshift of MCJG Model.

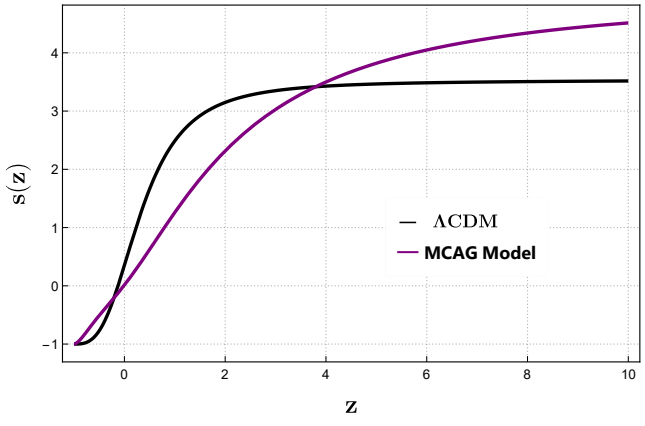

FIG. 14. Evolution of snap parameter with respect to the redshift of MCAG Model.

VII. STATEFINDER DIAGNOSTIC

The statefinder diagnostic pair, consisting of the parameters r and s, is a widely-used tool in cosmology for studying and understanding various dark energy (DE) models. It provides a dimensionless way to analyze the cosmic properties of DE, independent of specific models, by examining higher-order derivatives of the scale factor. This diagnostic pair was introduced in the literature ([106–109]). The parameter r in the statefinder diagnostic represents the ratio of the third derivative of the scale factor to the cube of the Hubble parameter. It quantifies the acceleration dynamics of the Universe. On the other hand, the parameter s is a linear combination of r and the deceleration parameter q. It characterizes the cosmic evolution and the nature of DE. The statefinder diagnostic pair can be calculated using the following expressions:

$$r = \frac{\dddot{a}}{aH^3}, \quad s = \frac{r-1}{3\left(q-\frac{1}{2}\right)}, \tag{43}$$

Here, H is the Hubble parameter, and q is the deceleration parameter. By computing the values of r and s, one can analyze the cosmic characteristics of DE models without relying on specific theoretical frameworks. Certain values of the statefinder pair have well-known interpretations in the context of standard DE models. For example, $\{r, s\} = \{1, 0\}$ corresponds to the ΛCDM model, which is the standard cosmological model with a cosmological constant. Similarly, $\{r, s\} = \{1, 1\}$ corresponds to the standard cold dark matter (SCDM) model in a Friedmann-Lemaître-Robertson-Walker (FLRW) Universe. The region with $\{r, s\}$ values ranging from $(-\infty, \infty)$ corresponds to the Einstein static Universe. In the r-s plane, different regions represent distinct types of DE models. For example, when $s > 0$, it indicates quintessence-like models, which involve a scalar field responsible for DE. Conversely, when $s < 0$, it indicates phantom-like models, characterized by the presence of a scalar field with negative kinetic energy. Deviations from the standard $\{r, s\} = \{1, 0\}$ values can signify an evolutionary process from phantom-like to quintessence-like behavior. Moreover, specific combinations of the deceleration parameter q and the statefinder parameter r are associated with well-known models. For instance, $\{q, r\} = \{-1, 1\}$ is linked to the ΛCDM model, which describes a Universe dominated by dark energy in the form of a cosmological constant. Another example is $\{q, r\} = \{0.5, 1\}$, corresponding to the SCDM model, which assumes a Universe dominated by non-relativistic matter without dark energy.

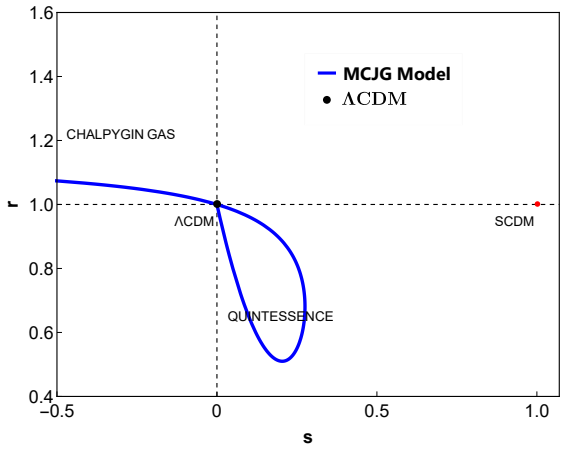

FIG. 15. This figure shows $\{s, r\}$ plots for MCJG Model .

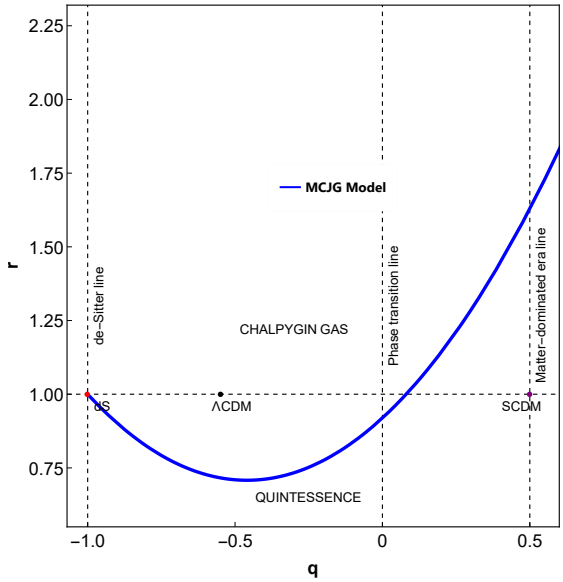

FIG. 16. This figure shows $\{q, r\}$ plots for MCJG Model.

VIII. DIAGNOSTIC ANALYSIS

The Om diagnostic is a valuable tool introduced in the literature ([110–113]) that serves as an effective null test for the ΛCDM (Lambda Cold Dark Matter) model. This diagnostic, similar to the statefinder diagnostic, offers a

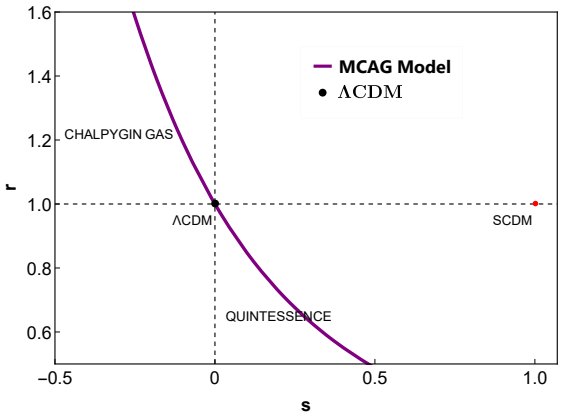

FIG. 17. This figure shows $\{s, r\}$ plots for MCAG Model .

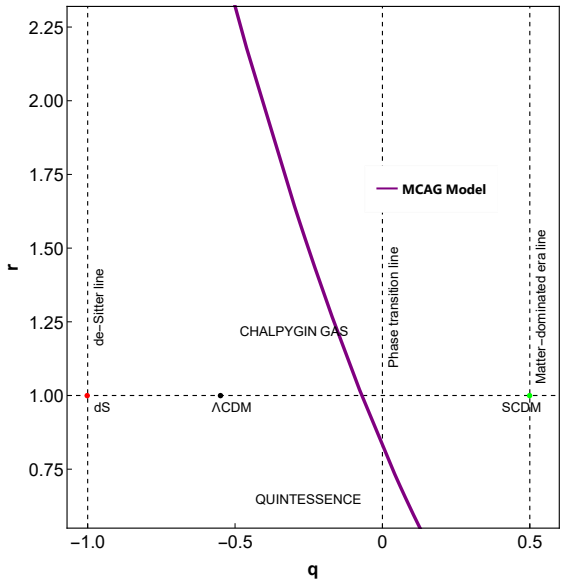

FIG. 18. This figure shows $\{q, r\}$ plots for MCAG Model.

viable approach for differentiating various dark energy (DE) models from the standard ΛCDM model by examining the slope variation of Om. The Om diagnostic provides insights into the nature of dark energy by characterizing its behavior and distinguishing between different regimes. The diagnostic is based on the analysis of the $\mathrm{Om}(z)$ function, where z represents the redshift, in a flat Universe. By studying the variation of $\mathrm{Om}(z)$ with respect to redshift, distinct features and properties of the underlying dark energy model can be identified. A negative slope in the Om diagnostic corresponds to a phantom nature of dark energy. This suggests that the equation of state of dark energy is less than -1, indicating an accelerated expansion with even stronger dynamics compared to the ΛCDM model. Conversely, a positive slope in the Om diagnostic implies a quintessence regime for dark energy. In this case, the equation of state is greater than -1, indicating a slower rate of expansion compared to the phantom scenario. Furthermore, a constant slope of the diagnostic curve with respect to redshift corresponds to the ΛCDM model. This indicates that the dark energy component behaves like a cosmological constant throughout cosmic history, providing a good fit to observational data. The Om diagnostic thus enables us to discern different dark energy models from the ΛCDM model based on the characteristic slope variation of Om. By analyzing observational data and comparing the slope of $\mathrm{Om}(z)$, researchers can gain valuable insights into the nature of dark energy and the validity of alternative models.

$$\mathrm{Om}(z) = \frac{\left(\frac{H(z)}{H_0}\right)^2 - 1}{(1+z)^3 - 1}. \tag{44}$$

IX. INFORMATION CRITERIA

To assess the viability of any model, a thorough understanding of information criteria (IC) is essential. The Akaike Information Criterion (AIC) [114–118] is commonly employed as a general IC tool. The AIC serves as an approximate measure of the Kullback-Leibler information divergence and asymptotically provides an unbiased estimator of this divergence. The AIC for Gaussian estimation is given by $\mathrm{AIC} = -2\ln(\mathcal{L}_{\max}) + 2\kappa + \frac{2\kappa(\kappa+1)}{N-\kappa-1}$, where $\mathcal{L}_{\max}$ denotes the maximum likelihood function, κ represents the total number of free parameters in the model, and N is the total number of data points used. Since the assumption is often $N \gg 1$ for the models considered, the formula simplifies to the original AIC form, $\mathrm{AIC} = -2\ln(\mathcal{L}_{\max}) + 2\kappa$. When comparing multiple models, the differences in IC values can be quantified as $\triangle\mathrm{AIC} = \mathrm{AIC}_{\mathrm{model}} - \mathrm{AIC}_{\min} = \triangle\chi^2_{\min} + 2\triangle\kappa$. The range of $\triangle$AIC that is considered more favorable is $(0, 2)$. The lower favorable range of $\triangle$AIC is $(4, 7)$, while values exceeding $\triangle\mathrm{AIC} > 10$ provide less support for the

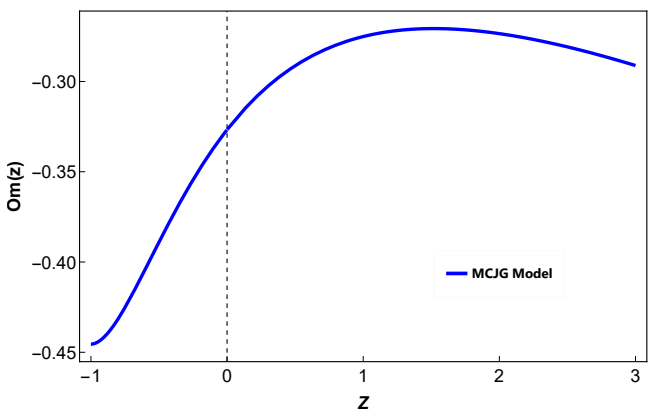

FIG. 19. This figure shows the $Om(z)$ with respect to redshift for MCJG Model.

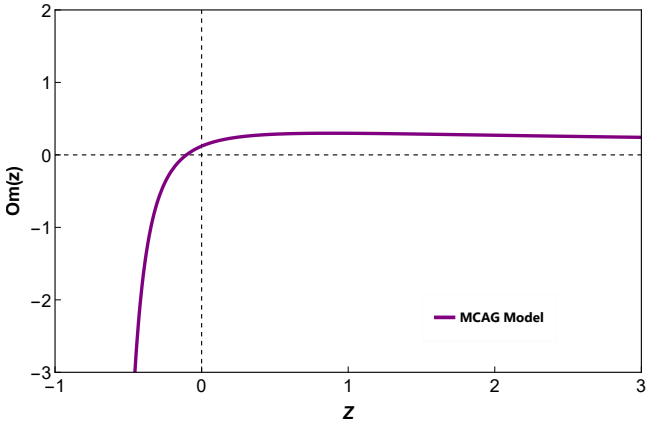

FIG. 20. This figure shows the $Om(z)$ with respect to redshift for MCAG Model.

model.

Model	χ^2_{min}	χ^2_{red}	AIC	ΔAIC
ΛCDM Model	2357.562	0.9837	1507.84	0
MCJG Model	2339.187	0.9827	1507.66	0.8202
MCAG Model	2338.167	0.9813	1507.81	1.9741

TABLE I. Summary of the χ^2_{min}, χ^2_{red}, AIC and ΔAIC.

X. RESULTS

a. Deceleration parameter The comparison of the redshift dependence of the deceleration parameter for MCJG Model and MCJG Model with respect to the ΛCDM model is presented in Fig:- 10 and Fig:- 9, respectively. In the considered redshift range of $z \in (-1, 10)$, all three models exhibit similar behavior in the evolution of the deceleration parameter. However, in the MCJG Model , noticeable deviations from the ΛCDM model can be observed at high redshifts beyond $z = 4$. This indicates that the MCJG Model may introduce differences in the expansion dynamics compared to the standard ΛCDM model. The numerical values of the transition redshift, denoted as z_{tr}, which marks the transition from a decelerating phase to an accelerating phase, are relatively close for all three models, including the ΛCDM model. This implies that, in terms of the deceleration parameter, the models share similar characteristics regarding the shift from deceleration to acceleration in cosmic expansion. Finally, it is noteworthy that all three models exhibit a de Sitter phase characterized by a deceleration parameter of $q = -1$. The de Sitter phase corresponds to a phase of accelerated expansion driven by a cosmological constant or a similar dark energy component. These findings suggest that while the MCJG Model and the MCAJ Model generally resemble the behavior of the ΛCDM model in terms of the deceleration parameter, deviations become apparent at high redshifts in the MCJG Model. However, all models share similarities in terms of the transition redshift z_{tr} and end in a de Sitter phase with $q = -1$, indicating accelerated expansion.

b. Jerk parameter The behavior of the jerk parameter, denoted as $j(z)$, for the (MCJG) Model and (MCAG) Model in comparison to the standard ΛCDM paradigm is depicted in Fig:- 11 and Fig:- 12, respectively. These models provide alternative frameworks to explain the dynamics of the Universe and explore departures from the ΛCDM model. In Fig:- 11, we observe that the predictions of the MCJG Model diverge significantly from the ΛCDM model at high redshifts. The MCJG Model exhibits a distinct behavior, showing a different trend in the evolution of cosmic acceleration. However, it is worth noting that at $z = -1$, both the MCJG Model and the ΛCDM model predict the same value for the jerk parameter. Similarly, in Fig:- 12, we examine the behavior of the jerk parameter for the MCAG Model. This model also presents deviations from the ΛCDM model, particularly at higher redshifts.

The MCAG Model showcases an opposite trend compared to the MCAG Model, suggesting a unique dynamic for cosmic acceleration. Remarkably, at $z = -1$, both the MCAG Model and the ΛCDM model yield identical values for the jerk parameter.

c. Snap parameter The behavior of the snap parameter, represented as $s(z)$, for the MCJG Model and MCAG Model, in comparison to the ΛCDM model, is depicted in Figure 13 and Figure 14, respectively. These figures clearly illustrate significant deviations between the alternative models and the ΛCDM model, particularly at higher redshifts. In the context of cosmology, the snap parameter, $s(z)$, characterizes the rate of change of the acceleration of the Universe with respect to redshift. It is an important quantity for discerning the dynamic nature of dark energy. Analyzing Figure 13, we observe that the MCJG Model exhibits discrepancies compared to the ΛCDM model, with the differences becoming less pronounced at lower redshifts. This suggests that the MCJG Model aligns more closely with the ΛCDM model as redshift decreases, indicating a better agreement in terms of the snap parameter. On the other hand, Figure 14 illustrates that the MCAG Model displays a similar behavior to the ΛCDM model. The snap parameter for the MCAG Model exhibits characteristics that are consistent with the ΛCDM model, implying a comparable agreement in terms of the dynamics of acceleration. These observations imply that the MCJG Model and MCAG Model have distinct behaviors in comparison to the ΛCDM model, as evidenced by the variations in the snap parameter. While the MCJG Model converges towards the ΛCDM model at lower redshifts, the MCAG Model demonstrates a level of agreement with the ΛCDM model throughout the redshift range.

d. Statefinder diagnostic In Figure 15, the evolution of the statefinder pair (r, s) for the MCJG Model is depicted. As the evolution progresses, the statefinder trajectory of the MCJG Model transitions from the quintessence region to the Chaplygin gas region at late times. This transition implies a change in the nature of dark energy, reflecting a shift in the dominant energy component driving the accelerated expansion of the Universe. It is worth noting that during this evolution, the MCJG Model bypasses the intermediate fixed point $(0, 1)$, which is associated with the standard ΛCDM model. Similarly, in Figure 17, the evolution of the statefinder pair (r, s) for the MCAG Model is presented. The behavior of the MCAG Model is analogous to the MCJG Model as it undergoes a transition from the quintessence region to the Chaplygin gas region. This transition is again accompanied by bypassing the intermediate fixed point $(0, 1)$, which characterizes the ΛCDM model. In the context of cosmology, the quintessence region corresponds to a scenario where dark energy behaves like a dynamical scalar field, while the Chaplygin gas region represents a different regime where dark energy is modeled as a perfect fluid with an equation of state given by the Chaplygin gas equation. The trajectory of the statefinder pair (r, s) provides valuable insights into the nature and evolution of dark energy within these alternative models. Fig 16 provides additional insight into the behavior of the MCJG Model. As the evolution progresses, the trajectory of the MCJG Model undergoes a transition from the line corresponding to the Matter-dominated era. This region is characterized by a decelerating expansion due to the dominant matter content in the Universe. As the MCJG Model evolves further, it enters the quintessence region, which is indicated by the deviation from the Matter-dominated era line. In this region, the dominant energy component responsible for the cosmic acceleration is a quintessence scalar field with an equation of state greater than -1. This scalar field drives the accelerated expansion of the Universe. The trajectory of the MCJG Model ultimately converges towards the de Sitter point, denoted as $(-1, 1)$. At this point, the expansion of the Universe becomes asymptotically exponential, mimicking a cosmological constant (dark energy with a constant equation of state equal to -1). On the other hand, Fig 18 illustrates the evolution of the statefinder pair (q, r) for the MCAG Model. The trajectory of the MCAG Model undergoes a transition from the quintessence region, similar to the MCJG Model. However, in the case of the MCAG Model, the trajectory deviates towards the de Sitter point $(-1, 1)$. This trajectory reveals the unique characteristics of the MCAG Model and its departure from the simple ΛCDM model.

e. Om diagnostic Figures 19 and 20 depict the behavior of the $\mathrm{Om}(z)$ parameter with respect to redshift z for the MCJG Model and MCAG Model, respectively. Analyzing Figure 19, we observe that for the MCJG Model, the $\mathrm{Om}(z)$ values are smaller than Ω_{m0} for redshifts greater than zero ($z > 0$). This indicates that the MCJG Model resides in the quintessence domain, where the expansion of the Universe is driven by a slowly-evolving quintessence field or dark energy component. As the redshift decreases, we notice a significant decrease in the $\mathrm{Om}(z)$ value for the MCJG Model. Eventually, the value becomes negative, signifying a transition from the quintessence regime to the phantom region. The phantom region is characterized by an equation of state for dark energy that is less than -1, leading to an accelerated expansion with more dramatic dynamics than the standard ΛCDM model. Similarly, in Figure 20 representing the MCAG Model, we observe that the $\mathrm{Om}(z)$ values are also smaller than Ω_{m0} for $z > 0$, placing the model within the quintessence domain. As the redshift decreases, the $\mathrm{Om}(z)$ value exhibits a significant

decrease and eventually becomes negative, indicating the transition from quintessence to the phantom region within the MCAG Model. The behavior observed in the transition from quintessence to phantom regions for both the MCJG and MCAG Models provides valuable insights into the cosmological dynamics and characteristics of these models. The change in the sign of Om(z) signifies a shift from a slowly-evolving quintessence field to a more rapidly-evolving dark energy component, leading to an accelerated expansion of the Universe with distinct dynamics compared to the standard ΛCDM model.

f. Information Criteria In our analysis, we compared the MCJG and MCAG models with the well-established ΛCDM model, and we assessed their relative support using the ΔAIC values. Table I presents the results, showing that MCJG has a ΔAIC value of 0.8202, while MCAG has a ΔAIC value of 1.9741. Positive ΔAIC values indicate that both MCJG and MCAG have slightly weaker support compared to the ΛCDM model. When the ΔAIC value falls within the range of (0, 2), it is considered most favorable, suggesting moderate evidence in favor of a model. In our case, both MCJG and MCAG fall within this range, indicating some degree of support for these models. Comparing the ΛCDM model to MCJG, we find that MCJG has a higher ΔAIC value, indicating that the ΛCDM model performs slightly better in terms of goodness of fit and model selection. Similarly, when comparing the ΛCDM model to MCAG, MCAG has a higher ΔAIC value, suggesting a better fit for the ΛCDM model. Our analysis suggests that the ΛCDM model performs slightly better than MCJG and MCAG based on the ΔAIC values.

XI. CONCLUSION

In this article, we consider a non-flat FLRW model of the Universe filled with radiation, dark matter and dark energy in the context of $f(T)$ gravity, which was proposed based on the corrections of the teleparallel equivalent of General Relativity (TEGR). It's 2nd order equations of motion makes it simpler than $f(R)$ gravity. Here we choose Modified Chaplygin-Jacobi gas (MCJG) and modified Chaplygin-Abel gas (MCAG) to play the role of dark energy. Also here we choose the power law form as viable $f(T)$ gravity model amongst various feasible $f(T)$ gravity models proposed in literature as this form exhibits both matter dominated and radiation dominated era and successfully confronts the cosmological test with observational data. Here we obtain the Constraints on the model parameters for DE as well as the $f(T)$ gravity models by fitting recent astronomical data. Exploiting the observational data coming from H(z), Pantheon, Gamma Ray Bursts, quasars and BAO measurements, we have determined the best fit values of the model parameters. We present the reduced Hubble parameter in terms of observable parameters like $\Omega_{r0}, \Omega_{m0}, \Omega_{k0}, \Omega_{CJ0}, \Omega_{CA0}, H_0$ for both the considered dark energy models. In the figures 1 and 2, we have drawn the contour plots of the MCMC confidence contours at 1σ and 2σ of MCJG model and MCAG model respectively. The best fit values of the parameters of MCJG model and MCAG model have been obtained by χ^2 minimum test as (i) H_0 = 69.158620, $\Omega_{\rm m0}$ = 0.190482, $\Omega_{\rm k0}$ = 0.001891, $\Omega_{\rm cjo}$ = 0.001891, α = 1.000928 β = 1.000928, A_s = -0.929042, K = 0.402158, γ=1.000928. (ii) H_0 = 69.158620, $\Omega_{\rm m0}$ = 0.190482 ,$\Omega_{\rm k0}$ = 0.001891, $\Omega_{\rm cjo}$ = 0.001891, α=1.000928, β=1.000928, A_s=-0.929042, K=0.402158, γ=1.000928. Contrasting the predicted values of the considered cosmological models with the Hubble 57 observational dataset and ΛCDM paradim, we have seen the models adequetly matches the Hubble and the Pantheon dataset. In conclusion, our analysis of the MCJG Model and MCAG Model in comparison to the ΛCDM model has provided valuable insights into the dynamics of cosmic expansion and the nature of dark energy. Through various diagnostic tools, including the deceleration parameter, jerk parameter, snap parameter, and statefinder diagnostic, we have examined the behavior of these alternative models and their deviations from the standard model. The comparison of the deceleration parameter revealed that while all models share similarities in terms of the transition from deceleration to acceleration, noticeable differences were observed at high redshifts in the MCJG Model. This suggests that the MCJG Model introduces variations in the expansion dynamics compared to the ΛCDM model. However, all models ultimately converge to a de Sitter phase with a deceleration parameter of $q = -1$, indicating accelerated expansion driven by a cosmological constant or a similar dark energy component. The analysis of the jerk parameter showcased distinct behaviors of the MCJG Model and MCAG Model compared to the ΛCDM model, particularly at higher redshifts. These models exhibited different trends in cosmic acceleration, highlighting their departure from the standard model. However, at $z = -1$, both alternative models aligned with the ΛCDM model, suggesting similarities in the acceleration dynamics at that specific redshift. The examination of the snap parameter emphasized the differences between the MCJG Model and the ΛCDM model, with a closer agreement observed at lower redshifts. In contrast, the MCAG Model displayed behavior consistent with the ΛCDM model throughout the entire redshift range. These findings underscore the unique characteristics of these models in terms of their acceleration dynamics. Furthermore, the statefinder diagnostic provided insights into the nature of dark energy within the MCJG Model and MCAG Model. The transitions from the quintessence region to the Chaplygin gas region indicated changes in the dominant energy component responsible for cosmic acceleration. These transitions

were accompanied by deviations from the intermediate fixed point associated with the ΛCDM model. The statefinder trajectories shed light on the evolution and behavior of dark energy within these alternative models. Our analysis highlights the distinct behaviors and deviations of the MCJG Model and MCAG Model from the ΛCDM model. These alternative models offer valuable insights into the dynamics of cosmic expansion and the properties of dark energy. While the MCJG Model exhibited notable differences at high redshifts, both models ultimately converged to a de Sitter phase characterized by accelerated expansion. The comparison of MCJG and MCAG with the ΛCDM model using ΔAIC values indicates moderate support for both models. While the ΛCDM model shows slightly better performance, further evidence from other observations is crucial to fully assess the viability of MCJG and MCAG in explaining dark energy and the universe's expansion. Our study has contributed to the ongoing quest for a deeper understanding of dark energy and its potential role in the cosmic acceleration. While the ΛCDM model remains a robust and successful framework for explaining various cosmological observations, exploring alternative models like MCJG and MCAG is vital for advancing our comprehension of the universe's fundamental properties. Our results open avenues for future research and inspire further investigations into the intriguing phenomena shaping the evolution of our cosmos

***Abstract*—Financial institutions are highly concerned about credit card fraud due to the growing frequency of deceitful activities linked with credit card transactions. To address this issue, a novel fraud detection system is proposed that combines advanced feature engineering and neural network architecture. The proposed approach. FFFW-RBN, employs a hybrid swarm intelligence model comprising the Fruitfly Optimization Algorithm and Fireworks Algorithm, (FFO-FWA) for feature selection, and the Neural Embeddings Generator in combination with a Shallow Radial Basis Network (RBF) for localized pattern classification. The proposed system achieves a 99.97% accuracy, 0.91 recall, and a precision of 0.94. The experimental results demonstrate that our methodology effectively and practically detects fraudulent credit card transactions. The paper presents a comprehensive evaluation of the system, including various performance metrics and a confusion matrix, highlighting its potential for real-world implementation.**

***Index Terms*—Credit Card Fraud, Metaheuristic optimisation, Neural Networks, Radial Basis Function Network, Imbalanced datasets**

I. Introduction

The rise of e-commerce and mobile internet technologies has resulted in a considerable advancement in online payment methods, such as credit cards, which have become increasingly popular [1]. In the present times, online transactions are fast, uncomplicated, and highly convenient. In case an individual uses a credit card that has been annulled, terminated, declared missing, or stolen, with the intention of deceiving to acquire any valuable commodity, it constitutes credit card fraud, which could potentially harm the cardholder's physical and psychological health.

Two kinds of Credit Card Fraud (CCF) can be recognized: Application fraud and Behavior fraud [2]. Credit Card Fraud (CCF) has worrisome effects on the entire world, costing businesses and people hundreds of millions of dollars yearly. According to a recent study, credit card fraud caused a loss of approximately $27.85 billion in 2018, which represents a 16.2% surge from the $23.97 billion lost in 2017. Furthermore, the report estimates that the losses will increase to $35 billion by 2023. [3]

Cybercriminals tend to prefer conducting their illicit activities online, where they can conceal their identity and location. The accuracy of CCF is significantly affected by the use of various testing, variable selection, and identification procedures. Data is constantly evolving, which means that actions that were previously considered legitimate may now be deemed fraudulent, and vice versa. The lack of reliable statistics is mainly attributed to financial institutions' concerns about their client's sensitive data and privacy violations, resulting in a scarcity of openly accessible data. The acceptance or denial of transactions happens within a fraction of a second, typically within milliseconds or microseconds of detecting the CCF. A problem arises when multiple transactions occur simultaneously and bear similarities to one another.

Therefore, prompt and effective identification of fraudulent conduct is vital. Given the variability of the issue depending on the context and industry, there is no single approach responsible for fraud detection that can be universally applied across all sectors. As a result, bespoke solutions are developed for each industry to aid in the reduction of fraud.

This paper introduces a novel framework for credit card fraud detection, incorporating a hybrid Fruitfly-Fireworks algorithm for feature selection, a neural embeddings generator for dense feature representation extraction, and a shallow Radial Basis Network for localized pattern classification. The proposed methodology is thoroughly evaluated using various performance metrics.

The key findings of this research are outlined below:

1) A novel Hybrid Fruitfly-Fireworks algorithm is proposed that incorporates enhanced exploration characteristics for feature selection.
2) A Neural Embeddings Generator based approach to extract dense feature representations for fraud detection is used for improved interpretability and dimensionality of the features.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:11:28 UTC from IEEE Xplore. Restrictions apply.

3) A Shallow Radial Basis Network is used for final classification that enhances the localized pattern discrimination in fraud detection.

Section II gives an overview of previous studies conducted on detecting credit card fraud, while Section III elaborates on the proposed methodology. Section IV presents the experimental outcomes and their analysis.

II. Literature Review

The detection of credit card fraud is a vital research field in the realm of information security. Customers and businesses may suffer financial losses as a result of deceitful actions in credit card transactions. In the early years, *Angus M Marshal et al. (2005)* [4] analyzed the motives and tactics of Internet-based identity theft and discussed how such incidents might be detected, investigated, and prevented in the future.

The study presented by *Jon T.S. Quah et al.(2008)* [5] focused on real-time fraud detection and proposed a novel approach to identify potential fraud cases by analyzing spending patterns. Self-organization maps were employed as a means of decoding, filtering, and analyzing customer behavior for fraud detection.

Rule-based systems are the earliest and most straightforward method for credit card fraud detection. *Suvasini Panigrahi et al. (2009)* [6] suggested a system that integrates three methods: Bayesian learning, Dempster-Shafer theory and rule-based filtering. The rule-based component filters incoming transactions based on predefined rules, while Dempster-Shafer's theory combines evidence from multiple sources to calculate the initial belief about each transaction. Bayesian learning, on the other hand, enables the system to learn from past transactions and update its beliefs accordingly. *Kang Fu et al.(2016)* [7] proposed a framework for fraud detection based on Convolutional Neural Networks (CNNs), which can identify complex patterns of fraudulent behavior through the analysis of labeled data.

Ishan Sohony et al. (2018) conducted a study that assessed the efficacy of a Random Forest and Neural Network fusion for the precise prediction of credit card fraud. Their research concluded that while Random Forest was better at detecting normal instances, Neural Network performed better at identifying fraudulent ones.

Vaishnavi Nath Dornadula et al. (2019) [8] explored an innovative approach, which involved the grouping of customers based on their transactional behavior and the extraction of behavioral patterns to develop a profile for each cardholder. The suggested method involved utilizing various classifiers to analyze the transactional data of three different groups, and generated rating scores for each classifier type.

In recent times, there has been a significant increase in the use of machine-learning techniques for detecting fraudulent credit card transactions. The objective of this literature review is to present an outline of these methods, with emphasis on ensembling and ML techniques. One such research proposed by *Dejan Varmedja et al. (2019)* [9] was aimed to evaluate and compare the efficiency of four widely-used ML algorithms in detecting fraudulent activities in credit card transactions. The assessed algorithms comprised of Random Forest, Logistic Regression, Multilayer Perceptron, and Naive Bayes. The research employed the SMOTE to tackle the problem of imbalanced data. The study discovered that among various algorithms tested, Random Forest algorithm produced the most precise outcomes in identifying fraudulent transactions.

Naoufal Rtayli et al. (2020) [10] conducted a comprehensive study and proposed a combined approach comprising three methods. One of these methods is the Support Vector Machine-Recursive Feature Elimination (SVM-RFE), which aims to extract the most effective predictive features and enhance the model's efficiency. The second method involves the SMOTE technique which is employed to convert a dataset that is imbalanced into one that is balanced. This is done in order to detect credit card frauds (CCFs) using a Random Forest Classifier (RFC). Additionally, the GridSearchCV method is used to optimize the parameters of the RFC, and it serves as a Hyper Parameter Optimization (HPO) solution.

Yvan Lucas et al. (2020) [11] introduced a novel approach for feature engineering using Hidden Markov Models (HMMs), which facilitated the integration of sequential knowledge in transactions by incorporating HMM-based features. As a result, a non-sequential classifier like Random Forest was able to efficiently incorporate sequential information during the classification process.

Taha et al. (2020) presented a fraud detection system for credit card transactions, which employs a Bayesian-based hyperparameter optimization and an optimized light gradient boosting machine (OLightGBM). The system includes dynamic parameter changes for adapting to new transactional behaviors and a feedback mechanism to address concept drift. The study evaluated various algorithms and found random forest, logistic regression, and decision tree to be the most effective for fraud detection using the proposed method.

In addition to traditional machine learning algorithms, researchers have also delved into deep learning methods for the identification of credit card frauds. *G. K. Arun et al. (2020)* [12] elaborated on the creation of a C-LSTM model for credit fraud detection, which encompasses data preprocessing and classification.

In another study by *Sumit Mishra et al. (2020)* [13], an autoencoder-based approach was proposed to convert transaction attributes into a feature vector of lower dimension, which was subsequently fed as input to a classifier in the second stage. *R. Asha et al.(2021)* [14] in their study, employed several machine learning algorithms, including Artificial Neural Network (ANN), Support Vector Machine (SVM), and K-Nearest Neighbor (KNN). To address the challenges associated with using an imbalanced dataset, they performed normalization, under-sampling, and data pre-processing.

Another such study was suggested by *Emmanuel Ileberi1 et al. (2022)* [15], where they used Genetic Algorithm (GA) to perform feature engineering in combination with different Machine Learning Algorithms.

Finally, researchers have also explored swarm intelligence

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:11:28 UTC from IEEE Xplore. Restrictions apply.

algorithms for credit card fraud detection. In a recent paper, *N. Prthenabhakaran et al. (2023)* [1] proposed the OCSODL-CCFD technique, which was used for the classification of fraudulent transactions involving credit cards. This technique consists of multiple subprocesses, including preprocessing, OCSO-based feature selection, the BiGRU classifier, and the CKHA-based hyperparameter optimizer

III. Proposed Methodology

This study proposes a novel approach for credit card fraud detection that consists of three key components: feature selection, neural embeddings generation, and classification. The feature selection step employs a hybrid fruitfly and fireworks algorithm to identify the most relevant features for the classification task. The selected features are then transformed into dense vector embeddings by a neural embeddings generator, which projects the feature space into a lower-dimensional, more informative space.

The resulting embeddings are fed into a shallow neural network with few dense layers, which captures the underlying patterns and relationships in the data. The final classification layer consists of a Radial Basis Network, which performs classification based on the spatial localities in the output of the neural network dense layers.

This approach offers several advantages over traditional methods, including improved interpretability of the features, more efficient computation due to the reduced dimensionality of the embeddings, and better classification performance due to the local nature of the Radial Basis Network.

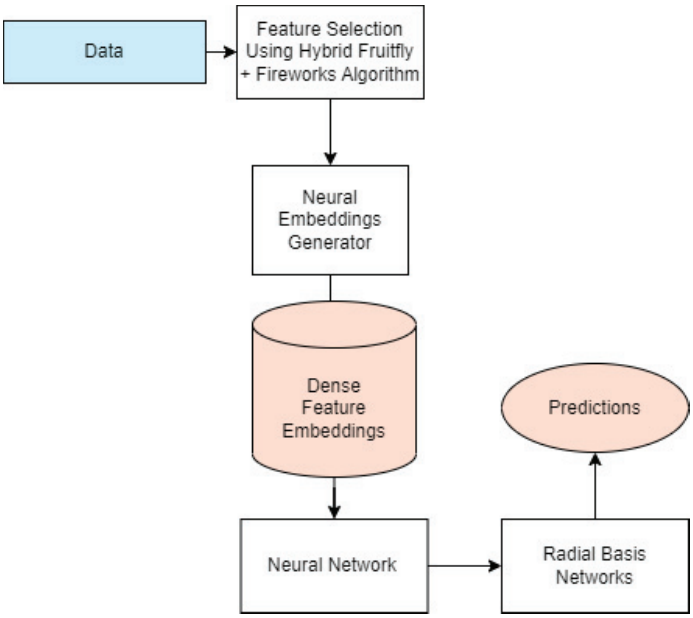

Fig. 1: Model Architecture

A. Hybrid Fruitfly-Fireworks Algorithm

Wen-Tsao Pan developed The fruit fly optimization algorithm [16], which is inspired by the foraging behavior of drosophila in their natural habitat. It is a population-based algorithm that mimics the foraging process of fruit flies, which rely on mutual information transfer via olfactory sense for migration of the entire population. The algorithm generates a population of fruit flies in the search space of a target problem and evolves the population to find the optimal solution.

The algorithm initializes the population with randomly generated individuals in the search space. Each individual has an x-axis and a y-axis representing its position. The algorithm assigns artificial search direction and search distance to the population, as shown in Equation 1 below, where L is the length of the search distance.

$$X_i = X_{axis} + \text{Rand}(L) \quad Y_i = Y_{axis} + \text{Rand}(L) \tag{1}$$

In the absence of knowledge regarding the location of food, the first iteration involves estimation of the distance from the origin (Dist), followed by the calculation of the smell concentration judgment value (S), which is the inverse of the distance. Subsequent iterations utilize the distance from the currently identified best candidate instead.

$$\text{Dist}_i = \sqrt{X_i^2 + Y_i^2} \tag{1}$$

$$V_i = \frac{1}{\text{Dist}_i} \tag{2}$$

The smell concentration judgment value (V_i) is utilized as an input to the Fitness function to determine the smell concentration ($Smell_i$) of each fruit fly's location.

$$\text{smell}_i = \text{Function}(V_i) \tag{3}$$

The population evolves by migrating in the direction of the best individual solution found so far. The algorithm records and preserves the individual optimal concentration and position coordinates using Equation 4 below, and the entire fruit fly population migrates in the optimal direction.

$$i^* = \underset{i}{\text{argmax}}(\text{smell}_i) \tag{4}$$

$$Smell^* = smell_{i^*} \quad X_{axis} = X_{i^*} \quad Y_{axis} = Y_{i^*} \tag{5}$$

However, a major disadvantage of FFAO is that the use of an elitist reproduction strategy in the fruit fly optimization algorithm may result in the swarm getting trapped in local extrema, thereby limiting its ability to effectively tackle complex, high-dimensional and nonlinear problems. Also, the smell concentration is not easily translatable to the problem of feature selection.

In our research, we address this issue by augmenting the exploration capabilities of the Fruitfly optimization algorithm. To achieve this, we have integrated the Fruitfly algorithm with the Fireworks algorithm [17]. This hybridization enables the Fruitfly algorithm to better explore the search space and overcome local optima. It also allows us to use the accuracy of the resulting model as the fitness function.

Fireworks Algorithm (FWA) is a metaheuristic optimization algorithm inspired by fireworks explosions. In FWA, a firework represents a candidate solution and the explosion of a firework represents the generation of new candidate solutions. Each firework explodes to produce a set of sparks, and the quality of the firework determines the number of sparks it generates.

The method presented in this study employs sparks produced by fireworks to facilitate exploration of the search space and enhance the quality of candidate solutions in the fruitfly algorithm. The quantity of sparks generated is determined based on the performance of the firework and the best performance discovered thus far, as illustrated in Equation 6. This enables more thorough exploration of the search space near suboptimal candidates, thereby enhancing the quality of the search process.

$$sparks_i = N_{sparks} \cdot \frac{f_{\max} - f(x_i) + \phi}{\sum_{j=1}^{S} (f_{\max} - f(x_j)) + \phi} \tag{6}$$

Here, the parameter N_{sparks} controls the overall number of sparks generated via S fireworks. The optimum of the objective function achieved among the S fireworks is represented as $f_{\max}$, where $f(x_i)$ denotes the objective function value for $i = 1, 2, \ldots, S.$, and ϕ represents the constant used in the computer to avoid zero-division errors.

We also define the amplitude of perturbation L which controls the amplitude of spark generation. This is decayed with every update to the solution candidate as per the following Equation:

$$L = L.2^{-k} \tag{7}$$

where k is the number of updates to the solution.

We combine these to enhance the exploration by performing fireworks update on each individual fruitfly population member

B. Neural Embeddings Generator

Let's denote our input dataset as X, which has n samples and m features. We can represent the output of the neural embeddings generator as E, which has n rows and d columns, where d is the dimensionality of the embeddings.

The process of generating neural embeddings can be represented by a feedforward neural network with a hidden layer. The input layer of this network consists of m neurons, each corresponding to a feature in the input data X. The output layer contains d neurons, each corresponding to a dimension in the resulting embeddings.

Let's denote the matrix for neurons weight between input and the first layer as N_1, which has dimensions $d \times n$, where n is the number of neurons and d the dimensionality of the feature space. The bias vector for the hidden layer can be denoted as b_1, which has length n. Similarly, the matrix of neuron weights between the hidden layer and output is denoted as N_2, which has dimensions $n \times d$. The bias vector for the output layer can be denoted as b_2, which has length d.

Algorithm 1: Hybrid Fruit Fly - Fireworks Algorithm

Input: Population size N, maximum number of iterations T, problem dimension D, initial amplitude of perturbation L, Fitness function Φ, number of sparks S
Output: Best solution $\mathbf{x}^*$
Initialize population $\mathbf{X}$ randomly within the search space;
for $t = 1$ *to* T **do**
  for $i = 1$ *to* N **do**
    Generate artificial search direction $\mathbf{r}_i \sim \mathcal{U}(0,1)^D$;
    Calculate artificial step size $\alpha_i = L \cdot |\mathcal{N}(0,1)|$;
    Calculate new position $\mathbf{x}_i = \mathbf{x}_i + \alpha_i \cdot \mathbf{r}_i$;
    Calculate fitness $f_i = \Phi(\mathbf{x}_i)$;
  end
  Update X using fireworks exploration: $\mathbf{X} \leftarrow$ explore_fireworks$(\mathbf{X}, \Phi, L, S)$;
  Identify best solution $\mathbf{x}^*$ and its fitness f^*;
  for $i = 1$ *to* N **do**
    Calculate taste concentration value $\text{Smell}_i = f^* - f_i$;
  end
  Identify individual with lowest taste concentration $\text{Smell}_{\text{min}}$ and corresponding position $\mathbf{x}_{\text{min}}$;
  if $Smell_{min} > 0$ **then**
    Update best solution $\mathbf{x}^* = \mathbf{x}_{\text{min}}$;
    Update amplitude of perturbation $L = L/2$;
  end
end

Algorithm 2: Fireworks Exploration Update

Input : Candidate solutions X, fitness function Φ, amplitude of explosion L, number of sparks S
Output: Best solution after exploration x'
Intialize $X' = \ ;$
Calculate $f^* = \max(\Phi(x))$;
for $x_i \subset X$ **do**
  $s = S * \frac{y_{\max} - f(x_i) + \xi}{\sum_{j=1}^{n} (y_{\max} - f(x_j)) + \xi}$;
  for $j \leftarrow 1$ **to** s **do**
    Generate Gaussian step $g \sim \mathcal{N}(0,1)$;
    Calculate amplitude of spark $A = Lg$;
    Generate new spark $spark_j = x_i + A$;
  end
  Select the best spark as $spark^* = \text{argmax}_{spark_j}(\Phi(spark_j))$;
  $x_i \leftarrow spark^*$;
  $X' \leftarrow X' \bigcup x_i$;
end
return X'

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:11:28 UTC from IEEE Xplore. Restrictions apply.

The output E of the neural embeddings generator can be computed as follows:

$$E = \sigma(N_2 \cdot \sigma(N_1 \cdot X + b_1) + b_2) \tag{8}$$

where σ is an activation function, typically chosen to be a nonlinear function such as the sigmoid or ReLU. The activation function introduces nonlinearities into the model, allowing it to capture complex patterns in the data.

The weights and biases of the neural embeddings generator can be learned through backpropagation, using a loss function that measures the discrepancy between the predicted embeddings and the true embeddings. The specific loss function will depend on the task being performed, such as classification or regression.

Neural embeddings are useful in credit card fraud detection because they can project the high-dimensional feature space of transactions into a lower-dimensional space that captures the relevant patterns and relationships between features. This can reduce the dimensionality of the data while preserving important information, and capture non-linear relationships between features that are difficult to model with traditional techniques.

C. Neural Network

After generating the neural embeddings, The subsequent stage in the suggested approach is to feed them into a shallow neural network that reprojects them into a higher-dimensional space, which the RBF network can then compare. Specifically, we use a feedforward neural network with a few dense layers, followed by a final output layer with the same number of dimensions as the RBF network.

Let $f(\mathbf{x})$ denote the function computed by the neural network, where $\mathbf{x}$ represents the input embedding. The output of the i-th dense layer is computed as follows:

$$\mathbf{o}_i = \sigma(\mathbf{N}_i \mathbf{o}_{i-1} + \mathbf{b}_i) \tag{9}$$

where $\mathbf{N}_i$ is the matrix for neuron weights for layer i and $\mathbf{b}i$ is the bias vector for the i-th layer. $\mathbf{o}_{i-1}$ is the mapping obtained by previous layer (or the input embedding $\mathbf{x}$ for the first layer), and $\sigma(\cdot)$ denotes an activation function.

The final output layer maps the output of the last dense layer to a vector of the same dimensionality as the RBF network. This can be computed as follows:

$$\mathbf{y} = \mathbf{N}_{out} \mathbf{o}_L + \mathbf{b}_{out} \tag{10}$$

where $\mathbf{W}_{out}$ and $\mathbf{b}_{out}$ are the matrix for neuron weights and bias vector for the output layer, respectively, and $\mathbf{h}_L$ is the output of the last dense layer. The resulting output vector $\mathbf{y}$ can then be used as input to the RBF network for classification.

D. Radial Basis Networks

Radial basis Networks (RBNs) [18] are a type of artificial neural network (ANN) commonly used for classification and regression tasks. A Radial Basis Network consists of an input layer, a hidden layer with radial basis functions, and an output layer.

The hidden layer computes the output z_j of each of its J nodes using the radial basis function $\phi_j(\mathbf{x})$:

$$z_j = \phi_j(\mathbf{x}) = \exp\left(-\frac{|\mathbf{x} - \mu_j|^2}{2\sigma_j^2}\right), \tag{11}$$

where $\mathbf{x}$ is the input vector, μ_j is the mean for the jth radial basis function, and σ_j is the width modifier for the function.

The output layer computes the output $\hat{y}$ as a linear combination of the hidden layer outputs:

$$\hat{y} = \sum_{j=1}^{J} w_j z_j + b, \tag{12}$$

where w_j is the matrix of weights connecting the jth hidden node to the output node, and b is a bias term.

RBF networks exhibit a local nature, as the output of each hidden node is determined by a radial basis function that is only active in a local region of the input space, defined by its center and width parameters. This allows RBF networks to perform well on problems with spatial locality or clustered data, while also providing some regularization that can prevent overfitting and improve generalization.

IV. Experimentation and Results

A. Dataset

The credit card transaction dataset used in this study was obtained from the ULB Machine Learning Group [19], consisting of data from September 2013 and focusing on transactions made by cardholders from Europe. The dataset contains 284,807 transactions, of which only 492 are instances of fraud, resulting in a highly imbalanced dataset with the positive class representing a mere 0.172% of all transactions.

The dataset exclusively includes numerical input variables, which have undergone PCA transformation. The features V1, V2, ..., V28 correspond to the principal components obtained via transforming the input with PCA. This transformation was carried out to maintain user anonymity and confidentiality. The variable of interest is represented by the 'Class' feature, with a value of 1 indicating a transaction that is fraudulent, and 0 indicating otherwise.

B. Performance evaluation

For assessing our model, we perform a train test split of 70% and 30%, respectively as depicted in II.

TABLE II: Train-Test Split on Data

	Number of samples	Fraudulent	Non-Fraudulent
Train set	199364	344	199020
Test Set	85443	148	85295

In order to train the model, Weighted Binary cross-entropy loss was used, which measures the difference between predicted and actual class probabilities for each sample. It is defined as follows:

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:11:28 UTC from IEEE Xplore. Restrictions apply.

TABLE I: Comparison of our approach with other past approaches

Author	Technique Used	Performance Measure			
		Accuracy	Recall	Precision	F1 Score
Ishan Sohony et al. (2018) [20]	RF + NN	0.9995	0.8763	0.8585	0.8628
Varmedja et al. (2019) [9]	Random Forest + SMOTE	0.9996	0.8163	0.9638	0.8839
Misra et al. (2020) [13]	Autoencoder with MLP Classifier	0.9994	0.8015	0.8534	0.8266
Taha et al. (2020) [21]	Optimized Light Gradient Boosting Machine	0.9840	0.4059	0.9734	0.5729
Asha RB et al. (2021) [14]	ANN	0.9992	0.7619	0.8115	0.7859
	KNN	0.9982	0.0393	0.7142	0.0745
	SVM	0.9349	0.8976	0.9743	0.9343
Emmanuel Ileberi et al. (2022) [15]	GA-RF	0.9996	0.9912	0.8068	0.8895
Our Proposed Model (FFFW-RBN)	**Fruitfly-Fireworks + Radial Basis Networks**	**0.9998**	**0.94**	**0.96**	**0.9498**

The weighted binary cross-entropy loss function is defined as:

$$\delta = -\frac{1}{N}\sum_{i=1}^{N}[\omega_1 \cdot h_i \log(\hat{p_i}) + \omega_0 \cdot (1-h_i)\log(1-\hat{p_i})] \quad (13)$$

where N is the number of samples, h_i is the true binary label (either 0 or 1), and $\hat{p_i}$ is the predicted probability of the positive class. During training, we applied class weights of $\omega_1 = 10$ for the positive class (fraudulent transactions) and $\omega_0 = 1$ for the negative class (non-fraudulent transactions). To evaluate the performance of our trained model, we used several metrics commonly employed in binary classification tasks. Specifically, we used the metrics derived from confusion matrix, i.e., precision, recall, and F1 score, as well as the area under the precision-recall curve (AUPRC).

The confusion matrix is a table that summarizes the performance of a binary classification model. Based on these, we calculate the precision and recall for the model performance.

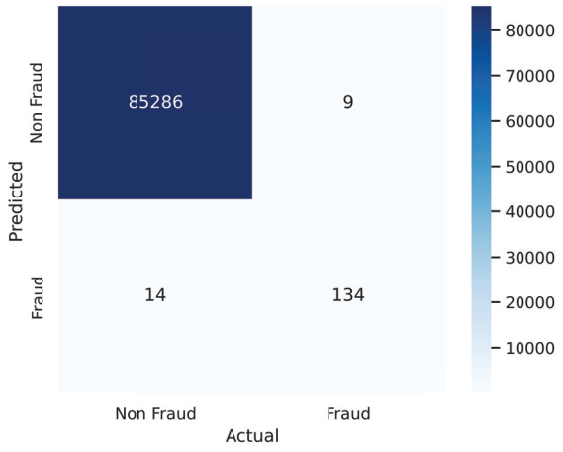

Fig. 2: Confusion Matrix

Precision is a performance metric that quantifies the proportion of correctly predicted positive cases out of all the cases that the model predicted as positive, and is defined as:

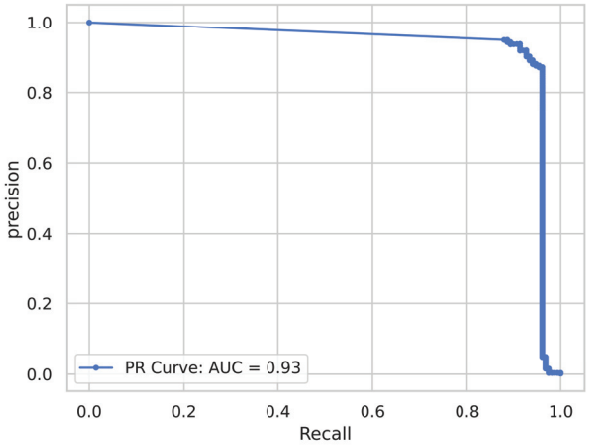

Fig. 3: Precision Recall Curve

$$Precision = \frac{True\ Pos.}{True\ Pos.\ +\ False\ Pos.} \quad (14)$$

Recall quantifies the proportion of true positive predictions in relation to all actual positive instances:

$$Recall = \frac{True\ Pos.}{True\ Pos.\ +\ False\ Neg.} \quad (15)$$

F1 score is a harmonic mean of precision and recall, and is useful for imbalanced datasets such as credit card fraud datasets.

$$F1\ Score = 2 \cdot \frac{Precision \cdot Recall}{Precision\ +\ Recall} \quad (16)$$

In addition to the above metrics, we also evaluate the AUPRC, which is the area under the precision-recall curve. It is a measure of the trade-off between precision and recall. It is a useful metric when the dataset is highly imbalanced.

V. Conclusion and Future Work

In this paper, we proposed a novel fraud detection system for credit card transactions that utilizes hybrid swarm intelligence models and advanced feature engineering processes.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:11:28 UTC from IEEE Xplore. Restrictions apply.

Our results demonstrate that our methodology provides a practical and efficient means of detecting fraudulent transactions with high levels of accuracy, precision, and F1 score. The combination of the Fruitfly Optimization Algorithm and the Fireworks Algorithm for feature selection, and the Neural Embeddings Generator with a Shallow Radial Basis Function Network for pattern classification, shows promise for further development and use in real-world applications. In future work, the proposed methodology could be extended to other datasets and tested on larger credit card datasets with varying degrees of imbalance. The use of sequential models, such as recurrent neural networks or transformers, with the proposed feature engineering approach should also be explored as an area of research.

***Abstract*—Social media has developed into a very powerful tool for teamwork, communication, and idea exchange. Due to the anonymity offered by these platforms, verbal abuse and cyberbullying cases have, sadly, proliferated globally. Researchers and academics from all around the world have conducted studies to create methods to automatically detect cyberbullying in response to this disturbing epidemic. Unfortunately, the research that is now accessible primarily focuses on more advanced languages, leaving low-resource languages like Bengali with a substantial research gap. As a result, in this study, we present a method for detecting cyberbullying in Bengali using Deep Learning Models such as Bidirectional Long Short-Term Memory (Bi-LSTM) and Convolutional Neural Network (CNN). Furthermore, we utilised the Bengali Cyber Bullying public dataset from kaggle.com to illustrate this. Also, when we examined the outcomes of the Bi-LSTM and CNN models, we discovered that CNN performed better. The precision, recall, and F1 score produced by the CNN model are on average 0.827, 0.850, and 0.855.**

Keywords—Bengali, Bi-LSTM, Cyber Bullying, Deep Learning, Machine Learning

I. INTRODUCTION

Bengali is an important language because it is the second most spoken language in India. Moreover, it is also the 7th most spoken language in the world [1]. It has a rich history along with its cultural heritage values. In recent years, Bengali has experienced a surge in popularity due to its widespread use on various social media sites. This has made it a useful language for people who are looking to connect with others from similar linguistic backgrounds. Bengali is the most commonly spoken language in several communities throughout many geographies, including Bangladesh, West Bengal in India, and in diaspora communities worldwide.

With the advent and growing popularity of social media sites such as Twitter, Instagram, Snapchat, Facebook, TikTok, Tumblr, etc., more and more people are able to express their opinions and thoughts freely. Due to their increasing popularity, particularly among teenagers, these social media platforms have become an essential part of our daily lives. Undoubtedly, the significant increase in the use of these platforms has certain drawbacks, and young teenagers are frequently exposed to a variety of behavioral and psychological risks.

One potential source of these hazards is cyberbullying in the form of powerful social attacks. Additionally, because social media platforms give users the choice to remain anonymous and conceal their identities, certain people may abuse their technical capabilities for their bad activities. Bullying that occurs more frequently over time makes things worse as well. The most dangerous behavior on social networking sites is now offensive language and abusive behavior intended to cause harm to others.

Cyberbullying may take many various forms, including offensive language, harassment, poisonous remarks, hate speech, sexism, racism, and other types of discrimination. Anxiety, despair, self-harm, social and emotional confusion, and even suicidal thoughts or attempts are all frequent negative effects of receiving abusive texts. The Pew Research Center found that teenage girls experienced the worst forms of cyberbullying and that around 59% of US users of social media platforms had encountered it [2].

Thus, the epidemic of cyberbullying has spread to every country. As a result, several international preventive and intervention strategies have been developed to enhance online users' safety and reduce such heinous cyberbullying. Hostile text detection is seen as a challenging and complex process even for humans, aside from the victims, because of the variations in the language used. Similarly, cyberbullying detection in Bengali has several challenges. Among those challenges, the first is the lack of sufficient data. One of the primary challenges is the lack of sufficient data to train machine learning models for cyberbullying detection. The Bengali language has a comparatively small amount of training data compared to other languages, making it difficult to create models that can accurately detect cyberbullying. The second is language complexity. Bengali is a complex language with multiple variations in grammar, syntax, and vocabulary. This complexity makes it challenging to identify the context and tone of messages, which is essential for detecting cyberbullying accurately. Slang and acronyms come in third place. Slang and acronyms are third on the list. When cyberbullying occurs, uncommon Bengali slang and acronyms are usually employed. These non-standard sentences may be difficult to recognize and analyze, which might lead to inaccurate detection. And fourth is cultural context. When creating models for the identification of cyberbullying, the cultural background of the Bengali language must be taken into consideration. What may be considered offensive or bullying in one culture may not be

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:13:02 UTC from IEEE Xplore. Restrictions apply.

the same in another, making it challenging to create a universal detection system. Lastly, the fifth is code-switching. Many Bengali speakers frequently switch between Bengali and English, particularly in digital communications. This code-switching can make it difficult to detect cyberbullying since models must be trained to recognize both languages.

In order to overcome the challenges of cyberbullying detection in Bengali, we provide "Deep Learning models such as Bi-LSTM and CN" [3] in this paper. We then evaluate the results using different metrics like the f1-score, recall, and precision.

The remaining paper is outlined as follows: Section 2 discusses related research on cyberbullying detection in Bengali. Section 3 describes the proposed methodology, whereas Section 4 summarizes the results and analysis. Lastly, Section 5 concludes the research paper by offering future research suggestions.

II. Related work

In today's society, there is increasing concern about cyberbullying, particularly among young people who use the internet. This term refers to a pattern of behavior based on electronic communication used to threaten, harass, or intimidate another person. Researchers are actively investigating various strategies to identify and stop cyberbullying due to the issue receiving more attention in recent years. Teenagers who use the internet today are particularly vulnerable to cyberbullying, also known as hate speech, cyber aggression, and toxic speech. Victims may suffer from serious consequences such as "low self-esteem, anxiety, depression, hopelessness and in some cases, a lack of motivation to be alive, ultimately resulting in the death of a victim" [4].

"In the field of machine learning and deep learning" [5], several studies have been conducted to classify comments as cyberbullying or not. Taawab et al. [6] employed various machine learning algorithms, such as decision trees, logistic regression, and recurrent neural networks, to classify abusive transliterated Bengali comments. To build their model, they created a custom dataset consisting of only 1,300 transliterated Bengali words, as there was no publicly available sized transliterated Bengali dataset available. They found that logistic regression with a count vectorizer achieved the highest accuracy and F1 score, at 85.76% and 85.70%, respectively.

In a study on deep learning methods, G and Uma [7] found that the Gated Recurrent Unit (GRU) had the highest accuracy 95.47% for identifying whether or not comments indicated cyberbullying. In another study, Emon et al. [8] tested several algorithms, such as Logistic Regression, Multinomial Naive Bayes, and "Recurrent Neural Network (RNN) with Long Short-Term Memory (LSTM)" [9] cells for classifying abusive Bengali text. They gathered data from the comment sections of various social media websites and internet resources. The dataset included both positive and neutral data as two separate classifications. They found that the Recurrent Neural Network (RNN) had the highest "precision, recall, and F1 score" [10], achieving 0.83, 0.82, and 0.82, respectively.

Altaf et al. [11] conducted a study on "cross-domain sentiment analysis on the Urdu language using" [11] deep learning and machine learning classifiers. They achieved an accuracy of 77%, a precision of 83%, a recall of 68%, and an F1 score of 74%.

In conclusion, the literature provides evidence that machine learning and deep learning can effectively detect and prevent cyberbullying in regional languages. Further research is needed to enhance the accuracy of the above-discussed algorithms and make them more robust in different languages and domains. Therefore, in this research paper, we provide cyberbullying detection using "Deep Learning models such as Bi-LSTM and CNN" [3] in the Bengali language, where we further enhance the F1 score as "compared to the state-of-the-art" [13].

III. METHODOLOGY

The methodology for cyberbullying detection using Deep Learning models in Bengali is built by evaluating it on a public dataset with the help of different standard performance metrics. The following Fig. 1 shows the research methodology.

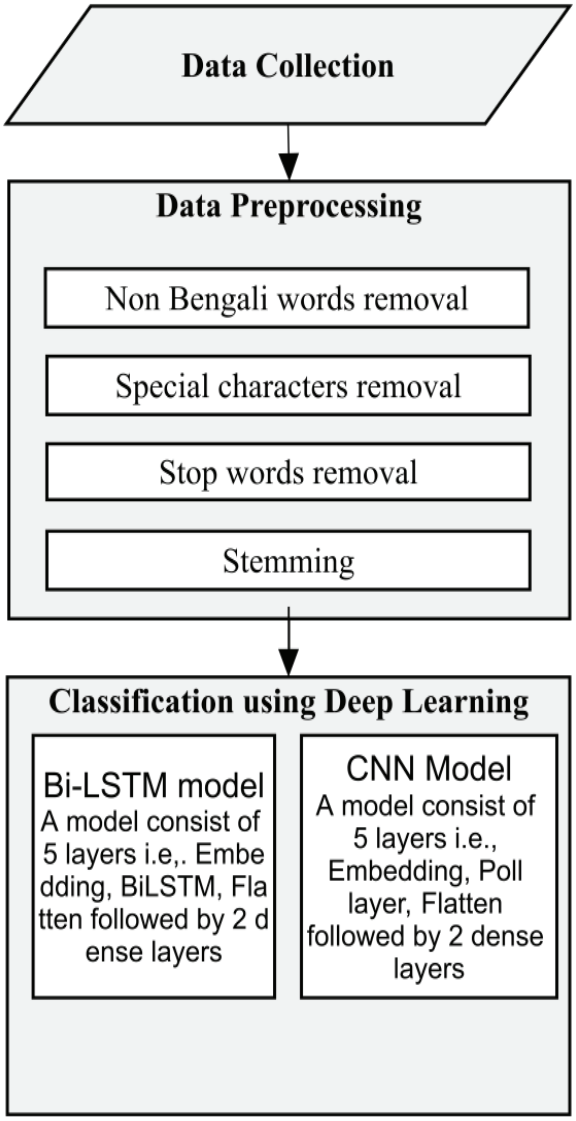

Fig. 1. The research methodology

The subsequent subsections explain the proposed research methodology used for cyberbullying detection using Deep Learning in the Bengali language.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:13:02 UTC from IEEE Xplore. Restrictions apply.

A. Dataset

The following Fig. 2 shows the distribution of the dataset.

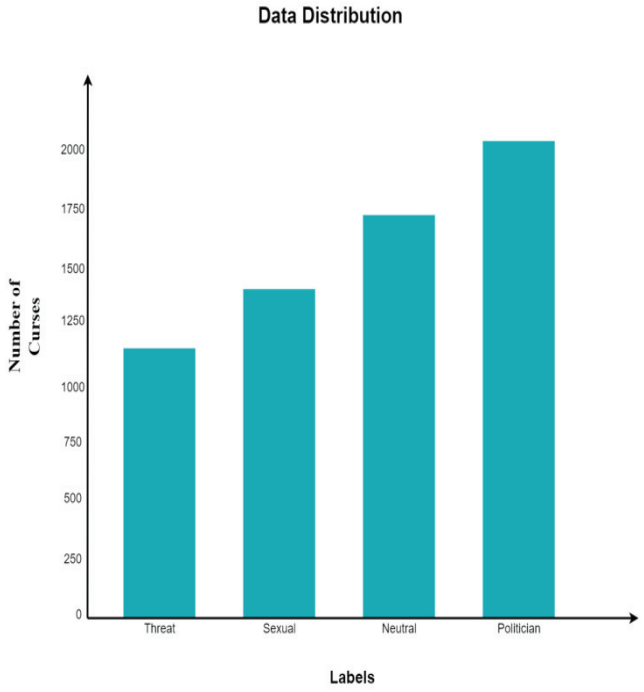

Fig. 2. Dataset distribution

To demonstrate the efficiency of the proposed research approach, we considered the Bengali Cyber Bullying public dataset available at kaggle.com [14]. This dataset was developed by Faisal using web scraping on different social media platforms, such as YouTube, Facebook, and Twitter. The dataset has more than 6000 comments, which are distributed among political, sexual, threat, and neutral domains. The dataset has both labeled instances of cyberbullying-positive as well as cyberbullying-negative cases.

B. Data preprocessing

Data preprocessing is carried out to eliminate noise from the dataset. Here, data preprocessing includes four steps. In the first step, we removed the non-Bengali words from the dataset. In the second step, we removed special characters such as white spaces, digits, and others like {, *, &, etc., which had no specific meaning [15]. In the third step, we removed the stop words. "Stop words are common English words such as the, am, their, which do not influence the semantics of the review" [15]. Finally, in the fourth step, we performed stemming. Stemming in Natural Language Processing (NLP) is the process of reducing words to their root or base form, also known as a stem, by removing prefixes or suffixes.

C. Classification using Deep Learning Models

This sub-section discusses the proposed Deep Learning models for cyberbullying detection in Bengali. Therefore, for cyberbullying detection, we use "Deep Learning models such as Bi-LSTM and CNN" [3] models.

1) Classification using Bi-LSTM

The following Fig. 3 shows the proposed Bi-LSTM model for classifying cyberbullying cases.

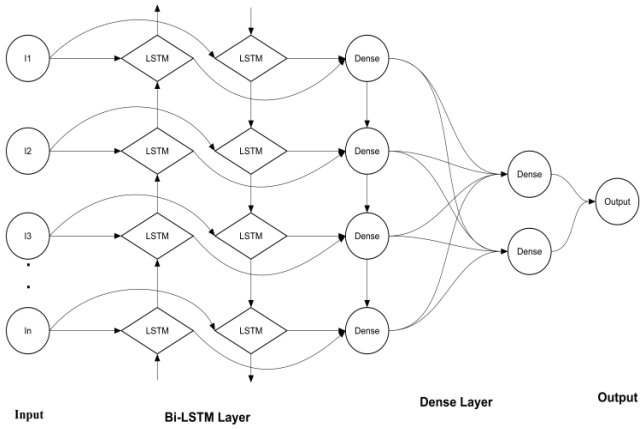

Fig. 3. Bi-LSTM Model

The Bi-LSTM model consisted of a total of five layers. The first layer was responsible for embedding and involved taking the integer-encoded vocabulary and searching for the embedding vector for each word-index. The output from this layer was then passed to the second layer, which was the Bi-LSTM layer. The Bi-LSTM layer learned the sequence information both in the forward and backward directions. Subsequently, the output from the Bi-LSTM layer was passed to the dropout layer, which eliminated the impact of certain neurons. Finally, the last two layers were dense layers, with the first layer using 'Relu' as the activation function, and the second layer using 'Softmax' as the activation function for the final output layer.

2) Classification using Convolutional Neural Network

The following Fig. 4 shows the proposed Convolutional Neural Network model for classifying cyberbullying cases.

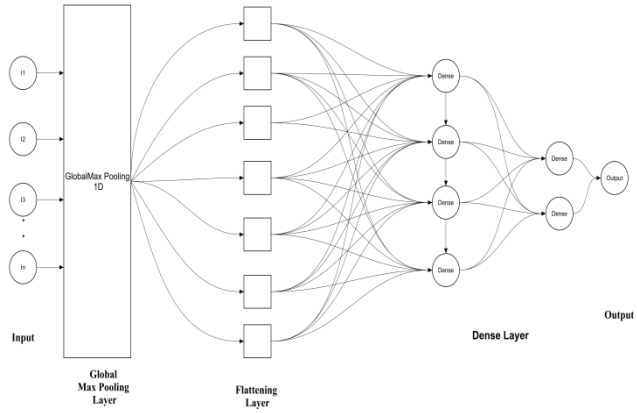

Fig. 4. The CNN Model

The CNN model consisted of a total of five layers. The only difference between the CNN and Bi-LSTM models was in the second and third layers. In the CNN model, the second layer was a global max pooling 1D layer, which downsampled information by taking the maximum over the time dimension. The output from this layer went to a flattening layer, which was used "to convert all the resultant 2-D arrays from pooled feature maps into a single linear vector" [7].

IV. RESULT AND ANALYSIS

The proposed methodology in this study is implemented using the Python programming language. In addition, the following performance indicators were used to evaluate the

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:13:02 UTC from IEEE Xplore. Restrictions apply.

classification results: "precision, recall, and F1 score" [10]. "Precision measures how many of the samples predicted as positive are actually positive. Thus, it is defined as the ratio of true positive (TP) values to the sum of all predicted positive values (TP and FP).

Precision =True Positive / (True Positive + False Positive)

Recall measures how many of the positive samples are captured by the positive predictions. Therefore, it is defined as the ratio of true positive (TP) values to the summation of all actual positive values (TP and FN).

Recall = True Positive / (True Positive + False Negative)

F1-Score is defined as the harmonic mean of precision and recall" [16].

F1 score = 2 × Precision × Recall / (Precision + Recall)

A. *Implementation details for data preprocessing phase*

Table I presents an overview of the Python libraries and functions that are utilized for the preprocessing of data.

TABLE I. LIBRARIES AND FUNCTIONS USED FOR DATE PREPROCESSING

S.NO.	Preprocessing Task	Python Library/ Function Used
1.	Non-Bengali words removal	Python lower() function
2.	Special characters removal	BNLP Library
3.	Stop words removal	BNLP Library
4.	Stemming	Bangla Stemmer Library

B. *Implementation details and classification results using Deep Learning Models*

We utilized the Python programming language, along with the TensorFlow and Keras libraries, to develop our proposed Deep Learning models, including the Bi-LSTM and CNN models, for cyberbullying detection in Bengali. The following two sub-sections expound the classification results of the Bi-LSTM and CNN models.

1) *Implementation details and classification results of the Bi-LSTM model*

The proposed Bi-LSTM model was implemented using the Python programming language. The following Table II describes the various settings used for the model.

TABLE II. DESCRIPTION OF EACH LAYER IN THE BI-LSTM MODEL

Layer	Output Shape
Embedding	(None, None, 64)
Bidirectional – LSTM	(None, 128)
Dropout	″(None, 128)
Dense (activation='relu')	(None, 64)
Dense(activation='softmax')	(None″, 4)

The following Table III shows the classification results of the Bi-LSTM model.

TABLE III. PRECISION, RECALL, F1-SCORE FOR BI-LSTM MODEL

Class name	Precision	Recall	F1-Score
Neutral	0.734	0.817	0.773
Political	0.809	0.886	0.845
Threat	0.818	0.823	0.820
Sexual	0.889	0.652	0.752

The average "precision, recall, and F1 score" [10] for Bi-LSTM model are 0.812, 0.794, and 0.801.

2) *Implementation details and classification results of the CNN model*

The proposed CNN model was implemented using Python programming language. The following Table IV describes the various setting used for the model.

TABLE IV. DESCRIPTION OF EACH LAYER IN CNN MODEL

Layer	Output Shape
Embedding	(None, 669, 128)
CNN (Global max pooling 1D)	(None, 128)
Flatten	″(None, 128)
Dense(activation='relu')	(None, 64)
Dense(activation='softmax')	(None″, 4)

The following Table V shows the classification results of the CNN model.

TABLE V. PRECISION, RECALL, F1-SCORE FOR CNN MODEL

Class Name	Precision	Recall	F1-Score
Neutral	0.806	0.839	0.822
Political	0.874	0.905	0.889
Threat	0.876	0.833	0.854
Sexual	0.873	0.824	0.845

The average "precision, recall, and F1 score" [10] for Bi-LSTM model are 0.827, 0.850, and 0.855.

C. *Comparative analysis between classification results of Bi-LSTM vs CNN models*

The following Fig. 5 shows the comparative analysis between the classification results of the Bi-LSTM and CNN models.

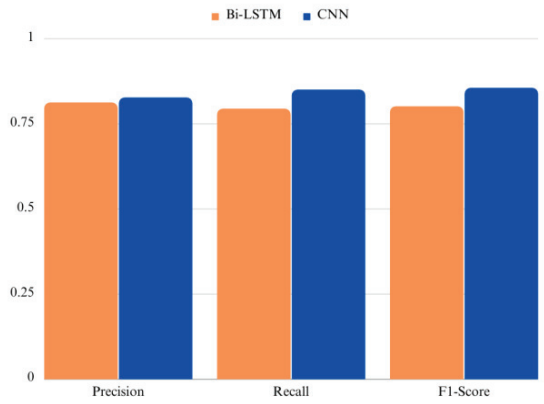

Fig. 5. Comparison of the Bi-LSTM and CNN model.

In Fig. 5, the orange bar displays the Bi-LSTM model's classification outcomes, whereas the blue bar displays the CNN model's outcomes. This figure makes it very evident that the CNN model's performance outperformed that of the Bi-LSTM model. The Bi-LSTM model has an average precision of 0.812, a recall of 0.794, and an F1 score of 0.801. On the other hand, the CNN model has an average precision of 0.827, a recall of 0.850, and an F1 score of 0.855.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:13:02 UTC from IEEE Xplore. Restrictions apply.

V. CONCLUSION AND FUTURE SCOPE

In this research paper, we provided a cyberbullying detection approach using "Deep Learning Models such as Bi-LSTM and CNN" [3] in the Bengali Language. We utilized the Bengali Cyber Bullying public dataset from kaggle.com to illustrate this. Also, when we examined the outcomes of the Bi-LSTM and CNN models, we discovered that CNN performed better. The "precision, recall, and F1 score" [10] for the CNN model were 0.827, 0.850, and 0.855, respectively.

There are several directions we might go in order to improve the model's accuracy in subsequent studies. One such method is ensemble modeling [17], which makes predictions by combining numerous models, greatly improving accuracy. Including strategies like word2vec or rapid tag-like vector embedding methods can also help the model perform better. Incorporating more data and fine-tuning the models for the Bengali language could also lead to improved performance. Furthermore, adding contextual information, such as user profiles and interactions, could enhance the accuracy of the models in identifying instances of cyberbullying. Additionally, exploring other techniques, such as transformer-based models, which have shown to be successful in various natural language processing tasks, could also lead to improvements.

In conclusion, our research has "demonstrated the effectiveness of deep learning models in" [18] identifying cyberbullying in the Bengali language and has highlighted the need for further research in this under-researched area. The developed models have the potential to be used in practical applications to detect and mitigate cyberbullying in the Bengali language.

Abstract
Person re-identification has received a lot of attention from the research community in recent times. Due to its vital role in security based applications, person re-identification lies at the heart of research relevant to tracking robberies, preventing terrorist attacks and other security critical events. While the last decade has seen tremendous growth in re-id approaches, very little review literature exists to comprehend and summarize this progress. This review deals with the latest state-of-the-art deep learning based approaches for person re-identification. While the few existing re-id review works have analysed re-id techniques from a singular aspect, this review evaluates numerous re-id techniques from multiple deep learning aspects such as deep architecture types, common Re-Id challenges (variation in pose, lightning, view, scale, partial or complete occlusion, background clutter), multi-modal Re-Id, cross-domain Re-Id challenges, metric learning approaches and video Re-Id contributions. This review also includes several re-id benchmarks collected over the years, describing their characteristics, specifications and top re-id results obtained on them. The inclusion of the latest deep re-id works makes this a significant contribution to the re-id literature. Lastly, the conclusion and future directions are included.

Keywords Person Re-Identification · Deep Learning · Convolutional Neural Network · Feature Extraction & Fusion

1 Introduction

Security and surveillance based applications in computer vision have gained tremendous popularity in recent times. Currently, security surveillances record videos and images whose analysis requires manual human interaction. Looking into yesterday's robbery can be challenging as it involves a manual search through twenty hours of surveillance videos by humans prone

to fatigue and making errors. The problem quickly becomes infeasible as the time span of recorded media under analysis is increased. The development of machine learning and later, deep learning approaches have opened a wide range of advanced possibilities that could lead to safer homes, offices, neighbourhood, bus stops, airports etc. The idea that machines can be taught to identify individuals of interest is a promising step towards a more secure environment.

Person re-identification means to find a person of interest in a query image/video from a large collection of recorded images and/or videos. While machine learning algorithms played crucial part in the early days, re-id approaches have made significant improvements with the rise of deep learning based systems [170]. Several deep learning based approaches proposed in recent years have boosted the matching accuracy results [149], significantly outperforming the handcrafted feature based machine learning algorithms [110, 126, 143]. Since deep learning models require a large number of training samples, recent years have also witnessed the collection of several medium to large-scale re-id datasets for training and testing different deep based re-id approaches.

The efficiency and real-time performance of person reidentification tasks were severely hindered by the fact that previous techniques relied on the manual extraction of distinctive features. Deep learning architectures have been used in nearly all current research in this field. There has been a surge in the number of published studies on the topic of human reidentification over the years. Some researchers have proposed various loss functions too to enhance the models' ability to extract the discriminative features. Additionally, others have introduced various attention modules to focus on important details of a person's body for the purpose to acquire more robust features of pedestrians. By merging both the local and global characteristics of a person, multiple research contributions improved the final representation of features.

In contrast, generative adversarial training was frequently employed for the tasks of person reidentification because of GAN's outstanding results in both the generation of images and feature acquisition. Some studies have found that video clips can effectively fuse more information than single-frame images due to the mutually beneficial temporal and spatial signals present in both. To simulate relationships in pedestrian pictures as well as to acquire more selective and reliable attributes, graph convolutional network-based approaches have recently emerged.

1.1 Motivation

Building a system to reidentify people is driven by a variety of different interests and priorities. The primary motivation to build person re-identification systems is as follows:

- *Safety:* There is an absolute requirement for the installation of person identification systems in all public areas, including shopping malls and airports, to maintain safety and put a stop to any criminal activity that may occur.
- *Scrutiny:* Monitoring people in public areas with the use of a person reidentification system can assist law enforcement organizations in the identification of potentially suspicious behaviors.
- *Marketing:* Using a person reidentification system, retailers can monitor customer activity to learn more about customer preferences and make more informed marketing decisions.
- *Traffic Regulation:* For traffic control, a person reidentification system may be utilized to enable tracking of passengers as well as automobiles.
- *Personalized Consumer Experience:* Identifying a given person allows for a custom and personalized shopping experience online since offers and recommendations can be arranged around individual consumer interests.

In general, these systems can serve businesses, government agencies, and the general public in a wide range of different ways, which is why they are becoming increasingly popular.

2 Research methodology

This section details the major contributions of this review, techniques followed in preparing this review and a comparison with some of the existing deep Re-Id reviews/surveys.

2.1 Contributions of this review

This review studies deep learning based person re-identification. While person re-identification is not a new topic in the research community, deep learning based methods have become increasingly popular due their tremendous success in various computer vision domains. Hence, it is natural that deep learning based methods take lead in the Re-Id problem due to their superior feature learning capability when compared to hand-crafted feature based methods. The focus of this review is to conduct an exhaustive study of the recent deep learning based Re-Id methods, specifying the various benchmark datasets and the classification of various image and video based deep methods.

Figure 1 presents the organization of this review. Specifically, Section 1 presents the Introduction to person re-identification. Then, Section 2 highlights the

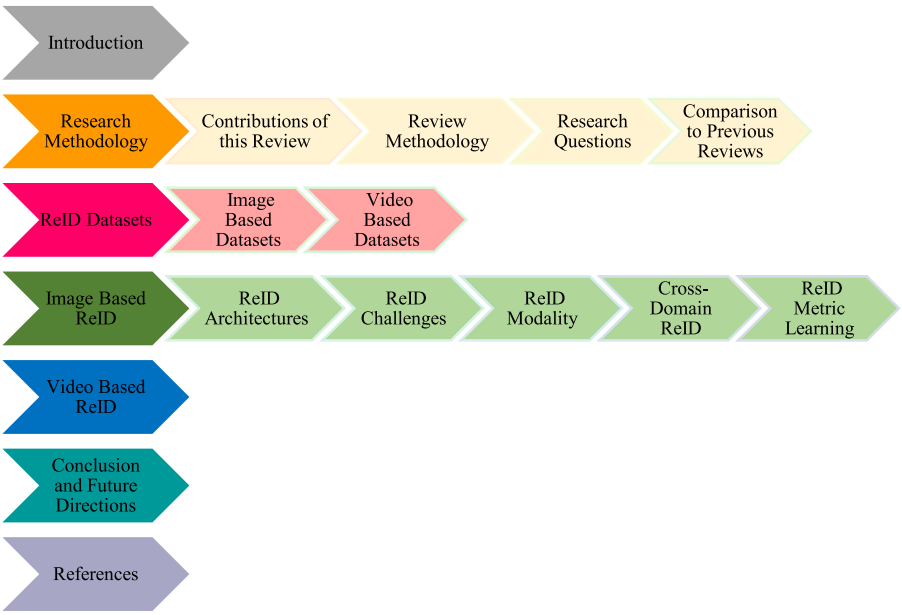

Fig. 1 Organization of this review

importance of this review by mentioning its major contributions, the review methodology followed, research questions being addressed by this review and finally a comparison with existing person re-identification reviews. Section 3 talks about the major publicly available benchmark datasets for person re-identification. Section 4 explores the different kinds of image-based person reid methods. Section 5 discusses video-based person re-id research papers. Finally, the conclusion and future work are discussed in Section 6.

Recent years have witnessed a sharp increase in the number of deep learning based Re-Id approaches and this review cites the latest developments in deep learning based Re-Id research. Figure 2 describes the taxonomy of deep learning based Re-Id methods included in this review. Re-Id methods have been categorized into image-based and video-based methods. Image-based contributions have been explored from numerous aspects such as architectures involved, common visual challenges, modality specific methods, cross-domain approaches and metric learning methods.

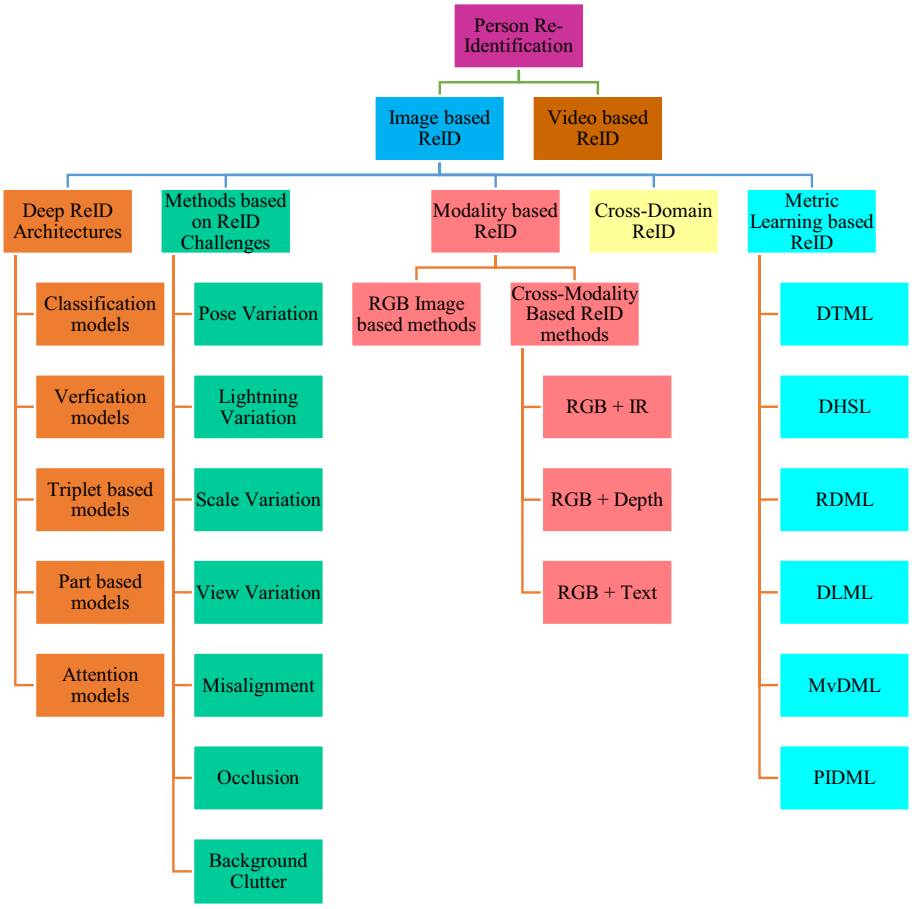

Fig. 2 Taxonomy of Re-Id methods

The major contributions of this review are as follows:

- Provides a comprehensive review of deep learning based person re-identification methods.
- Conducts an exhaustive study of deep Re-Id methods (Tables 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11) by describing the "key ideas" behind numerous approaches mentioned.
- Since deep learning methods have gained popularity in recent years, this exhaustive review automatically incorporates the most recent contributions to deep learning based Re-Id approaches.
- Details several image based and video based benchmark datasets, specifying their technical specifications, challenges posed by samples and top results reported on them.
- Analyses deep learning based methods from several crucial aspects like architecture types, loss functions, Re-Id challenges, data modalities, cross-domain approaches and metric learning methods, helping the readers to understand and appreciate deep Re-Id from multiple perspectives.
- Explores the growing popularity of video based deep Re-Id methods that combine temporal data providing important motion cues with the usual visual characteristics.
- This review helps readers to gain a comprehensive and exhaustive understanding of the recent deep Re-Id contributions by categorically analysing contributions from numerous perspectives like architecture, challenges, modality, cross-domain approaches, metric learning and video based methods.

	SYSU-MM01 [123]	2017	4 RGB 2 IR	491	287,628 images 15,792 IR images	Color and exposure variation	65.10 [26]
	Airport [49]	2019	6	9651	3.13 images per person on average	Viewpoint and illumination variation, detection error, occlusion, background clutter	-

Table 2 (continued)

Dataset Type	Dataset	Release Year	Camera	Identity Count	Images/Videos Count	Challenges	Top Results—Rank 1 Accuracy (%)
Video Re-Id Datasets	ETHZ [23]	2007	2			Partial occlusion	93.00 [18]
	PRID2011 [40]	2011	2	983	100 to 150 images per individual	Viewpoint, pose, lightning and background variations	98.80 [52]
	3DPES [4]	2011	6	200	500 videos		72.23 [169]
	iLIDS-VID [118]	2014	2	300	600 videos, 73 frames per video on average	Viewpoint and lightning variation, occlusion, cluttered background, similar clothing for different identities	88.00 [152]
	MARS [162]	2016	6	1261	20,715 videos	Viewpoint and pose variations, partial occlusion, detection error, small inter-class and large intra-class variation	87.30 [94]
	DukeMTMC-VideoRe-Id [136]	2019	-	1812	12 frames per second in a tracklet, 2196 training tracklets, 2636 testing tracklets	Lightning, pose and viewpoint variation, noisy background, occlusion	-

Re-Id datasets can be broadly classified into two types: image-based and video based datasets.

Table 3 Triplet loss improvements for Re-Identification

References	Year	Triplet Loss Improvements	Benefit
Ding et al. [20]	2015	Triplet Loss	Works on relative distance among intra-class and inter-class identities
Cheng et al. [16]	2016	Improved Triplet Loss	Ensures intra-class compactness
Hermans et al. [39]	2017	Batch Hard Triplet Loss	Removes triplet mining step overhead. Learning from similar inter-class and varying intra-class samples
Zhu et al. [173]	2017	Hash Based Triplet Loss	Ensures that the hamming distance of hash codes from the anchor and positive sample is less than that of anchor and negative sample
Su et al. [96]	2018	Attribute Triplet Loss	Learns a large number of human attributes considering their contextual cues
Wu et al. [128]	2019	OIM + Improved Triplet Loss	Learn similarity metric and fully utilize label information of samples
Yuan et al. [147]	2019	Mini-Cluster Loss	Reduce intra-class and enlarge inter-class differences
Si et al. [93]	2019	Compact Triplet Loss	Reduce intra-class and enlarge inter-class differences
Yang et al. [144]	2019	Adaptive Nearest Neighbour Loss (ANN)	Solves slow convergence and local optima for triplet based loss
Choe et al. [18]	2019	Mixed Distance Maximization Loss	Maximize intra-distance and keep triplet distance larger than sample distance
Zhou et al. [170]	2019	Symmetric Triplet Loss	Gradients derived for positive samples are symmetric allowing consistent minimization of intra-class distances
Fan et al. [24]	2019	Sphere Softmax Loss	Maps image samples to a hypersphere manifold
Zhang et al. [160]	2020	Hybrid Triplet Loss (HTL)	Learns domain invariant and camera invariant properties
Jiang et al. [47]	2020	Weighted Triple-Sequence Loss (WTSL)	Reduce impact of outlier frames in video sequences
Zhang et al. [155]	2020	Wasserstein Triplet Loss	Uses the Wasserstein Distrance to rearrange global distance between samples
Sikdar et al. [92]	2020	Batch Adaptive Triplet Loss	Exponential learning from hard positives compared easier positives in triplet scheme

Table 4 Contributions of attention modules in Re-Id methods

Reference	Year	Region of Attention	Benefit
Yang et al. [143]	2019	Whole body and body parts	Discriminative feature extraction
Bao et al. [6]	2019	Body parts	Robust to part misalignment and background clutter
Zhou et al. [170]	2019	Image foreground	Robust to background clutter
Wu et al. [129]	2019	Spatial regions in video frames, temporal pooling over entire video	Extract discriminative Re-Id features from essential frames within video
Li et al. [54]	2019	Convolutional features	Learns interdependence of channels within convolutional features
Zhang et al. [152]	2019	Video frames	Select informative frames for dimensionality reduction of features
Wan et al. [106]	2019	Spatial region of input images	Local parts discovery
Tay et al. [102]	2019	Physical appearance attributes like gender, hair, upper clothing color, lower clothing color, pant etc	Discriminative representation of identity based on appearance attributes (Fig. 3)
Hou et al. [42]	2019	Generated Frames created by GAN generator	Generate occluded regions in video frames using temporal attention module to remove occlusion
Subramaniam et al. [97]	2019	Common visual features across frames of a video	Robust to background noise and extracts common features in video frames
Chen et al. [10]	2019	Spatial and Channel-wise attention	Improved attention quality due to self-critical attention learning
Zhang et al. [154]	2020	Video frames focussed at multiple scales	Spatio-temporal video representations
Li et al. [60]	2020	Global image features at multiple scales	Robust to spatial misalignment and local feature dependencies
Qian et al. [86]	2020	Spatial regions of input, multi-scale features	Discriminative feature extraction
Zhang et al. [155]	2020	Global and local features	Robust to misalignment, helps to distinguish between important and misleading parts

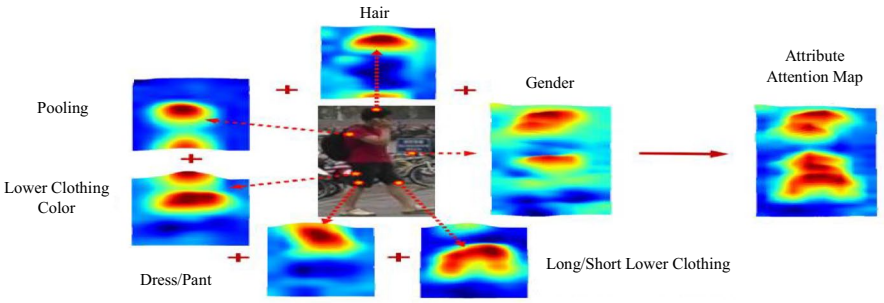

Fig. 3 Attribute Attention Map (AAM) generated from six heat maps corresponding to attributes such as gender, hair, clothing etc. [102]

2.2 Review methodology

This review includes journal papers, conference and workshop papers from several well-known repositories including IEEE Xplore, ScienceDirect, Springer, ACM and Google Scholar. The keywords used to search for relevant contributions include "person re-identification", "Re-Id", "deep", "deep learning", "review" and "survey". Due to the growing popularity of deep approaches, this initial search resulted in a comprehensive list of contributions. Higher priority was given to publications from high-quality journals such as IEEE Transactions, Pattern Recognition, Neurocomputing etc. and top conferences such as CVPR, ECCV and ICCV. A separate search was conducted to include Re-Id dataset contributions. Finally, the included papers were analyzed and a taxonomy of deep Re-Id methods was formulated as demonstrated in Fig. 2. Figure 4 shows the graph of year-wise deep Re-Id contributions cited in this review clearly depicting a high percentage of recent deep Re-Id works.

2.3 Reseach questions

This section presents the research questions explored in this survey. Specifically, it highlights the key issues of person re-identification and how different research contributions aim to address them. Exploring several research papers on person re-identification, various key ideas have been identified. *Firstly,* deep learning-based approaches are primarily about designing novel architectures to solve a given problem. Hence, understanding the different types of deep architectures for person re-identification is important. *Secondly,* researchers face several challenges in person re-identification and identifying these barriers is crucial. *Thirdly,* loss functions can be modified to enforce robust feature learning capability. *Fourthly,* how can the recently proposed attention mechanism be used for person re-identification? cation? *Finally,* how is it possible to build multi-modal approaches for person re-identification systems?

In this regard, the key research questions for person re-identification are as follows:

- *What are the different types of deep learning architectures that are used for person re-identification?*
- *What are the major challenges for person re-identification systems?*

Table 5 Re-Id contributions based on different architectures

Ref	Architecture	Key idea	Loss Function	Pros	Cons
Ding et al. [20]	Triplet	Propose "Triplet loss" the utilizes three samples to learn discriminative features and also propose a triplet generation scheme	Triplet loss	Proposed model reduces the intra-class variations and increases inter-class variations via L2 distance metric based triplet inputs	Requires additional preprocessing step to formulate triplets with positive, negative and neutral samples
Zhu et al. [172]	Classification	Combine Softmax and Center Loss [121] to improve discriminative capability of CNN features	Softmax + Center Loss	Reduces the intra-class variations via a combined combination of softmax and center loss	Requires large number of training samples per identity
Zhu et al. [173]	Triplet + Part	Propose a "Part Based Deep Hashing" (PDH) network that integrates hashing for higher efficiency of large scale Re-Id. Implement a triplet loss that reduces the Hamming distance of positive sample parts and increase that of negative sample parts	Triplet loss	Proposed model utilizes hasing for fast approximate nearest neighbour search	Requires large-scale reid datasets to utilize the full strength of hashing mechanism
Huang et al. [45]	Part	Propose a novel method DeepDiff to evaluate similarity between corresponding parts using original data, feature maps and spatial variations from three deep subnets	Softmax loss	Utilizes a novel pyramid partition architecture for difference granularities of human parts	Final score is attained by accumulating similarity scores of individual parts
Koo et al. [53]	Part	Use information from face and body to obtain discriminative representations in indoor camera surveillance environment	Softmax loss	Proposed a multimodal human recognition method that used both face and body	Proposed approach uses multiple CNNs which increases the computational cost of training the model

Table 5 (continued)

Ref	Architecture	Key idea	Loss Function	Pros	Cons
Tao et al. [101]	Triplet	Propose a "Deep Multi-View Feature Learning" (DMVFL) method that fuses handcrafted and deeply learned features to obtain robust representations	Triplet loss	Proposed approach extracts complementary information from deep features and cross-view quadratic discriminant analysis metric learning	Proposed model is small and has limited learning capability
Su et al. [96]	Triplet	Propose a three-stage "Weakly Supervised Multi-Type Attribute Learning Framework" using a novel "Attribute Triplet Loss" to predict visually invariant features containing contextual cues	Attribute triplet loss	Extract human attribute features that are invariant to changes in pose and viewpoint	Proposed model does not consider the spatial locations of human attributes
Zhang et al. [159]	Classification + Verification + Part	Learn deep features from body parts and entire body using verification and classification models respectively to obtain final representation	Softmax loss	Proposed model combines the benefits of part-based and body-based feature learning	Proposed method requires the additional processing of pairing positive and negative samples
Zhong et al. [168]	Classification	Propose a novel "Inter-Center Loss" to improve the discriminative capability of CNN features	Softmax + Center + Inter-Center Loss	Combining multiple losses helps to reduce intra-class variations	Combining three losses requires the additional tuning of loss weight parameters

Table 5 (continued)

Ref	Architecture	Key idea	Loss Function	Pros	Cons
Fan et al. [24]	Classification	Propose a novel CNN based network "SphereRe-Id" adopting a novel sphere loss mapping sample images to hypersphere manifold and a balanced sampling strategy to address class imbalance	Sphere Softmax Loss	Proposed a novel loss function that lears the underlying feature embedding hypersphere which is often ignored methods	Sphere softmax is computationally expensive due to the calculation of cosine similarity between two vectors
Bao et al. [6]	Classification + Attention	Propose a dual-branch CNN based network having a global branch to process features from overall human body and an attention branch to selectively focus on attentional part of information from input	Softmax Loss	Uses visual attention mechanism to focus on spatial regions of important body parts	Basic CNNs are used as individual branches. More recent architectures will extract better features
Yang et al. [143]	Part based + Attention	Introduce a novel attention driven multi-branch network to learn discriminative representations from whole body and body parts focussing on spatial and channel-wise information	Softmax loss	Uses attention mechanism to focus on important spatial and channel regions	Semantic part parsing was not used in the proposed network
Yan et al. [142]	Part + Attention	Propose a feature attention block for Re-Id that pays attention to sliced part features in a weighted manner to highlight the most discriminative part regions which are robust to misalignment	Softmax loss	Uses attention mechanism to learn weighted part-level features that are discriminative	Sample re-weighting is not used in the proposed approach

Table 5 (continued)

Ref	Architecture	Key idea	Loss Function	Pros	Cons
Zhou et al. [170]	Triplet + Part + Attention	Propose a novel "Foreground Attentive Neural Network" (FANN) that utilizes a foreground attentive subnetwork and a novel regression loss function to learn foreground regions which is then fed to body part features using novel symmetric triplet loss	Regression loss + Symmetric Triplet loss	Proposed model contains a foregroud mask reconstruction mechanism to suppress irrelevant background information	Computing multiple losses increases the computational overheads
Wu et al. [126]	Classification + Triplet	Combine classification loss, triplet loss and center loss to constrain Euclidean distance of same identity samples closer than those of different identities	Softmax loss + Triplet loss + Center loss	Proposed model enjoys the benefits two types of achitectures—identification and triplet model	Computing multiple losses increases the computational overheads
Zhang et al. [158]	Classification + Triplet	Introduce a dual-branch "Multi Branch Slice-Based Network" (MSN) learning multi-level local and global features using a novel "triplet-center loss"	Triplet-Center loss	Proposed model extracts multi-level pyramid features from global region and local body part regions	Dual-branch architecture makes the proposed approach computationally expensive
Zhao et al. [161]	Triplet	Introduce a multi-level triplet model MT-net, extracting multi-level features which are both global and local	Triplet loss	Proposed model combines fine features from shallow layers and coarse features from deep layers	The three branch architecture contains GoogleNet in each branch which makes it computationally heavy

Table 5 (continued)

Ref	Architecture	Key idea	Loss Function	Pros	Cons
Yuan et al. [148]	Classification + Triplet	Introduce a deep joint embedding learning framework that uses classification and an improved triplet loss. The improved triplet loss works on hard triplets generated	Softmax loss + Improved Triplet loss	Proposes an improved triplet loss that swaps the neutral and positive sample in a triplet to compute robust loss	Performance on large-scale reid datsets is unknown
Wu et al. [128]	Classification + Triplet	Combine classification and triplet loss to make full use of labels as well as learn similarity measure simultaneously	Online Instance Matching loss + Triplet loss	Use of online instance matching loss is better for larger datasets as compared to Softmax loss	Local descriptor features are not extracted in the proposed approach
Tian et al. [103]	Part	Propose a two-branch CNN to combine learning global and local part level features simultaneously	Softmax loss	Weighted combination of local and global losses allows for intelligent local and global feature extraction	Dual-branch architecture is computationally heavy
Li et al. [54]	Classification + Verification + Attention	Propose a novel network with attention module to highlight essential features and a multi-loss function to reduce intra-class distance and increase inter-class distance	Cross-entropy loss + novel verification loss	Attention mechanism highlights important regions of features and multi-loss function helps in faster model convergence	Siamese networks contains two CNNs adding a large number of parameters to the network

Table 5 (continued)

Ref	Architecture	Key idea	Loss Function	Pros	Cons
Yuan et al. [147]	Triplet	Propose a novel "mini-cluster" loss that ensures the largest distance of same identity samples (inner divergence) to be less than the smallest distance of different identity samples (outer divergence)	Mini-cluster loss	Proposed mini-cluster loss reduces intra-class variations and expands inter-class differences	The proposed approach does not extract effective detailed local features
Ling et al. [68]	Classification + Verification	Introduce MTNet with four losses for identification and verification of person identity and person attributes	Softmax loss	Attribute loss helps to extract discriminatory pedestrian information	The proposed approach does not utilize complementary benefits of attributes and reid tasks
Si et al. [93]	Classification + Triplet	Propose a novel "Compact Triplet Loss" that improves the batch hard triplet loss to reduce intra-class variations and increase inter-class differences. Combine with a classification loss for better discrimination capability	Compact triplet loss + Softmax loss	Proposed loss is robust against pose variations	Limited generalization to unseen dataset examples
Tian et al. [104]	Verification + Triplet	Propose a novel "Adaptive Verification Loss" (ADV loss) that learns only from meaningful hard sample pairs mined by using a weighted triplet loss	ADV loss + Triplet loss	Proposed loss handles unbalanced datasets better than other commonly used methods	Results are highly prone to distortion due to outlier examples

Table 5 (continued)

Ref	Architecture	Key idea	Loss Function	Pros	Cons
Zhong et al. [167]	Classification + Verification	Introduce a novel "Feature Aggregation network" (FAN) network to learn features from various layers of deep network along with multiple losses	Softmax loss	Multiple feature extraction techniques and multi-loss learning approach for discriminative learning	High forward pass time per batch
Wang et al. [119]	Part	Propose a novel "Part-Based Pyramid Loss" that takes quadruplet input samples and learns body part features using relationship of distance and angle among samples	Part based pyramid loss	Proposed method captures both local and global features	Part-based pyramid loss requires large amount of training data and hence, is ineffective for small datasets
Yao et al. [145]	Classification + Part	Propose a "Part Loss Network" (PL-net) that trains on body part and global features	Classification loss + Part loss	Robust to occlusion and viewpoint variants	Part-based loss function increases the training time of the model
He et al. [38]	Classification + Verification	Adopt the "lifted structured loss" due to its superiority to contrastive and triplet losses. Combine it with identification loss to learn relative identity information from pairs and true identity information	Softmax loss + Lifted structured loss	Proposed model minimizes intra-class variations and maximizes inter-class variations by using lifted structured loss	Using lifted structured loss limits model scalability as the computational overhead increases with number of samples and feature dimension

Table 5 (continued)

Ref	Architecture	Key idea	Loss Function	Pros	Cons
Choe et al. [18]	Triplet	Consider intra-distance between positive samples of a triplet and distance between triplets using a novel "mixed distance" function to improve Re-Id performance	Mixed distance loss	Proposed method solves the local optima problem by using "mixed distance maximization "	Limited generalizability to unseen data
Quispe et al. [87]	Classification + Triplet	Propose a novel "Saliency Semantic Parsing Re-Id" (SSP-Re-Id) network. The Saliency guided subnetwork learns from essential parts of image while semantic parsing guided subnetwork deals with Re-Id challenges	Softmax loss + Triplet loss	Proposed model is robust to pose / illumination variations and occlusion	High computational overheads due to saliency and semantic parsing with deep learning networks
Wan et al. [106]	Part + Attention	Propose a novel "Concentrated SPR network" (CSPR-Net) having a "constrained attention module" to find discriminative local parts that work better than body parts and a novel "statistical-positional-relational (SPR) descriptor that gives better the performance than global features	Classification loss	Proposed model is robust to pose and illumination variations	Proposed model is not robust to occlusion

Table 5 (continued)

Ref	Architecture	Key idea	Loss Function	Pros	Cons
Zhang et al. [155]	Classification + Triplet + Attention	Propose a novel triplet loss based on the "Wasserstein distance" (Earth Mover distance) to handle the part misalignment problem using part probabilities obtained from attention maps and part features	Softmax loss + Wasserstein triplet loss	Proposed method is view-invariant and lighting invariant	The proposed approach has limited scalability to larger datasets because computing Wasserstein distance between two images is computationally expensive
Li et al. [55]	Part	Propose a novel "Attributes-Aided Part Detection and Refinement Network" (APDR) that uses attribute learning for part localization handling the misalignment problem. Attribute features are fused to obtain discriminative features	Softmax loss + Triplet loss	Proposed model is robust to occlusion	Proposed model relies on extracting attribute information which may not always be consistent or reliable
Qian et al. [86]	Classification + Triplet + Attention	Propose a novel "Multi-Scale Deep Architecture" (MuDeep) having a "multi-scale deep learning layer" to learn features at different scales and a "leader-based attention learning layer" to determine optimal weighting for features from each scale	Softmax + Triplet loss	Attention mechanism of the proposed model dynamically finds the spatial regions of importance at each feature scale	Increased computational cost due to multiple attentional modules and feature fusion steps

Table 5 (continued)

Ref	Architecture	Key idea	Loss Function	Pros	Cons
Bai et al. [3]	Classification + Triplet + Part	Propose a three-branch "Deep Person" framework that learns contextual body part information using LSTM and learn discriminative features using identification (global and part level) and triplet losses	Softmax loss + Triplet loss	Proposed approach considers human body as a sequence of body parts and learns their spatial context using LSTM	Proposed approach does not use attention mechanism
Zhang et al. [150]	Part	Propose a dual-branch "Heterogeneous Part-Based Deep Network" (HPDN) to learn part based features using batch hard triplet and cross entropy loss	Batch hard triplet loss + Cross-entropy loss	Model searches for the person based on the local part alignment score	The proposed dual-branch architecture is computationally heavier than single branch models
Li et al. [60]	Classification + Triplet + Attention	Introduce a self-attention guided model that learns weighted features from different regions of human image	Softmax loss + Triplet loss	Self-attention module extracts weighted person regions and non-local features	Multi-scale feature fusion increases the model's computational complexity

Table 6 Contributions robust to Re-Id challenges: variations in Pose (P), Scale (S), Lightning (L) and View (V), Occlusion (O), Background clutter (B) and Misalignment (M)

Reference	Year	Key Idea to Avert Re-Id Challenges	Robust to Challenges						
			P	S	L	O	B	V	M
Yu et al. [146]	2018	Use skeleton joint information and cloth-color type features to achieve pose and lightning invariance	✓		✓				
Feng et al. [26]	2018	Use Cross-View Euclidean constraint (CV-EC) to reduce distance of deep features of an identity from multiple views						✓	
Zhou et al. [169]	2018	Propose a "self-paced learning" (SPL) method to isolate noisy samples in weighted way using model age and iteration and train CNN model with faithful samples gradually moving from easy to hard samples				✓	✓		
Chen et al. [12]	2018	Fuse attribute features learned from part-specific CNN and fuse them with Local Maximal Occurance (LOMO) features to obtain robust features	✓		✓		✓	✓	
Fu et al. [28]	2019	Introduce a two stream spatial segmentation network that derives spatial and fine local features	✓		✓			✓	
Zheng et al. [166]	2019	Use a novel "alignment branch" to learn the affine transformation of high level convolutional features utilizing a spatial transformer network that crops images with too much background and pads zero borders to missing part features thereby solving scale variation and misalignment		✓			✓		✓
Chen et al. [14]	2019	Study correlation among cross-view visual data from multiple camera views to compose view-specific representations						✓	
Luo et al. [78]	2019	Propose a novel "Dynamically Matching Local Information" (DMLI) method that automatically aligns horizontal stripes from input samples without any labelling supervision or pose estimation	✓						
Zhou et al. [170]	2019	Use a novel "foreground attentive subnetwork" having a decoder trained on a novel "local regression loss" to create a binary mask suppressing background					✓		
Qi et al. [85]	2019	Train CNN on six Re-Id datasets to learn robust features			✓			✓	
Yang et al. [144]	2019	Learn spatial dependencies among local regions of pedestrians in both horizontal and vertical directions using LSTM to overcome occlusion				✓			
Zheng et al. [163]	2019	Propose a novel "pose invariant embedding" (PIE) by constructing a novel PoseBox through pose estimation and then training using two-stream PoseBox Fusion network	✓						
Wei et al. [122]	2019	Estimate four human key points that are robust to pose and view variations. Head, upper body and lower body features are generated using these key points and a four-stream CNN is trained to generate the novel "Global Local Alignment Descriptor" (GLAD) features from both global and local regions	✓						✓
Wu et al. [133]	2020	Use adversarial learning to learn asymmetric transformations to transform view-specific distribution to a generic view invariant feature space						✓	
Li et al. [55]	2020	Use attribute learning to detect body parts thereby solving part misalignment problem							✓

Table 6 (continued)

Reference	Year	Key Idea to Avert Re-Id Challenges	Robust to Challenges						
			P	S	L	O	B	V	M
Tang et al. [100]	2020	Propose a novel "Gradual Background Suppression" method that extract CNN features based on different weights assigned to body parts and background thereby suppressing the background					✓		
Sikdar et al. [92]	2020	Resize input to different scales and convolve with a fixed size filter to obtain multi-resolution pyramid which is re-scaled back to fixed size to obtain scale invariant features		✓					
Li et al. [60]	2020	Propose a "multi-scale attention" model evaluating important person regions in a weighted fashion and train on features fused globally and locally using cross-entropy and triplet loss	✓			✓		✓	

Table 7 Image based Re-Id contributions

Reference	Year	Key Idea	Benefit	Dataset	Rank 1 Result (%)
Wu et al. [124]	2018	Introduced a deep embedding approach using optimized robust features, positive mining and local adaptive similarity learning	Discriminative features	VIPeR	49.04
				CUHK01	71.60
				CUHK03	73.02
				Market-1501	84.14
Wu et al. [125]	2018	Introduce a multiplicative integration gating function combined with Hamadard product	Cross-view feature alignment	VIPeR	49.11
				CUHK03	73.23
				Market-1501	67.15
				Market-1501	93.91
				DukeMTMC	83.35
Ke et al. [50]	2018	Introduce ID-AdaptNet to adapt “seen” identity features to “unseen” identities	Discriminative features	CUHK03	30.36
				Market-1501	81.59
				DukeMTMC	67.77
Zhang et al. [151]	2019	Use group symmetry theory to extract and utilize information from middle layers of Resnet50 (ResGroupNet)	Discriminative features	CUHK03	71.20
				Market-1501	92.80
				DukeMTMC	86.20
				Market-1501	93.50
				DukeMTMC-Re-Id	85.00
Wu et al. [130]	2019	Introduce a five-branch deep model that learns body features in horizontal and vertical directions, relationship between feature channels and part features	Discriminative features	CUHK03	95.00
				Market-1501	94.70
				DukeMTMC-Re-Id	86.70
Liu et al. [73]	2019	Fuse Gaussian features with deep features	Fused discriminative features	Market-1501	84.40
				VIPeR	57.20
Zhang et al. [153]	2019	Introduce a PAAN network using layered partition strategy to fully utilize part-level and global attributes	Fused discriminative features	Market-1501	91.86
				DukeMTMC-Re-Id	81.73
Tian et al. [103]	2019	Introduce a two-branch RJLN network to jointly learn global and local features	Fused discriminative features	CUHK03	66.60
				Market-1501	93.70
				DukeMTMC-Re-Id	85.50

Table 7 (continued)

Reference	Year	Key Idea	Benefit	Dataset	Rank 1 Result (%)
Wu et al. [131]	2019	Introduce a multi-branch MFML network to represent features from multiple layers	Weighted multi-layered fused features	CUHK03	94.40
				Market-1501	92.50
				DukeMTMC-Re-Id	84.00
Zhao et al. [161]	2019	Introduce a multi-level triplet model MT-net, extracting multi-level features which are both global and local	Fused discriminative features	CUHK03	79.34
				Market-1501	81.95
Wang et al. [113]	2020	Propose a novel exclusively regularized softmax objective function	Multi-scale multi-patch features	CUHK03	70.40
				Market-1501	93.70
				DukeMTMC	84.40
Wang et al. [114]	2020	Fuse handcrafted features from local and global regions with deep features	Fused discriminative features	VIPeR	52.22
				CUHK01	71.91

Table 8 Cross modality Re-Id contributions

Reference	Year	Modality	Key Idea	Device
Ren et al. [89]	2017	RGB + Depth	Fuse anthropometric features from depth images and visual features from RGB images using a novel "multi-modal fusion layer" to obtain discriminative features	RGB Camera + Kinect V1 sensor
Feng et al. [27]	2019	RGB + Infrared Data	Extract "modality specific representations" (MSR) from modality-specific networks trained on a modality-specific loss to learn discriminative features from each domain. Use a cross-modality Euclidean constraint to learn modality-invariant features	RGB + Infrared Cameras
Xiang et al. [137]	2019	RGB + Infrared	Propose a dual-branch neural network that fuses modality specific information from two branches using multiple granularity network (MGN) to obtain modality shared features	RGB + Infrared Cameras
Ren et al. [37]	2019	RGB + Depth	Propose a novel "uniform and vibrational deep learning" (UVDL) method that uses an auto-encoder to visible and deep features extracted from two neural nets into a common features space	RGB-D camera (Kinect)
Chang et al. [9]	2020	RGB + Textual	Combine visual CNN features with textual CNN features from textual descriptions including details of gender, clothes color and bag type information to obtain a generalized feature embedding	RGB Camera
Gohar et al. [32]	2020	Gait Data	Propose a novel "non-visual gait based" Re-Id method that uses gait data captured from accelerometer and gyroscope to learn discriminative features using Gated Recurrent Unit (GRU) to capture discriminative temporal information from input sequences	Accelerometer, Gyroscope
Wang et al. [117]	2020	RGB + Infrared	Propose a novel "multi-patch networking network" (MPMN) that utilizes a single deep neural net to process both RGB and thermal images. A novel "multi-patch modality alignment" loss mines for hard subspaces. A novel "cross-patch correlation distillation" (CPCD) loss enforces cross-patch similarity to boost cross-modality embedding. A novel "patch aware priority attention" (PAPA) method prioritizes training of hard patch tasks over others	RGB + Infrared Cameras

Table 9 Cross-domain Re-Id contributions

Reference	Year	Cross-Domain Approach
Xiao et al. [138]	2016	Learn generic CNN features embedding from multiple dataset domains and use a novel "Domain Guided Dropout" to mute neurons learning domain specific information thereby improving Re-Id performance
Ganin et al. [29]	2016	Use few standard layers and a novel "gradient reversal layer" to learn from labelled source domain samples and unlabelled target domain samples
Xu et al. [141]	2019	Propose a novel "Deep Augmented Attribute Network" (DAAN) to learn augmented feature representations using augmented features and labels from source dataset and refine the learned features to unlabelled target dataset
Zhou et al. [171]	2019	Propose a novel "Multi-Camera GAN" (CTGAN) to transfer source dataset samples to multi-camera styles of target dataset
Genc et al. [30]	2019	Perform domain adaptation by training on different dataset combinations, learning part specific features and learning features form multiple layers and use a CycleGAN to perform camera view adaptations
Wang et al. [109]	2020	Propose a novel "Deep Multi-Task Transfer Network" (DMTNet) network for unsupervised cross domain Re-Id including cluster number estimation algorithm, learning of attribute attention importance and transfer of specific multi-task learning across domains
Sun et al. [99]	2020	Propose a novel "Conditional Transfer Network" (cTransNet) implementing conditional viewpoint transfer using StarGAN and obtain hybrid feature embeddings from original and transformed images to obtain similarity rankings
Zhang et al. [160]	2020	Propose a novel "Dual Generation Learning" (DGL) method to transfer source dataset images to target style domain and target dataset images to source camera styles to obtain better Re-Id results

Table 10 Deep metric learning methods

Reference	Year	Metric Learning Method	Short Form	Key Idea
Hu et al. [43]	2016	Deep Transfer Metric Learning	DTML	Cross domain metric learning
Lin et al. [67]	2017	Generic Similarity Metric	-	Robust to translation and shearing deformation
Zhu et al. [174]	2018	Deep Hybrid Similarity Learning	DHSL	More discriminative than Euclidean or Cosine distance based similarity
Duan et al. [22]	2018	Deep Localized Metric Learning	DLML	Metric learning over locally varying data
Hu et al. [44]	2018	Sharable and Individual Multi-View Deep Metric Learning	MvDML	View invariant metric learning
Chen et al. [15]	2018	Pose Invariant Deep Metric Learning	PIDML	Pose invariant metric learning
Ren et al. [88]	2019	Deep Structured Metric Learning	-	Robust person re-identification
Ding et al. [21]	2019	Robust Discriminative Metric Learning	RDML	Robust to noise
Xiong et al. [139]	2019	Multiple Deep Metric Learning	-	Instead of feature extraction, utilize a stacked auto-encoder to recognize individuals using multiple similarity probabilities from Softmax regression models

Table 11 Video based deep Re-Id contributions

Reference	Year	Key Idea	Dataset	Rank 1 Result (%)
Sun et al. [98]	2018	Extract visual features using a "Two-Branch Appearance Feature sub-structure" (TAF) and temporal features using a "Optical Flow Temporal Feature sub-structure" (OTF) and use a pair of Siamese networks to learn similarity measure among pairwise visual and temporal features. A saliency learning fusion layer learns fusion of global and local appearances	MARS iLID-VIDS PRID2011	73.00 59.00 79.00
Wang et al. [108]	2018	Perform image-to-video Re-Id using a novel end-to-end "Point-to-Set Network" (P2SNet) that takes both image and video as input and jointly learns their features using point-to-set distance metric. A *k*NN-triplet module helps to focus only on relevant video frames	MARS iLID-VIDS PRID2011	55.25 73.31 40.00
Meng et al. [80]	2019	Learn view-specific and feature-specific transformations using a novel "Deep Asymmetric Metric Learning" from a two stream neural net to counter view-specific bias and feature-specific bias in appearance and motion features due to variations in view, lightning, background clutter etc	MARS iLID-VIDS PRID2011	74.65 77.33 87.00
Wu et al. [129]	2019	Propose a novel "Siamese attention architecture" to jointly learn feature representation and similarity measure for video Re-Id using an attention mechanism focussing on relevant frames (when) and regions of interest within frames (where)	MARS iLID-VIDS PRID2011	86.60 86.50 98.80
Ksibi et al. [52]	2019	Propose a "Deep Spatio-Temporal Appearance" (DSTA) descriptor that uses a "Deep Salient-Gaussian Wighted Fisher Vector" (SGFV) to exploit trajectory information to handle misalignment of person tracklets and eliminate background noise using Gaussian and Saliency maps	MARS iLID-VIDS PRID2011	76.70 80.00 92.70
Zhang et al. [152]	2019	Propose a novel "Self-and-Collaborative Attention Network" (SCAN) that utilizes two attention sub-networks (self-attention subnetwork and collaborative attention subnetwork) to select features from informative video frames and align discriminative frames from probe and gallery frames respectively and finally use a generalized similarity measure to compare video pair representations	MARS iLID-VIDS PRID2011	87.20 88.00 95.30
Wu et al. [132]	2019	Utilize novel "3D Person VLAD Aggregation layer" based on the vector of locally aggregated descriptors to capture motion based features along with appearances which is usually missed by 2D ConvNets and learn "global representations" for a full length video robust to occlusion and misalignment using soft attention module to learn 3D part alignment	MARS iLID-VIDS PRID2011	80.80 69.40 87.60
Liu et al. [71]	2019	Propose a novel "Dense 3D Convolutional Network" (D3DNet) that uses numerous three dimensional dense blocks and transition layers to extract discriminative features from appearance and temporal domains capturing visual and motion cues (both short term and long term) from videos without additional modules. Implement a combination of identification and center loss to reduce intra-class disparity and increase inter-class disparity	MARS iLID-VIDS	76.00 65.40

Table 11 (continued)

Reference	Year	Key Idea	Dataset	Rank 1 Result (%)
McLaughlin et al. [79]	2019	Extract frame-wise CNN features and use a temporal pooling recurrent layer to combine all time step features and obtain feature representation for entire video sequence	iLID-VIDS	58.00
			PRID2011	70.00
Zhang et al. [154]	2020	Propose a novel "Multi-Scale Spatial–Temporal Attention" (MSTA) model that pays attention to different regions within each video frame at different scales to incorporate essential regions into whole video spatio-temporal representations. MSTA contains an encoder to extract frame wise features and an aggregator to fuse features	MARS	82.28
			iLID-VIDS	70.10
			PRID2011	91.20
Wu et al. [134]	2020	Use variational recurrent neural networks (VRNNs) to conduct a deep few-shot adversarial learning to extract discriminative features that are view invariant	MARS	54.60
			iLID-VIDS	60.10
			PRID2011	79.20
Avola et al. [2]	2020	Propose a novel "LSTM based Re-Id Hashing model" that exploits bone proportion, gait and movement features of 2D skeletons extracted from RGB video frames. LSTM is used to learn temporal correlation between different frames while two dense layers are responsible for implementing bodyprint hashing via binary coding capable of unbounded labelling of all individuals possible	MARS	86.50
			iLID-VIDS	73.40
			PRID2011	82.70
Wu et al. [135]	2020	Propose a novel "Adaptive Graph Representation Learning" method that uses adaptive structure-aware adjacency graphs via graph neural networks (GNN) highlighting two kinds of relations: pose alignment connection to capture human part relations and feature affinity connection to model semantic relationship among features from various regions across frames. A novel regularization is used to capture temporal resolution invariant features for the entire video sequence	MARS	89.80
			iLID-VIDS	83.70
			PRID2011	93.10
			Duke-MTMC VideoRe-Id	96.70
Jiang et al. [47]	2020	Propose a novel framework "Spatial Transformed Partial Network" (STPN) that aligns frames to extract robust regional features. A novel "Weighted Triple-Sequence Loss" (WTSL) is used to exclude outlier frames in video-level features. Model is jointly optimized for frame-level and video level features	MARS	85.90
			iLID-VIDS	82.20
			PRID2011	95.20

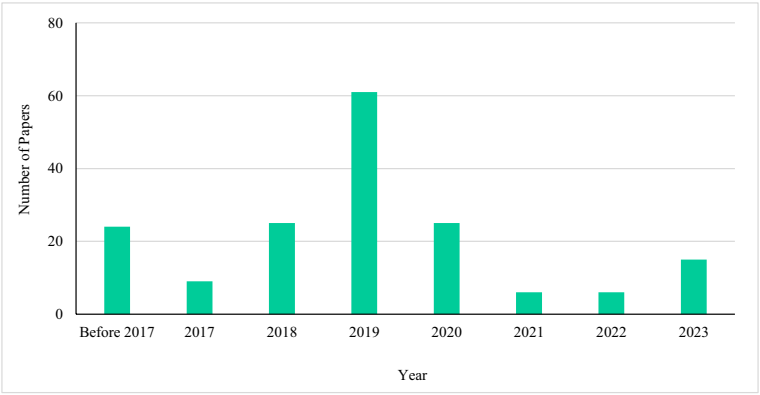

Fig. 4 Count of cited articles (year-wise)

- *What novel loss functions have been proposed to compute robust features towards person re-identification?*
- *How can the attention mechanism boost the performance of person re-identification systems?*
- *Can multi-modal person re-identification systems perform better than methods with single modality?*

This survey addresses these research questions. Section 4.1 talks about different types of architectures for person re-identification. Section 4.2 gives the major challenges. Section 4.1.3 presents several novel losses for person re-identification. Section 4.1.5 presents the attention-based person reid methods. Multi-modal person re-identification research has been discussed in Section 4.3

2.4 Comparison with existing reviews

While the number of deep Re-Id implementations have grown exponentially in recent years, there are very few reviews/surveys keeping pace with the growth of deep Re-Id research. This section presents a comparative analysis of this review against some existing deep learning based Re-Id surveys. Compared to other surveys, this review includes the latest research publications (up to 2020). Table 1 presents Re-Id comparisons on the basis of several deep learning aspects such as architecture types, Re-Id datasets, challenges, modality, cross-domain approaches and metric learning methods. The green rows indicate the presence of theoretical analysis while the orange rows indicate the presence of tabular information.

Table 1 clearly shows the comprehensive nature of this review when compared to other existing surveys, presenting both theoretical and tabular analysis of various deep Re-Id aspects.

3 Benchmark datasets for person Re-Identification

Several benchmark datasets have been collected over the years to train and test the robustness of person re-identification systems. These datasets are useful in validating different re-identification approaches in terms of recognition accuracy. Table 2 gives detailed information about various re-id datasets.

3.1 Image based Re-Id datasets

The VIPeR [34] dataset has been created for viewpoint invariant pedestrian recognition. It contains 1264 images of 632 identities that have been captured from 2 cameras. The iLIDS [165] dataset has been acquired at an airport arrival hall and has 476 images of 19 identities from 2 cameras. The GRID [76] dataset is acquired from a busy underground train station having images of 800 identities from 8 cameras. CUHK03 [57] is another large scale re-id dataset having 13,164 images of 1360 identities collected using 2 cameras.

Datasets like Market-1501 [164], DukeMTMC-Re-Id [33] and CUHK02 [56] have used 6,8 and 10 cameras respectively, thereby increasing the number of camera views used to collect people images. A few multi-modal re-id datasets also exist such as the RGBD-ID [7], KinectRe-Id [82] based on RGB-depth images and RegDB [81], SYSU-MM01 [123] containing both RGB and infrared images. The largest image based re-id dataset is the Airport [49] collected from 6 cameras of a mid-sized airport containing images for 9651 identities. Figure 5 shows some sample images from the Market-1501 dataset.

3.2 Video based Re-Id datasets

PRID2011 [40] dataset contains 983 identities collected from 2 cameras. iLIDS-VID [118] contains 600 videos of 300 people from 2 cameras. Another popular video based re-id dataset is the large scale dataset MARS [162] which contains 20,715 videos of 1261 identities from 6 cameras. The most recent addition to the video re-id dataset is the DukeMTMC-VideoRe-Id [136] containing 1812 identities.

Considering the growth of re-id datasets over the years, several inferences can be made. *Firstly*, Re-Id datasets have grown both in number and scale which is a great benefit since deep models require large amount of samples for effective training. *Secondly*, the variety of samples within these datasets present numerous re-id challenges such as variations in pose, lightning and scale, occlusion, background clutter, same people wearing different clothing (large intra-class disparity) or different people wearing similar clothing (small inter-class disparity), thereby allowing deep models to learn

Fig. 5 Sample Images from Market-1501 dataset

effective generalization of appearance. *Thirdly*, very few datasets are multi-modal [7, 82] leading to an over reliance on RGB image and video based approaches. *Fourthly,* in a supervised environment, deep models require labelled samples for learning. As the size of datasets grow, it becomes less feasible to annotate them manually. While most of the datasets discussed above have manually annotated samples, datasets like Market-1501 or CUHK03 have used Deformable Part Model (DPM) [25] for sample labelling.

4 Image based deep Re-Id contributions

This section details the recent image based deep Re-Id contributions. These contributions have been categorized according to the following aspects: 1) Architecture types for Re-Id 2) Re-Id challenges 3) Data Modality for Re-Id 4) Cross-Domain Re-Id 5) Metric Learning for Re-Id. These categories are not exclusive and often overlap in various implementations but each has a distinct conceptual aspect to it.

4.1 Deep Re-Id architecture types

This section talks about the different kinds of architectures used for deep learning based re-identification. Specifically, the Re-Id contributions have been categorized as 1) Classification Models 2) Verification Models 3) Triplet Based Models 4) Part-Based Models 5) Attention Based Models as shown in Fig. 6.

4.1.1 Classification models for Re-Id

Classification models (also known as Identification models) consider Re-Id as a multi-class classification problem [62, 168]. Given a dataset with a finite number of identities and each identity having a number of samples, these models are trained using identity labels from samples. Classification models can be formally described as follows. Let there be an image gallery of κ people $P = \{p_1, p_2, p_3 ... p_\kappa\}$ with identity labels $L = \{l_1, l_2, l_3 ... l_\kappa\}$. The model is trained with labels L from various sample identities of people P. After training, given a query sample p_x having identity l_x the classification model tries to output a high score for label x and low score for all other identity labels. Since Re-Id models are trained on samples from various identities, they require large number of samples per identity to capture diverse features from each individual. Lack

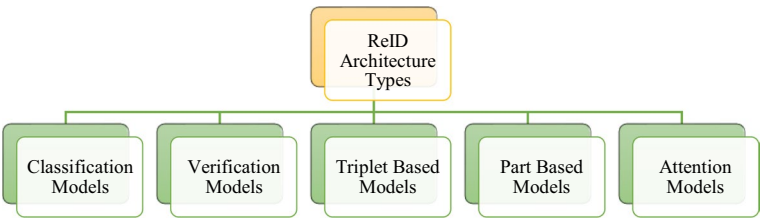

Fig. 6 Different Kinds of Deep Architectures used for Re-Id methods

of diverse samples often lead to over-fitting. The softmax loss is usually employed in classification models which encourages the separation of different identity samples [62, 172]. However, Re-Id presents large intra-class variations such as pose variations, view variations, lightning variations, occlusion, background clutter etc., for which the softmax loss has performed poorly. Several improvements have been suggested over the softmax loss to handle these intra-class challenges.

Zhu et al. [172] aim to overcome the inability of softmax loss to handle intra-class variations by using it in conjunction with the center loss [121] which was originally used for facial recognition. Authors train a convolutional neural network (CNN) with the proposed combination of softmax and center loss to extract discriminative features and obtain better Re-Id results.

Zhong et al. [168] enhance the Re-Id classification performance by using a multi-loss training setup having a combination of softmax loss, center loss and a novel "inter-center loss". While the softmax loss differentiates between different identity samples, the center loss brings same class identities closer to their center and the inter-center loss maximizes the distance between centers of different identity.

Fan et al. [24] propose a novel "Sphere Softmax Loss" by modifying the softmax loss. Instead of mapping sample images to a Euclidean space embedding, sphere loss maps sample images to the surface of a hypersphere manifold, thereby limiting spatial distribution of data points to angular variations. The proposed loss trains using the angle between sample vector and target class vector.

4.1.2 Verification models for Re-Id

Verification Models consider Re-Id to be a binary-classification problem. Given a pair of images, these models classify them to be either same or different. These models implement a pair of CNNs to extract features from input pair and compare their similarity [157]. Verification models use the contrastive loss [36] which was first used for dimensionality reduction. In Re-Id, the contrastive loss tries to pull same identity pairs to zero distance in the feature space while pushing different identity pairs beyond a given margin. Verification models suffer from the *class imbalance problem*. Consider a dataset having K number of identities, each of which has M number of image samples. The dataset is balanced with respect to different identity samples. However, if we consider the number of positive and negative samples present with respect to a single identity, there are M positive samples and (K-1)M number of negative samples. This leads to class imbalance in training verification based models.

Zhang et al. [159] combine the verification and classification Re-Id models to learn "deep features from body and parts" (DFBP). Specifically, the verification model is implemented using two neural networks that are trained by comparing body parts from image sub-regions of input pair while the global region features are extracted from a classification model to learn body-based features. The concatenated body-based and part-based features form the final representation. Zhong et al. [167] propose a novel "Feature Aggregation Network" (FAN) which also combines the classification and verification tasks. FAN extracts multi-level CNN features from input image pairs. Then, Recurrent Comparative Network (RCN) containing attention module compares appearance of input image pairs for verification loss. The CNN features are pooled directly using the Global Average Pooling (GAP) for classification loss. Figure 7 shows the proposed model.

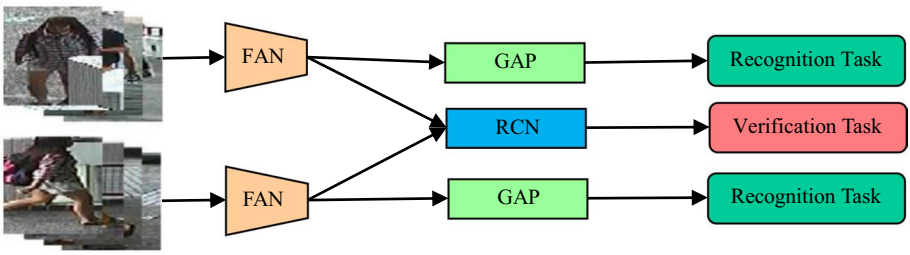

Fig. 7 Overview of proposed hybrid model. CNN features are extracted from input image pair using FAN networks. RCN learns joint representation for verification task while GAP is used for recognition task [167]

4.1.3 Triplet based Re-Id models

Triplet models for Re-Id take triplet input units. Each triplet unit contains three image samples: the anchor, a positive sample (having same identity as the anchor) and a negative sample (different identity from the anchor) [8]. The triplet loss [20] is trained to keep the Euclidean distance between anchor and positive sample less than anchor and negative sample. Let T_i represent the ith triplet such that $T_i = \langle T_i^a, T_i^p, T_i^n \rangle$ having anchor image T_i^a, positive sample T_i^p and negative sample T_i^n. $\Gamma(I)$ represents the extracted CNN features for image I. $\|x\|$ represents the $\mathcal{L}_2$ norm. The proposed triplet loss enforces the following condition:

$$\|\Gamma(T_i^a) - \Gamma(T_i^p)\| < \|\Gamma(T_i^a) - \Gamma(T_i^n)\| \tag{1}$$

Figure 8 demonstrates the preservation of condition (1).

The main drawback of triplet models is that they only use weak annotations from a triplet to learn discriminative features, unlike a classification model learning from numerous samples of a given identity available in the dataset [128]. The traditional triplet loss has

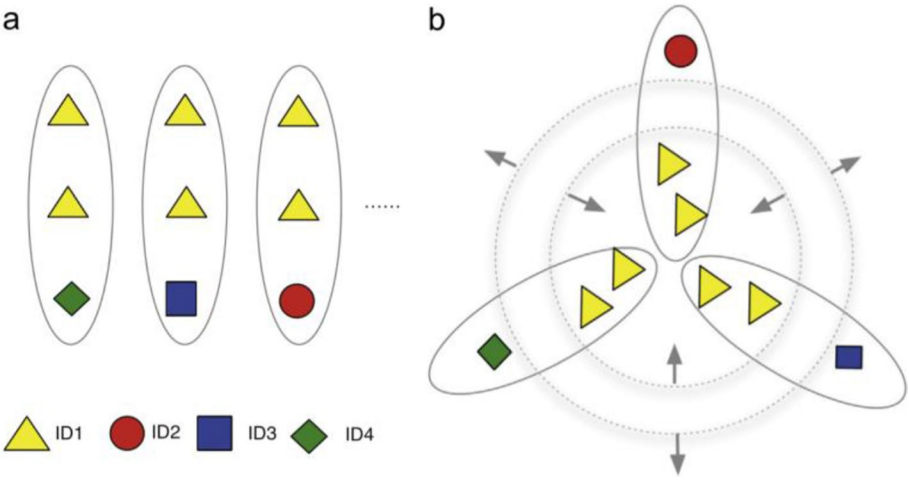

Fig. 8 **A**) Three triplet units having anchor identity (yellow triangle), positive sample (also yellow triangle) and negative sample (green/purple/red shapes). **b**) The Triplet Loss enforces the features of positive samples closer meanwhile pushing the negative samples away [20]

faced the issue of slow convergence and hence, several improvements have been formulated to improve the discrimination ability of triplet based models. Table 3 demonstrates these novel improved triplet losses.

4.1.4 Part-based Re-Id models

In the initial years, deep Re-Id methods focussed mostly on extracting global image-level features to identify individuals [35, 74, 120]. However, this approach quickly became ineffective in handling small inter-class variations such as identifying different people wearing same color clothes. This has led to a gain in popularity of part-based Re-Id methods due to their superior discrimination capability based on finer part-level cues which are usually suppressed while extracting global features [143]. Part-Based Re-Id methods extract different image regions to find discriminative part-level features.

Yan et al. [142] propose a feature attention block for part-based Re-Id. The authors slice features maps into spatial features and assign them weights thereby highlighting the important part regions as demonstrated in Fig. 9. Tian et al. [103] propose a novel Strong Part Based Network (SP_Net) that divides feature maps into $\mathbb{N}$ parts, thereby learning part level features using $\mathbb{N}$ part losses combined to obtain a local loss. The local loss is combined with global loss in a weighted manner to obtain discriminative capabilities. The major challenges faced by part-based models are the variations in pose, alignment and scale of corresponding image regions (parts) under comparison.

4.1.5 Attention-based Re-Id models

Attention based Re-Id models aim to selectively choose regions of high interest from input information [107, 120]. The proposed "Attention Modules" focus on extracting regions containing highly discriminative features while ignoring other regions having little or no discriminative capability. Such an approach of targeting specific regions helps to overcome Re-Id challenges like background clutter, misalignment etc. [69]. Attention models have proven their superior performance in several computer vision applications including Re-Id

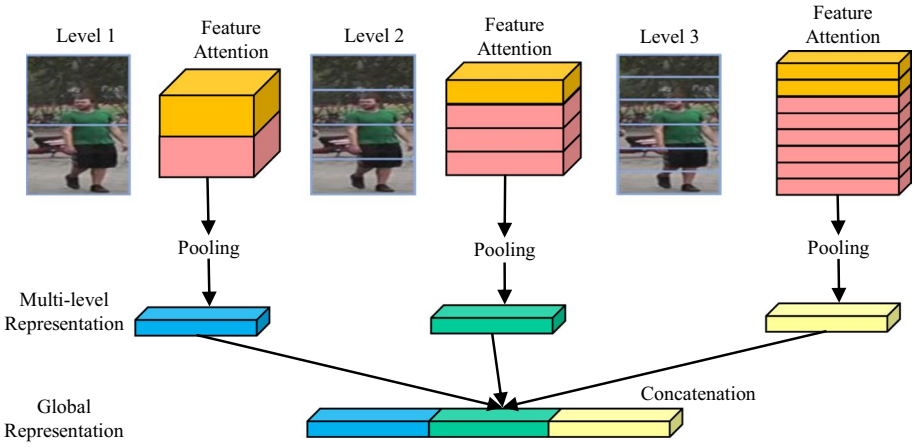

Fig. 9 Multiple feature attention networks used to generate different levels of part features. Extracted feature vectors are concatenated to obtain global representations [142]

with the growth of Recurrent Neural Networks (RNN) based on Long Short Term Memory (LSTM) [41]. Various Re-Id implementations have incorporated the attention mechanism to enhance their performance. Table 4 presents an analysis of contributions of attention modules in Re-Id methods.

Table 5 gives a detailed overview of various deep Re-Id contributions based on their architecture types.

The **highlights of deep Re-Id architectures** are:

- Deep learning based Re-Id architectures can be classification models, verification models, triplet-based models, part-based models and attention based models.
- Classification models treat Re-Id as a multi-class classification problem that use the softmax loss to predict the class of an input query. Softmax loss encourages the separation of different classes but struggles with large intra-class variations. Several Re-Id works combine classification with other model types to overcome this limitation [68, 91, 121].
- Verification models treat Re-Id as a binary classification problem, taking a pair of inputs and categorizing them as same or different. These models suffer from the class imbalance problem since the number of positive pair combinations is far less than the negative pairs where each identity contains same number of samples in the dataset.
- Triplet models input triplets of images containing an anchor, a positive and a negative sample. These models are trained on the triplet loss that aims to pull the positive sample closer and pushes the negative sample away in feature space. Several improvements have been suggested over the traditional triplet loss having convergence issues. These improvements include solving slow convergence [144], removing triplet mining overhead [39], maintaining intra-class compactness [16] etc.
- Part-based Re-Id models aim to focus on sub-regions within input to extract finer feature representations crucial in differentiating samples with small inter-class variations, usually missed in global image level representations. Focus on different parts of feature maps [103, 142], face and body regions [53], attribute guided body parts [55] etc., have yielded discriminative feature representations.
- Attention models highlight regions of high interest within input holding highly discriminative information. Gaining popularity since the growth on RNN and LSTM, attention modules have helped in implementing *spatial attention* within image/frame regions such as human body parts [6], foreground [170], physical attributes. [102] and *channel attention* within deep features [54].

4.2 Methods based on Re-Id challenges

The task of person re-identification has faced several challenges like sample variations in view, pose, lightning and scale, partial or complete occlusion [13, 140, 156], background clutter etc. Figure 10 demonstrates some of these Re-Id challenges presented by samples from various Re-Id datasets as detailed in Table 2. Any re-id system striving to achieve competent recognition rates must be able to counter these challenges effectively. Numerous research works have been conducted with this motivation.

Feng et al. [26] attempt to overcome the challenge of large intra-class disparity caused by view variations from images captured by cameras placed at different viewpoints. Authors propose a framework capable of learning view-specific features consistent with

Fig. 10 Re-Id challenges posed by dataset samples. Each column demonstrates samples from a unique identity. Columns (i) and (ii) show variations in pose, (iii) and (iv) show scale variations, (v) and (vi) display occlusion examples, (vii) and (viii) describe background clutter, (ix) and (x) show view variations in samples. All samples have been derived from the Market-1501 dataset

each camera view which utilizes a cross-view Euclidean constraint (CV-EC) and cross-view center loss to decrease the distance of features of same person from different views. Qi et al. [85] tackle lightning and viewpoint variation at two levels. Firstly, they extract deep features trained on multiple datasets which are robust to differences in illumination and view. Secondly, they use the learned features to find an optimal ensemble of metrics including the Cosine distance metric that reduces the intra-class disparity even further. Sikdar et al. [92] achieve scale-invariance by modifying the convolution functionality within a deep network. Instead of learning a kernel on a fixed scale input, the input is first transformed to a pyramid of multiple resolutions. The network then learns multiple scaled feature maps which are then re-scaled to original size before applying max pooling. Such an operation has proven to produce scale invariant results for re-id system. Input image misalignment can seriously hamper the feature learning and matching process. To handle the misalignment problem, Zheng et al. [163] introduce *pose invariant embedding* (PIE) which aligns identities within sample images to a standard pose using pose estimation. The transformed standard pose promotes learning of discriminative feature extraction and matching and is alignment invariant. Table 6 presents some novel Re-Id contributions that are robust to Re-Id challenges.

The **highlights of contributions based on Re-Id challenges** are:

- Finding a person of interest is challenging due to visual variations in pose, view, lightning, scale, partial or complete occlusion, background clutter and misalignment.
- Several deep Re-Id contributions have aimed to develop robust methodologies against these Re-Id challenges.
- Skeleton joints data and clothe colors have produced pose and lightning invariance [146], learning view-specific representations for view invariance [14], utilizing foreground attentive network to suppress noisy background [170], convolving with multi-scale input to obtain scale invariant features [92] and using pose estimation to achieve pose invariance [163] are some of efforts to overcome these challenges.

4.3 Re-Id methods based on modality

Visible images have proven to be the most common source of discriminative information crucial for identifying individuals. Hence, research literature is filled with visible image based Re-Id methods due to their superior identification power. Despite their popularity, the visible image based methods are prone to several challenges already discussed in Sect. 4.2. Hence, some cross-modal Re-Id methods have also been proposed to enhance the ability of Re-Id systems further. This section discusses various visible light based and cross-modality based Re-Id methods.

4.3.1 Visible image based Re-Id methods

Numerous visible image based Re-Id contributions have focussed upon extracting discriminative deep features to achieve high recognition rates for re-identification [37, 105, 112, 115]. Table 7 details some novel Re-Id image based contributions.

Wu et al. [130] propose a five-branch deep model that is capable of learning features not only from the usual horizontal direction but also in the vertical direction. The model scans for spatial information of body parts from left to right and head to foot, thereby learning discriminative information. Working with one type of features is often limiting in finding discriminative capabilities for re-id systems. Hence, an obvious direction of improvement is to fuse different features together to obtain higher differentiation in re-id. Zhao et al. [161] introduce a novel deep triplet model (MT-net) performing multi-level feature extraction. Both detailed and global features from each layer are combined together in an optimal proportion through training. The fused features prove to have high discriminative capabilities. While most deep learning based re-id approaches extract features only from the top layer, middle layer features can also contribute to discriminative capabilities of the model in certain situations. Wu et al. [131] introduce a *multi-level feature network with multiple losses* (MFML) which is a multi-branch architecture representing multiple middle layer representations trained on triplet loss and top layer representation trained on the hybrid loss. The representation from various layers are fused in a weighted manner based on their importance in obtaining differentiating characteristics. Based on the idea that color features hold key information in reference to re-id task, Liu et al. [73] fuse traditional Gaussian of Gaussian (GOG) features from four color channels (RGB, Lab, HSV, RnG) with deep features to obtain highly discriminative features which achieve state-of-the-art performances.

4.3.2 Cross-modality Re-Id methods

While image based methods have proven to be most popular in the Re-Id research community, these visual feature based methods have several limitations. Visual Re-Id methods face several challenges such as variations in pose, view, lightning, scale, partial or complete occlusion, background clutter which are already discussed in Sect. 4.2. Also, visual Re-Id methods are highly ineffective in dark environments such as nighttime, due to the poor illumination that suppresses most of the visual cues [27]. This has led to the development of multi-modal Re-Id methods [72, 72] that combine data from multiple modalities to reduce dependency on visual information. Table 8 lists the

novel multi-modal Re-Id methods combining RGB, depth, text and infrared (thermal) based data modalities.

Chang et al. [9] learn a similarity metric for visual and textual representations. Authors use the Resnet architecture to extract visual features from image samples. A 2500-dimensional textual feature embedding is extracted from textual description of each sample (gender, clothe color etc.) using tokenization, lemmatization and stemming. The model is trained in an end to end manner using a triplet architecture on both visual and textual representations.

Gait information has proven to be highly discriminative for Re-Id tasks. Gohar et al. [32] formulate a multi-modal Re-Id method performing non-visual gait analysis on information extracted using wearable sensors namely, accelerometer and gyroscope. The proposed method learns discriminative information integrating the temporal aspect of gait data using Recurrent Gated Units (GRU).

Other significant multi-modal approach is [59].

The **highlights of modality based deep Re-Id contributions** are:

- Visible RGB images are the most widely used data modality for deep Re-Id methods due to the rich variety of visual information they contain and the growth of several image based Re-Id datasets developed over the years.
- Visible RGB image methods aim to extract discriminative features by using multi-branch networks [130], fusing multiple features together [161], proposing novel loss functions [113] etc.
- Visible RGB image methods face several visual challenges as discussed in Sect. 4.2 and lose most of their discriminative capabilities in dark/night environments.
- Multi-modal Re-Id methods reduce the dependency on visual information for extracting discriminative features.
- Several multi-modal Re-Id contributions have extracted anthropometric features from depth data [89], modality specific representations from thermal images [137], gait information from accelerometer and gyroscope [32] and combined with visual information to formulate multi-modal representations.

4.4 Cross-domain Re-Id methods

Based on the kinds of samples present, different re-id datasets hold different generalizations of human appearance. Hence a re-id model trained on one dataset performs poorly on a different dataset. Several works have addressed this issue with domain adaptation techniques [19, 75, 95] attempting to bridge the gap between the learned source domain to the unknown target domain as demonstrated in Table 9. Zhang et al. [160] introduce a novel *Dual Generation Learning* (DGL) method for unsupervised domain adaption such that a re-id model when evaluated on any relevant dataset shows acceptable recognition results. The DGL method generates target style images for samples from source dataset and camera style images for those from target dataset, thereby expanding them to consider varying domain styles. Ganin et al. [29] propose to augment few standard layers and a novel *gradient reversal layer* into deep architectures to learn features that are trained on both labelled source domain as well as unlabelled target domain. Such features cannot discriminate between source and target domain and hence are suitable for domain adaptation. Wang et al. [109] propose a *Deep Multi-Task Transfer Network* (DMTNet) to transfer discriminative features learnt from source domain to target domain by utilizing a cluster estimating

algorithm, attribute attention important learning and multi-task learning. Other domain adaptation based re-id works involve refining learned augmented attribute features according to target domain [141], image to image translation using generative adversarial network [171], viewpoint transfer using generative adversarial network [99] etc.

The **highlights of cross-domain Re-Id methods** are:

- Most deep Re-Id methods that are trained/tested on few datasets perform poorly on other datasets.
- Several cross-domain Re-Id approaches have been developed to either learn better generalization across multiple datasets or transfer learned characteristics of source domain to another target domain.
- The cross-domain approaches have achieved sample style transfer from source to target dataset [160], training from multiple dataset combinations [30], transformation of learned features from labelled source to unlabelled target dataset [141], thereby improving the generalizability of deep Re-Id methods.

4.5 Metric learning methods for Re-Id

Metric learning has proven to be a significant step in computer vision problems such as person re-identification, face recognition etc. [175]. Metric learning aims to find a similarity function on extracted features that is used to decrease positive pair distance while increasing negative pair distance [5]. Table 10 highlights the different kinds of metric learning contributions reviewed in this article. Since the underlying data distributions varies with the nature of the computer vision task, the ideal similarity function is mostly task-specific [43]. Traditional metric learning methods focussed on learning linear Mahalanobis based metrics. Such linear metrics utilized the sample distribution centroid and standard deviation to evaluate the similarity with a give sample point. However, such linear metrics often failed to comprehend nonlinear relationships among the samples.

Recently, deep metric learning techniques have become increasingly popular due to their ability to capture hierarchal nonlinear affiliations. Hu et al. [43] propose a *deep transfer metric learning* (DTML) method that transfers discriminative information from labelled source domain to unlabelled target domain. DTML learns hierarchical nonlinear transformations, maximizing the inter-class disparity, minimizing the intra-class differences and restricting the divergence of source and target domain. Ding et al. [21] increase the generalizability of metric learning by introducing *robust discriminative metric learning* (RDML) which is insensitive to noise unlike most metric learning techniques. A fast low rank model is also used to discover global structure within data and ensure scalability to larger datasets. Lin et al. [67] argue that similarity transformations cannot capture deformations like translation and shearing in cross domain visual matching tasks. The authors propose *a generic similarity metric* that generalizes the similarity transformation to affine transformation capable of capturing complex deformations. While most metric learning techniques focus on the overall similarity learning of samples, Duan et al. [22] propose the *deep localised metric learning* (DLML) to learn multiple metrics fine-grained over numerous local subspaces. DLML specializes in handling data varying locally. Hu et al. [44] introduce the *sharable and individual multi-view deep metric learning* (MvDML) to utilize multi-view data in best possible manner. MvDML learns the best combination of distance metrics by focussing on both individual view specifics metric as well as a combined

multi-view representation. Chen et al. [15] propose a novel *pose invariant deep metric learning* (PIDML) method that utilizes pose invariant embedding [163] and an improved triplet loss to achieve pose invariance for metric learning. Ren et al. [88] propose a *deep structured metric learning method* that utilizes a novel structured loss function to achieve robust person re-identification. The proposed loss skips positive sample pairs of small distance and negative sample pairs having large distance.

The **highlights of deep metric learning based Re-Id methods** are:

- Metric learning means to learn a similarity function that pulls features from same identity samples closer and pushes different identity features away.
- Deep learning based metric learning have gained popularity in recent years due to their ability to learn nonlinear sample associations unlike the traditional Mahalanobis metric learning only linear relationships.
- Several novel deep metric learning approaches have been proposed that give better discrimination capability than the usual Euclidean or Cosine measure [174], can perform cross-domain learning [43], and are robust to noise [21], deformation [67] etc.

5 Video based deep Re-Id contributions

This section explores the video based deep person re-identification methods.

Video Re-Id methods received less attention compared to image based techniques in the initial years of Re-Id research [129]. A major reason was the lack of large-scale video datasets. However, recent years have witnessed the growth of several video based Re-Id datasets such as [40, 83, 118, 162] encouraging the development of video Re-Id methods. Compared to images, video sequences have advantageous characteristics that can be exploited for Re-Id tasks. *Firstly*, a video sequence comprising of multiple frames holds essential temporal information across frames giving crucial motion cues which are absent from image samples. *Secondly*, multiple frames from each video provide numerous visual examples per identity adding diversity in samples. *Thirdly*, while image based methods mostly focus on exploiting visual features, video Re-Id methods target a combination of visual and temporal features to extract discriminative features for Re-Id tasks which prove to be more robust to Re-Id challenges. While video based methods give rise to more discriminative feature embeddings, they also add to the existing Re-Id challenges as demonstrated in Fig. 11. *Firstly*, since the simplest way of generating video features is by fusing frame level features together and frame level features are based on 2D convolution operations that totally neglect the temporal aspect of frame sequences, the fusion operation misses all of the temporal cues crucial for video Re-Id. *Secondly*, videos have different frame rates and

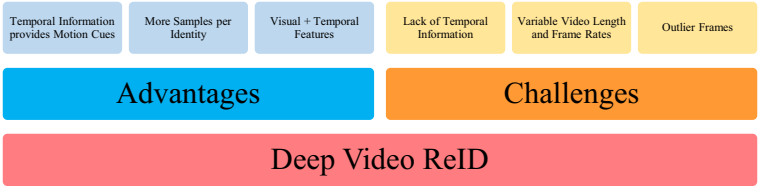

Fig. 11 Advantages and Challenges of Video based Person Re-Identification methods

different time series that makes it hard to make comparisons among samples. *Thirdly*, not all frames provide discriminative information and some outlier frames prove misleading in learning robust video representations.

Recent developments in Recurrent Neural Networks (RNN) and Long Short-Term Memory (LSTM) models [41] have boosted video Re-Id by providing the capability of extracting motion cues from temporal information for robust video representations. McLaughlin et al. [79] propose a video re-identification system based on recurrent neural network for wide area tracking. The proposed network uses a recurrent layer to combine frame-level details from all frames into a single combined appearance feature representing the entire video showing competent recognition results. Attention modules have played key role in video Re-Id to identify and isolate outlier frames. They also help in extracting discriminative regions within video frames. Wu et al. [129] propose a Siamese attention network that learns to realize which regions (where) from which frames (when) are relevant for comparing identities. The attention mechanism learns the most relevant features by focussing on distinct regions helping to identify given identity. Zhang et al. [152] propose a *self and collaborative attention network* (SCAN) for video re-id. The proposed model takes a pair of videos as input, aligns and compares their discriminative frames using a generalized similarity measurement module and refines intra-sequence and inter-sequence features from videos using a non-parametric attention module. Wu et al. [132] argue that merely combining frame-wise features to obtain overall video features is ineffective as the temporal cues get lost in 2D convolutions. Authors propose a novel 3D Person VLAD Aggregation layer that helps to extract appearance and motion characteristics of entire video. The model also handles occlusions and misalignments through soft attention modules. Zhang et al. [154] propose a *multi-scale spatial–temporal attention network* (MSTA) that focusses attention to regions within video frames at different scales. It contains a ResNet50 based encoder responsible for extracting frame-level features from discriminative regions and an aggregator to fuse features from different scales Fig. 12.

Table 11 dives into several contributions highlighting the diverse approaches towards video person re-identification using deep learning.

6 Conclusion and future directions

6.1 Conclusion

This review provides a comprehensive and exhaustive analysis of deep learning based person re-identification methods. The objective of this work is to give the readers a thorough understanding of different approaches towards deep Re-Id. This reviewed literature has been divided into several logical categories as demonstrated in the taxonomy diagram Fig. 2. These approaches have been classified on the basis of adopted architecture types (classification, verification, triplet based, part based and attention models) integrating

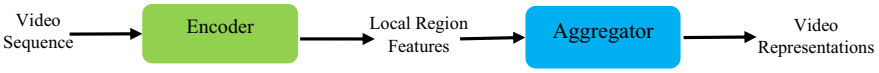

Fig. 12 Architecture of proposed MSTA model. The encoder extracts framewise features and the aggregator fuses the frame-level features to obtain video representations [154]

different kinds of losses (softmax, triplet), the common Re-Id challenges faced (variations in pose, lightning, view, scale, partial or complete occlusion, background clutter), image based methods and multi-modal Re-Id methods reducing the dependency on visible RGB approaches, cross-domain methods to improve generalizability of approaches across different datasets, metric learning approaches to learn ideal similarity functions and deep video Re-Id methods exploiting both spatial and temporal cues from multiple frames of a video sequence. Each category presented as a separate section provides an extensive look into these contribution types and the highlights at the end of each section gives a quick overview of the reviewed methods. Tables 3, 4, 5, 6, 7, 8, 9, 10, 11 provide the *key ideas* behind numerous deep Re-Id methods across various categories.

Part-Based and Attention architectures are the more popular architecture types in recent times owning to their ability to find regions of rich information and extraction of finer visual cues. Re-Id challenges have been conquered using different techniques like using pose estimation to achieve pose invariance [163], obtain scale invariance through multi-scale input convolutions [92] etc. Some multi-modal approaches have helped to reduce the over dependence on visible RGB based methods making them more viable for darker environments with fewer visual cues [137]. Deep video Re-Id methods provide more discriminative information when compared to image based approaches due the motion cues present in temporal information across frames. However, video Re-Id presents its own challenges of finding discriminative regions both spatially (within frames) and temporally (across frames) as demonstrated in Fig. 11.

6.2 Future directions

This section presents the possible future research directions for the benefit of the readers in deciding upcoming research possibilities.

Transformer-based Approaches: The recent rise in the popularity of transformer achitectures proves their effectiveness in solving computer vision problems. Novel transformer models can be used to extract more discriminative features leading to better identification results6.
Multi-Modal Information Fusion: Fusing discriminative information from multiple modalities such as visual, depth, thermal images etc. can be a great way of improving the discrimination capabilities of deep person re-identification networks. There is also a need to develop multi-modal reid datasets that help to build such approaches 7.
Cross-Modality Query Search: Real-world person re-identification systems requires cross modality query search facility. This means that a query can be an image while it is being matched with a video dataset. Reid approaches should be capable of searching the same person in a different modality8.
Cross-Domain Adaptation: The performance of person re-identification systems degrade when they are trained on one dataset and tested on another. This is due to the changing degree of variations in lightning, pose, alignment, scale etc., in different person re-identification datasets. More focus can be given in developing robust and generalized cross-domain approaches of person re-identification that perform well across multiple datasets9.
Privacy Preservation: Person re-identification has widespread applications for surveillance in public places. Hence, maintaining the anonymity of individuals is a key issue. Future research works can focus on developing techniques that preserve the identity of individuals in public spaces while deploying person re-identification systems.
Real-World Deployment: Person re-identification approaches suffer in real world settings. Hence, there is an urgent need to build robust person re-identification systems that

work well in realistic scenes like [49] and aid in the utilization of person re-identification in retail, security and law enforcement.

Long-Term Appearance Variation: While most reid approaches have focussed on common reid challenges such as variations in pose, lightning etc., very few methods have focussed on identifying the long-term variations of a person's appearance and clothing style. This includes variations of facial attributes, dressing etc. Robust reid systems are needed that can identify the same person after a long period of time.

Semi-Supervised and Unsupervised Methods: While supervised methods have scored better than semi or unsupervised reid methods, creating labelled datasets for supervised approaches is a huge research challenge. Hence, more novel semi and unsupervised reid approaches are needed that bridge the performance gap between them and supervised methods.

Federated Learning based ReID: Since reid has critical applications in surveillance based tasks, federated learning is a promising upcoming paradigm that allows for decentralized training of models from non-overlapping geographical regions for better recognition capabilities.

Other Possible Improvements: There are few end-to-end Re-Id research contributions that involve both person detection and re-identification together in a single framework. Since most datasets are collected under controlled environment, the person detection is usually performed automatically. Re-Id can also be used for continuous authentication purposes [61, 63, 64, 65]. End-to-end Re-Id is a promising research direction. GAN based Re-Id works have greatly supported the style transfer requirements of cross-domain Re-Id approaches. However, the low to medium quality of generated samples has limited the performance of these approaches. An improvement in sample generation quality can significantly boost cross-domain Re-Id approaches. Most part-based Re-Id contributions have focussed on systematic comparison between corresponding part regions of input pairs. But the contextual relationship among different regions is mostly ignored. Preserving the semantic relationship among different parts like [3] is a potential way of improving part-based methods further. Attribute-based methods have become increasingly popular in finding finer visual cues. These attribute-based methods can be extended further for applications like part localization like in [55] to achieve better Re-Id performance.

Data availability Data sharing not applicable to this article as no datasets were generated or analyzed during the current study.

Declarations

Conflict of interest The authors declare that they have no conflict of interest.

Deep Learning-based Binary Classification for Spam Detection in SMS Data: Addressing Imbalanced Data with Sampling Techniques

Dr. Manoj Sethi, Naman Tyagi, Parmeet Singh Kalsi and Parupalli Atchuta Rao

Computer Science Department, Delhi Technological University

E-mail : manojsethi@dce.ac.in namantyagi_2k19co241@dtu.ac.in parmeetsinghkalsi_2k19co269@dtu.ac.in parupalliatchutarao_2k19co271@dtu.ac.in

Abstract- This research paper presents a deep learning-based approach for detecting spam in SMS (text) data. The study uses various models namely Dense, LSTM, Bi-LSTM, and GRU to conduct binary classification and predict spam text messages. To address the imbalanced data problem, the study employs undersampling, downsampling, and SMOTE sampling techniques on a public dataset of SMS messages from UCL datasets. The paper presents a study on detecting spam messages in SMS using a dense model. The researchers visualize the commonly used words in spam and non-spam messages and analyze their impact on the model's performance. The findings from this study demonstrate that the proposed dense model exhibits high accuracy in detecting spam messages on the test dataset. This suggests that the model can be useful in identifying spam messages in SMS.

Keywords— Neural Networks; LSTM; Bi-LSTM; GRU; Text Classification; Spam; Ham; Deep Learning.

I. INTRODUCTION

The widespread use of mobile devices and messaging applications has led to an increase in the frequency of unsolicited messages or spam. These spam messages not only cause inconvenience to users but can also pose security threats. Therefore, the development of effective spam detection techniques for SMS text data is crucial.

Spam detection refers to the process of identifying unwanted messages, typically through electronic communication, that are not relevant to the recipient and can potentially cause harm [1], [2]. Different approaches have been proposed for detecting spam, like machine learning-based, statistical and rule-based methods. Machine learning-based approaches, particularly those utilizing deep learning algorithms, have demonstrated significant success in detecting spam messages [3].

Deep learning algorithms are a type of machine learning that takes inspiration from the structure and function of the human brain [4]. They have the ability to learn features from raw data without requiring explicit feature engineering, which makes them more versatile and powerful compared to traditional machine learning algorithms. In the context of natural language processing, some common deep learning algorithms include dense networks, LSTM, Bi-LSTM, and GRU.

The effectiveness of deep learning methods, particularly dense networks, Bi-LSTM, GRU, and LSTM, in natural language processing (NLP) tasks, such as text classification, has been demonstrated in recent years [5], [6]. This research focuses on using these techniques to detect spam in SMS text data. By comparing the performance of these models, the study aims to determine the most effective approach for spam detection.

The proposed approach will involve preprocessing and feature extraction techniques, followed by building and training the deep learning models on the preprocessed data. The performance of the models will be evaluated using quality metrics.

The paper is structured into different sections, and Section 2 specifically provides a review of existing literature on spam detection in SMS text data. Section 3 outlines the Materials and methods used, including the dataset, preprocessing and feature extraction techniques, and deep learning models utilized. Section 4 shows the experimental outcomes and their analysis. Finally, Section 5 winds up the paper and summarizes the research contributions.

II. Related Work

A multitude of techniques have been suggested for detecting spam in SMS text data, spanning from traditional rule-based methods to machine learning-based approaches [7]. In recent times, deep learning has become increasingly favored in this field due to its capacity to automatically learn intricate features from the input data.

Alvaro Reyes and Juan Garcia proposed an LSTM-based model for SMS spam detection in their work [8]. They preprocessed the data by cleaning and tokenizing the messages, and then used an LSTM network with multiple layers to categorize the SMS as spam or not spam. Rui Ma et al. proposed a hybrid LSTM and CNN model for spam detection in SMS in their work [9]. They used a combination of LSTM and CNN layers to classify the messages after preprocessing the data using tokenization and word embedding techniques.

Suman Saha and Syed S. Islam proposed a Bi-LSTM model for SMS spam detection in their work [10]. They used word embedding approaches to preprocess the data and then used a Bi-LSTM network to categorize the messages as spam or not spam.

Trung and Trang proposed a spam detection system for SMS messages based on a hybrid approach that combines decision trees and SVM [11]. Similarly, Samant and Thakare used random forests to classify SMS messages as spam or non-spam [12].

For instance, Shaikh and Rathod proposed a spam SMS detection model based on convolutional neural networks (CNNs) [13]. Vyas used deep learning techniques for spam SMS detection [14].

Other researchers have also explored more complex deep learning models for this problem. For example, Rahman, Islam, and Akhand proposed a spam SMS message detection system based on a bidirectional LSTM (Bi-LSTM) [15]. Park and Park used gated recurrent units (GRUs) to develop a spam SMS message detection model [16].

Taken together, the proposed techniques display encouraging outcomes in identifying SMS spam, and deep learning-based methods have illustrated their capability to achieve remarkable accuracy in this field. Nonetheless, there is scope for refinement, and more investigation is necessary to examine the effectiveness of alternative deep learning architectures in the detection of SMS spam.

III. Materials and Methods

A. Research Framework

This study utilizes Keras, a Python library for deep learning model development with the TensorFlow backend. Keras provides a range of tools for data preparation, including word tokenization, padding and truncating data, and word embedding [17]. Word tokenization transforms text inputs into sequential data represented as index values of the words. Padding and truncating data ensure that all sequences have the same length, while word embedding converts sequences with multiple dimensions into vectors.

The dense networks, LSTM, Bi-LSTM and GRU algorithms are utilized in order to train the model after the process of data preparation. The models' performances are then evaluated. The focus of this study is to detect spam messages in SMS text data, and the use of models related to deep learning is expected to enhance the precision of detection.

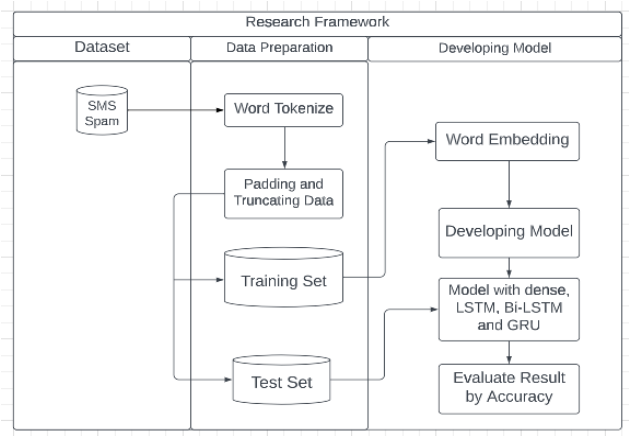

Fig. 1. Research framework.

B. Datasets

The SMS Spam Collection Dataset was selected for this study. The dataset includes 5,574 phone messages that were gathered as part of cellular device spam research and have been categorized as either spam or not spam. This dataset has been extensively used in previous investigations on SMS spam detection and is considered a standard benchmark for this type of research. By utilizing this

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:26:30 UTC from IEEE Xplore. Restrictions apply.

dataset, the study can ensure that the results obtained are comparable with other studies in the field.

	label	message
0	ham	Go until jurong point, crazy.. Available only ...
1	ham	Ok lar... Joking wif u oni...
2	spam	Free entry in 2 a wkly comp to win FA Cup fina...
3	ham	U dun say so early hor... U c already then say...
4	ham	Nah I don't think he goes to usf, he lives aro...

Fig. 2. Records of dataset for detecting spam.

Dataset for detecting Spam is an imbalanced dataset, with approximately 86% of the messages labeled as ham and 14% labeled as spam. The dataset includes messages in English and contains a variety of spam messages, such as phishing scams, fraudulent offers, and unwanted advertisements.

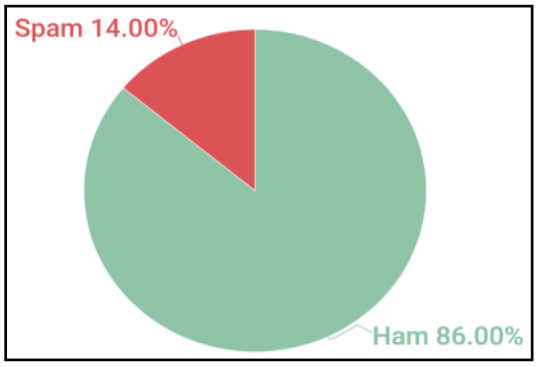

Fig. 3. Pie chart of spam Vs ham.

C. Data Sampling

The dataset consists of 4,825 non-spam (ham) messages and 747 spam messages, indicating an imbalance in the dataset. The most commonly occurring ham message is "Sorry, I'll call later," while the most frequently occurring spam message is "Please call our customer service..." with 30 instances. These results underscore the importance of balancing the dataset prior to training the spam detection model using Dense, LSTM, Bi-LSTM, and GRU architectures.

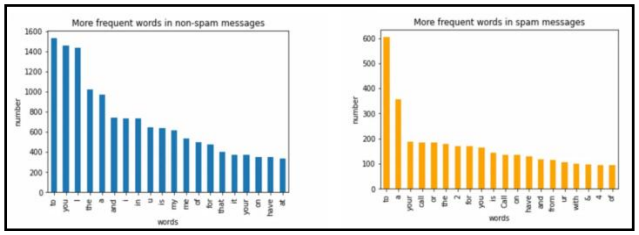

Fig. 4. Most frequent words in spam and ham messages.

The WordCloud for ham messages indicates that the words "now", "work", "How", "Ok", and "Sorry" are frequently used. On the other hand, the WordCloud for spam messages shows that the words "Free", "call", "text", "claim", and "reply" are the most common. The WordClouds provide insights into the vocabulary used in each message type, which can be helpful in developing an effective spam detection model. The bar chart illustrates the class imbalance in the dataset, with ham messages comprising the majority (86%) and spam messages only accounting for a small proportion (14%).

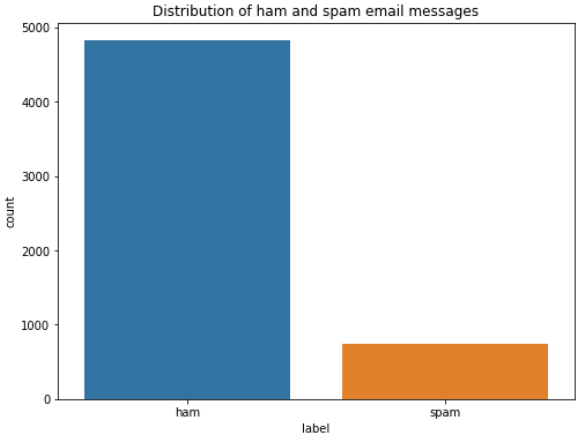

Fig. 5. Distribution of spam and ham messages.

In order to address the imbalanced class distribution in the dataset, various sampling techniques has been employed such as

1. Downsampling : It involves randomly removing instances from the majority class to reduce its size and balance the class distribution with the minority class. This can help prevent the model from becoming biased towards the majority class.
2. *Upsampling :* It involves randomly duplicating instances from the minority class to increase its size and balance the class distribution with the majority class. This can help ensure that the model has enough examples to learn from the minority class.
3. *SMOTE :* A data augmentation strategy called as SMOTE (Synthetic Minority Over-sampling Technique) produces new manufactured instances for the class in deficit by interpolating among existing instances. This technique can assist in increasing the size of the minority class without causing overfitting.

D. Training/Tesing the Data and Text Processing

To prepare the dataset for training deep learning

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:26:30 UTC from IEEE Xplore. Restrictions apply.

models, the text labels were first converted into numerical numbers. Subsequently, this research divides the data into two subsets, namely, a training and a testing set, in which 80% of the data is allocated for training and the remainder 20% for testing purposes. Additionally, the labels were transformed into numpy arrays to enhance their application in deep learning models.

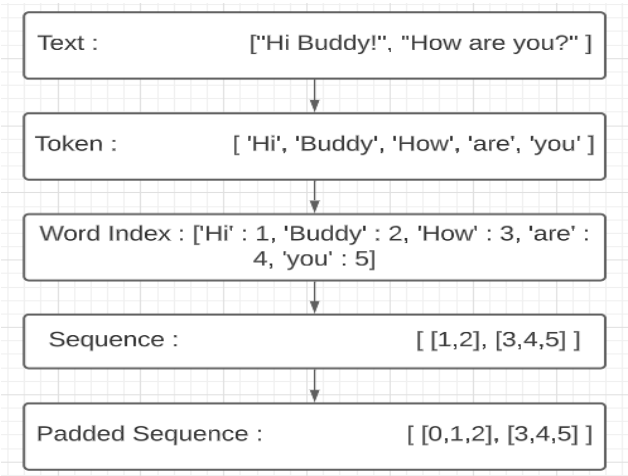

Fig. 6. Process flow in text preprocessing.

Tokenization : Numerical representation of text is essential in deep learning. Tokenization is the initial step in this process. Preprocessing hyperparameters are defined, which includes tokenizing text into words, setting a maximum number of unique tokens to discard rare words, removing punctuation marks, converting all words to lowercase, and converting all words to integer indexes. These hyperparameters will be further explained in the subsequent sections of the paper.

The hyper-parameters used in Tokenizing includes the number of distinctive words to fill in training and testing data, oov_token is utilized in replacing out-of-vocabulary words, and char_level specifies whether to treat every character as a token.

Sequences and Padding : After tokenization, sequences of numbers are obtained to represent each sentence. Then, padding is applied to make all sequences have the same length. Both the types of data : training and testing undergoes through same process.

The padding hyperparameters are used to control the padding process in text sequences. The padding can be added either before or after the sequence using padding = 'pre' or padding = 'post'. The maximum length of sequences can be set using maxlen, where longer sequences will be truncated. The truncating can be done at the beginning or end of the sequences using truncating='pre' or truncating='post'. These hyperparameters play a crucial role in ensuring that all sequences have the same length, which is a requirement for building a neural network model.

E. Modelling

In this study, LSTM, Bi-LSTM, GRU, and dense neural network models were trained and developed for text classification. Each model was evaluated based on its ability to accurately classify spam and non-spam messages.

Dense Model : The dense model is a kind of feedforward neural network. The input layer takes preprocessed text data as input, and the output layer produces a binary classification indicating whether the text is spam or not.

In the training phase, the deep learning model determines the best weights and biases to reduce a loss function that calculates the deviation between the predicted output and the actual output [18], [19]. Binary cross-entropy is the frequently utilized loss function for binary classification. Gradient descent is employed to modify the model's weights and biases. This involves computing the loss function's gradient with respect to the parameters and modifying them in the direction of steepest descent [20].

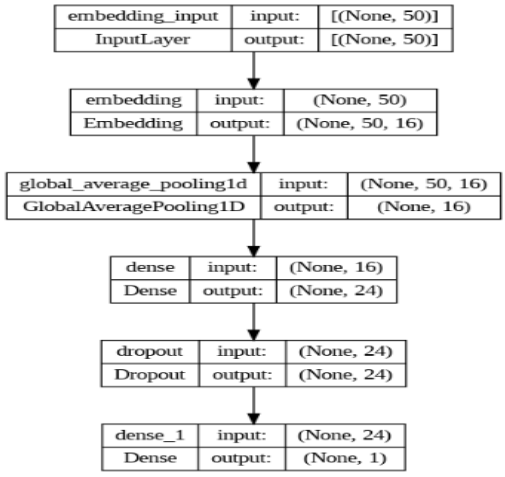

Fig. 7. Model summary of dense model architecture.

The successive model from Keras is utilized to add layers sequentially. The primary layer is the embedding layer, which plots every word to a 16-dimensional real number's vector

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:26:30 UTC from IEEE Xplore. Restrictions apply.

(embedding_dim). The input layer is defined by input_length = max_len. To minimize the count of parameters and stay away from overfitting, the GlobalAveragePooling1D layer is utilized as the pooling layer. The sigmoid function is appropriate for binary classification tasks. The dense layer and dropout layer are included to prevent overfitting.

The ReLU (Rectified Linear Unit) activation function takes an input value 'x' and returns the maximum value between 0 and 'x'. If 'x' is negative, it returns 0. The sigmoid activation function takes an input value 'x' and gives back a positive less than 1.

To configure and train the model, the 'binary_crossentropy' loss function, 'adam' optimizer, and 'accuracy' metric were utilized in current study. During model fitting process, the training data and labels are passed to the model along with the validation data. The research train the model for 30 epochs and add early stopping functionality via the EarlyStopping() callback function. This stops the training process if the validation loss does not improve following two consecutive epochs, preventing overfitting. Additionally, setting of verbose=2 to display the accuracy and loss on each epoch.

LSTM Model : Natural language processing (NLP) and other sequential data-related apps frequently use recurrent neural networks (RNNs), specifically Long Short-Term Memory (LSTM). LSTM networks have a more intricate architecture than conventional RNNs, which allows them to capture long-term dependencies and prevent the vanishing gradient issue [21].

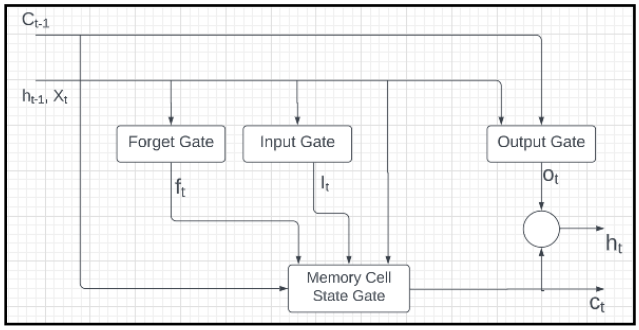

Fig. 8. Structure of LSTM cell.

These networks are built around a memory cell that comprises a hidden state and a cell state. The cell state functions as a conduit of information, carrying it from one point in time to the next, while the hidden state serves as the LSTM's output at each point in time. Three gates—the input gate, the forget gate, and the output gate—are used by LSTMs to alter the status of the cell. The input gate controls how much new information is introduced to the cell state at each time step, and the forget gate controls how much information is subtracted [22]. Finally, the output gate controls the portion of the cell state that is utilized to compute the output. LSTMs are highly desirable for their ability to prevent the problem of vanishing gradient, which commonly affects conventional RNNs.

InputLayer	output:	[(None, 50)]
embedding_1	input:	(None, 50)
Embedding	output:	(None, 50, 16)
spatial_dropout1d	input:	(None, 50, 16)
SpatialDropout1D	output:	(None, 50, 16)
lstm	input:	(None, 50, 16)
LSTM	output:	(None, 20)
dropout_1	input:	(None, 20)
Dropout	output:	(None, 20)
dense_2	input:	(None, 20)
Dense	output:	(None, 1)

Fig. 9. Model summary of LSTM model architecture.

Bi – LSTM : BiLSTM builds on the LSTM architecture by processing the input sequence in both forward and backward directions using two separate LSTM layers. This makes it possible for the model to incorporate data from the input sequence's past and future. In a BiLSTM architecture, each input element is processed by both the forward and backward LSTMs, and the outputs from these two LSTMs are concatenated. This concatenated output is then fed into the next layer of the network, which can be another BiLSTM layer or a fully connected layer for classification or regression tasks.

Gated Recurrent Unit (GRU) : Another variety of recurrent neural network includes GRU model, that is similar to LSTM but with less parameters. It uses two gates, namely the reset gate and the update gate, to manage the stream of information.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:26:30 UTC from IEEE Xplore. Restrictions apply.

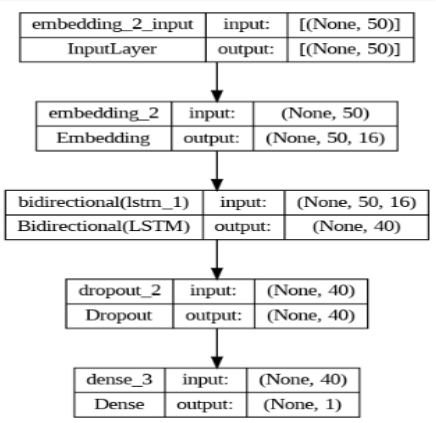

Fig. 10. Model summary of Bi-LSTM model architecture.

The reset gate ensures how much of the previous hidden state is retained for the current time step. It is a vector that is multiplied element-wise with the previous hidden state to determine which parts of it to forget and which parts to keep [23]. This mechanism allows the model to selectively remember or forget past information as needed.

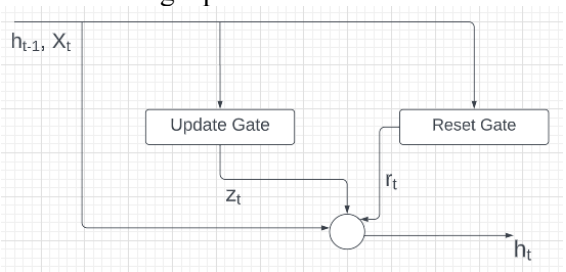

Fig. 11. Structure of GRU cell.

The update gate also ensures how much of the existing input and last hidden state are used to modify the memory cell. It is a vector that is computed based on the existing input and last hidden state, and helps in deciding the amount of information that should be added to the cell.

The hidden gate is the output of the GRU at each time step, and it is computed based on the existing input and last hidden state [24]. It is also used as the input to the next time step, allowing the model to capture information from both the past and the present of the input sequence.

GRUs have the benefit of handling long-term dependencies in sequential data without experiencing the vanishing gradient issue.

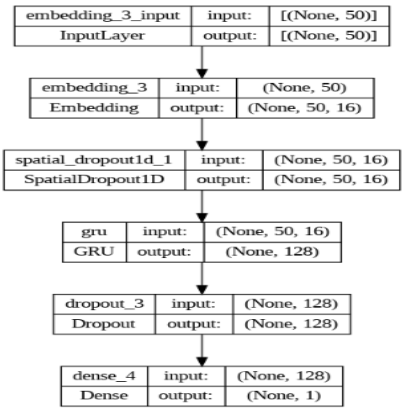

Fig. 12. Model summary of GRU model architecture.

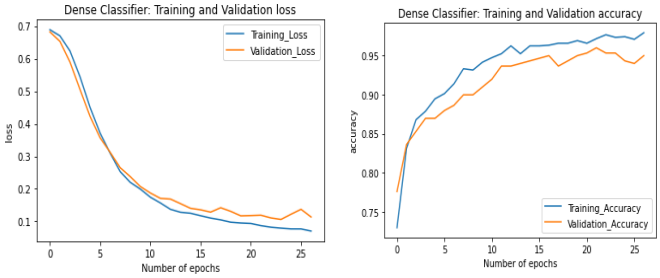
V. Results and Discussions

After training the model, the study evaluated the performance of dense network, LSTM, Bi-LSTM and GRU models and plotted the graph of loss and accuracy by number of epochs. The research also compares the results of models with different sampling techniques such as downsampling, upsampling and SMOTE sampling. However, the accuracy of model based Dense and Bi-LSTM is similar but dense model outperformed other models in different sampling techniques.

Dense Model



(i). (ii).

Fig. 13. Training and Validation plots in dense model (i) loss vs epochs (ii) accuracy vs epochs.

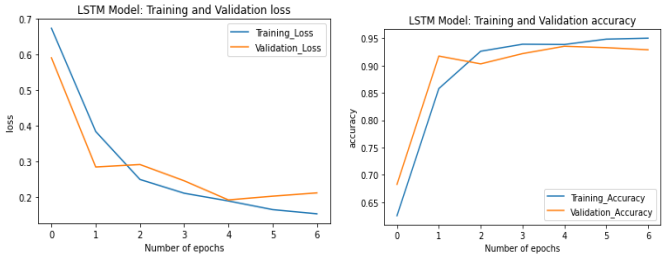
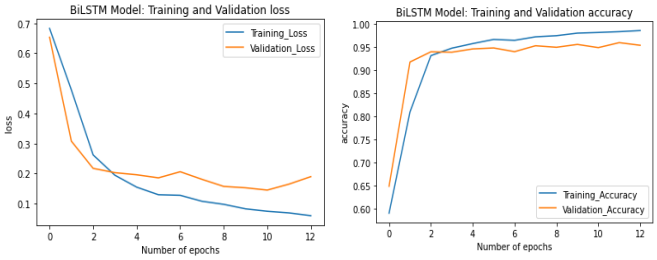
LSTM Model



(i). (ii).

Fig. 14. Training and Validation plots in LSTM model (i) loss vs epochs (ii) accuracy vs epochs.

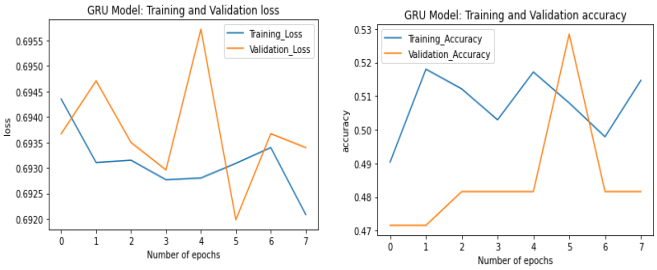
Bi-LSTM Model



(i). (ii).

Fig. 15. Training and Validation plots in Bi-LSTM model (i) loss vs epochs (ii) accuracy vs epochs.

GRU Model



(i). (ii).

Fig. 16. Training and Validation plots in GRU model (i) loss vs epochs (ii) accuracy vs epochs.

For the Dense model, the best results are obtained using upsampling, with the lowest loss and highest accuracy achieved. This indicates that upsampling was able to effectively balance the dataset and improve the performance of the model.

TABLE I. Comparison of Deep Learning Models with Different Sampling Techniques.

Models	Resampling Techniques					
	DownSampling		UpSampling		SMOTE	
	Loss	Accuracy	Loss	Accuracy	Loss	Accuracy
Dense	**0.082**	**0.9665**	**0.036**	**0.9891**	**0.11**	**0.9715**
LSTM	0.173	0.9531	0.092	0.9782	0.11	0.9689
BiLSTM	0.142	0.9565	0.062	0.9870	0.05	0.9829
GRU	0.693	0.4816	0.060	0.9777	0.06	0.9849

For the LSTM and BiLSTM models, the best results are obtained using upsampling and SMOTE techniques, with similar performance between the two techniques. This suggests that both techniques were able to address the class imbalance issue and improve the execution of the models.

In contrast, for the GRU model, the best results are

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:26:30 UTC from IEEE Xplore. Restrictions apply.

obtained using upsampling and SMOTE techniques, with the highest accuracy achieved using SMOTE. This indicates that both techniques were effective in improving the performance of the model, which was otherwise performing poorly with down sampling.

Overall, the results suggest that different resampling techniques can have varying effects on the performance of deep learning models, and the best technique will depend on the specific dataset and problem being addressed.

VI. Conclusion

In this research, the selection of the resampling technique for spam classification tasks using deep learning models can have a considerable influence on their performance. The performance of the models varied depending on the sampling technique used, with upsampling, downsampling, and SMOTE techniques each showing different levels of effectiveness depending on the specific model and dataset.

Overall, upsampling appeared to be the most effective technique, consistently improving the performance of the models across all architectures, while downsampling showed poor performance in all cases. SMOTE was also shown to be effective, particularly for the LSTM and BiLSTM models, but its effectiveness varied depending on the specific model being used.

These findings suggest that researchers and practitioners working on spam classification tasks should carefully evaluate the performance of different resampling techniques to identify the best method for their specific dataset and model.

Overall, the use of resampling techniques can be an effective strategy for addressing class imbalance and improving the performance of deep learning models for spam classification tasks.

***Abstract*—An interleaved boost converter-based full bridge phase shift converter (PSFB) for charging an electric vehicle is illustrated in this paper. To attain a PF around unity at the AC input of supply, the suggested charger uses an interleaved boost converter as a front-ended device that runs in continuous conduction mode (CCM), and PSFB to process the battery charging of the EV. Almost all boost converters run at a fixed frequency with pulse width modulation (PWM), and the PSFB converter tries to maintain the power required by the battery. This paper gives a systematic and detailed design for a 2.0 kW prototype along with a controller design for the said converters, which is designed and validated with simulation using MATLAB/Simulink whose results show that at 100 kHz switching frequency, peak efficiency is 95%, THD is maintained to be less than 5% in variation from half load to full load, and PF is constant at 0.99 from 1950 W to 2.2 kW.**

Keywords— EV charger, phase-shift full-bridge converter (PSFB), DC-DC converter, power factor correction (PFC), total harmonic distortion (THD), interleaved boost converter (ILBC).

I. INTRODUCTION

Non-renewable energy sources and their supply are rapidly running out.; Thus, research has focused more and more on renewable or "sustainable" energy sources. Electric vehicles (EVs) are gaining popularity in the automotive sector. EVs are mainly powered by motors powered by battery, and hence best possible battery technology is a requirement for now, to make E-Vehicles a proper replacement to in use conventional IC engine vehicles, it is essential to develop a battery charging device working on high power with good efficiency, excellent power factor.

As the market in Electric Vehicle (EV) sector expands, so does the demand for quick and efficient battery charging services. To reach the demand, research in the field of battery technology attempts to push the boundaries of quick charging on several fronts, such as the type of materials used, incorporated topologies and design of cell package. Although from the perspective of energy transfer, the vehicle battery and its charger are the most pivotal elements of the charging process, Nevertheless, the adopted charging technique also has a big impact on the entire procedure, specifying how this circuital energy gets transmitted from the charger to the vehicle battery, to make EVs a viable choice. [1]

In today's light electric vehicles (LEVs) sector, the power capacity of the main battery is kept at around 10kW. At this rating, a 2 kW battery charger is decent to use. With the ability to be plugged directly into an AC mains outlet, on□board chargers are handy, but regulating the supply of current power from sources like domestic, commercial, and charging stations is important.[2]

Typically, a diode bridge rectifier (DBR) followed by a DC link capacitor is initially constituted in battery chargers, which is followed by an isolated DC-DC converter working on a high frequency. This arrangement leads to poorly formed and out of phase current waveform to a voltage waveform, producing a low input power factor which adversely affects the supply, and to match the required quality standards, a power factor correction (PFC) device is also used in the battery charger. [3]

The objective here is to develop an efficient, safe, economical better power quality EV Charger with low charging time. Out of various acceptable line current conditioning converters and PFC topologies are explained in [4-6], the ILBC has shown to be one of the most dependable and efficient solutions for line regulation as well for supply current shaping. And similarly among all available different topologies of DC-DC converter [7-9], The PSFB converter as it has a high efficiency among all, becomes a recommended DC-DC converter for car batteries. This is made possible by the PSFB converter devices' ability to switch at zero voltage, which allows for a greater operating frequency and reduced magnetic size for the converter..

II. TOPOLOGY SELECTION

In Fig. 1 the employed EV Charger topology diagram. On the primary side of the system, we have an interleaved boost converter. The interleaved boost converter has the advantage of paralleling the switching devices. Cancelling the ripple (likely to be reduced to half at least) at the output while effectively increasing the switching frequency, it also reduces stress on the output capacitor, hence reducing the filter size. As the wattage rating rises, it is frequently necessary to connect converters in a cascaded manner. Interleaving two boost converters is frequently used in high-power applications to enhance performance and decrease the size of the PFC device. Furthermore, for higher current applications and voltage step-ups, the currents flowing through the switches become mere fractions of the supply current. [4]

For the n-channel interleaved PFC circuit, the PFC channels are operated (360/n) phase shifted from each other. The study in [6] shows that to achieve high efficiency and PF the interleaved configuration is preferred. The results of different simulations in Table 1 show the efficiency for interleaved topology is over 96% and the PF can be up to 0.99 for the entire universal line range at full load.

The second stage of the charger is a DC-to-DC converter. It regulates the charging and discharging of the vehicle, here on the secondary side, regulation is achieved with the phase shift full bridge rectifier (PSFB) maintaining the power flow control to the battery.

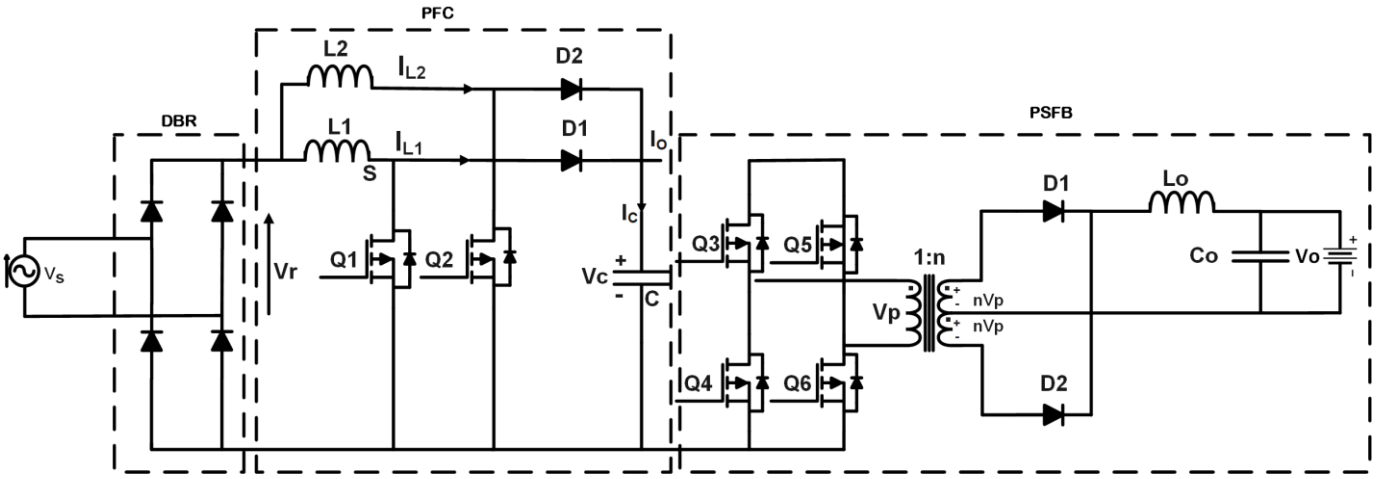

Figure 1 : Circuit Diagram of a proposed PFC Interleaved boost converter fed PSFB converter.

Table 1: COMPARISON OF AC–DC PFC TOPOLOGIES FOR BATTERY CHARGING

Topology	Efficiency	THD	Power Rating
Boost	93	5.64	<1000W
Interleaved	97	3.4	<3000W
Bridgeless	96	4.83	>3000W
Semi-Bridgeless	98	5.0	>3000W

III. WORKING PRINCIPLE OF PROPOSED CHARGER

The said EV charger device as shown in Fig. 1 employs two separate converters, each with a specific set of functions as explained in the prior segment. Though the foremost aim of the PFC interleaved converter is to keep supply current distortion and harmonics free with a well-regulated DC link voltage, The PFC output voltage, V_c, acts as an input of the PSFB converter, which charges the EV battery. As the regulation in the line voltage and so in DC link voltage is less likely.

An interleaved dual inductor boost PFC converter is proposed for the first-stage setup. So it regulates the output voltage to the desired value while improving the input power factor.The Average current controller is used to achieve PFC. Interleaved PFC topology corporate power switches and their body diodes for the rectification process. This topology operates with either duty ratio D higher than 0.5 or lower than 0.5 depending on whether the input voltage is less than or greater than half of the output voltage. As mentioned in [10], Interleaving is achieved by a phase shift of 360/n° between the PWM signals of the switch controllers. Two current loops are shown in Fig. 2(a) is provided for two inductors L_1 and L_2. The input current is the sum of the two inductor currents in L_1 and L_2. The ripple currents among these interleaved inductors are out of phase, which makes them neutralize the effect, therefore bringing down the high-frequency ripple current of supply caused by the converters' switching action, and so the EMI filter at the input can be made smaller. For equal sharing of load between converter interleaved channels, the net reference value of voltage loop controller is chopped down to half, which is given as a reference to every current controller.

Working of a PSFB DC-DC converter as explained in detail in [11,12]. Switching legs operate within fewer than 50% of duty, but they're given a shift in phase between both the switching legs of the converter. This phase shift determines enhancement in voltage, The switching pulses are separated by dead time, given to the switching leg in order to give parasitic capacitance adequate time to release or store the charge. The output variation of this converter is influenced by the duty cycle and its loss. There can be multiple sources for duty cycle loss in this type of converter. One among them can be because to the dead time given between the switching legs, and the other can be due to ΔD which occurs with the reversal of the primary current. Marking secondary voltage to zero, Effective duty ratio (D_e) is given by

$$D_e = D - \mu - \Delta D \tag{1}$$

Where μ is the value of loss in the duty cycle due to dead time. Indecent value of dead time can result incorporate in the loss of ZVS, reduced efficiency, or even up to the device failure due to shoot-through.

IV. DESIGN OF PROPOSED CHARGER MODEL

The design of the converter is carried out for a 2 kW operation rating, working in CCM mode at the switching frequency in kHz's with assumptions such as that the switching devices are ideal is considered for ease of understanding.

A. The PFC InterleavedBoost Converter

A 230V AC (RMS) supply with a supply frequency of 50Hz is given to the filter circuit which uses a capacitor as a filter. Once after rectification, capacitors remove the ripple and smoothen the pulsating DC output so a near to constant DC voltage is supplied. For high power application, more than one boost cell can be operated in parallel to increase the power capability of the PFC circuit and reduce the capacitor current ripple, known as interleaved system.

For our system to work at the rated output power of 2kW, with the regulated DC link voltage (V_c) maintain at 400V under normal conditions. The duty cycle for the same can be expressed as

$$D = \frac{V_C - V_i}{V_C} \tag{2}$$

where V_i is the peak value of the voltage supply and can be represented as $\sqrt{2}$ times of AC line Voltage (V_S). At times of the lowest AC line voltage supply, i.e 200V the maximum current from the input line will pass and so will the highest value of Duty Cycle will be reached which will make the (2) as

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:52:12 UTC from IEEE Xplore. Restrictions apply.

$$D_{\max} = \frac{V_C - \sqrt{2}\,V_{S\min}}{V_C} = \frac{400 - \sqrt{2}(200)}{400} = 0.3 \quad (3)$$

Considering the inductor ripple current to be 20% of the inductor current for both of the inductor values.

$$\begin{aligned}\Delta i_{L1} = \Delta i_{L2} &= \frac{P_o}{V_C}.20\% \\ &= \frac{2000}{400} * 0.20 \\ &= 1A\end{aligned} \quad (4)$$

Major part of design process is the selection of inductor value, as that assures the proper PFC functionality. The selection of this value depends on inductor ripple current.

$$L = \frac{V_i * D}{f_S . \Delta i_L} \quad (5)$$

From (3), the value of inductor L_1 *and* L_2 are calculated as

$$\begin{aligned}L_1 = L_2 &= \frac{400 * 0.3}{50000 * 1} \\ &= 2.4mH\end{aligned} \quad (6)$$

The ripple in DC link voltage (ΔV_C) is taken at 1% of its nominal value.

$$\Delta V_C = \frac{1 * 400}{100} = 4V \quad (7)$$

From (6) the output capacitor can be estimated at the given voltage ripple.

$$\begin{aligned}C &\geq \frac{P_O}{4\pi f_{Supply} * V_C * \Delta V_C} \\ &\geq 1986\mu F\end{aligned} \quad (8)$$

B. The PSFB DC-DC Conveter

In this part of the system, voltage at the DC link capacitor output of the previous stage converter works as input of an isolated full bridge phase shift (PSFB) DC to DC Converter for the vehicle charging. Batteries of these vehicles are generally made of lithium ion phosphate (LFP) cell, charging around at 48V.

The equation for output voltage in PSFB can be expressed as,

$$V_O = 2 * V_C * n * D \quad (9)$$

where, V_O is the demand voltage of battery load from the converter for charging, V_C is the input fed to the DC-DC Converter from the previous state and n is the ratio of secondary to primary side of transformer and D is the duty cycle for the converter.

The Value of D should be less than 50% for avoiding the saturation of the core [11].

$$n = \frac{Ns}{Np} = \frac{50}{400} = 0.125 \quad (10)$$

If the output Voltage of the charger is expected to be at 48V the from (9) & (10) we get D to be 48%,

$$\begin{aligned}48 &= 2 * 400 * 0.125 * D \\ D &= 0.48\end{aligned} \quad (11)$$

The Value of Filter Inductor is calculated for 20% inductor ripple current,

$$\begin{aligned}\Delta i_{Lo} &= \frac{P_O}{V_O}.20\% \\ &= \frac{2000}{48} * 0.2 \\ &= 8.3A\end{aligned} \quad (12)$$

Transformer leakage inductance (L_k) often referred as shim inductance also, calculated with equation (13) as in the same load condition, it stores more energy than parasitic capacitance does, helping in achieving the Zero Voltage Switching (ZVS) condition.

$$L_K > 2C_{OAVG(eff)} X \frac{V^2_{dc}}{I_P} \quad (13)$$

Hence, form (12) we get the value of output inductor

$$L_O = \frac{V_O(1-D)}{2 * \Delta i_{LO} * f_{SW}} \quad (14)$$

The switching frequency (f_{SW}) of the DC-DC Converter is 500 KHz, upon substituting the parameters in (14) we get,

$$\begin{aligned}L_O &= \frac{48(1-0.48)}{2 * 8.3 * 100000} \\ &= 15.03\mu H\end{aligned} \quad (15)$$

Similarly, the output capacitor depends upon the voltage ripple and can be measured by,

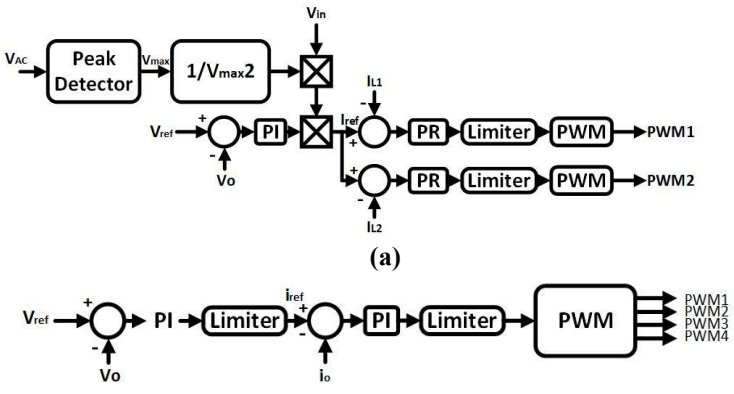

Figure 2: Control Algorithm for (a) PFC Converter (b) PSFB DC-DC Converter

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:52:12 UTC from IEEE Xplore. Restrictions apply.

$$C_O = \Delta_{iL} * \frac{D}{f_{SW} * \Delta V_O} \quad (16)$$

Where the ΔV_O is the output ripple voltage, kept at 1%, giving the output capacitance to be around 100uF.

V. CONTROL SCHEME OF PROPOSED SYSTEM

Controller of both the PFC part & PSFB Converter part of the charger, shown below in fig. 2(a) and (b) respectively are made of two controller loops, one for a Voltage and other for Current Control. Small signal modeling is crucial to the right controller design for any converter controller. The parameters for the controllers' are derived from the required dynamic behavior, requirements, & aims [5], [9]. The interleaved bridgeless power stage is almost identical to the traditional boost converter. As a result, the converter's single channel is modeled.

A. *Design of Voltage Control Loop*

A voltage control loop is a pre-regulator with a sluggish response time, here we measure the output voltage and compare it with a reference voltage, the difference in both the voltages is what we consider as an error and that is fed to an PI controller, the output of which is given to a PWM generator which generates the Phase shift PWM signal pairs, which are fed to the switching devices.

B. *Design of Current Control Loop*

Current control loop is immediate in nature, and creates inductor currents so that they are sinusoidal and in-phase with the rectified line voltage input. For all current control loop reference current (i_L*) is obtained via outer band of voltage control loop. This Controllers' Output is compared with an saw tooth carrier signal with unity amplitude, which generates the duty cycle. Since the reference current is sinusoidal in shape, PR controller gives better performance and zero steady state error

In PSFB DC-DC Converter a limiter is provided at both the voltage and current control loop of the controller, while the limiter at voltage loop restricts the battery charging current and the same limits the phase shift of PWM to 180°.

VI. SIMULATION RESULT

A simulation prototype of the suggested EV charger is simulated using the MATLAB/SIMULINK software. Table 2 lists all of the parameters that were determined in section IV.

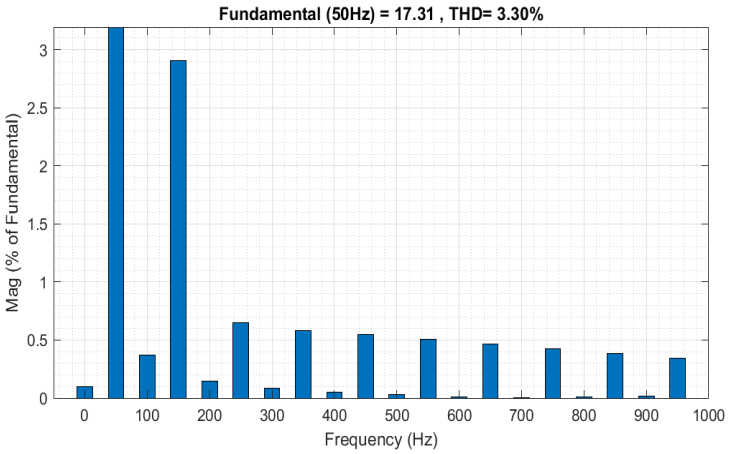

Figure 3: THD (%) of the input current

Table 2: PARAMETERS FOR TAKEN BATTERY CHARGING MODEL

Parameter	Variable	Value
Supply Voltage	V_s	230V
Input inductor	L_1,L_2	3mH
DC-link Voltage	V_C	400V
DC-link Capacitance	C	2000 µ F
Transformer Ratio	n	0.125
Filter Inductance	L_o	15 µ H
Filter Capacitance	C_o	100 µ *F*
Output Power	P_o	2kW
Switching Frequency	F_{sw}	100Khz

The performance results of both the stages of the charger are displayed and discussed under steady and dynamic behavior .

A. Performance at steady-state for the PFC-Interleaved Boost converter

Under steady-state operation, Waveforms of the voltage supplied from grid, supply current and the voltage at the output of the PFC converter are provided in Fig.5 for the said test conditions at switching frequency of 50 kHz the output of the bus voltage is maintained at 400Vdc. The supply current and the supply voltage are well in phase, having a nearly perfect sinusoidal waveform, as expected. Maximum amplitude of the sinusoidal waveform of the AC mains supply current is scaled up 5 times in waveform for sinusoidal behavior study. With a maximum inductor current of 6.5A, I_{L1}, I_{L2} are functioning in CCM which is effectively obtained using the Proportional-Integral Controller.

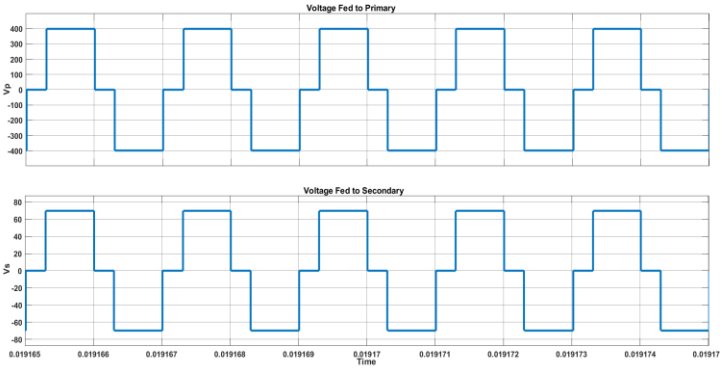

Figure 4: Primary and Secondary Voltages Waveform of high frequency transformer

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:52:12 UTC from IEEE Xplore. Restrictions apply.

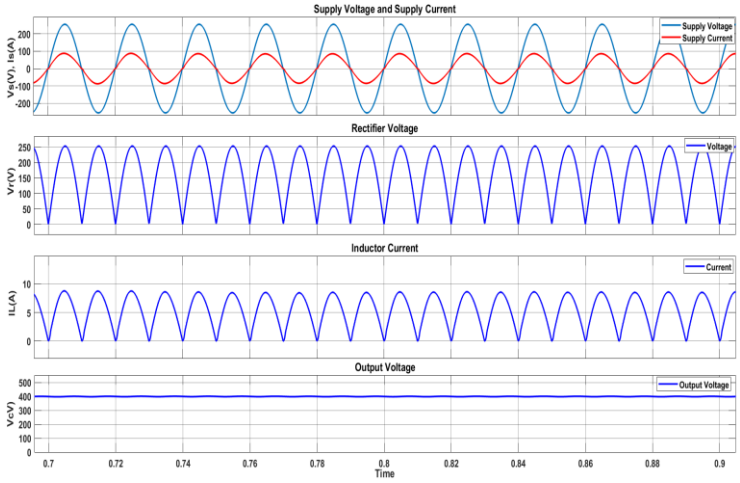

Figure 5: Steady-State performance for supply current (Is) and Voltage (Vs), Rectified Voltage (V_r), Inductor current (I_{L1}, I_{L2}) & DC-link voltage (V_{dc}) at supply voltage (Vs) = 220V

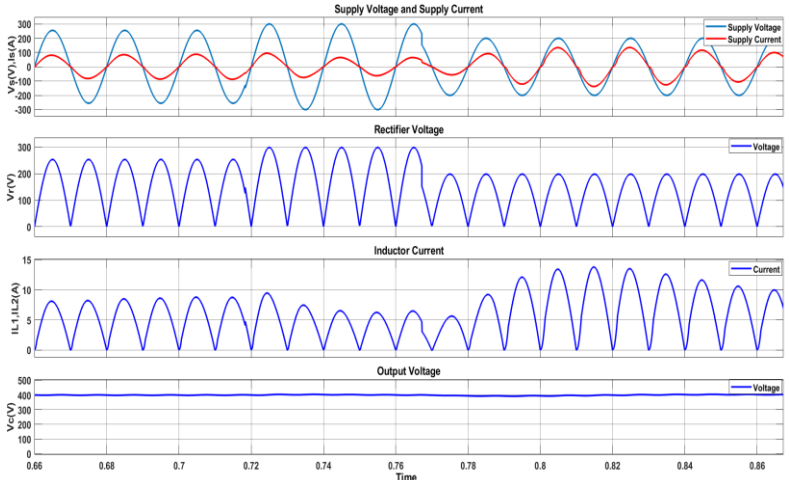

Figure 7: System Dynamic performance of supply current (Is) and Voltage (Vs), Rectified Voltage (V_r), Inductor current (I_{L1}, I_{L2}) & DC-link voltage (V_{dc}) at variable supply voltage.

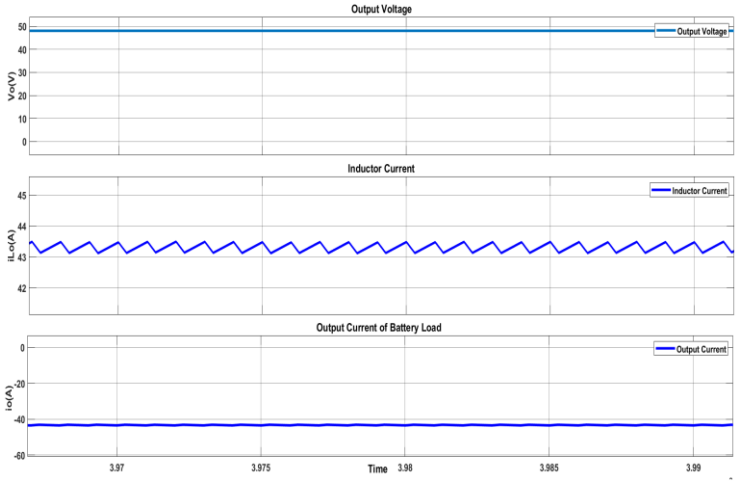

Figure 6: Steady-State performance of PSFB DC-DC for Output Voltage (V_O), Inductor current (I_{LO}) & Battery Load Current (i_O) at full load

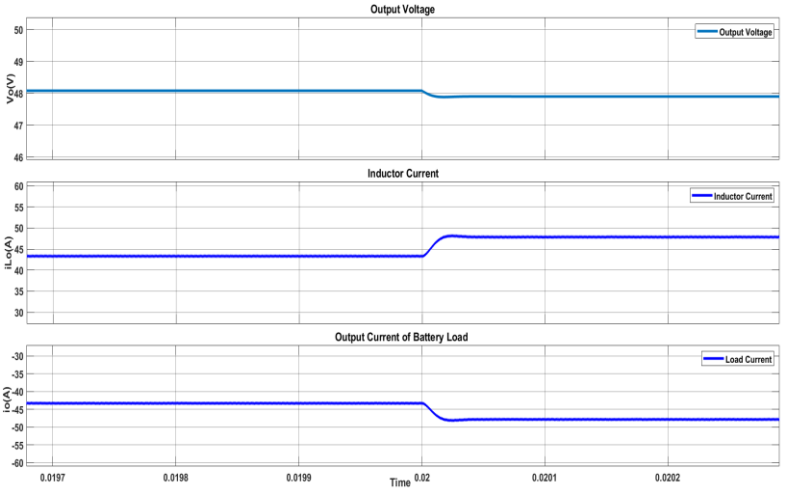

Figure 8: System dynamic performance of PSFB DC-DC for Battery Voltage (V_O), Inductor current (I_{LO}) & Battery Load Current (i_O) at variable load

B. Performance at steady-state for the PSFB converter.

The phase shifted waveforms of primary and secondary voltages of high frequency transformer are shown in Fig. 6. Given a load current of 42A, the output of PSFB converter is regulated at 48V. Inductor current has a 43.5A peak value when the current waveform is triangular, which is the region most suited for the converter's ideal performance, as seen by the waveforms of I_{Lo}.

C. Performance of the dynamic behavior for the PFC-Interleaved Boost converter.

Fig.7 displays dynamic performance of PFC-Boost converter over a variety of input voltages. To examine the dynamic behavior, PFC-Boost is analyzed with varying the supply voltage to 10% up and down.In the beginning, V_s was kept at 230V initially as in ideal condition and after that rises to 250V at 0.7 second which then later dropped to 200V at time 0.77 second. Figure 7 also shows that the source current decreases as the supply voltage rises and rises as the supply voltage falls with a harmonic free waveform. I_{L1} & I_{L2} both are following same patter as shown in fig. 7 and. V_{dc} is maintained to be constant throughout even with varying V_s because of good PI-controller tuning.

D. Performance of the dynamic behavior for the PSFB converter.

The second stage converter's dynamic performance is confirmed by changing load from 2.0KW to 2.20KW. PI-Controller well regulates and keeps the output voltage constant. Io goes from 44A to 48A in terms of load current. Figure 8 illustrates the same behavior of the load variation of the system.

VII. CONCLUSION

Design of an EV battery charger rated at 2KW, which consists of ILBL type PFC as a front end converter followed by a PSFB converter is described in this paper. Power factor of the supply is obtained near to unity. Results of the simulated model are presented with design model and waveforms. This topology has less switching losses, better PF value and can also be implemented for high power ratings, exhibiting excellent transient and steady state behaviors. The system PF range i also provided for the supply voltage variation ranging from 180 V to 250 V input. The power factor is maintained at 0.99 for full load. The designed converter gains its peak efficiency of 95% at 100kHz switching frequency, 220V input and 2 kW output power.

Table 3 summarizes information for various Vs and the resulting PFs, Is, THD and system efficiency at constant 2KW full load.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:52:12 UTC from IEEE Xplore. Restrictions apply.

Table 3: SYSTEM CURRENT THD AND SYSTEM EFFICIENCY WITH RESPECT TO SUPPLY VOLTAGE

V_S (V)`	I_S(A)	PF	THD (%)	Efficiency (%)
180	11.7	0.995	3.46	95.7
190	11.5	0.996	4.22	92.2
200	10.75	0.992	3.56	93.7
210	10.2	0.9994	4.02	94.2
220	9.6	0.9998	4.12	95.0
230	9.34	0.9998	3.47	94.6
240	9.0	0.9998	3.19	94.4
250	8.5	0.9997	3.51	94.8

VIII. FUTURE SCOPE

The future scope EV chargers largely depends on the development and adoption of electric vehicles (EVs) and the associated infrastructure. While Level 1 chargers are relatively slower compared to higher-level chargers, they still play a significant role in the overall EV charging landscape. Residential level charging, workplace and destination charging, smart and wireless charging are some potential future trends and possibilities for Level 1 EV chargers.

ABSTRACT

Wireless sensor networks (WSNs) are an emerging military and civilian technology that uses sensors. Sensor networks are hierarchical and chaotic in remote, unmonitored sites. Wireless sensor networks pose unique security threats due to their public location and wireless transmission. WSNs are vulnerable to various routing attacks, including Black holes, Sybil, sinkholes and wormholes. In this paper, we proposed advanced intrusion detection systems based on hybrid machine learning (AIDS-HML) in wireless sensor networks to identify and classify attacks. Hybrid machine learning classifiers identify wireless sensor network dangers. Benchmark datasets are used to compare the proposed model to baseline models in terms of precision, recall, f1-score, and accuracy. The scheme is trained and evaluates prediction models. This confirms that the detection accuracy achieved 99.80% using the NSL-KDD benchmark dataset based on hybrid random forest and extreme gradient boost (RF-XGB). The hybrid cluster labelling K-Means (CLK-M) s achieved better classification accuracy of 100% using UNSW_NB15, and CICIDS2017 benchmark datasets for binary classification of label attacks. Different attack detection metrics were compared against various benchmark datasets to evaluate the quality of this work. The proposed system is efficient in simulations for feature extraction and route discovery and detection attacks achieving an accuracy of 99.46%.

1. Introduction

Wireless sensor networks (WSNs) are Affordable and low-power sensor nodes (Gao, 2014). Sensor nodes with multi-hop routing and self-organising intelligent sensor networks fall into this category (Gebreyesus, 2021). WSNs are autonomous spatially disseminated devices using sensors for physical and environmental conditions. Cooperatively, nodes in WSNs collect data on some physical or environmental characteristic, including noise, vibration, temperature, pressure, motion, or pollution, and relay that data to a hub node (Alsaedi et al., 2017; Farooqi et al., 2013; Han et al., 2019; Pundir et al., 2020). Raw data sensed and collected

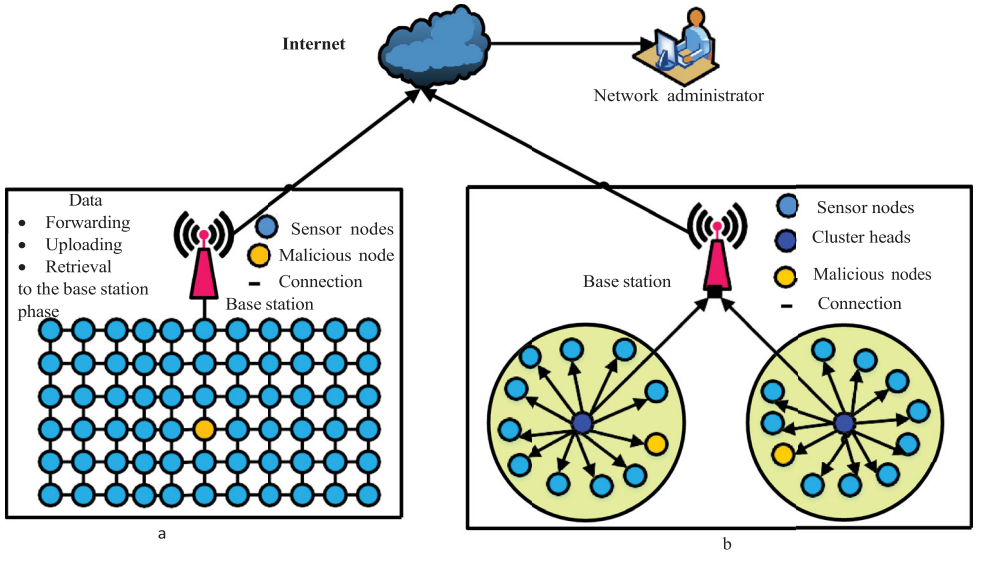

Figure 1. Architecture of distributed (a) and hierarchical (b) WSNs.

sent to the cluster head was stored and analysed at the base station (Blywis, 2009; Choi et al., 2004) as shown in Figure 1. WSNs are composed of self- configured and connected by radio signals having a low operating battery and low cost distributed hierarchically and randomly (Saravana Kumar et al., 2021; Singh et al., 2017). WSNs are recent technology and have gained significant attention for research scenarios (Singh et al., 2017). They comprise low-power and cost sensors randomly distributed over the target localisation. The sensors are distributed to act on specific tasks (Mangrulkar & Negandhi, 2018; Rouissi et al., 2019). The sensors have sensing and signal processing capabilities and activate wireless communication in WSNs (Vinitha et al., 2019). In WSNs, A gat way provides wireless connectivity using wired and distributed nodes. WSNs are the main components of the internet of things (IoT), with small, low-power sensors for data collecting and monitoring from the environment (Saidi et al., 2020; Zhao et al., 2023). Wireless sensor nodes can be configured as distributed or hierarchical fashion in the target area for deployment as shown in Figure 1.

The frequency of cyber-attacks targeting international businesses is increasing, leading to the rapid development of intrusion detection systems (IDS) in both industry and academia (Mahbooba et al., 2021). The availability and confidentiality of the data may have been compromised as a result of attempts by attackers to break the network's security through vulnerabilities in the security measures (Abdulganiyu et al., 2023). IDS is a network security solution that collects and analyses network data to detect abnormal behaviour and protect system resources (Zhang et al., 2020). It is crucial in maintaining network security (Wang et al., 2021). Anomalies and misuse are two types of intrusions that can occur in WSNs. Anomaly detection utilises mathematical models and compares estimated feature values with reference values to identify deviations from normal behaviour (Godala & Vaddella, 2020). Misuse detection, on the other hand, relies on previously observed malicious activities and their specific patterns to identify intrusions.

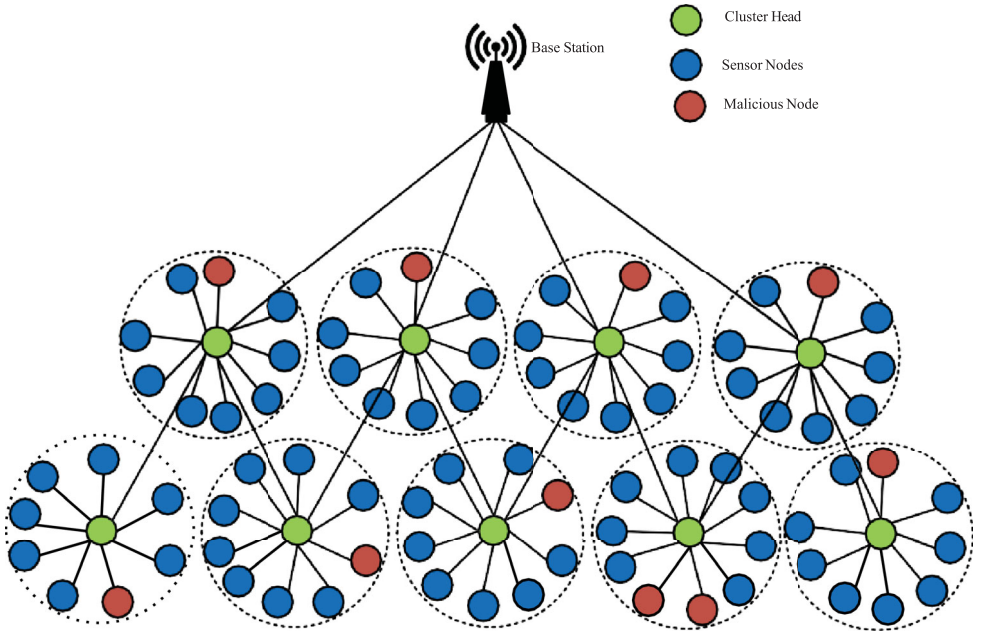

Figure 2. Wireless sensor networks model with clustering Nodes for data aggregation to the sink node.

Common causes of cybercrimes include DoS and web attacks. Attacks in WSNs can be active or passive, involving unauthorised eavesdropping, information gathering, and packet manipulation (Elsaid & Albatati, 2020). To ensure protection, WSNs employ two layers of defence. intrusion detection and prevention technologies. IDS tracks intruders, their activities, time, location, and network layer, providing valuable information to system administrators (Elsaid & Albatati, 2020). Cybercrimes pose significant threats to businesses as they introduce malicious attacks into networks. Intrusion detection is vital to cybersecurity and involves examining and identifying security breaches in an information system.

Machine learning (ML) techniques offer generic solutions and continuously improve their performance (Praveen Kumar et al., 2019). In WSNs, ML finds applications in various fields, enhancing performance and reducing the need for manual maintenance. It facilitates information extraction from large sensor-generated data, enabling machine-to-machine (M2M) communications, cyber-physical systems, and the Internet of Things (IoT). ML proves valuable in WSNs for optimising sensor nodes, energy management, localisation, node classification, routing, and detecting attacks across multiple layers of sensor networks. Machine learning strategies are employed for selecting the cluster head to enhance energy performance in Wireless Sensor Networks (WSNs) as shown in Figure 2.

ML techniques also helpful in detecting and removing malicious nodes at the cluster head, improving network reliability and operational lifetime (Praveen Kumar et al., 2019). ML algorithms efficiently classify DoS attacks and handle data aggregation and forwarding tasks to the sink node. Data aggregation plays a critical role in WSNs, impacting energy consumption, storage requirements, network load, and processing speed as in Figure 2. Various data aggregation methods, such as cluster-based, tree-based, in-network,

or centralised approaches, can improve network reliability and lifespan. ML algorithms offer advantages in collecting and organising data, contributing to the security and efficiency of WSNs.

1.1. Problem statement

The problem addressed in this research is developing an advanced Intrusion Detection System (IDS) based on hybrid machine learning (AIDS-HML) to protect hierarchically structured Wireless Sensor Networks (WSNs). Current IDSs face difficulties achieving high detection accuracy and minimising false alarms. The hierarchical organisation of sensor nodes adds complexity to the design of advanced IDSs (Paliwal & Kumar, 2018).. The objective is to create a robust and efficient IDS that effectively identifies and responds to intrusions while considering the hierarchical structure of the WSN. Specific challenges to be addressed include:

1. Developing a hierarchical IDS architecture that can adapt to the structure of the WSN and effectively handle data collection and aggregation.
2. Extracting relevant features from sensor data in a resource-constrained environment and employing techniques to reduce dimensionality and select the most informative features.
3. Integrating multiple machine learning algorithms in a hybrid approach to leverage their strengths and enhance intrusion detection accuracy.
4. Addressing the challenge of stolen sensitive information in WSNs, where the absence of physical defence lines makes it crucial to monitor network traffic flow.
5. Evaluating the proposed IDS in terms of detection accuracy, recall, precision, false alarm rate, resource utilisation, and scalability.

Addressing these challenges will contribute to developing advanced IDSs tailored for hierarchically structured WSNs, providing enhanced security and maintaining the efficiency of the network. The proposed solution will aim to overcome the limitations of existing IDSs and provide insights into the effective integration of hybrid machine learning techniques in the context of WSNs. The NSL-KDD, UNSW_NB15, and CICIDS2017 datasets are utilised for training and testing, serving as benchmarks for evaluating the proposed system. Specifically, the NSL-KDD dataset, which includes four types of attacks (Root to Local attacks, Denial of Service, Probing, and User to Root attacks), is used to test the effectiveness of the proposed approach.

1.2. Research motivation

Attacks affect Wireless Sensor Networks (WSNs) applied in different applications, including healthcare systems, industrial applications, traffic light management systems, and intelligent power generation and distribution systems for keeping the real-time demand. So it is essential to survey and study hybrid security methods by combining two schemes, such as hybrid IDS, hybrid routing, and hybrid anomaly detection techniques. Hybrid security techniques are famous for the detection of attacks in WSNs. The hybrid security techniques utilise datasets and hybrid models to evaluate the system's effectiveness for attack

classification and detection. The significant contributions of this work are to explore the various hybrid security techniques in wireless sensor networks as follows.

1. Design and simulate a secure attack detection scheme against routing attack scenarios in wireless sensor networks.
2. Explore the various design of hybrid security techniques using a combined attack-defence strategy.
3. Explore data processing transformation techniques for evaluating security performance using benchmark datasets.
4. Exploration of the various hybrid machine learning models for effective DoS attack detection and classification using a public dataset to evaluate the system's effectiveness.
5. Explore wormhole tunnels and routing techniques to provide the optimal path for data transmission nodes and suitable solutions for secure routing and monitoring mechanisms.
6. Analyse the Location and detection of multiple attacks like a wormhole and black hole attacks using hybrid and combined schemes.
7. Explore the hybrid techniques used for WSNs traffic analysis and detecting complicated attacks with the public dataset with normal and malicious behaviours of the network traffic data.

1.3. Paper of contribution

This paper's primary contribution is to set a novel, hybrid machine-learning approach for intrusion detection to bolster the security and performance of WSNs while minimising resource consumption. In the past, many IDS strategies have been implemented with benchmark machine learning approaches to improve the detection accuracy of WSN assaults. However, as the quantity and interconnectivity of wireless sensor nodes grow, the frequency with which routing assaults are launched also rises. Here are some key contributions of this research:

- Design and planning of secure advanced intrusion detection systems for scalable and resources optimised WSNs.
- The research specifically addresses the challenges of hierarchically structured WSNs. By considering the multi-level organisation of sensor nodes, the IDS can adapt its detection mechanisms more effectively, providing improved coverage and response throughout the network.
- Explore how advanced hybrid machine learning models can be used in WSNs intrusion detection systems with metrics to examine the most important aspects of intrusion detection systems.
- The research provides valuable insights into the effective integration of different machine learning approaches in the context of WSNs. This knowledge can be extended to other domains where hybrid ML solutions may be beneficial.
- It helps decrease the number of false alarms and boosts the efficiency of intrusion detection systems for Secure data transmission across the network for data privacy and protection in WSNs.

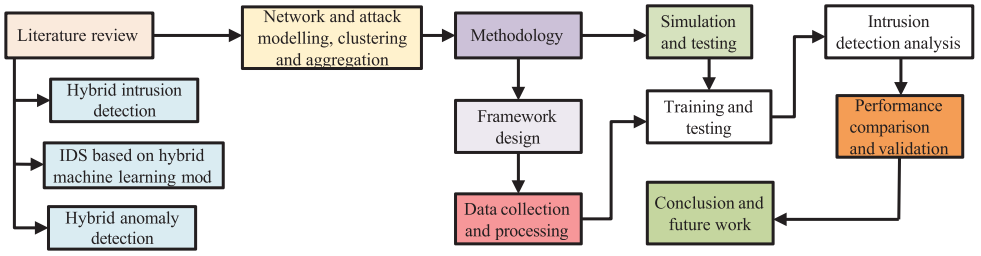

Figure 3. The organisation and framework of the proposed work.

The other sections of this paper are divided into distinct parts for easier readability and comprehension. The first section provides a high-level overview of wireless sensor networks, sensor clustering, our inspiration for this study, and the results. Section 2 summarises prior research on sophisticated machine-learning strategies that utilise IDS data. Section 3 explains the network models underpinning the proposed hybrid security system for intrusion detection. Methodology and dataset processing for hybrid security methods are described in Section 4. In part 5, we will examine the simulation and its outcomes. Section 6 depicts the experimental setup, data collection, and analysis, while the final section discusses the takeaways and suggestions for the future as depicted as shown in Figure 3.

2. Related works

This section's extensive literature review is conducted on various hybrid security techniques, including hybrid intrusion detection systems, machine learning techniques, and anomaly detection using benchmark datasets. The hybrid techniques effectively detect WSN attacks such as wormholes, flooding, sinkhole, and Sybil attacks in WSNs. These include hybrid intrusion detection systems, advanced HIDS, and intelligent and artificial immune hybrid intrusion detection systems (AIHIDS) (Singh et al., 2017). The hybrid routing protocols, hybrid misuse, hybrid optimisation algorithms, anomaly detection techniques, and hybrid clustering techniques are discussed in this section.

2.1. Hybrid intrusion detection systems

(Singh et al., 2017) presented an Advanced Hybrid Intrusion Detection System (AHIDS) for Wireless Sensor Networks (WSNs). AHIDS employs a cluster-based architecture with an improved LEACH protocol to reduce power consumption in sensor nodes. Hybrid Artificial Neural Networks (HANNs) are used to detect and classify potential threats like Sybil, wormhole, and Hello flood attacks. The proposed system achieved high detection rates: 99.40% for Sybil attacks, 98.20% for Hello flood attacks, and 99.20% for wormhole attacks. Similarly, (Cepheli et al., 2016) examined a hybrid intrusion detection technique that combines flexible and tunable parameters using parallel detection methods. Their hybrid system, guided by a central node, improves DDoS attack detection accuracy. Figure 4 shows signature-based and anomaly-detection block diagrams for attack detection as normal traffic and DDoS attacks.

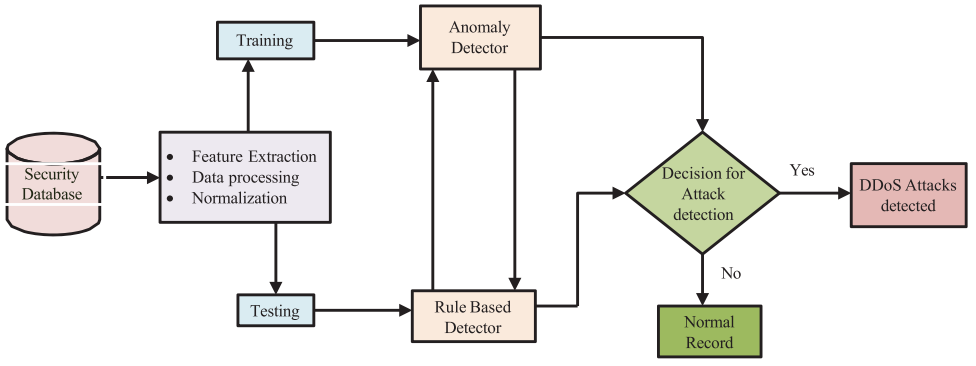

Figure 4. hybrid intrusion detection model with anomaly detector and rule-based detector.

The detection process analyses network traffic and extracts building activity model features. DARPA 2000 dataset is used to evaluate the intrusion detection system, focusing on DDoS attacks and normal network traffic. The hybrid detection employs anomaly and signature detectors. Anomaly detector identifies normal and abnormal traffic data through feature extraction, while the signature detector uses predefined sets for traffic data features. AHIDS uses anomaly detection blocks to identify normal and abnormal data packets and misuse detection blocks to recognise various attacks as shown in Figure 4. The detection of malicious nodes in AHIDS, based on fuzzy rules, involves three steps as follow:

- It measures the transmission of data packet history in WSNs through base nodes.
- It selects the feature set and looking the key elements for packet classification.
- Anomaly intrusion detection techniques are established based on data packet resolution.

The fuzzy-based intrusion detection technique uses MPNN, which consists of BPNN and FFNN for anomaly and misuse detection, as shown in Figure 5. It is applied for the highest detection rate using supervising learning technique. The fuzzy base AHIDS with FFNN and BPNN achieves greater attack detection accuracy using massive clustered training. The multilayer perception is utilised for estimating the error rate, e_i, using the formula as in Equation (1).

$$e_i = d_i - a_i \tag{1}$$

Where d_i represents the preferred output and a_i is the true output obtained from MPNN. The MPNN model consists of BPNN and FFNN and is applied to evaluate the detection accuracy of the various class attacks in WSNs.

The MPNN utilises BPNN and FFNN techniques for IHIDS to manage huge datasets and the system's stability. FFNN detects the new type of attacks, and BPNN clusters the mysterious attacks for MPNN supervised learning. The membership vector applied for the fuzziness F(V) is given by Equation (2).

$$F(V) = -\frac{1}{n}\sum_{k=1}^{n}(\mu_i \log \mu_i) + (1-\mu_i)\log(1-\mu_i) \tag{2}$$

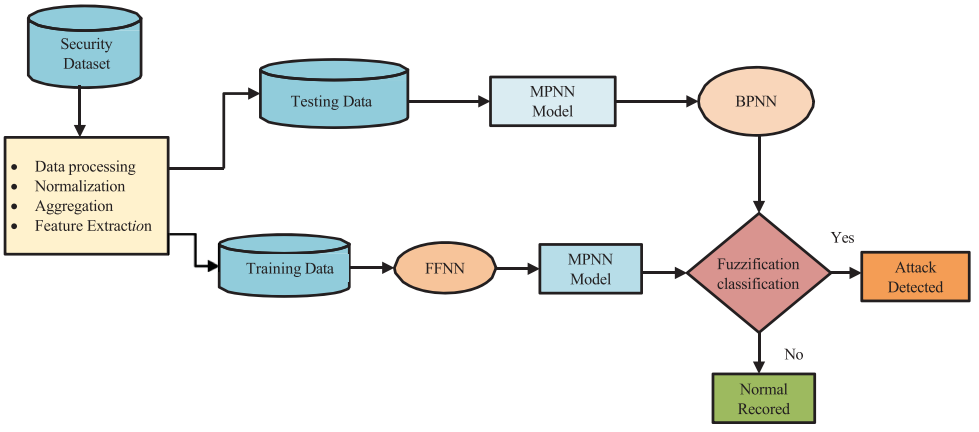

Figure 5. Block diagram for advanced and hybrid intrusion detection system.

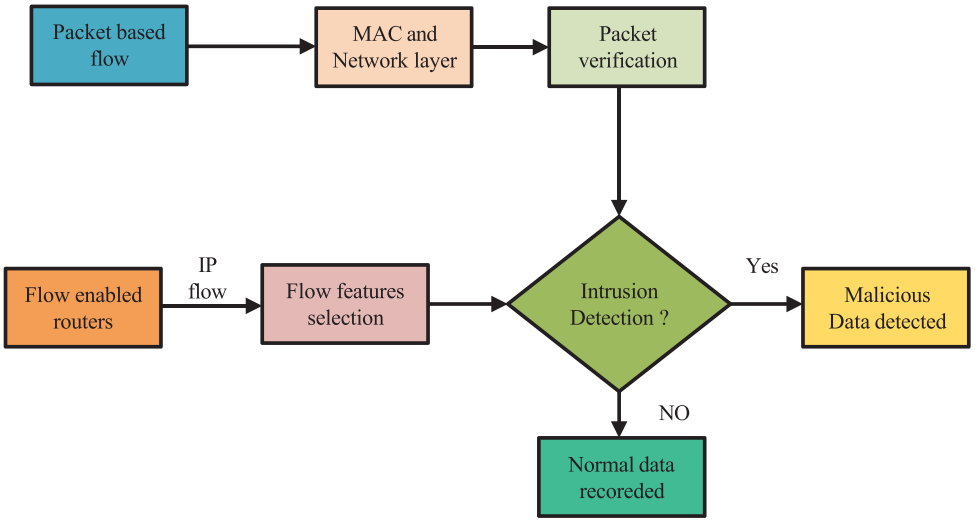

Figure 6. Block diagram of an intrusion detection system using the flow-based technique.

Where $V = \{\mu_1, \mu_2, \ldots, \mu_n\}$ is a set of fuzzy, the fuzziness values are categorised into high, low, and mid fuzziness groups with training and testing samples.

(Gandhimathi & Murugaboopathi, 2020) conducted research on flow-based and cross-layer hybrid intrusion detection. Their approach aims to detect anomaly traffic and identify potential attacks based on narrow features. The process involves two phases: In the first phase, flow-based IDS is used to classify malicious nodes, and in the second phase, packets are analysed using cross-layer features to verify and detect potential threats. The flow-based IDS monitors network traffic, utilising network information to classify data as either normal or malicious, as shown below in Figure 6. Flow-based anomaly detection can exhibit a regular profile of behaviour by keeping tabs on network activity and keeping track of many parameters.

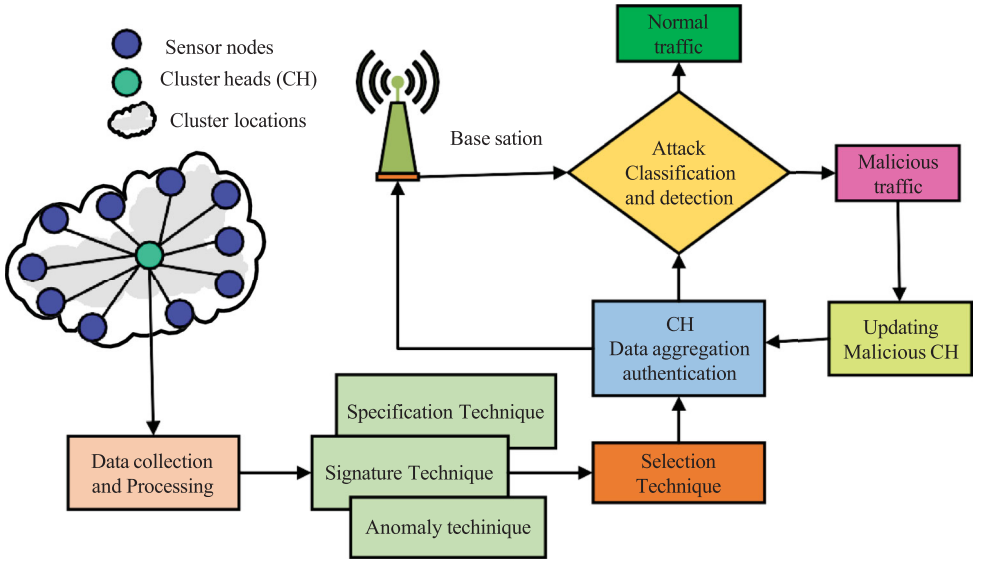

Figure 7. Hierarchical hybrid intrusion detection technique in wireless sensor networks using three phases of attack detection.

The flow-based intrusion detection scheme identifies network connections, hosts, users, and applications. Anomaly detection analyses recorded network traffic for training and detection. Cross-layer characteristics connect with packet-based IDS, extracting routing information for forwarding nodes. Hybrid IDS combines flow-based and packet-based techniques to reduce false positives and improve detection accuracy in WSNs. Correlating flow-based and layer IDS effectively detects DoS and sinkhole attacks. L. Moulad et al. (Moulad et al., 2019) proposed a hierarchical hybrid IDS technique for WSNs, using support vector machines and anomaly detection-based clustering and specification methods to detect and classify DoS attacks. The specification-based technique adopts a statistical model and behavioral/manual specifications to identify normal and malicious data, detecting anomalies and intrusion attacks in the network as shown in Figure 7. The figure illustrates the specification, signature, and anomaly detection techniques.

(Swarna Priya et al., 2020) proposed a deep neural network (DNN) model using hybrid principal component analysis and grey wolf optimisation (PCA-GWO) for intrusion detection in wireless sensor networks for medical applications. The model utilises autoencoders in a fully connected DNN with trainable parameters for training and testing. (Kanna & Santhi, 2022) examined hybrid deep learning models for effective intrusion detection systems using MapReduce based on black window-optimised long-term convolutional memory with feature selection techniques.

(Abduvaliyev et al., 2010) proposed a hybrid intrusion detection system for WSNs, utilising clustering and aggregation techniques to improve security and energy performance. Misuse and anomaly detection techniques are used to enhance detection accuracy and rate, with misuse detection targeting known attack patterns and anomaly detection employing automated training for abnormal behaviours as shown in Figure 8.

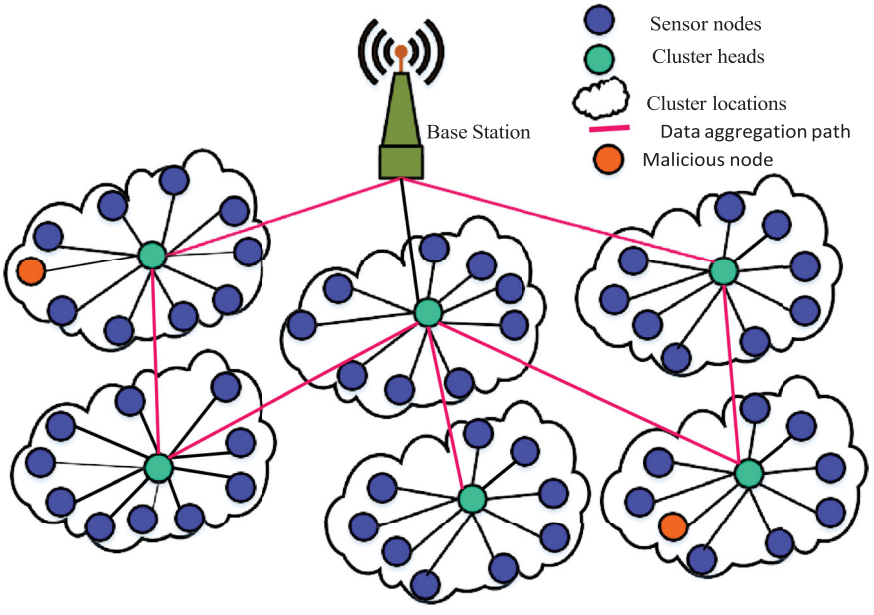

Figure 8. Illustration of data aggregation and clustering in WSNs.

Misdetection, a hybrid technique, effectively detects blackhole attacks by utilising K-medoid clustering on a synthetic data set (Ahmad et al., 2019). This approach employs the K-medoid individualised clustering method to identify anomalies caused by diversion and blackhole assaults. Additionally, a novel SDN-based Hybrid Clone Node Detection (HCND) technique has been developed for Wireless Sensor Networks (WSNs) by (Devi & Jaison, 2020). This technique proactively identifies cloned nodes using software-defined networking, ensuring the maintenance and enhancement of Quality of Service (QoS) limitations in the WSN. Hybrid multi-tiered IDS detects cyber-attacks on vehicular networks by reducing energy consumption and malicious anomaly nodes (Yang et al., 2022). Hybrid IDS detects cloning attacks in WSNs (Devi & Jaison, 2020) and classifies IoT-based security attacks for healthcare applications using feature selection and hybrid DT-GA (Saif et al., 2022).

2.2. Hybrid machine learning techniques

(Rabbani et al., 2020) proposed an effective intrusion detection system that combines machine learning with traditional security techniques. This scheme ensures mathematically secure communication among nodes and detects malicious behaviour using data pre-processing and recognition modules. Recognition techniques involve training and prediction using an optimised probabilistic neural network (PNN) with the UNSW-NB15 dataset containing normal and malicious data traffic. The hybrid PSO-PNN scheme builds a self-optimised network using particle swarm optimisation (PSO) to reduce misclassification errors and increase classification accuracy in the PNN system. PSO adapts the PNN structure, making it a self-adaptive network model using swarm behaviour patterns. Figure 9 depicts the architecture of the proposed system.

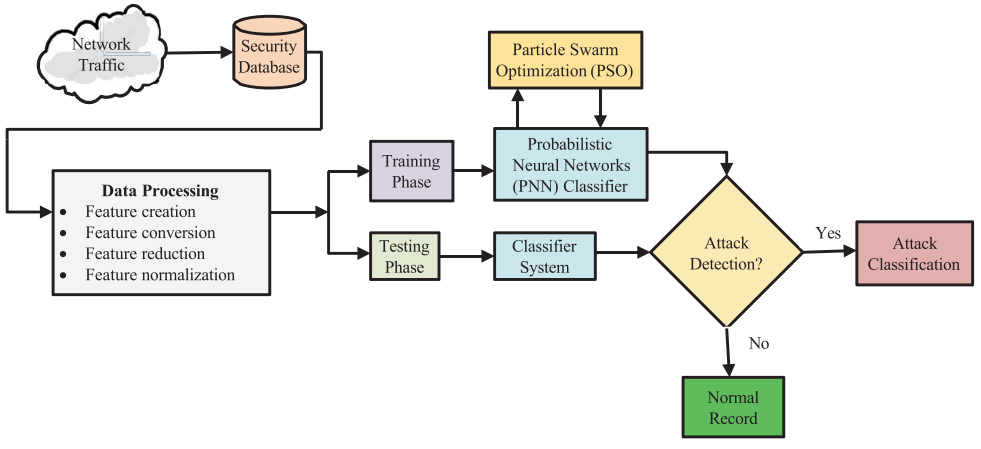

Figure 9. Hybrid PSO-PNN technique for attack classification and detection.

The features of the data network traffic are collected from the raw network packets using tools including Netmate, BRO-IDS, and Argus. The noisy features are removed to detect malicious attacks in WSNs effectively. Numeric values and symbolic variables represent the necessary features. The numeric and symbolic representations are normalised and transformed using the statistical characteristics of Equation (3).

$$Z_{normalized} = \frac{(Z - \min(Z))}{(\max(Z) - \min(Z))} \tag{3}$$

Where Z is the feature value, min (Z) is the minimum value, and max (Z) is the maximum value from the feature of the samples in the dataset.

S. M. Kumar (Kumar, 2022) presented an optimised hybrid deep neural network using a feature section algorithm for improving the intrusion detection of attacks using benchmark datasets UNSW-NB15 and NSL-KDD. The selected features are processed into the convolutional neural network consisting of layers using distance measurement and the correlational coefficient for input packets. The distance between two data points (a_i,b_i) with x and y input data, D, for arranging and selecting the features is given by Equation (4) as shown below.

$$D(x,y) = \sqrt{\sum_{i=1}^{n} (a_i - b_i)^2} \tag{4}$$

A convolutional neural network is used to compute the selected features. The outputs are incorporated into long-term memory configuration and modified materials to improve classification precision.

(Mahajan et al., 2022) explored hybrid machine learning and deep learning techniques for network traffic analysis and classification in wireless sensor networks, including attack detection using benchmark datasets. (Faysal et al., 2022) proposed machine learning techniques to detect IoT-based WSN attacks using benchmark datasets. Hybrid eXtreme Gradient Boosting and Random Forest (XGB-RF) were effective in detecting botnet attacks with feature selection and classification using various metrics. In the same year, (Alghamdi,

2022) introduced a novel optimiser technique called PO-CFNN for IoT-based IDS. The PO-CFNN method involves three stages: preprocessing, classification, and parameter optimisation, transforming networking information into a more usable format for intrusion identification.

(Sadikin et al., 2020) presented a research study on a hybrid intrusion detection system for ZigBee-based IoT systems. They combined anomaly and rule-based machine learning techniques to detect attacks. A hybrid Long Short-Term Memory Network (LSTM) and Convolutional Neural Network (CNN) learning approach extracts network traffic features using a hybrid IDS with the CICIDS2017 dataset, achieving 99.50% overall accuracy for attack type detection (Sun et al., 2020). In another study, a hybrid classification strategy combines Kalman filter (KF) and Extreme Learning Machine (ELM) to train a predictive classifier on the sink node. It detects random WSN anomalies with promising results using normal and faulty datasets (Biswas et al., 2019).

For binary classification of attack detection, Hybrid k-means and Support Vector Machine (SVM) reduce training and testing times while maintaining high classification accuracy (Rose et al., 2020). Federated learning techniques are utilised to create a privacy-friendly framework across multiple devices using benchmark datasets (Liu et al., 2022). Hybrid optimisation and deep-learning-centric intrusion detection systems are deployed in IoT-enabled smart cities using the Hybrid Chicken Swarm Genetic Algorithm (HCSGA) method (Gupta et al., 2022). The proposed solution involves pre-processing the dataset, feature selection with HCSGA and K-means, and classification with the Deep Learning-based Hybrid Neural Network (DLHNN) classifier using the NSL-KDD benchmark dataset. Hybrid machine learning techniques utilise sampling methods and feature selection analysis to achieve better detection accuracy (Cao et al., 2022). To address sample imbalance, a hybrid sampling method combining ADASYN and RENN is employed. Hybrid deep learning methods have shown effective identification of malicious attacks when tested on performance benchmark datasets (Ullah et al., 2022).

2.3. Hybrid anomaly detection

(Umarani & Kannan, 2020) proposed hybrid anomaly detection techniques based on artificial immune systems using hybrid tissue growing techniques in wireless sensor networks to detect malicious traffic. (Yin et al., 2019) presented an anomaly detection technique that recognizes and separates normal and abnormal behaviours based on patterns of normally labelled behaviours. Data mining techniques like regression analysis, clustering analysis, outlier detection, and classification are used to extract valuable knowledge for identifying patterns of malicious nodes, improving detection accuracy and efficiency. Anomaly detection requires a machine-learning model with human effort and is error-prone. The rest of the related works are summarised as in Table 1.

Despite the existing research efforts in developing IDS based on hybrid machine learning techniques in hierarchically wireless sensor networks, some research gaps still need to be addressed. Additionally, there is a need for further exploration of the optimal combination and configuration of machine learning algorithms in the hybrid approach. Different algorithms may have varying strengths and weaknesses depending on the characteristics of the WSNs. Investigating the most effective combinations and configurations can improve detection accuracy and efficiency. These include.

Table 1. Summary of different hybrid techniques from previous works.

Ref.	Security Technique	Research Findings
Vinitha et al. (2019)	Taylor-based Cat Salp swarm Algorithm	The LEACH protocol provides an energy-efficient multi-hop routing for reliable data transfer. Throughput, energy, and delay may all be accurately measured with this method.
Singh et al. (2023)	deep learning architecture based on a fully connected feed-forward Artificial Neural Network	R = 0.78 and RMSE = 41.15 were obtained for a Gaussian sensor distribution. In contrast, R = 0.79 and RMSE = 48.36 were found for a uniform sensor distribution, indicating that the model accurately predicts the number of k-barriers for both distributions.
Singh et al. (2021)	Machine learning approach based on Gaussian Process Regression (GPR) model	An analytical method is used to extract these characteristics. Based on the simulation results, the technique provides the most accurate prediction of the k-barrier probability, with a correlation coefficient (R) of 0.85 and a Root Mean Square Error (RMSE) of 0.095.
Singh et al. (2022a)	Automated Machine Learning using Bayesian optimisation.	Compared to other explainable machine learning models, they discovered that the Gaussian process regression performed exceptionally well, with a correlation coefficient of 1, a root mean square error of 0.007, and a bias of 0.006.
Ahmad et al. (2019)	Misdetection and K-medoid clustering	K-medoid clustering with a synthetic data set proves to be an efficient way of spotting hybrid black hole attacks.
Devi and Jaison (2020)	SDN-based Hybrid clone node detection	The hybrid clone node detection detects the cloned node using proactive and verification processes based on software-defined networking in WSNs, maintaining and enhancing the quality of service.
Singh et al. (2022b)	log transformation and feature scaling on the feature set and trained the tuned Support Vector Regression (SVR)	They discovered that the model accurately predicts the number of barriers with a correlation coefficient (R) equal to 0.98, a root mean square error (RMSE) equal to 6.47, and a bias equal to 12.35.
Davahli et al. (2020)	Genetic Algorithm (GA) and grey wolf optimiser(GWO)	Reduce the dimensionality of wireless network traffic using selective features for the Internet of Things intrusion detection system with the SVM classifier.
Sun et al. (2020)	Convolutional neural network (CNN) and long short-term memory network (LSTM)	Extracts the network data traffic features using the hybrid IDS with the CICIDS2017 dataset for evaluation and achieves an overall accuracy of 99.50% for attack type.
Biswas et al. (2019)	Kalman filter (KF) with extreme learning machine (ELM)	A hybrid classification technique to train the sink node using a predictive classifier. The scheme is evaluated using the detection of random WSN anomalies data with the normal and faulty datasets.
Ren et al. (2019)	hybrid data optimisation	The practical technique uses data sampling and feature selection using a Genetic algorithm and random forest classifiers using the optimal training UNSW-NB15 dataset.

(*continued*).

Ullah et al. (2022)	Hybrid deep learning	Proficient in the detection of malicious attacks using benchmark datasets.
Reshma et al. (2022)	The hybrid Neighbor discovery protocol	Maximizes energy efficiency and improves security performance for detecting malicious nodes based on hybrid machine learning.
Saif et al. (2022)	Hybrid IDS approach using feature selection	Utilised hybrid DT-GA to detect and classify security attacks on IoT for healthcare applications with reduced cost.

1. **Limited evaluation on real-world WSN deployments.** Many studies have focused on simulation-based evaluations or used benchmark datasets. Future research should include more experimentation and evaluation of real-world WSN deployments to validate the effectiveness of the proposed hybrid IDS techniques.
2. **Scalability and resource constraints.** Hierarchically structured WSNs often operate under resource-constrained environments. There is a need for IDS solutions that can handle scalability issues and optimise resource usage while maintaining high detection accuracy.
3. **Dynamic adaptation.** WSNs are subject to dynamic environmental changes and evolving attack patterns. IDS solutions should be capable of dynamically adapting to these

changes and updating their detection models to ensure continuous and effective protection.

The literatures show that there is still a research gap in comprehensive studies that address the unique challenges and opportunities presented by the hierarchical structure of WSNs. Furthermore, exploring the optimal combination and configuration of machine learning algorithms in the hybrid approach is crucial for achieving improved detection accuracy and efficiency in WSNs. Future research should aim to fill these gaps and provide valuable insights into the design and implementation of advanced IDSs for hierarchically structured WSNs.

3. Network models and clustering techniques

The base station, cluster head (CH), and sensor nodes comprise the hierarchically distributed wireless sensor networks (SN) network paradigm. In this setup, the sensor nodes use a wireless connection to communicate with the cluster node and the sink node (Ghugar et al., 2019). When designing and planning the network model, the following assumptions are incorporated as shown below.

- Every mobile sensor node can roam freely within the network area (Pajila et al., 2021).
- The sensor nodes are deployed randomly.
- All of the sensor nodes are the same in every way.
- Any location within the network's range is possible for a sink to be installed.

As a result, the position of unknown nodes in the network can be calculated using beacon and sink nodes, both aware of their position and location. When it comes to routing assaults, the WSN's nodes are unprotected. In most cases, this kind of attack shortens the lifespan of the sensor nodes and causes them to run out of juice. Tunnels created by routing assaults distort the route path and use routing resources. To protect against denial-of-service and routing attacks, the proposed network model incorporates node-level security measures. The proposed system uses cutting-edge intrusion detection systems founded on hybrid machine learning approaches to identify and pinpoint cyberattacks.

The proposed network model includes five types of nodes: sensor nodes, malicious nodes, central nodes, cluster nodes, and sink nodes shown in Figure 10. The CH acts as a root node to prevent malicious communication, and the central node and CH serve as the backbone for communication with the BS. The CH uses the isolation table to conserve energy and detect attacks, with primary and secondary cluster heads for intrusion detection (Ismail & Amin, 2019). The CH also avoids depletion energy using the isolation table for attack detection. Two primary and secondary cluster heads for intrusion detection of attacks.

The attack models provide a graphical representation of the network topology, along with details about key identities and routing information that can be used to identify and exploit security flaws in the system. As seen in Figure 11, it is presumed that they have limited means and intellect to interrupt network traffic. Several variants of WSN attacks are simulated to test the effectiveness of the proposed IDS—the attack model measures how well and securely the system functions.

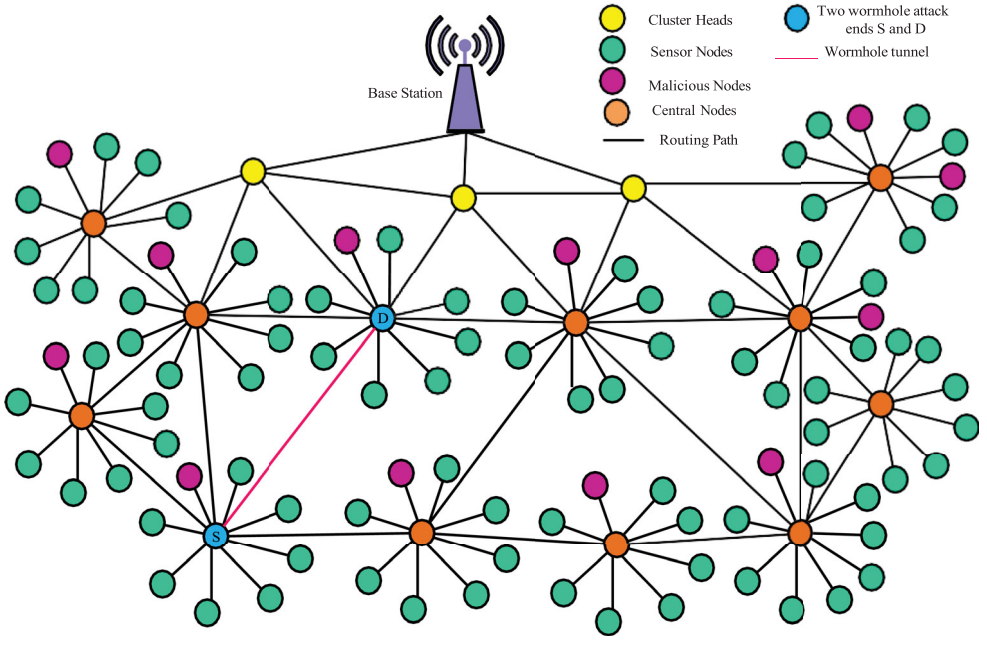

Figure 10. Hierarchical topology and configuration model for secure wireless sensor networks.

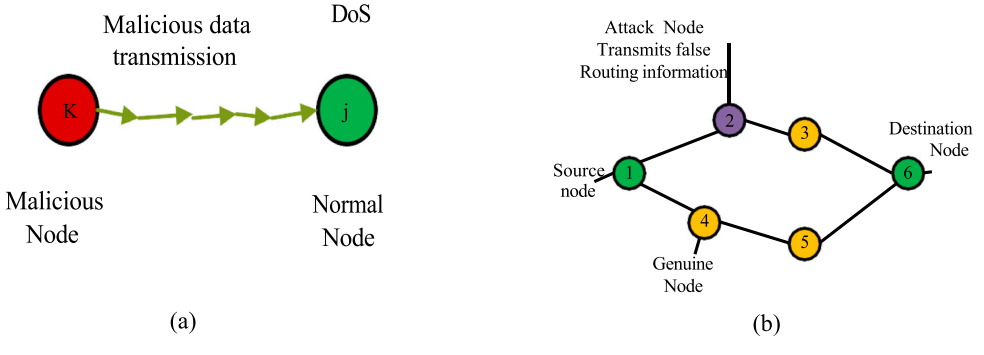

Figure 11. Jamming (a) and Sinkhole (b) attacks at the physical and network layers. (a) Jamming attacks and (b) Sink hole attacks

The application layer defines the network's threads, the Media Access Control layer, the Physical layer, the Transport layer, and the Network layer (Zou et al., 2016). Jamming security threats continuously sends harmful data, disrupting short-range connections. The transmission of jamming signals causes legitimate user and service blocking. Following is a mathematical model of an attack as in Equation (5).

$$I_a = e_i + m_i \tag{5}$$

Where I_a is the transmitted information depending on the IDS, that can be correct or incorrect, e_i is the expected information, and m is the malicious content information (Gebreyesus, 2021). The data is detected as malicious nodes have considered the network's transmitted data and energy auditing.

The channel priority is the major factor in the medium access control layer. The malicious nodes modify and change the back-off time using the manipulation approach. The attackers advertising false information in the network affects the layer routing information like the minimum hope count.

4. Methodology

The proposed system starts with system design and simulation for generating and extracting datasets. Since getting real datasets in WSNs is difficult, we use standard datasets to evaluate the effectiveness of the new advanced intrusion detection system based on hybrid machine learning models. The usefulness and efficiency of the proposed enhanced intrusion detection method based on hybrid machine learning on various classes of assaults are demonstrated by utilising publicly available datasets (Wu et al., 2020). The KDDCup 99, NSl-KDD, UNSW_NB15, and CICIDS2017 datasets are extensively used for academic study and research for attack detection evaluation as benchmark datasets. The system's effectiveness is tested using the KDD Cup 99 datasets and the intrusion detection techniques. These datasets aim to measure the IDS using a predictive decision model. The 1999 DARPA dataset is also used in this work. The dataset is evaluated using offline and real-time evaluation modes. The data is handled in several modes to establish the normal functioning of the network.

4.1. Benchmark datasets

Some of the issues with the KDD'99 data set are discussed, and a data set called NSL-KDD is proposed as a solution (Meena & Choudhary, 2017). Although it is a new and standardised genre of the KDD data set, it still suffers from some of the problems studied by McHugh. It may not be a perfect illustrative of existing real networks. Still, it is used and applied effectively as a standard data set to help researchers compare the various network-based IDSs. In addition, the NSL-KDD training and testing sets have a manageable quantity of records. The cost of doing trials on the entire dataset, as opposed to a sample, is reduced by using this method. By combining the KDD'99 Data Set with the NSL Data Set, we get several advantages over the original KDD data set.

- It avoids training classifiers on duplicate or redundant records by omitting them from the train set.
- The proposed test sets don't reuse any records, thus, the approaches with higher detection rates on common data won't unfairly boost the learners' performance.
- The proportion of records in the original KDD data set is inversely proportional to the number of records chosen from each group of challenging levels.
- Since there aren't many records in the train or test sets, we can afford to perform the experiments on the whole set without randomly picking a subset.

The NSL-KDD dataset is also used as a benchmark to test the detection performance of the proposed system using the semi-supervised machine learning (Praveen Kumar et al., 2019) models for a class of attacks with 42 attributes and class labels. Forty-one attributes are classified into content, host, traffic, and basic features. The dataset has a total record

Table 2. Frequency distribution of various attack classes in the NSL-KDD with training and testing samples for testing performance (Li et al., 2018).

samples	Normal	DoS	Probes	U2R	R2L	Total
Training samples	67,343	45,927	11,656	52	995	125,974
Testing samples	9,711	7,458	2,421	200	2,654	22,544
Total number	77,054	53,385	14,077	252	3,649	148,518

Table 3. Provides a detailed technical description of the four types of attacks in the dataset.

Attack	Attack description in the dataset
DoS	The attacker makes the network busy and denies the legitimate user access.
R2L	The intruder tries to gain access to the network or machine for a specific version of the FTP.
U2R	The attacker accesses the system's root and makes unauthorised attempts to the network.
Probe	It endeavours to assemble the data behind evading the security of the system.

of 148,515 samples sectioned into 80% of training and 20% of testing samples, as shown in Table 2, with four different classes of attacks. The vector features are extracted for training by splitting the dataset into clusters as normal and abnormal. After training, the vector features are received for classification as normal and abnormal clusters.

The dataset consists of 23 classes of attack types and is clustered into four classes of attacks, including denial of service (DoS), remote to local (R2L), user to root (U2R), and probe category. The DoS attack makes the network service busy and the authorised user inaccessible from the network (Elsaid & Albatati, 2020). The U2R attack applies vulnerabilities to the host system by sniffing the passwords of the legitimate user. The R2L injects vulnerabilities remotely into the system of the network host. The probe attack scans the network for information collecting and gathering, violating the security rule. The probe and DoS attacks have multiple links, whereas the others have single links (Pande et al., 2021). Table 3 shows the description of the four classes of attacks in the NSL-KDD benchmark dataset.

The UNSW_NB15 dataset is used as a benchmark for evaluating the effectiveness of the proposed system. This dataset has hybrid synthesised attack activities and normal network traffic data (Jatti & Kishor Sontif, 2019). The IXIA traffic generator is arranged with three virtual servers for generating the UNSW_NB15 dataset containing normal and malicious activities in the network traffic. The servers are established using public and private network traffic having IP addresses with routers. The routers are configured with a firewall that filters the traffic as normal and malicious activities. The tcpdump tool is installed on routers for capturing from the IXIA tool dispersed among the network nodes utilised as attack traffic generators with normal network traffic. The frequency distribution of the class of DoS attacks is shown in Table 4 with training and testing samples.

The method's effectiveness for identifying flooding assaults in WSNs is measured against the CIC-IDSS2017 dataset. Table 5 details some of the key elements of the training and testing dataset that can be found online at the Canadian Institute for Cyber Security Research LAB. Data about network traffic, both benign and malicious, is included in the dataset. It was manufactured to serve as a plausible in-the-background activity while gathering data. Twenty-five individuals utilising a variety of protocols were used to compile the dataset.

Table 4. Frequency distribution of attacks in the dataset.

	Training samples		Testing samples

Overall	1596	315382	1881	7884	159128	10

Table 6 shows that the dataset used to develop the predictive machine learning models contains 485881 occurrences and 31 characteristics divided into training 80% and 20% testing subsets. There are five distinct varieties of DoS attacks (Bansal & Kaur, 2018), including the widely-known Slowhttptest, Slowloris, Hulk, Heartbleed, and GoldenEye. DoS attack samples used for training and testing are shown in Table 6.

Normalisation, missing value imputation, and aggregation are all part of the data processing required to rearrange the data before the training and testing phases begin. We fill in the blanks by averaging the current values (Anbarasan et al., 2020). It is possible to convert the data into binary values as 0 and 1 by using the minimum and maximum values.

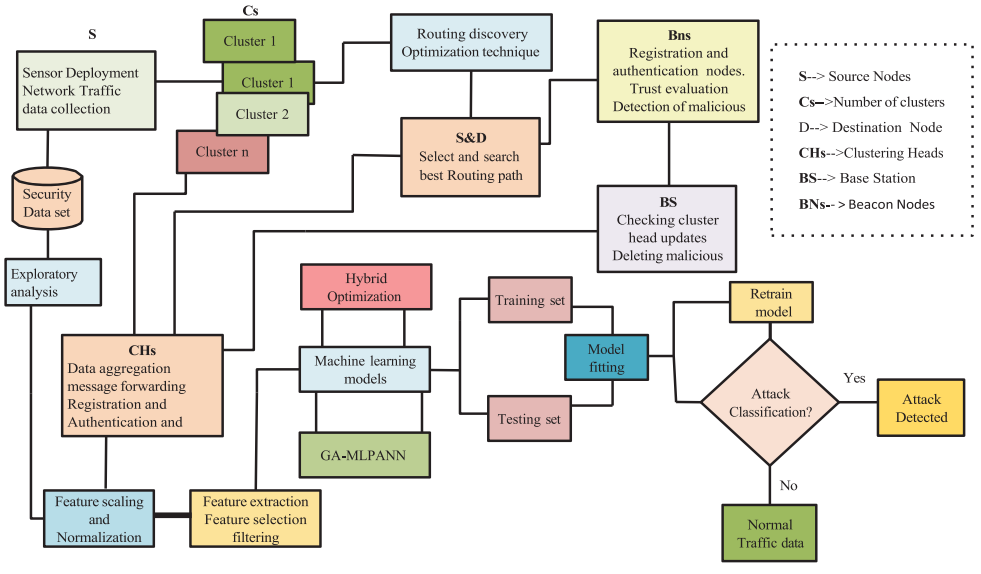

Figure 12. Framework for advanced hybrid intrusion detection system (AHIDS) Block diagram using attack detection and classification Model.

5. Proposed AHIDS framework

Figure 12 depicts how the hybrid machine learning models used in the proposed system are used to categories network data flow as either normal operation or harmful attacks. Hybrid machine-learning approaches are mostly combined to complete the intrusion detection system for attacks in WSNs (Shi & Li, 2022). Figure 12 depicts the major technical components of the proposed framework, including sensor deployment, data collection and information processing, data aggregation and clustering, decision-making, preprocessing, machine learning and optimisation for training and testing, classifier generation, and a detection and classification module for records. Since the proposed method is simple and effective, it has great potential for deployment in real-world wireless sensor networks in hierarchical clusters. Conditional control statements are a key component of the hybrid machine learning approaches for decision-making events' outcomes. The new aspect of this decision-making method is the use of a collaborative process for data analysis, which in turn aids in the automatic construction of predictive models. Decision nodes are used for prediction, while leaf nodes are used for the final classification, as seen in Figure 12, using hybrid machine learning models. Splitting training and testing benchmarks is governed by rules and reasoning generated by the hybrid machine learning models. Target categorisation is performed using the statistical metric.

Finally, the proposed system employs hybrid machine learning approaches (Gupta et al., 2022) to detect and localise attacks utilising data from both the attack and non-attack phases. Using the modified dataset, the suggested AIDS-HML learns to identify potential attacks. Assuming that all features of every sample belong to the designated class label, AIDS-HML is an efficient classification method (conditional independence assumption). Enhanced Advanced Hybrid Machine Learning (AIDS-HML) is a more advanced and hybridised version of machine learning.

Designing advanced intrusion detection systems based on hybrid machine learning techniques in hierarchically wireless sensor networks can offer several advantages and disadvantages. Here are some potential benefits and drawbacks of the proposed system to consider.

Advantages.

1. **Improved Detection Accuracy.** Hybrid machine learning techniques combine the strengths of multiple algorithms, such as neural networks, decision trees, or support vector machines. This combination can enhance intrusion detection accuracy by leveraging each technique's unique capabilities.
2. **Adaptability to Dynamic Environments.** Hierarchically wireless sensor networks often operate in dynamic environments where network topology, traffic patterns, and intrusion characteristics can change over time. Hybrid machine-learning approaches can adapt to these changes and update their detection models accordingly, leading to better performance in dynamic scenarios.
3. **Enhanced Scalability.** Wireless sensor networks may consist of many nodes, making scalability a critical factor. Hybrid machine learning techniques can handle large-scale networks more effectively by distributing computational tasks among nodes and optimising resource utilisation.
4. **Reduced False Positives and False Negatives.** By combining multiple machine learning techniques, hybrid systems can mitigate individual algorithms' weaknesses, reducing false positives (incorrectly identifying benign activity as intrusion) and false negatives (failing to detect actual intrusions).

Disadvantages.

1. **Increased Complexity.** Implementing hybrid machine learning techniques in intrusion detection systems adds complexity to the design and deployment process. Combining different algorithms and managing their interactions requires expertise in both machine learning and wireless sensor network domains.
2. **Higher Computational Demands.** Hybrid systems may require more computational resources compared to single-method approaches. The processing and memory requirements can be significant, particularly in resource-constrained wireless sensor networks, which can impact system performance and energy efficiency.
3. **Training and Maintenance Overhead.** Hybrid machine learning models typically require more extensive training and maintenance processes. Ensuring accurate model updates, handling concept drift (changes in intrusion patterns over time), and managing retraining procedures can be time-consuming and resource-intensive.
4. **Increased Vulnerability to Attacks.** Advanced intrusion detection systems may become targets for attackers seeking to manipulate or evade detection. Hybrid machine learning models can be susceptible to adversarial attacks, where attackers exploit vulnerabilities in the learning algorithms to deceive the system. Robustness against such attacks must be considered during system design.

5.1. Sensor deployment and routing techniques

Sensor nodes are deployed based on various network models for attack detection and classification attacks in WSNs. However, WSNs face significant routing difficulties because of their restricted power supply, poor transmission bandwidth, less memory capacity, and processor capacity (Praveen Kumar et al., 2019). Due to limitations like short battery life, small memory, and low processing power, an adversary can quickly target individual nodes of WSNs when deployed in a dangerous area (Rouissi et al., 2019). It is crucial to identify malicious attacks to prevent being tricked by the adversary's fabricated data supplied by compromised nodes. Here, we distinguish between internal and external attacks on WSNs. The goal of the external attack is to reduce the effectiveness of the WSN and is carried out by parties outside of the network. Therefore, we shall elaborate on the proposal that protects against routing attacks with data while maintaining its integrity. This paper uses HML methods for WSNs to create safe protocols for extracting features and locating new routes in moderately complex hybrid and tree network topologies. The following are a few of the many advantages that machine-based routing brings to WSNs.

- Without requiring re-programming, machine learning techniques can adapt to new environments and select new CHs for routing in WSNs.
- Hybrid machine learning models can be used for various purposes in WSNs, including optimal routing, reducing communication overhead, and delay-awareness.

In this study, we employ the GA-ANN method for detecting wormhole assaults and determining energy-efficient and robust routing for WSNs. WSNs utilise GA-ANN to train their protocols based on a wide range of inputs, including residual energy, node distances, routing discovery, path selection, feature extraction, cluster heads (CH), border nodes, and the sink or base station. An enormous training set is produced, and even ANN is provided with effective threshold values for picking a set of trustworthy CH via backpropagation. Data loss in WSNs can be prevented, and energy consumption among sensor nodes is balanced with this technique.

The engineering optimisation problems used in this study find the optimal solutions under special conditions for selecting cluster head and shortest path for routing in WSNs, such as design principles, resource limitations, and safety requirements (Agushaka et al., 2022) as shown in Figure 13. Typically, metaheuristic algorithms cannot directly find the solution to constraint optimisation problems. Designing and optimising WSNs pose several challenges due to the constraints of limited energy, communication bandwidth, and processing capabilities of the sensor nodes (Ovelade & Ezugwu, 2021). However, equipped with constraint-handling techniques (CHTs), the optimisers can contend with the objective function and corresponding constraints. The purpose of optimisation is to locate the optimal answer to a problem while taking into account all relevant factors. The essence of optimisation methods lies in the gradual improvement of the generated set of solutions using a set of optimisation rules and the evaluation of those solutions using a defined objective function (Abualigah, Diabat, et al., 2021).

Unknown search space, discrete or continuous search space, non-derivative objective functions, high dimensions, and non-convexity are only a few of the characteristics of optimisation problems that prevent them from being solved in a reasonable amount of time

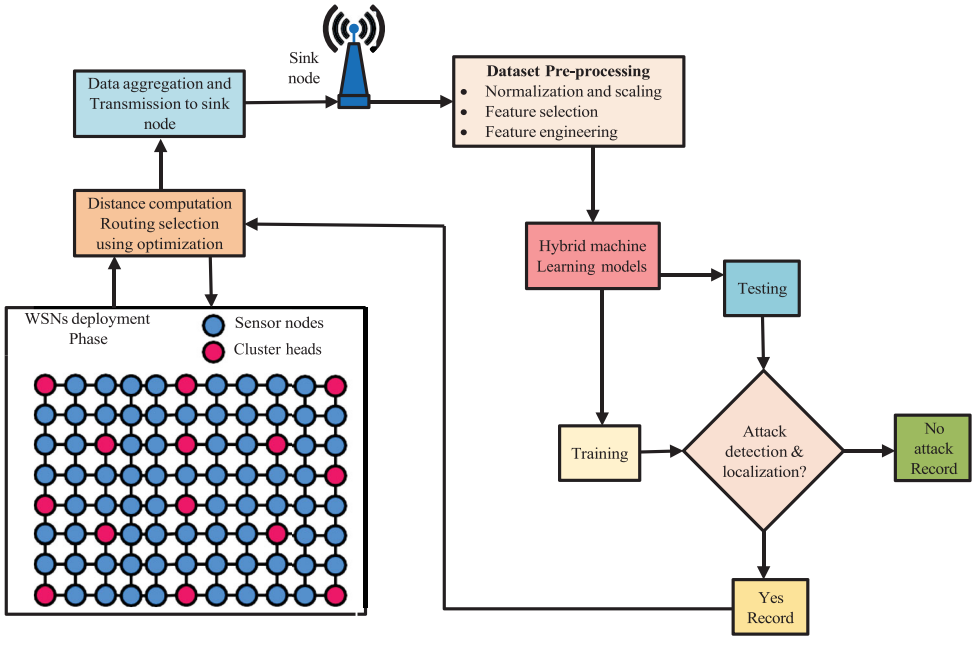

Figure 13. Illustration of flow chart diagram based on various phases of the proposed system.

using only classical methods (Ezugwu et al., 2022). These algorithms, coupled with appropriate fitness functions and problem-specific adaptations, have been used to improve the performance, reliability, and energy efficiency of IoT-WSNs (Abualigah et al., 2022). The algorithm evaluates the fitness of the candidate population using the objective function and constraints in each iteration, and the next generation of the candidate population is evaluated based on the calculated fitness function.

In the context of IoT-WSNs, an optimisation process involves finding the optimal values for specific parameters of the system in order to meet the system design requirements while minimising cost and finding the shortest path (Abualigah, Yousri, et al., 2021). The goal is to achieve an optimal configuration or solution that optimises the system's performance and efficiency. The parameters that are typically optimised in IoT-WSNs can vary depending on the specific application and design objectives. Some common parameters that are often optimised include.

- **Node Placement.** The optimal locations for sensor nodes are determined to achieve desired coverage, connectivity, and energy efficiency. This involves finding the optimal positions or coordinates for deploying the sensor nodes within the network area.
- **Routing.** The optimal routing paths are identified to transmit data from source to destination nodes efficiently. This includes finding the shortest or most energy-efficient paths considering network dynamics, congestion, and quality of services (QoS) requirements.
- **Energy Management.** Energy consumption is optimised by dynamically adjusting parameters such as sleep-wake schedules, duty cycles, or transmission power levels. The objective is to prolong the network lifetime while meeting the application requirements.

- **Resource Allocation.** The allocation of network resources, such as bandwidth and time slots, is optimised to ensure efficient utilisation. This involves determining how resources should be allocated among sensor nodes or applications to maximise overall system performance.
- **Data Aggregation.** The optimal strategies for aggregating data from multiple sensor nodes are identified to minimise redundant transmissions and conserve energy. This involves determining which nodes should aggregate data and how the data should be fused or compressed.

By employing an optimisation process in IoT-WSNs, system designers and engineers can identify the most efficient and cost-effective network configurations, enabling improved performance, energy efficiency, and overall system design.

5.2. Data pre-processing

The performance of a machine learning model is indeed influenced by the quality of the datasets on which it is trained (Singh et al., 2022b). The quality of the datasets can significantly impact the model's ability to learn patterns, generalise to new data, and make accurate predictions. Here are some key points regarding the importance of dataset quality in machine learning.

- High-quality datasets should be accurate, free from errors, and reflect the true values or labels of the target variable.
- Datasets should contain all the features and attributes required for the learning task.
- The datasets should represent the real-world problem the model aims to solve.
- Balancing the dataset or using appropriate techniques to handle class imbalance is crucial to ensure fair and accurate predictions.
- Proper preprocessing steps, such as cleaning, normalisation, and feature engineering, are essential for data preparation before training the model.
- The size of the dataset can also influence the model's performance.
- Rigorous quality assurance measures should be applied to datasets, including data validation, outlier detection, and error handling.

The data preprocessing model converts raw network traffic into the format the classification model needs in the next stage (Zhao et al., 2023). In order to offer both training and testing data, this study measures and normalises raw network traffic using a variety of data preparation approaches. A raw dataset may not have undergone any preprocessing (Roy & Chowdhury, 2021). A raw dataset is incomplete, noisy, and possibly presented unfavourably. As a result, building machine learning models from scratch using a raw dataset is impossible, as shown in Figure 14.

Preprocessing the raw data by eliminating duplicates and standardising the format improves the efficiency of a machine-learning model. This is why the training phase of a machine learning model is so important. Here are the pre-processing techniques.

Filtering: One way to clean up data is through filtering. This filter roughly estimates a desired signal pattern from a distorted signal pattern. The major goal of this filtering method is to minimise the mean square error between the estimated and intended signal patterns.

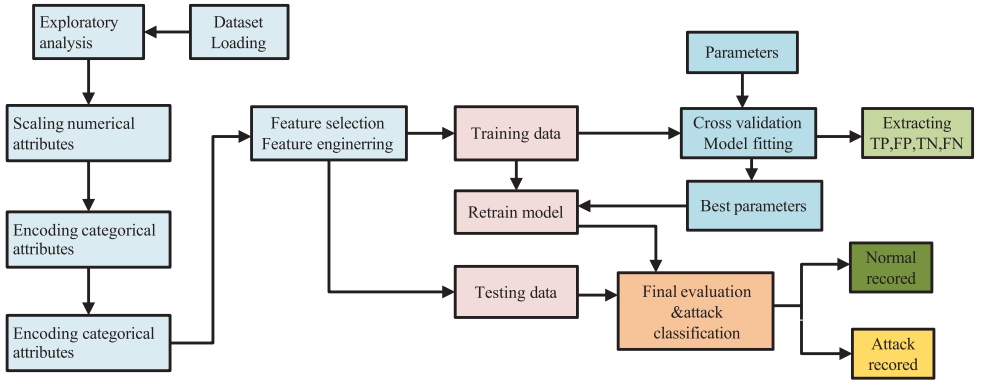

Figure 14. Data pre-processing, training and testing for model evaluation framework using benchmark datasets.

Feature Selection: Feature selection approaches are essential for choosing relevant and useful features for model learning, enhancing prediction accuracy and reducing overfitting, training time, and complexity. Common methods include Filtering, Wrapping, and embedding. Selecting the right features is crucial for data mining projects, and Figure 15 illustrates selected features using the NSL-KDD benchmark dataset (Intelligence et al., 2019). To improve application performance, identifying the best feature selection method and implementing it in relevant processes is necessary. This reduces the dataset's attributes and makes associations between them, streamlining the procedure. However, there is no universal approach to feature selection, and the dataset's condition should be considered when choosing an appropriate method. The primary challenge is finding the best feature to discriminate between classes, requiring different strategies for various datasets.

The feature selection method employs a plethora of different methods. Spearman's rank correlation coefficient formula is used for a recursive feature selection process, which then dynamically selects features, as shown in Equation (6).

$$\rho = \frac{\sum_i (x_i - \bar{x})(y_i - \bar{y})}{\sum_i (x_i - \bar{x})^2 (y_i - \bar{y})^2} \tag{6}$$

Where ρ is the correlation coefficient, x_i and y_i are the feature variables and $\bar{x}$ and $\bar{y}$ are the mean values of x and y.

Feature engineering: Each pattern can be isolated with the help of a single clue provided by the feature engineering phase. When a raw dataset has a large feature set that is considered redundant, the feature extraction approach is used to create a derived set of non-redundant and informative features from the original feature set.

Windowing: Each pattern can be isolated with the help of a single clue provided by the feature engineering phase. When a raw dataset has a large feature set that is considered redundant, the feature extraction approach is used to create a derived set of non-redundant and informative features from the original feature set.

Filter Method: The filter technique employs feature ranking methods for feature selection. Ranking features indicate how crucial they are when constructing a model. The results of numerous statistical tests are used to rank the features. Each feature's connection with the

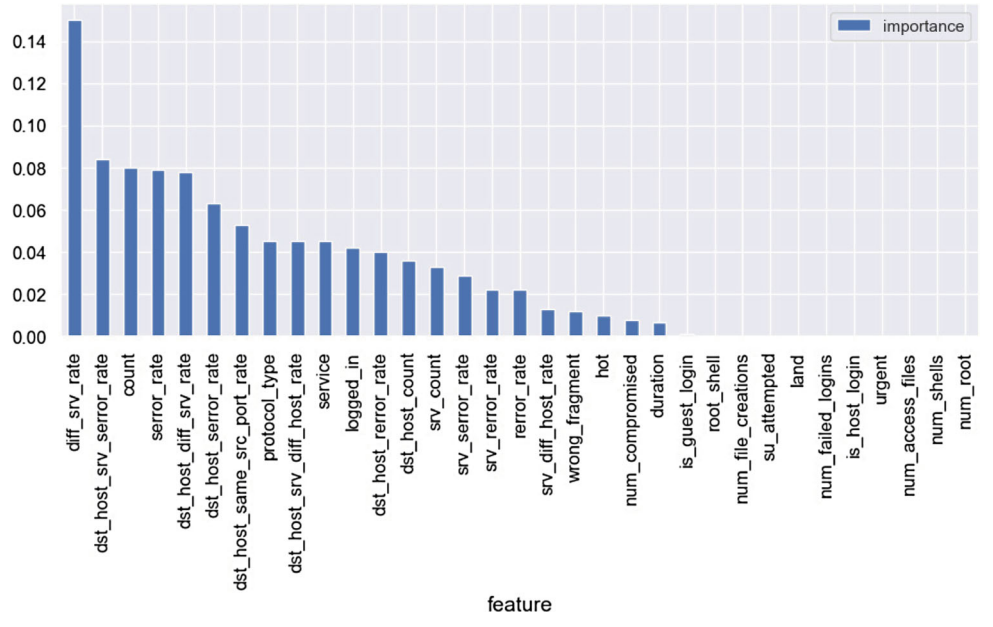

Figure 15. Selection of important feature technique using NSL-KDD benchmark dataset.

result variable is calculated in these statistical analyses. Pearson's correlation, Linear discriminant analysis, Analysis of variance, Chi-square, Variance threshold, Information gain, and so on are only some of the many statistical tests available.

Transformation and Normalization Operations: The NSL-KDD dataset utilises quantified nominal values, transforming attributes like protocol type, service, and flag numbers into numeric values (TCP = 1, UDP = 2, ICMP = 3, service = 1, flag = 2). Dataset normalisation is a crucial preprocessing technique, ensuring consistent and rescaled attribute values for effective classification (Saheed et al., 2022). Machine learning algorithms benefit from normalised data, achieving remarkable results in generalised prediction models. Minimum and maximum normalisation is used to standardise the dataset, scaling information between 0 and 1, avoiding overshadowing of lower numeric range features (Mojtaba et al., 2016). Normalisation also eliminates numerical issues in calculations, improving overall performance (Mojtaba et al., 2016; Saheed et al., 2022).

5.3. Machine learning and classification techniques

Data mining operations can utilise various data mining techniques, including hybrid machine learning methods such as Naive Bayes (NB), Artificial Neural Networks (ANN), Decision Tree (DT), Extreme Gradient Boosting (XGB), Extra Tree (ET), Random Forest (RF), Ensemble Stacking (ES), and cluster labelling K-Means (CLK-M) for attack detection and categorisation (Intelligence et al., 2019). Machine learning enables systems to learn and improve from experience without explicit programming, enhancing reliability, efficiency, and cost-effectiveness in computational procedures (Praveen Kumar et al., 2019). ML models are developed using automated and accurate processing of complex data with the extracted or chosen feature set used in conjunction with machine learning methods to

create classification algorithms. Supervised learning is suitable for standard fingerprinting data, while unsupervised or semi-supervised learning can be appropriate for crowdsourced data. Selecting the right data mining algorithm based on the dataset's structure is crucial for optimal performance. This overview outlines the use of data mining methods in classification procedures on representative benchmark datasets.

5.3.1. Naive Bayes

Naive Bayes is a basic technique for classifying data based on probability theories to identify which classes should be included. Predictions can be made after just one scan, which is straightforward. The technique is predicated on a streamlined version of the Bayesian theorem.

Conditional probability theory is used to predict to which class a given sample from a dataset will belong. Classes for test dataset samples are determined using knowledge gained during training on the training dataset. Despite its seeming lack of complexity, the Naive Bayes algorithm is highly effective. Below are the mathematical formulations for the probabilities involved in Bayes' theorem as in (7).

$$P(c|x_1,x_2,\ldots.,x_n) = \frac{P(x_1,x_2,\ldots.,x_n|c)P(c)}{P(x_1,x_2,\ldots.,x_n)} \tag{7}$$

Where P(x) is the probability of event x, c is the desired outcome, and x is the entire dataset's properties.

Based on Naive Bayes, an optimal cluster head selection method is utilised for safe and low-power routing in WSNs. An ideal collection of CHs will always maximise the network's lifetime while minimising the energy drain on individual sensor nodes. Naive Bayes ensures continued network flexibility in the face of dynamically added or modified features. This study describes a new adaptive integrated routing architecture for data collecting using a Bayesian approach.

5.3.2. Random forest

When several decision trees are trained using many different data sets, the resulting algorithm is called a random forest algorithm (RF). Breiman created this multi-technique classifier back in 2001 as an algorithm. Sub-training clusters are generated in the random forest algorithm. When forming a training cluster, preloading is used. In order to grow the trees, we employ a mechanism in which the attributes are randomly picked. The algorithm works by picking a random value from each node and utilising that as the basis for a branch as shown in Figure 16. Randomly selected factors produce the derived trees. The collected datasets are utilised as input into the Classification And Regression Trees (CART) algorithm for tree building. Each created tree is used to label the training sample and the classes assigned to which the sample is then compiled. To be processed instances are often included in the most common classification to which they belong. The RF method does not include pruning, while the CART algorithm does. An important reason why the RF algorithm outperforms the other decision tree approaches is that it doesn't rely on pruning.

The RF algorithm is quick, flexible, and more effective than alternative decision tree approaches despite using numerous tree topologies. The CART algorithm uses the GINI idex value to decide which branch to create from each node. Tree development parameters include the number of trees and the number of variables per node. The RF algorithm's

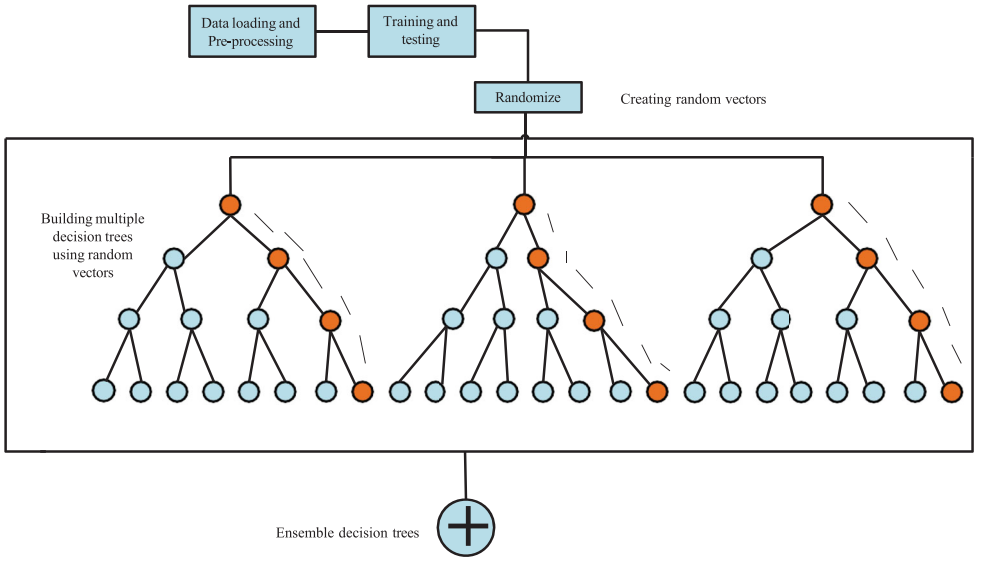

Figure 16. Block diagram of random forest operation for training and testing benchmark dataset.

basic operation is depicted in Figure 16 for attack detection and classification using training and testing the benchmark datasets.

5.3.3. Decision trees

Decision trees (DTs) are a type of supervised ML technique to classification that uses a set of if–then rules to simplify the process and improve human comprehension. The two types of nodes in a decision tree are the leaf nodes, which represent the outcomes, and the decision nodes, which represent the choices that lead to those outcomes (choice between alternatives). A decision tree can be used to predict a class or target by inferring decision rules from training data. The decision tree has the benefits of being easy to understand, helping eliminate confusion while making choices, and facilitating in-depth research. Connectivity, anomaly detection, data aggregation, and mobile sink path selection are just a few of the many problems that WSNs can address with the help of adopted decision trees.

The algorithm employs a divide-and-conquer technique. This algorithm, in contrast to ID3, incorporates normalising procedures. The algorithm determines the ratio based on the values of the information acquired. Building and repositioning intermediate trees is feasible at the time of the decision tree's inception. The decision tree method also employs branch pruning to eliminate potentially incorrect data and lower the error rate. Identifying a single node to begin the tree-building method is necessary if all of the samples belong to the same class; otherwise, the node will be labelled as a leaf and will not represent any classes. An optimal segmentation attribute is chosen if a node has characteristics from multiple classes, and the tree expands from there.

Each feature's information gain is computed, and the feature with the highest value is chosen as the tree's decision node. During the election of the cluster leader, this is the best time to identify and remove any malicious nodes. After identifying a decision node, the

procedure continues by creating a child branch off that node. If all the elements in the subgroups listed above have the same value, the procedure ends, and that value is used as the output. The process ends if the subset contains exactly one node and no distinguishing features are identified.

5.3.4. K-Means clustering

With minimal effort, the k -means method can divide a data set into a specified number of groups. Starting with a random sample of k locations, the nearest centres are assigned to each remaining point. After the data is partitioned into clusters, the centroid of each cluster is recalculated. Each time the algorithm is run, the cluster's centroid shifts until the algorithm reaches a plateau and no cluster centroid shifts. Suppose we define n as the total number of points and k as the total number of centroids. In that case, i is the total number of iterations, and d is the total number of attributes, then we can say that the time complexity of the k -means algorithm is O (n∗k∗i ∗d). In Equation (8), we see the minimisation function for the sum of squares of errors.

$$\min f(x) = \sum_{i=1}^{k} \sum_{j=1}^{N} ||x_i - y_j||^2 \tag{8}$$

Where *N* is the number of data points in the i^{th} cluster and $||x_i - y_j||$ is the Euclidean distance between x_i and y_j. The simplest clustering method, k-means, is also useful in WSNs for identifying ideal cluster heads (CHs) and detecting of malicious nodes to employ while transmitting data to the base station. This method also works well for locating productive mobile sink rendezvous spots. Choosing a different value of K can affect the outcomes in some situations. Getting the best results from the analysed data is crucial to get the value of k right. Euclidean, Manhattan, and Minkowski are just a few of the distance and neighbour node formulas that can be applied. Here are the relevant formulas given by Equation (9).

$$\begin{aligned} Euclidean &\rightarrow \sqrt{\sum_{i=1}^{k} (x_i - y_i)^2} \\ Manhant\tan &\rightarrow \sum_{i=1}^{k} |x_i - y_i| \\ Minkowski &\rightarrow \left[\sum_{i=1}^{k} (|x_i - y_i|^q) \right]^{1/q} \end{aligned} \tag{9}$$

5.3.5. Hybrid-ensemble machine learning techniques

When multiple machine learning algorithms are combined into an ensemble, the resulting classification is both more accurate and faster. This approach involves several learning procedures using various machine learning approaches and then combining and categorising the results. The underlying algorithm performs two basic steps. At first, the original dataset is partitioned, and the distribution of a basic model is generated on those subsets. After doing so, the distribution is aggregated into a single model, and the results are obtained. The stacking strategy differs from standard machine learning methods because it involves a model production step. Models built from the training set are combined. You can describe the algorithm's function as follows.

- Models are created during training by employing the dataset and the training method.
- Each derived model has full annotations for all the dataset's training samples.
- The final model is built from the other models in the training dataset using the combiner method. After a final model is obtained, it categorises and tests dataset samples.
- A final prediction is made using the final model once all test dataset samples have been classified and the class predicted by the stacking algorithm of the sample is chosen.

The term ensemble technique is used to describe three distinct approaches. We're bagging, boosting, and stacking here. Data mining approaches and the capabilities of the combiner models used by each of these methods are where they diverge. Stacking strives to do both instead of maximising predictive power like boosting and minimising variance like bagging does. The function that generates a single model uses the average weight in the bagging strategy, the weighted majority vote in the boosting approach, and Logistic regression in the stacking approach.

For the suggested strategy, a tree-based Parzen estimation (PTE) is employed with hyperparameter and Bayesian optimisation (BO) techniques to further enhance the classification of the hybrid machine learning models on the benchmark dataset. Fine-tuning these parameters, or hyperparameters, is integral to every machine-learning process. Hyperparameter optimisation (HPO) enhances ML performance with decreased practitioner involvement (Feurer & Hutter, 2019). Hyperparameters are optimised in a black box and global optimisation for more accurate function evaluation. This allows us to provide a non-technical explanation of Bayesian Optimization's inner workings. Bayesian optimisation (BO) is becoming increasingly prominent in HPO for deep neural networks as a framework for the global optimisation of networks that contain expensive blackbox functions. Bayesian optimisation is a recursive method that uses a probabilistic surrogate model and an acquisition function to evaluate choices with the help of the Gaussian process. Random forest and tree Parzen estimators are just two tree-based approaches to dealing with hyperparameters (PTE). This suggested effort combines Bayesian-based optimisation (BBO) with tree Parzen estimators (TPE) to determine the optimal evaluation point for fully automated machine learning.

5.4. Performance evaluation metrics

Detection rate [18], precision, false-negative rate, and the receiver operating characteristics curve (ROC) are the performance parameters that may be measured and analysed. These indicators evaluate the system's performance, generate a categorisation report, and compare the results to those of other studies. We used a complexity matrix as one of our criteria for rating submissions (Intelligence et al., 2019). Some of the metrics used in this paper are bulleted as follow:

Routing Attack Detection Rate: This metric indicates the percentage of detected routing attacks, including blackhole, wormhole, Sybil and misdirection assaults, out of the total number of simulated attacks. A higher detection rate signifies the effectiveness of the hybrid technique in identifying malicious routing behaviours.

False Positive Rate: This metric measures the proportion of legitimate network activities falsely identified as routing attacks. A low false positive rate is desirable to avoid unnecessary alarms and ensure the reliability of the detection system.

False Negative Rate: This metric represents the percentage of actual routing attacks that were not detected by the hybrid technique. A low false negative rate indicates that the method can effectively capture most routing attacks without missing significant ones.
Precision: Precision is the ratio of true positive detections to the sum of true positive and false positive detections. A higher precision indicates that the reported routing attacks are more likely to be genuine, reducing the chances of false alarms.
Recall (Sensitivity): Recall measures the proportion of true positive detections to the sum of true positive and false negative detections. A higher recall signifies that the hybrid technique successfully identifies a larger portion of routing attacks, ensuring better coverage.
F1 Score: The F1 score is the harmonic mean of precision and recall. It provides a balanced assessment of the algorithm's accuracy in detecting routing attacks. A higher F1 score indicates a better trade-off between precision and recall.
Execution Time: This metric measures the time taken by the hybrid technique to analyse network data and detect routing attacks. A shorter execution time is preferred to enable real-time or near real-time response to potential threats.
Resource Utilization: This metric evaluates the amount of computational resources, memory, or network bandwidth required by the hybrid technique to perform routing attack detection. Efficient resource utilisation including time and energy is essential for practical deployment.

Values from the complexity matrix are used to determine the criterion for evaluation. Following is a breakdown of the values in the complexity matrix.

- In the dataset, TP (true-positive) refers to the number of samples that were accurately predicted to be incursions.
- Several samples in the normal class were correctly predicted to be in the normal class (true-negative or TN).
- False-negative (FN). The fraction of intrusions samples that were wrongly classified as normal.
- Number of normal samples in the dataset that were wrongly classified as incursions (FP, or false positive).

The detection rate is calculated by dividing the TP value by the total number of samples for which intrusion estimates were calculated. The accuracy value measures how well a system performs in classifying data by comparing the fraction of data points that were correctly labelled by the system to the total number of data points. To demonstrate the system's efficiency, we employ the following mathematical Equation (10).

$$\text{Detection Rate} = \frac{\text{TP}}{\text{TP} + \text{FN}}$$

$$\text{False alarm rate} = \frac{\text{FP}}{\text{TN} + \text{FP}}$$

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}}$$

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}}$$

$$\text{Accuracy(Acc)} = \frac{\text{TN} + \text{TP}}{\text{TN} + \text{TP} + \text{FN} + \text{FP}}$$

$$\text{F1 - score} = \frac{2 \times \text{Recall} \times \text{Precision}}{\text{Recall} + \text{Precision}} \tag{10}$$

It has been noted that the designed IDS can perform four different outcomes for each traffic operation. The following scenarios are generated using the confusion matrix. First, a True Positive (TP) occurs when an intrusion detection system (IDS) reports a successful detection of malicious activity on a network (Mohd et al., 2020); second, a True Negative (TN) occurs when an IDS does not report a successful detection of malicious activity, third, a False Positive (FP) occurs when an IDS reports no malicious activity, and fourth, a False Negative (FN) occurs when an IDS reports a successful detection.

Mean squared error (MSE). Mean squared error (MSE) measures the amount of error in statistical machine learning models for computing the position and distance of the wormhole attack between two points as in Equation (11). It assesses the average squared difference between the observed and predicted values of each sensor node's position and location, having its unique identity to detect routing attacks. When a model has no error, the MSE equals zero. As model error increases, its value increases. The mean squared error is also known as the mean squared deviation (MSD).

$$\text{MSE} = \frac{\sum_{i=0}^{n} (x_i - \bar{x}_i)^2 + (y_i - \bar{y}_i)^2}{n} \tag{11}$$

Where.

- x_i, and y_i is the i^{th} observed values.
- $\bar{x}_i$, and $\bar{y}_i$ are the corresponding predicted values.
- n is the number of observations.

The mean squared error uses a formula that is quite close to the variances. The MSE is calculated by square root, the difference between the observed and anticipated values. That should be done for every observation. After that, divide the total by the total number of observations to get the square root.

5.5. Simulation and environmental setup

Network design and model simulations were executed in MATLAB R2021a on a Windows 10 64-bit x64-based processor running an Intel Xeon Silver 4214 CPU at 2.20 GHz 2.19 GHz (2 processors), with 128GB (128GB useable) of installed RAM. Data processing and analysis with machine learning classifiers are performed in Python libraries, including Keras numpy, Sklearn, Seaborn, and pandas using Anaconda navigator and MATLAB R2021a. The simulation parameters for running network attack scenarios are depicted in Table 7, along with the values. This study assumes that Node-0 is the final destination for network traffic. A total of 5 s are allotted for the simulation.

Simulations of wormhole routing attacks are undertaken, with the results being created using an artificial neural network and a genetic algorithm that have been genetically

Table 7. WSN configuration of simulation setting.

Parameter	Setting	Parameter	Setting
Base Station	1	Topology	Hierarchical
Filed size	1500 m × 1500 m	Number of attacks	2
Number of Nodes	200	Mobility Model	Random
Protocol type	Routing	Number layers	10
Cluster size	10	Max epochs	200
Attack type	wormhole	Data size	5000 Kb
Number iterations	200	Simulation Time	5 s

enhanced for optimal effectiveness. After that, a malicious node is added to the network in order to generate and extract features for both benign and malicious network traffic. This procedure is then repeated for another five seconds of simulation time in order to develop a new database. The simulation scenarios that make use of a mobility and routing protocol that is based on a random selection of intermediate nodes and mobility nodes to identify and extract features from probable routes are outlined in Table 7. Between two malicious nodes, a wormhole attack is injected, which results in the creation of a tunnel.

6. Experimental results and analysis

In this section, each sensor node in the network is capable of establishing connections with all other nodes, resulting in a fully connected network topology. This dynamic connectivity allows the formation of wormhole tunnels. Wormhole tunnels refer to virtual tunnels or channels created between two malicious nodes in the network. as in Figure 17 20 (a) and (b). These tunnels bypass normal routing mechanisms and enable attackers to disrupt the routing discovery process. By exploiting these tunnels, attackers can carry out various routing attacks, such as selective forwarding, blackhole attacks, or Sybil attacks. The purpose of this study is to investigate the detection and prevention of such routing attacks in wireless sensor networks. By simulating the fully connected network topology and incorporating wormhole tunnels, the researchers aim to develop effective mechanisms to discover and mitigate routing attacks.

The routing wormhole attack highly affects the sensor nodes' energy consumption and timing operation for effective communication, as shown in Figure 17 (c) and (d).

The simulation results show that the proposed attack detection and classification techniques are effective, with an average detection accuracy of 99.46%, varying the hope count and wormhole tunnel of the routing attacks across the network. The results also show that hybrid techniques improve the prediction error and maximise the performance, as shown in Figure 18 (a) and (b) histograms. Figures show the differences between targets and actual outputs for computing the errors of the unknown nodes. Targets represent expected outputs, and outputs represent the actual outputs (Constraints, 2016). The error of the training data is almost 0, whereas the error of testing data is higher than that of training errors. This confirms and validates the proposed technique is effective for detecting the wormhole attack in WSNs. The validation and efficiency of the proposed system are depicted in Figure 18 (c) and (d) for detection of routing attacks at epochs 7 and 200 epochs with minimum mean squared error (MSE) of 0.0067 and $2.143x10e^{-08}$.

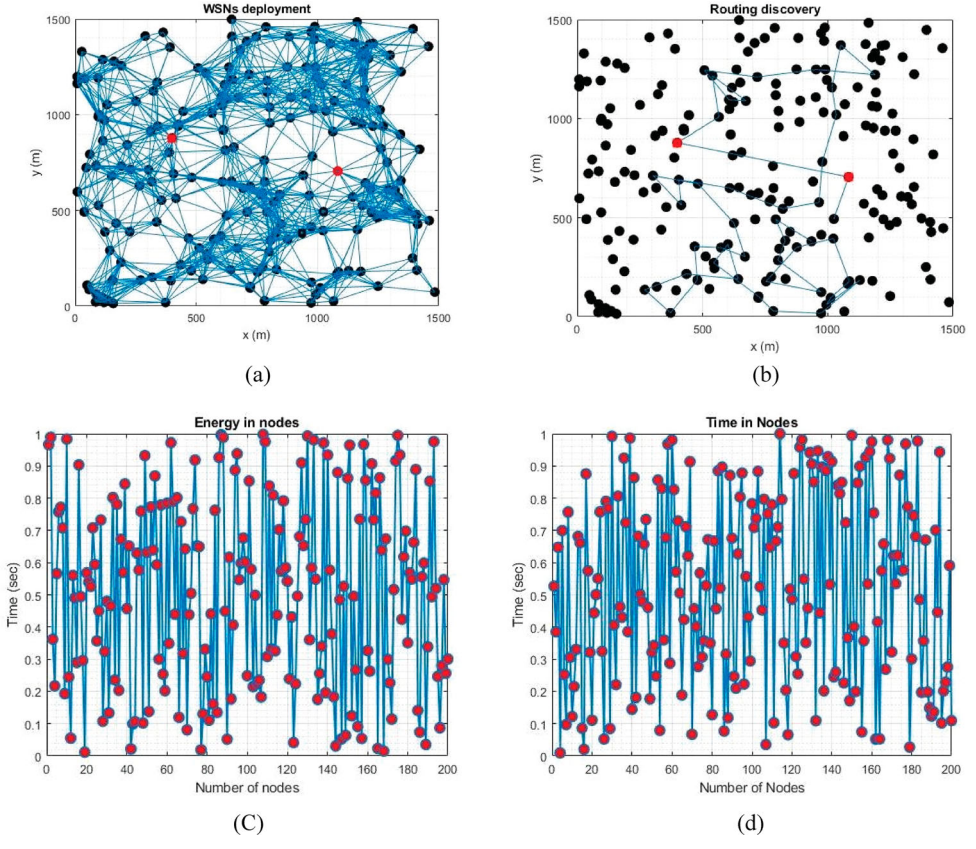

Figure 17. wireless sensor network deployment and routing discovery for analysing energy consumption and time elapsed. (a) Dynamic network deployment. (b) Routing discovery and feature extraction. (C) Energy consumed for nodes with time and (d) Time elapsed for each node.

6.1. Attack detection analysis

The samples from the reference datasets have been put through training and testing processes (Panigrahi et al., 2022). First, we randomly assign each sample to two groups. the training and test sets. Step two involves using the whole training set for both training and testing. Finally, cross-validation was utilised to test how well the proposed model actually worked. The area under the curve, false alarm rate, precision, and classification accuracy are used to evaluate performance. Machine learning models are used to assess how well the proposed method performs on benchmark datasets that simulate a variety of assaults against wireless sensor networks. When assessing the efficacy of the proposed system for detecting routing attacks in WSNs, the hybrid optimised machine learning also uses the same benchmark dataset. Table 8 provides a comparison of the results obtained by using various machine learning algorithms. Cluster labelling (CL) k-means binary classification methods are used to boost the suggested system's performance further. Table 8 shows the comparative performance of the various hybrid machine-learning techniques.

The hyperparameter and Bayesian optimisation (BO) techniques and the tree-based Parzen estimation (BO-PTE) are used to boost the performance of hybrid machine learning

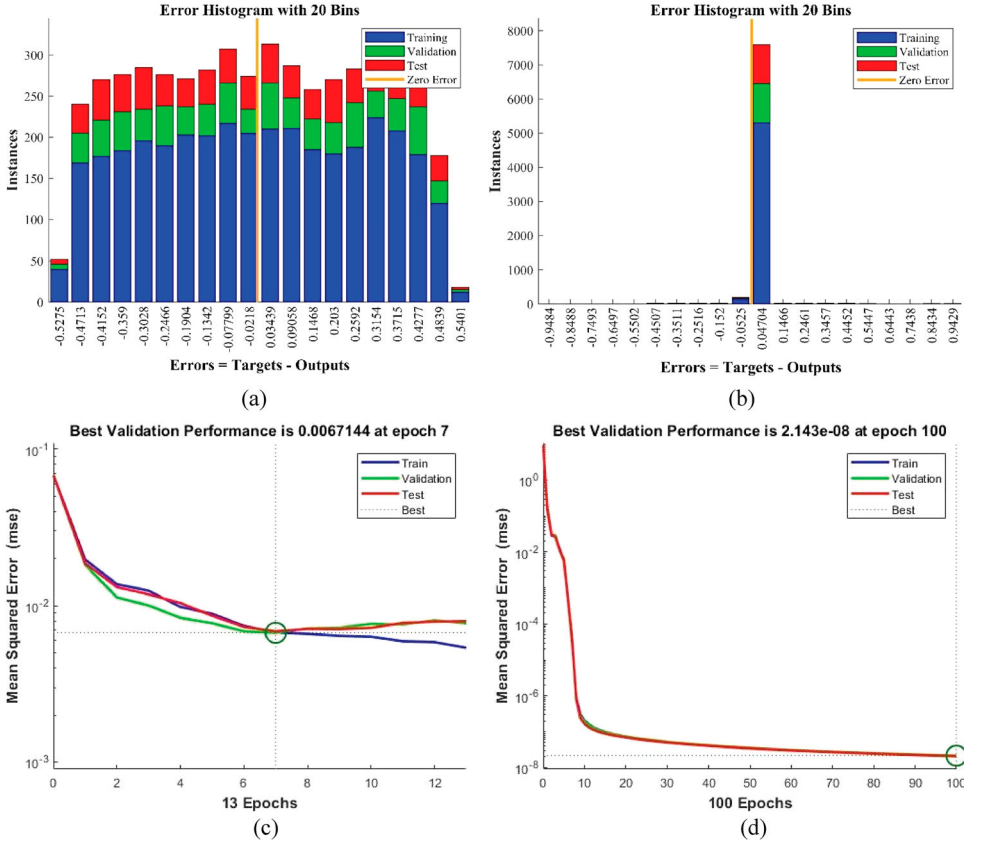

Figure 18. The proposed system's performance evaluation using hybrid GA-ANN takes 100 samples and varying the number of epochs. (a) Histogram with 300 instances. (b) Histogram with 300 instances. (c) Best performance ate epoch of 7 and (d) Best performance at the epoch of 100.

Table 8. Evaluation of hybrid machine learning models on standard datasets.

	Results against the UNSW_NB15 dataset				Results against the CICIDS2017 dataset			
Classifier	Accuracy	Precision	Recall	F1-Score	Accuracy	Precision	Recall	F1-Score

models for the proposed system. Table 8 displays the results of evaluating the proposed scheme's performance using the UNSW NB15 benchmark dataset and many other machine-learning models. When applied to the benchmark dataset, the binary classification method employing hybrid cluster labelling K-means obtains a classification accuracy of 100%.

Table 9 shows how merging different hybrid machine-learning models and moving data frames from one machine-learning to the other improves the proposed system's performance even further. The results demonstrate that hybrid ML models outperform their

Table 9. Comparison of various hybrid ML models using NSL-KDD dataset for attack detection and classification.

	Performance evaluation metrics					
ML Classifiers	validation	Accuracy	Precision	Recall	F1-score	Training time
Naive Baye (NB)	83.94	83.71	90.35	83.71	85.68	0.025
Decision Tree (DT)	87.94	88.10	88.34	88.10	88.07	0.22

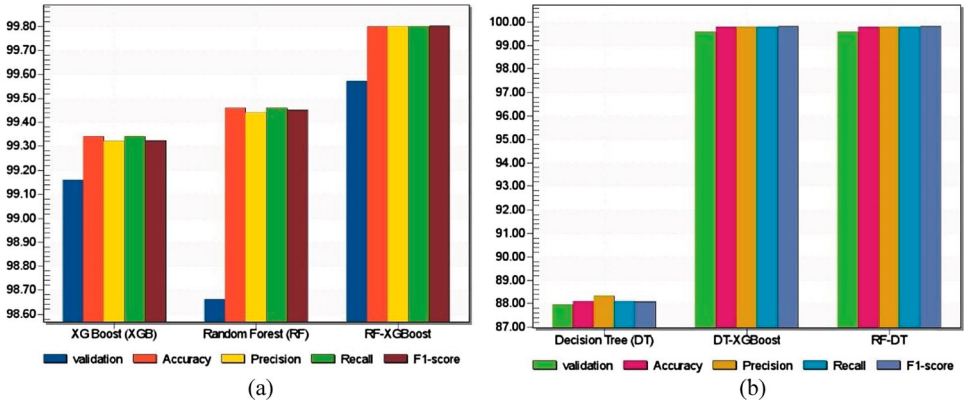

Figure 19. Performance comparison of various machine learning models using NSL-KDD. (a) RF-based comparative analysis and (b) DT-based comparative analysis

standalone counterparts in terms of Validation, Accuracy, Precision, Recall, F1 score and training time. When it comes to classification and detection, based on the results and model validation, we can say that the created system has high classification and detection accuracy against DoS attacks in WSNs.

The results show that hybrid machine techniques perform better attack detection and classification of attacks using the NSL-KDD benchmark dataset, as shown in Figure 19 (a) and (b). For attack detection and classification, the extreme gradient boosting (XGB)-an enhanced hybrid of a random forest and a decision tree achieves better results than either the random forest or the decision tree alone in terms of validity, accuracy, precision, recall, and f1-score.

The performance of the proposed technique is effective compared to L. Yang et al. (Yang et al., 2022) developed multi-tiered hybrid intrusion detection systems (MTH-IDS) for secure vehicular networks using the benchmark dataset CICIDS2017 for known and unknown attacks. They achieved average detection accuracy of 99.88% using binary classification. P. Sun et al. (Sun et al., 2020) developed a hybrid deep learning-based intrusion detection system (DL-IDS) using a convolutional neural network and a long short-term memory network (CNN-LSTM). The scheme achieved an average detection accuracy of 98.67% by extracting the network traffic. This proves that the proposed scheme effectively detects DoS attacks using the benchmark dataset in wireless sensor networks, as shown in Figure 20 (b), using

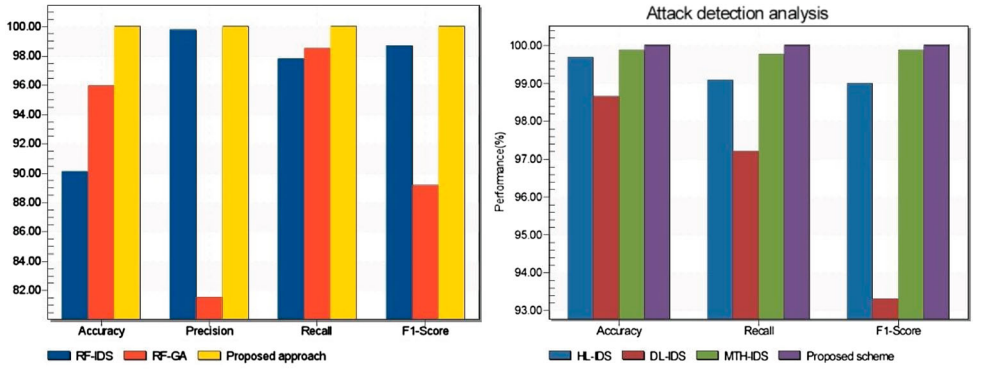

Figure 20. Performance comparison of the proposed scheme-based hybrid machine learning techniques using benchmark datasets. (a) Comparison based on UNSW_NB15 and (b) Comparison-based CICIDS2017

attack detection performance metrics. (Kasongo, 2021) presented an intrusion detection system for the Internet of Things using random forest based on a genetic algorithm (RF-GA) for feature selection, as shown in Figure 20. This achieved average detection accuracy of 87.61%, which is less than compared to 100% using hybrid binary classification. (Suleiman & Issac, 2018) Evaluated six machine learning classifiers using UNSW_NB15, phishing and NSL-KD benchmark datasets for intrusion detection system. Random forest based intrusion detection system (RF-IDS) produced better detection accuracy using UNSW_NB15. Temporal and spatial features to enhance attack detection and classification. This confirms the proposed technique is effective for detection and localisation of attacks as shown in Figure 20 (a).

In order to achieve high-performance intrusion detection across a wide range of attack types, B. Media et al. (Intelligence et al., 2019) proposed a hybrid-layered IDS (HL-IDS) that employs several distinct machine learning and feature selection approaches as shown in Figure 20 (b). The size of the NSL-KDD dataset is decreased in the created system by first performing data preprocessing on the dataset using various feature selection algorithms.

G. H. Lai (Lai 2016) Proposed detecting wormhole attacks in WSNs using low-power routing protocol and achieving 100% accuracy with fixed range and wormhole tunnel points. This confirms the proposed technique is effective for localising and detecting routing attacks in wireless sensor networks using a benchmark dataset. Y. Yuan et al. (Yuan et al., 2018) Presented a novel lightweight method for Sybil attack detection in distributed WSNs using the approximate point in a triangle (APIT) localisation approach. They achieved an average detection rate of 90%, which is less than the proposed work. D. Upadhyay et al. (Upadhyay et al., 2021) proposed a framework for intrusion detection systems in smart grids using Gradient boosting feature selection by applying machine learning classification techniques. The scheme combines feature engineering with machine learning classifiers and achieves the performance as in Figure 21 (a). This confirms that the proposed method is effective for various applications of DoS attacks in wireless sensor networks.

A unique feature selection algorithm, the dynamic recursive feature selection algorithm, was introduced by Nancy P et al. (Nancy et al., 2020), which chooses an optimal number of

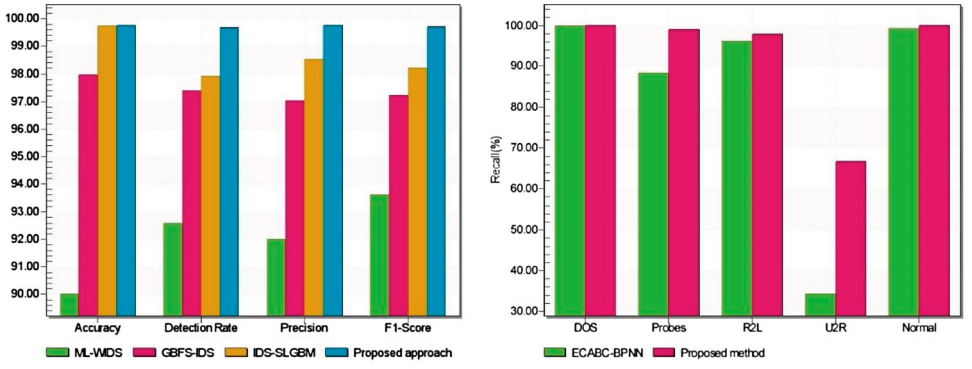

Figure 21. Performance comparison of the proposed technique with other previous works. (a) Comparative analysis of the proposed scheme and (b) Comparative analysis based on recall

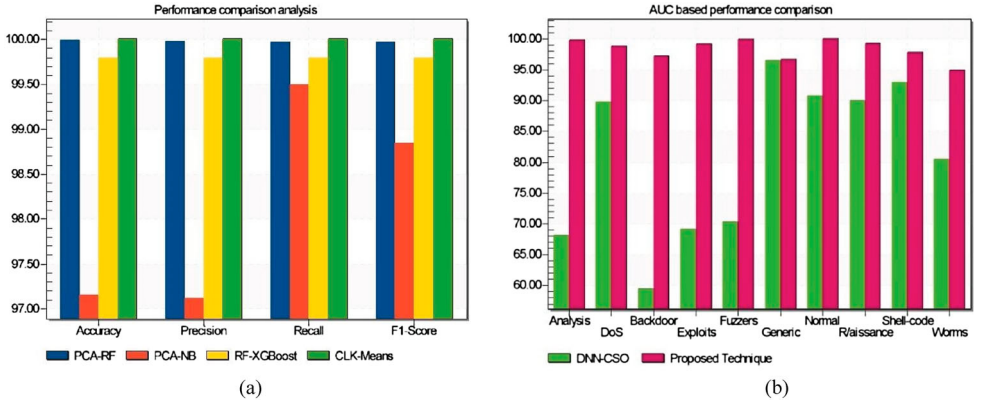

Figure 22. Examining the proposed system's performance of similar works using standard benchmarks. (a) Comparison of the proposed system with recent works and (b) AUC-based performance comparison using the UNSW-NB15 benchmark dataset.

features from the data set. Moreover, a sophisticated intrusion-detection system based on a fuzzy logic algorithm (IF-IDS) using the NSL-KDD dataset is shown in Figure 20. Extending the decision tree approach and including convolution neural networks are also presented as means by which to detect the invaders efficiently. The technique of intelligent feature selection algorithm named dynamic recursive feature selection algorithm (DRFSA) has been proposed in this work, which picks the important features to construct the data set. G. Qi, J. Zhou et al. (Qi et al., 2021) presented a new ECABC-BPNN, a combination of back propagation neural networks (BPNNs) and elite clone artificial bee colonies (ECABCs), that improves upon the standard BPNN's weight and threshold settings as depicted in Figure 21 (b).

The proposed system is evaluated using benchmark datasets based on accuracy, precision, recall, F1-score and AUC criteria. The proposed scheme's performance is effective compared to R. Khilar et al. (Khilar et al., 2022) and (Saheed et al., 2022) in terms of various evaluation metrics. This proves the system effectively detects and localises DoS assaults in WSNs, as in Figure 22 (a) and (b).

Table 10. Performance evaluation of the proposed system using the NSL-KDD benchmark dataset.

	Proposed AIDS-HML approach			Intelligent fuzzy-based IDS			ECABC-BPNN
Class of attacks	Precision	Recall	F1-Score	Precision	Recall	F1-Score	Precision
DOS	99.89	99.93	99.91	99.99	97.23	98.72	98.56
Probes	99.30	98.87	99.08	92.67	97.97	93.34	86.70

The next step is using ECABC-BPNN to identify threats in a computer system's network. The comparison and Conducted experiments on assault classification using benchmark dataset as shown in Table 10.

The proposed scheme is further compared for validation with previous works to detect and localise routing attacks in WSNs. S. Jiang et al. (Jiang et al., 2020) Proposed an intrusion detection system based on a secure light gradient boosting machine (IDS-SLGBM) in wireless sensor networks using the WSN-DS benchmark dataset with the class of routing attacks.

The experimental results and analysis show that designing advanced intrusion detection systems (IDS) based on hybrid machine learning techniques in hierarchically wireless sensor networks introduces several novel aspects and contributions. Here are some key points that highlight the novelty of this design:

Hierarchical Wireless Sensor Networks: Hierarchical architecture in wireless sensor networks introduces an additional layer of complexity and organisation. The network is divided into multiple levels or tiers, with different roles assigned to nodes at each level. This hierarchical structure helps in efficient data aggregation, routing, and management in large-scale sensor networks.

Hybrid Machine Learning Techniques: The IDS design incorporates hybrid machine learning techniques, which combine multiple algorithms or approaches to enhance the accuracy and effectiveness of intrusion detection. This hybridisation can involve integrating different machine learning models, such as combining supervised and unsupervised learning methods or combining traditional rule-based techniques with machine learning algorithms.

Advanced Intrusion Detection: The IDS focuses on advanced intrusion detection, aiming to detect sophisticated attacks beyond simple rule-based or signature-based detection methods. Advanced attacks often exhibit complex patterns or behaviours that can be challenging to identify using traditional approaches. By leveraging machine learning techniques, the IDS can learn and adapt to evolving attack patterns, enabling the detection of novel and unknown attacks.

Novelty in Feature Selection: The design may introduce novel approaches to feature selection, which involves identifying the most relevant and discriminative features from the sensor data to train the machine learning models. Effective feature selection plays a crucial role in improving the accuracy and efficiency of intrusion detection systems, especially in resource-constrained wireless sensor networks.

Scalability and Efficiency Considerations: The design considers wireless sensor networks' scalability and efficiency requirements. Hierarchical structures and optimised machine-learning techniques are employed to reduce the network's computational overhead,

energy consumption, and communication overhead. These considerations ensure that the IDS is suitable for deployment in resource-constrained environments.

6.2. Limitation of the proposed system

While design of advanced intrusion detection systems based on hybrid machine learning techniques in hierarchically wireless sensor networks presents promising approaches to intrusion detection in wireless sensor networks, it also has certain limitations that should be acknowledged:

Scalability: The performance of the proposed advanced intrusion detection system may degrade with the increase in the size of the wireless sensor network. Handling a large number of nodes and data traffic could pose challenges in terms of computational resources and memory requirements.

Complexity and Overhead: The hybrid machine learning techniques used in the system may introduce additional complexity and computational overhead, particularly for resource-constrained sensor nodes. This could impact the real-time responsiveness and energy efficiency of the overall network.

Training Data Collection: Obtaining labelled training data for machine learning algorithms in wireless sensor networks can be challenging. Collecting a diverse and representative dataset of intrusion scenarios, including rare attacks, might be difficult due to the limited resources and controlled environment.

Intrusion Diversity: As new intrusion techniques and attack patterns emerge, the detection system may face challenges in generalising and adapting to previously unseen or zero-day attacks, especially when using pre-trained machine learning models.

Security and Privacy: Deploying an intrusion detection system in the network itself could potentially become a target for attacks. Adversaries might try to manipulate the system's behaviour or exploit its vulnerabilities to evade detection.

Adaptability to Network Changes: As the wireless sensor network topology changes due to node failures, additions, or mobility, the intrusion detection system should be able to adapt and maintain its effectiveness.

False Alarms: Hybrid machine learning techniques might lead to false alarms in certain situations, triggering unnecessary responses and consuming valuable resources for investigating non-existent attacks.

7. Conclusion and future work

The proposed advanced intrusion detection system based on machine learning effectively detects and classifies attacks for scalable and manageable in hierarchically distributed wireless sensor networks. This research aims to create a classification model for an advanced intrusion detection system based on hybrid machine learning, specifically tailored for use in wireless sensor networks to detect intrusions. Each sensor node collects information on the state of its features and reports it to the cluster's central processing node. The cluster leader checks the data and then forwards it to the main cluster head. The proposed hybrid machine learning models use training and testing data to identify attacks. Our suggested IDS-HML outperforms state-of-the-art systems regarding detection and localisation

accuracy in a simulated attack on a WSN. By comparing the hypothetical outcomes to earlier research, we find that they are credible. The simulation results show that the proposed system is effective for detecting routing attacks with a localisation accuracy of 99.46% of the wormhole routing attacks. The effectiveness of the suggested system has been measured in accuracy, precision, TP Rate, FP Rate, F-Measure, Mean squared error, and Time. The designed IDS-HML achieved 99.82%, 99.91%, 99.85%, 99.82%, and 100% for average detection accuracy, precision, F1-score, recall, and CLK-Means respectively, in the presence of normal and intrusion traffic using CICIDS2017 dataset as a benchmark for multiclass and binary classifications. This work is implemented using MATLAB for network planning and simulation of attack scenarios. The Python libraries are utilised for hybrid machine-learning classification techniques. This model uses logic rules for decision-making and interpretable predictive models.

Overall, the novelty lies in the combination of hierarchical wireless sensor networks, hybrid machine learning techniques, advanced intrusion detection capabilities, novel feature selection approaches, and considerations for scalability and efficiency. These elements contribute to the development of a robust and effective IDS for wireless sensor networks.

Although the proposed method performs well, it is essential to note that IoT-based WSNs are still susceptible to attacks not addressed in this study. Since the dynamics of the attacks change with time, the topology and design should cope with the attack scenarios. The countermeasures module is only provided in concept, which is another shortcoming. Therefore, we plan to investigate and eventually offer specialised advanced hybrid intrusion detection systems for each type of assault utilising benchmark datasets to evaluate hybrid machine learning techniques. In future work, we will explore collaborative advanced intrusion detection systems based on machine learning in IoT-based wireless sensor networks for different applications using benchmark datasets for evaluations.

***Abstract*— Carbon Nanotubes Field Effect Transistors (CNFETs) have shown numerous advantages over conventional Metal Oxide Semiconductor FETs (MOSFETs) and CMOS in terms of decreased short channel effect, lower power consumption and high performance. As the transistor channel length shortens to below 10 nm in length, short channel effects, such as drain-induced barrier lowering and velocity saturation, becomes prominent, which negatively impact transistor performance and reliability. As CNFETs do not show scaling issues, CNFETs based digital circuit designs, such as adder and multiplier, can possibly show better results in terms of power consumption and propagation delay. Multiplication operation is a crucial operation whose application ranges from computing convolution to fast fourier transform. Hence, it is important to have an efficient architecture and high-performance multiplier. Array multipliers, Wallace and Booth's multipliers are some of the existing multipliers. One approach to perform high-performance multiplication is through the Vedic Multiplier, whose algorithm reduces delay and power consumption. Many of the pre-existing Vedic multipliers implementations techniques such as MUX based adder, Carry select adder, Hybrid 13T Full Adder rely on CMOS technology for their implementation which brings the challenges like short channel effect while scaling of CMOS transistors. Because CNFETs do not show scaling issues the performance of Vedic multiplier can be improved using CNFETs. This paper proposes a 4*4-bit Vedic Multiplier using 32nm CNFET Technology. The proposed implementation is simulated using HSPICE simulation tool, CosmosScope (cscope) software and Stanford CNFET Model file. The delay and power consumption parameters are measured for various supply voltages. Moreover, the comparative analysis of the aforementioned parameters has also been done by changing the chirality of the transistors.**

Keywords*— *Carbon Nanotubes Field Effect Transistors, Vedic multiplication, Urdhva Tiryagbhyam, Chiral Vector

I. INTRODUCTION

Carbon Nanotubes Field Effect Transistors (CNFETs) have developed as potential replacement to the conventional Metal Oxide Semiconductor FETs because of scaling down related issues which are seen in MOSFET. Some of the issues that are confronted with MOSFETs during scaling down are short channel effects, hot carrier generation, drain-induced barrier lowering, high leakage current and velocity saturation [1]. In the area of having decreased short channel effect, lesser area, lower power consumption and higher performance, CNFETs show better performance than CMOS [2]. Along with CNFETs, FinFET, single-electron transistor (SET), and tunnel FET have been made to solve the issues faced with conventional MOSFET and CMOS. MOSFETs depend on the phenomenon of diffusion and drift whereas CNFETs, which have high carrier velocity, are based on the ballistic transport conduction mechanism [1]. While, in MOSFET, the channel material is Si-based, CNFET have their channel material constructed using carbon. It can be observed that thinner structures of CNFETs support better gate control in comparison with conventional MOSFET.

Multiplication is one of the most fundamental operations in any mathematical operation, complex or simple. It is widely used in Arithmetic Logic Units, and in Embedded Systems, like in Digital Signal Processors. Operation like Multiplication is one such operation which can decide the overall execution time for any processing unit. Hence, building an efficient multiplier can have important applications in computation. Operations involving convolution and fast fourier transform, which have their own importance, are primarily based on multiplication. There exist many architectures which have been developed to increase the efficiency of multiplication, for instance, array multipliers, Wallace Multipliers, Booth's multipliers, etc.

Another approach to perform multiplication is with the help of Vedic Multipliers. A Vedic Multiplier has better performance than conventional multiplier [3]. The term 'Vedic' basically comes out from the root word "Veda", signifying storage of data and information. Vedic mathematics is an interesting as well as important field of study. It is useful in reducing the steps for obtaining the summation or multiplication results as it offers the easiest steps in calculations. Over the years, there have been several Vedic multipliers which have reduced the input to output delay and enhanced area and power efficiency, by improving the circuit as well as by using different Transistor technologies. Some of the previous Vedic multiplication implementation include using MUX based adder [3], carry select adder [4], GDI logic [5], Manchester carry chain (MCC) adder [6], hybrid 13T full adder [7], Brent Kung Adders [8], etc. [3] uses full adder based on MUX which improves speed of Vedic multiplier, [5] uses a reduced transistor approach to implement Vedic multiplier, [6] shows better power-delay product (PDP) than existing designs with minimum area and [7] reduces power consumption and delay using 90nm CMOS technology. The demerits of existing Vedic multipliers is that it is based on CMOS technology which raises challenges like short channel effect while scaling of CMOS transistors. As the various advantages of CNFET have been previously discussed, through this paper an approach has been presented to implement Vedic multipliers using CNFETs. As CNFETs have significant merits over other transistors such as lesser short channel effect, lower power consumption, the proposed approach to implement CNFET based Vedic multiplier is expected to show a more preferable result. As per our literature survey and to the best of our knowledge, previous implementation of CNFET based Vedic multiplier is unexplored. As the novelty, the paper proposes architecture of CNFET based Vedic multiplier.

In this paper, we have implemented a 32 nm CNFET based 4*4-bit Vedic multiplier and various analysis such as delay and power consumption have been found via utilizing the

HSPICE simulation tool, CosmosScope (cscope) and CNFET model developed at Stanford University [9]. Section II describes about CNFETs and Section III presents algorithm for Vedic multiplication. Section IV shows proposed methodology and includes measured results like power consumption and delay for implemented multiplier circuit.

II. Carbon Nanotubes Field Effect Transistors (CNFETs)

CNFETs have been developed as an improvement to conventional transistors [10-11]. The fabrication of CNFETs is done using multiple Carbon Nanotubes (CNTs), which are used as channel in the transistor. Techniques like Chemical Vapor Deposition (CVD), LASER ablation and Arc Discharge are used for developing the CNTs. Various fabrication processes like doping, masking, etching and lithography help in CNFETs' development [1]. Metal deposition is then carried out to connect the CNTs with the gate, source and drain regions of the CNFET.

In CNFETs, which are primarily based on the phenomenon of ballistic transportation, the channel length is a factor responsible for such transportation because ballistic transportation is possible when the channel length of CNFET is lesser than mean free path of charge carrier [12]. Carbon nanotubes or CNTs, which form the channel material of CNFETs, are responsible for favorable features possessed by CNTFETs such as high mechanical strength, lower power consumption, high electrical conductivity and reduced size which is suitable for nanoelectronics. These properties of CNTs improves overall performance of any digital circuit made using CNFETs. CNTs can be categorized on the basis of two parameters, namely chirality and number of walls.

On the basis of the walls, CNTs are of two kinds : single walled (SWCNT) and multiwalled (MWCNT). For the manufacturing of CNFETs, single-walled are preferred over multi-walled because it exhibits better semiconductor properties vis–a-vis multiwalled, and also has the capability of withstanding the large flow of current.

Chirality is a unique property in CNTs which defines its electrical, optical and mechanical characteristics [13]. It is explained as the orientation in which graphene, which has a hexagonal lattice of carbon atoms, is arranged to form the wall of the carbon nanotube. For SWCNTs, this orientation is described by a set of pair of integers (n,m). The coordinates of the vector gives us the direction of the graphene lattice that is rolled up to form the wall of the carbon nanotube [14]. Moreover, the chirality of the nanotube also determines its bandgap of electrons, thus, making it an important factor to be considered when considering the design and engineering efficiency of carbon nanotube-based materials. On the basis of chirality or chiral vector(n,m), CNTs can have three varieties : zig-zag, helical and armchair [1]. Armchair CNTs have chiral vectors that are of the form (n,n), while zigzag CNTs have chiral vectors of the form (n,0) or (0,n), where n is an integer. Helical chirality in CNTs refers to the twisting of the graphene lattice as it is rolled up into a tube along the length of the tube. Usually, zig-zag type CNTs have a larger bandgap as compared to armchair type, due to chiral symmetry. Any CNT with indices (n, m) is metallic on the following condition: n=m or n-m = 3i (where, i is an integer). Any CNT with indices (n, m) is semiconducting on the following condition: n-m ≠3i (where, i is an integer). CNFETs are developed using semiconducting CNTs. Using the SWCNT chiral vector (n,m) can help in determining its diameter as follows [15-16]:

$$d_{CNT} = \frac{\sqrt{3}a_{c-c}}{\pi}\sqrt{m^2 + n^2 + mn} \quad \text{... (i)}$$

where a_{c-c} is the carbon-carbon bond length, whose value is about 1.42 Å.

Chirality plays a significant role in creating CNFETs and can impact their performance. A CNFET is a type of transistor that uses a carbon nanotube as the conducting channel, with a gate electrode controlling the flow of current through the channel. CNTs with different chiral vectors have different bandgap energies, which can affect the threshold voltage of a CNFET [17]. Chirality also affects the conductivity of CNFETs [18]. Since semiconducting CNTs have moderate bandgaps, they are ideal for their use as transistors. Whereas, metallic CNTs have lower resistance, which can be used as conducting channels in the same CNFET. CNFETs can have either a p-channel (PCNFET) or a n-channel (NCNFET). Keeping the Chirality at (19,0), Drain Current-Drain to Source Voltage (I_D-V_{DS}) Characteristics is plotted for an NCNFET, for different gate-source voltages (V_{GS}), shown in Fig. 1.

As described above, CNFET is a field Effect Transistor built out of Carbon Nanotube. CNFETs have several advantages over traditional silicon-based transistors, including low power consumption and improved thermal stability [17]. Its high electron mobility, or the velocity of electrons through the channel, compared to traditional silicon-based transistors, is higher, which allows for faster switching times and lower power consumption [19]. They can also withstand higher temperatures without thermal degradation [17]. Moreover, as the name 'carbon nanotube' suggests, they are quite small in diameter and thus can be used extensively in areas which have severe constraints on the size of appliance, such as nanoelectronics.

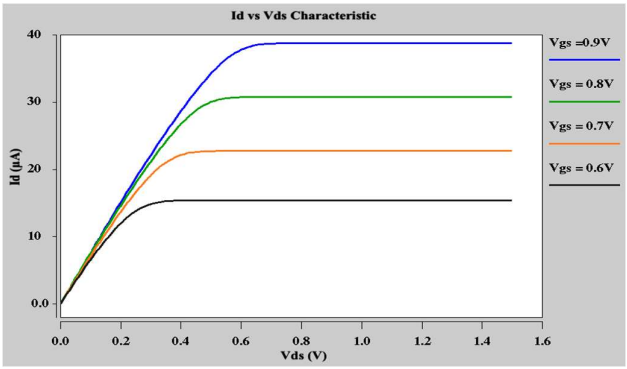

Fig. 1. I_D-V_{DS} characteristics of an NCNFET

Chirality also affects the optical properties of CNTs, like its absorption and emission spectra. Thus, controlling these properties allows researchers to develop newer technologies in optoelectronics applications [20], healthcare applications [21-23] , in photovoltaic devices [24]. Of late, researchers have also developed various methods for synthesizing CNTs of specific chirality to suit the application-specific demand.

III. Algorithm For Vedic Multiplication

The initial references to the Vedic Multiplication techniques were documented in [25] with other 16 principles and concepts, of which the Urdhva Tiryagbhyam (UT) Sutra is one of the important principles concerned with multiplication. The UT Sutra is one of the oldest in Vedic mathematics history, applicable to various techniques and applications in math, as it holds in all situations of multiplications. The algorithm depends on the idea, "vertical and crosswise" multiplication. It is recursive for complex or high no. of bits multiplications, with base condition at 2*2 bit. For base condition, the LSB bits of the two numbers are multiplied vertically, then the remaining corresponding non-MSB bits (2 bits) are multiplied crosswise and added. Then, the MSB bits are vertically multiplied. The result at the end of each step will be appended to give the result.

For even *n*, consider two *n* - bit numbers, P and Q, which can be divided into *n*/2 bits, say P_H, P_L, Q_H and Q_L respectively. P_H and P_L represent most significant and least significant *n*/2 bits of P. Similarly, Q_H and Q_L represent most significant and least significant *n*/2 bits of Q. Using this we can obtain the following partial product:

$$P_0 = P_L * Q_L \qquad P_1 = P_L * Q_H$$
$$P_2 = P_H * Q_L \qquad P_3 = P_H * Q_H$$

where, P_0 , P_1 , P_2 and P_3 partial products can be added as following to get required result:

$$P * Q = P_3 * 2^n + (P_2 + P_1) * 2^{n/2} + P_0$$

IV. Proposed Architecture

A. Full Adder

A Full adder is a quintessential component of the Vedic Multiplier. From the top-level design, it involves taking 3 sets of 1-bit inputs, while giving out the Sum and Carry generated by adding the 3 data inputs. Consider the inputs as A, B, C_{in} and the results as CARRY and SUM. Then, the Boolean function of the SUM and CARRY as a function of the inputs is given as:

$$\text{SUM} = A \oplus B \oplus C_{in} \quad \dots (1)$$

$$\text{CARRY} = AB + (A \oplus B) C_{in} \quad \dots (2)$$

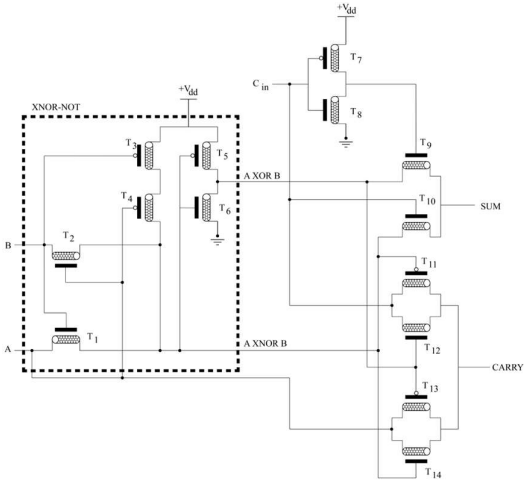

Fig. 2. 14T CNFET 1-bit Full Adder (adapted from [26])

The 1-Bit Full adder used in our architecture, shown in Fig. 2. , works by realizing the design for the boolean expressions in equation (1) & (2). It consists majorly of the XNOR-NOT module followed by the SUM and CARRY operations. The XNOR-NOT module realizes both XOR as well as XNOR expressions. This Module is created using 6 Transistors. Transistors T_1, T_2 (NCNFET)and T_3, T_4 (PCNFET) create the XNOR gate, the output of which is then passed through a CNFET inverter to generate XOR output. The third input (C_{in}) has also been passed through an inverter for the next step. Both XNOR and XOR are used subsequently in the SUM and CARRY Module. Subsequently, the SUM operation can be performed by XORing the 3 data inputs and knowing that the first two data inputs have already been XORed previously, we can use a Pass-Transistor Logic (PTL) to generate the result. The logic behind PTL, besides reducing transistor count, is also to reduce the delay of the SUM module. The total transistors of 2 NCNFET transistors (T_9 & T_{10}) are used in this module.

To generate CARRY, the use of the Transmission Gates Logic (TG) has been taken. As Eqn. (2) denotes, there are two minterms and consequently, there will be two TGs used in the Carry Module – one each to generate the respective minterm, i.e., AB & (A⊕B) C_{in}. Each submodule uses a PCNFET (T_{11} & T_{13}) and NCNFET (T_{12} & T_{14}) transistors respectively, thus making the total of 4 Transistors (T_{11}-T_{14}) in the Carry Module. Hence, the entire 1-Bit CNFET Full Adder is made using 14 Transistors. The full adder's use has been extended to create the other components, thus realizing the Vedic Multiplier's architecture.

B. Proposed 4*4-Bit Vedic Multiplier

The presented architecture is the 4*4-bit Vedic multiplier based on 32nm CNFET Technology. Fig. 3. shows CNFET based 2*2-bit Vedic multiplier which computes the binary multiplication of a pair of 2-bit numbers using Urdhva Tiryagbhyam Sutra. The proposed 4*4-bit Vedic multiplier, as depicted in Fig. 4. is considered as a black box which takes in a pair of 4-bit data as inputs and gives out an 8-bit result. It constitutes CNFET based 2*2 - bit Vedic multiplier and CNFET based Ripple Carry Adders. The CNFET based Ripple Carry adder functions as a serial full adder, which generates sequentially the output bits viz. sum and carry bits. Then, 4-bit Ripple Carry Adder (i) is used to add the partially generated array of SUM bits generated by the 2-bit Vedic Multipliers (ii) and (iii). The result obtained is used to add the result with the result of 2-bit Vedic Multipliers (i) and (iv). The 2-bit Ripple Carry Adder is used to add M3[3:2] with the result of 1-bit Full Adder, i.e., sum of the two carries generated by the two 4-bit Ripple Carry adders. The results are the two most significant bits of the final result. The carry generated in the final step is discarded.

P[1:0]	01	1	2-bit CNFET Vedic Multiplier (i) - Output

C. Implementation And Result

The proposed 32nm CNFET based Vedic multiplier (Fig. 4) has been implemented using HSPICE and simulated using CosmosScope. The CNFET model file was developed by and resourced from the Nanoelectronics Lab, Stanford University. For the purpose of carrying out a simulation for the 4*4-bit Vedic Multiplier, single walled CNFETs were used and the dimensions for a chiral vector were set to be (19,0).

The reason for keeping the chirality at (19,0) is to have a lower threshold voltage of CNFET, which facilitates in having an increased range of operation. The single-walled CNFETs are used to have a more uniform control over the properties of the transistor, which makes its study with variation with chirality easier. The simulation result of the proposed Vedic Multiplier at a supply voltage of 1V and chiral vector (19,0) is shown in Fig. 5.

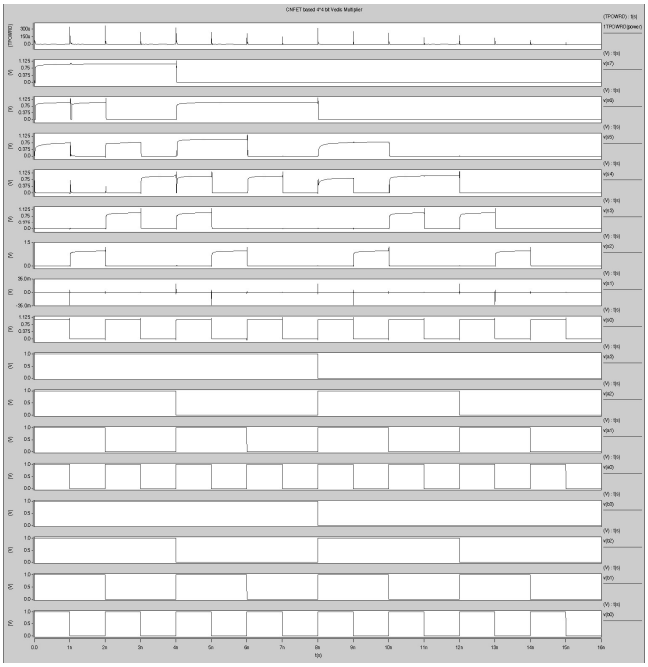

Fig. 5. HSPICE Simulation at supply voltage of 1V

Furthermore, to facilitate a deeper understanding of the proposed Vedic Multiplier, a comparative analysis of the maximum input-to-output delay and power consumption is performed. This is done by varying the supply voltages from 0.6V to 1.0V, by giving a step size of 0.1V. However, the chiral vector is the same as used above, i.e., at (19,0), to ensure that transistor characteristics are kept constant during the simulation. The results obtained are consolidated in Table 2. The trends of the variation in measured values for delay and power consumption are also plotted in Fig. 6. and Fig. 7. respectively. Further, to observe the effect of chirality on overall performance of the proposed circuit, analysis of propagation delay and power consumption is performed by varying chiral vector. Thus, as chirality is varied, the supply voltage(V_{dd}) is kept constant. Chiral vector is varied as, (16,0), (17,0), (19,0), (20,0) and then (22,0). While the chiral vector is varied, the supply voltage (V_{dd}) is first kept constant at 0.7V and then at 0.9V. Table 3 provides the obtained result for supply voltages 0.7V and 0.9V. The trends of the variation in measured values for delay and power consumption in Table 3 are also plotted in Fig. 8. and Fig. 9. respectively.

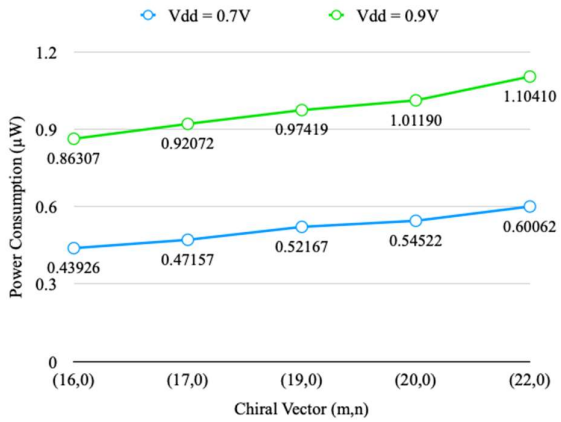

Fig. 9. Power Consumption on varying chiral vector at supply voltages 0.7V and 0.9V

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on August 10,2023 at 06:40:09 UTC from IEEE Xplore. Restrictions apply.

For the proposed architecture, it is observed that as supply voltage is varied from 0.6V to 1.0V (for chiral vector (19,0)), propagation delay decreases and power consumption increases. As supply voltage increases, faster switching occurs in transistors present in the circuit which results in reduced propagation delay. Also, as chiral vector is varied as (16,0) , (17,0), (19,0), (20,0) and (22,0) and supply voltage is kept at 0.7V and 0.9V respectively, it is observed that propagation delay decreases and power consumption increases.

The proposed model, when simulated at supply voltage of 0.9V and chiral vector (19,0) results in a propagation delay of 52.411ps and power consumption of 0.974µW. Even though based on different technologies, the proposed results can be analyzed by taking into account already existing methods, as presented in [4] using CMOS-based Carry Save Adder wherein the propagation delay is 376ps and power consumption is 4.11µW. Also considering the results obtained in [6] using CMOS-based MCC Adders, the propagation delay is 698ps and power consumption is 39.81µW.

V. Conclusion

In the proposed method, a novel Carbon Nanotube FET (CNFET) based 4*4-bit Vedic Multiplier is implemented using the 32nm Stanford University CNFET Model. The performance of the Vedic Multiplier is tested by simulating it at different supply voltages from 0.6V to 1V (keeping the chirality at (19,0)) and measuring the maximum delay and the power consumed by the circuit. It has been noted that for a supply voltage of 0.6V, the circuit runs with a highest delay since being closer to threshold voltage, it has slow switching speed. Moreover when supply voltage is increased, it is observed that the delay progressively reduces with a depreciating rate of decrease. Between 0.6V and 0.7V, the rate of decrease is ~37%, while the same for 0.7V to 0.8V is 28.4%, 0.8V to 0.9V is 19.4%, and 0.9V to 1V is 15.9% . Similarly, it is seen that with increase in supply voltage, the power consumption also gradually increases, which conforms with the view that increasing power supply leads to power consumed by the circuit. The maximum delay and power consumption by this Vedic Multiplier is also compared on the basis of chirality of CNFET. The chirality (n,m) is varied as (16,0) , (17,0), (19,0), (20,0) and (22,0) for two supply voltages, 0.7V and 0.9V. The trend observed is that while keeping the voltage constant, the delay progressively decreases and power consumed increases with increasing chirality (i.e. for n=16, 17, 19, 20 and 22).

In future, the proposed work can be extended to multiply two numbers of higher bit-width. Moreover, the scope of the proposed architecture can be explored further by analyzing the effect of channel length of CNFET on the performance of Vedic Multiplier.

***Abstract*— In today's modern era where the world has advanced with latest technologies, still there is scope of improvement in various fields. Currently we are witnessing modern techniques using Artificial Intelligence and Machine learning. We can use them to enhance and improve the human health and lifestyle. One research area less explored is Diabetic Retinopathy and Hypertensive Retinopathy. Both are caused by Chronic Diabetic conditions or Hypertension Condition, which can cause serious damages in one's eye including blood vessel rupture cotton wool-spots etc. We can capture high resolution images and can use them to classify and detect the condition and help the patient with early diagnosis that can save them from losing their eyesight.**

***Keywords*— Deep Learning, Retina, Autoencoder, Hypertension Retinopathy, Diabetic Retinopathy, Hard Exudates, Cotton Wool**

I. INTRODUCTION

The eye consists of many membranes, one of which include the inner layer called the retina, which lies in the choroid and receives almost all nourishment from the blood vessels inside the choroid, with the rest coming from the retinal blood vessels that lie on the surface and can be seen with an ophthalmoscope. With Age retina tends to become weaker and more likely to be damaged. Retina is an important part and diagnosis of any disease in this part becomes a high priority. With tools like Machine Learning and AI we can help in preventing loss of eyesight in people. Usually there are two main diseases that are likely to cause harm to retina one is Diabetes and the other is Hypertension.

Hypertension - High blood pressure is a one of the conditions which his affecting the body's arteries. Also called Hypertension. In high blood pressure, the pressure of the blood through the arteries' walls is consistently very high. The heart would have to try harder and more to circulate blood. Blood pressure is measured in millimetres of mercury (mmHg). Hypertensive retinopathy is a condition of the blood vessels in the retina caused by high blood pressure. Symptoms usually occur in the later stages of the disease. On fundus examination, arteriovenous stenosis, arteriovenous dissection, changes in blood vessel walls, flaming or burning haemorrhage, cotton spots, yellow solid exudate, and papilledema were observed.

Diabetes - Diabetes is a disease that usually comes due to inefficient functioning of pancreas in creating insulin or the when body is not able to utilize use the insulin it produces. Insulin is a hormone that keep our blood sugar levels in check. Diabetes is of two types and usually people with diabetes mellitus are more prone to retinal disease called Diabetic retinopathy. Diabetic retinopathy is a condition caused due to advancement of diabetes. Diabetes can cause the tiny blood vessels in the retina to get swelled up which eventually led to bleeding and then leaking of fluid. In the eye, this process can lead to damage the retina. Usually, it affects our both eyes. Non-proliferative and proliferative are two main types of diabetic retinopathy. Non-proliferative: This is usually common type of retinopathy and occurs when the capillaries from backside of the eye get swelled up to form pockets. Non-proliferative retinopathy is categorized into three stages considering severity of the lesion. Proliferative: It is the advanced stage of diabetic eye condition. It occurs when the new blood vessels start growing in retina of eye.

II. RELATED WORK

From a long time, many studies have been done on automatic detection of diabetic retinopathy using different feature and techniques. M. Chetoui et al. [1] proposed a machine learning model to detect diabetic retinopathy from texture feature.U. Köse et al. [4] proposed a deep learning model that diagnosis diabetic retinopathy using convolutional neural networks.M. -C. Chang et al. [5] classified the severity of diabetic retiopathy using deep neural network. whereas talking about hypertensive retinopathy M. F. Syahputra et al. [6] proposed a

probabilistic neural network model to identify hypertensive retinopathy from retinal fundus images, V. Savant et al. [7] did analysis of the vessel parameters to help in detection of hypertensive retinopathy, N. Deepa et al. [11] that used a Dense Net on various features of hypertensive retinopathy to classify E-TLCNN, S. Irshad et al.[10] proposed a model to automatically detect cotton wool spots that helps in diagnosis of hypertensive retinopathy. There have been very few studies that actually classify diabetic and hypertensive retinopathy in an one single model with a good accuracy, because there are minor differences between them which can only be differentiated at an early stage of the disease by using the parameters of retinal arteries, veins and cotton wool spots.

III. AUTOENCODER

Autoencoder is generally used in the subject of unsupervised machine learning algorithms. You can use Encoders to compress the facts of images and reduce their dimensionality and through decoders, you can regenerate the original image. Autoencoders are generally compared with principal component analysis (PCA). PCA unearths the instructions along which you can undertake the records with the

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:52:38 UTC from IEEE Xplore. Restrictions apply.

most variance, and in the case of Autoencoders reconstruct our original enter given only a compressed model of it. If anybody desires impressive statistics and wants to generate good results from their algorithms can reconstruct image data into encoded data and also can reconstruct the image data by use of autoencoders. An Autoencoders are a type of neural network that may learn how to regenerate photographs, textual content, and other features from compressed versions of themselves. An Autoencoder includes three layers: Encoding, Coding, and Decoding.

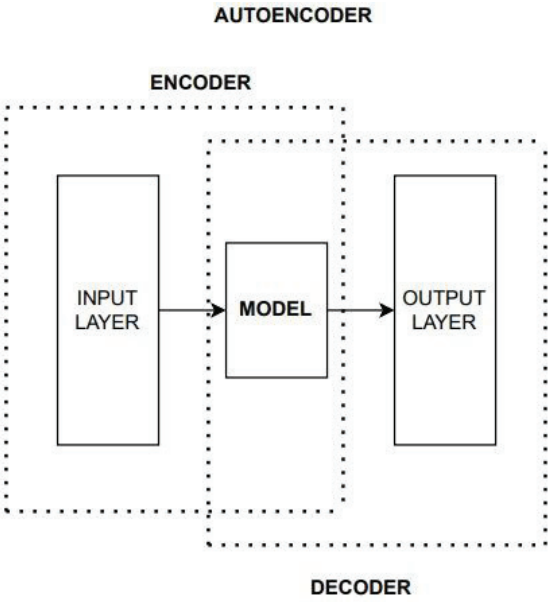

Fig. 1. Overview of Autoencoder

The Encoder layer is compressing the entered image into a compressed array which is in latent representation. It encodes the input photo as a compressed or encoded illustration in a discounted measurement. After processing of original image, the compressed image is distorted. In code, the layer consists of the user algorithm for encoding images. Compressed or input is passed to the decoder layer through code layer. The decoder layer decodes the encoded picture back to its original size. Latent space represents the decoded photo is reconstructed, and it ensures that there is no loss of data in the reconstructed image. The construction should be lossless construction.

IV. CNN MODEL

In this modern world deep learning techniques have proved to be a promising thing in medical field it helps in detecting and classifying diseases at an early stage. Deep Learning is a subfield of Machine learning that aims to learn from the data or images in a unsupervised way also called unsupervised learning. CNN or Convolutional Neural Network consist of several layers that include pooling , convolutional, fully connected and SoftMax layer. The output of each layer is passed through an activation function. At each convolutional layer a set of kernel is used to extract features depending on the depth of layer. Pooling layer comes into use when we have to reduce the complexity and or number of parameters. At the end comes the SoftMax layer for calculating the cross entropy loss and this loss is reduced by using stochastic gradient descent, which is achieved by readjusting weights and biases.

V. METHODOLOGY

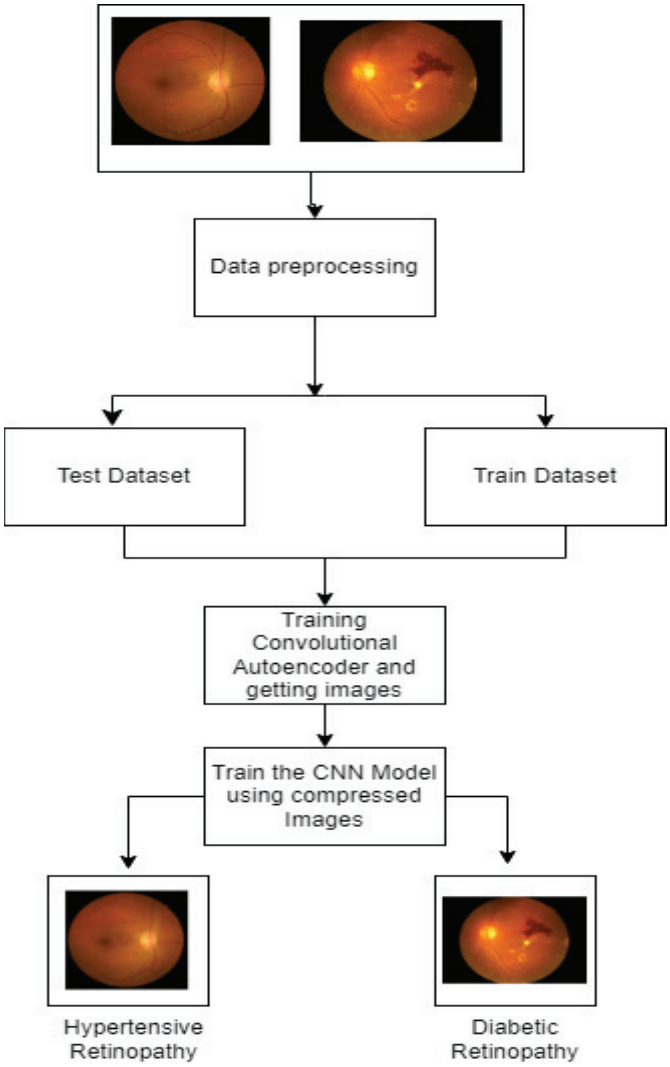

Fig. 2. Overview of Methodology

A. Dataset

The Dataset was collected from all sources available on internet some major sources for diabetic retinopathy specific fundus images were Kaggle which contains around 2100 images, MESSIDOR-2 Dataset that contains 1748 images, IDRiD Dataset that contains around 500 images.

Diabetic retinopathy Dataset contained different labels but we only needed a single label so we cleared the labels and classified the data under one label named Diabetic Retinopathy. For Hypertensive Retinopathy opensource dataset was not available so we collected the data from local eyecare centres and hospitals which was further pre-processed and labelled manually by experts as Hypertensive Retinopathy.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:52:38 UTC from IEEE Xplore. Restrictions apply.

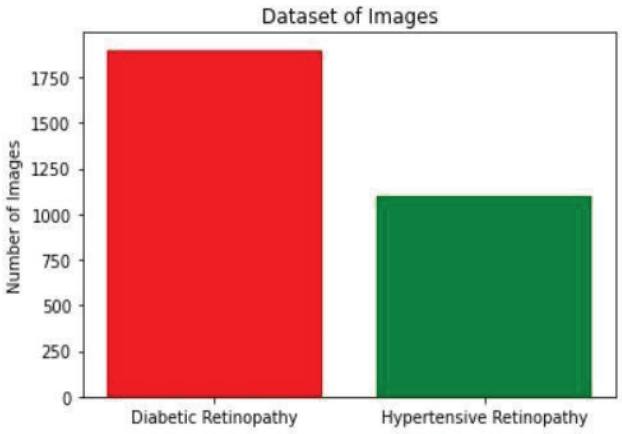

Fig. 3. Number of Images of Diabetic and Hypertensive Retinopathy

B. *Pre-processing*

The original dataset had been collected from various sources. It was in many formats like PNG, JPG, etc. It was converted to JPG format for better clarity and understanding of data and it also reduce the space with the help of the pillow library in python. The next step was the augmentation of images. It is a technique by which we can reduce or expand the size of the dataset. It is very helpful if our dataset is too large or too small.

As we collected data from various sources therefore the image size varies a lot. For tackling this we resized all the images into 256*256 matrix. Then the next step of pre-processing was the normalization of images.

For Normalization, we included Gaussian Blur Technique. It consists of two main parameters i.e., sigma and kernel size. Sigma is equivalent to the radius of the retina. Both the parameters were set to (0,0) for better clarity of the image. Then we pass data into encoders. The last part of pre-processing was to eliminate the excess part of the image which had no impact.

C. *Feature Extraction*

Retinal arteries and vein's width is calculated which makes up the Arterial Venous (AV) ratio. AVR is calculated as the ratio of the mean arteriolar diameter (AD) to the mean venous diameter (VD) of the vessels within the measurement area. There are two methods to calculate the AVR- it is calculated using the average of AW (Articole Width) and VW (Venules Width), the sum of the AW and VW, sum of the square of the AW and VW, CRAT (Central Retinal Artery Equivalent), and CRVA (Central Retinal Venous Equivalent). These values are repeated and hence the AVR is determined.

The other method to determine AVR is by classifying retinal vessels based on colour variations. The condition is known as copper wiring and if the conditions get worse it is known as silver wiring. As we know that there are some steps implemented for the detection of Hypertensive and Diabetic Retinopathy that use colour information. Therefore, it is important to normalize the image before the extraction of features. We already normalize the images by using encoders and gaussian normalization.

Using histogram stretched processed images helps to achieve normalized entropy for all available images, this is batter extraction technique. After this, colour normalization is performed by using the mean intensity value as 100, 75 and 40 for red, green, and blue respectively. Accurate blood vessel segmentation is an important step that helps us to achieve vessel measurements such as width for Arterial Venous ratio.

The hard exudates are composed of lipid and proteinaceous material. It is generally found in Hypertensive Retinopathy. These exudates are capable of building a star shape within the macula, especially when hypertension is critical. In serious hypertensive Retinopathy, the optic disk becomes choked and swollen with excessive accumulation of fluid. It is very helpful for classifying the images as hypertensive Retinopathy.

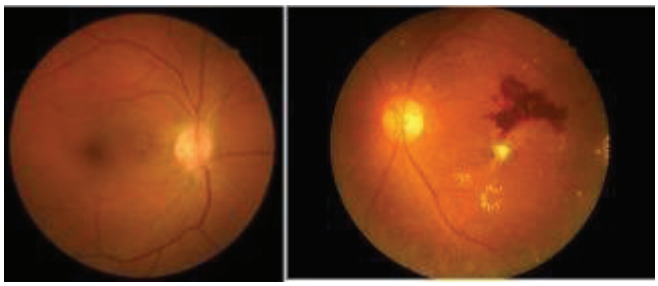

Fig. 4. Images showing exudates, cotton wool, Haemorrhage in Diabetic and Hypertensive Retinopathy.

VI. MODEL BUILDING

To carry out this research we have built a Convolutional Neural Network (CNN) model. This model will accurately classify the fundus images into Diabetic or Hypertensive Retinopathy 2D Convolutional, Max Pooling, Fully Connected, and SoftMax layers makes this proposed CNN Model.

For the first stage encoded RGB Fundus images are resized into 512*512*3 for the input layer of CNN that was reduced in dimensionality using autoencoders. Then comes a 2D convolutional input layer with 5 kernels and 1 stride taking each filter size to 5*5*3. Then comes the max pooling layer with 5 filter and 2 stride that reduces the feature map to 254*254 by doing all this we have reduced the high dimension images to low dimension with maintaining the quality by using autoencoders, this all thing would help in increasing the processing speed of Convolutional Neural Network. After this a fully connected layer is deployed output which corresponds to 2 different classes either diabetic or hypertensive retinopathy Finally the actual probability of each output class is calculated using SoftMax function.

VII. RESULT AND ANALYSIS

In this paper, we were using dataset of 3000 images in which 1100 was images of Hypertensive Retinopathy and remaining was images of Diabetic Retinopathy. Rather than training the whole set of images. The images were split into batches of 100 images and we have a 30 batches of images. In the current study, we trained the network for 25 and 30 epochs where a single epoch represents the 30 iterations. Leave out one batch for cross validation. Repeated this steps 30 times. We were using the learning rate around 10^ (-5). Training and testing accuracies were computed using the following equations.

$$Accuracy = \frac{TP+FN}{TP+FP+TN+FN} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$$

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on September 05,2023 at 09:52:38 UTC from IEEE Xplore. Restrictions apply.

The graph of training accuracy and validation accuracy show in fig 5. Loss and validation loss were computed using the following equations.

$$A_{loss_train} = \frac{\sum_i^{31}\sum_j^{30} z(i,j)}{31} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (2)$$

$$A_{loss_test} = \frac{\sum_i^{31}\sum_j^{30} z(i,j)}{31} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (3)$$

z(i,j) was a function which was calculated the root mean square difference between actual and predicted values. The graph of training loss and validation loss accuracy and validation accuracy show in fig 6.

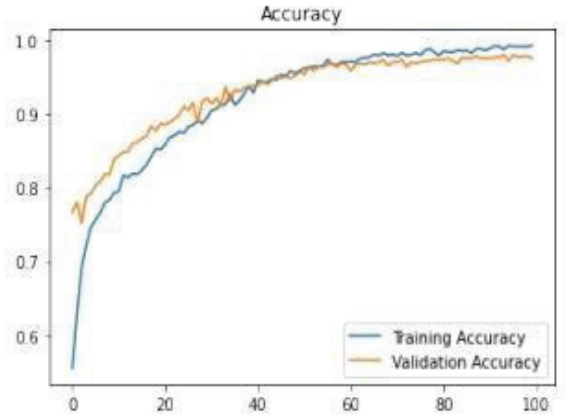

Fig. 5. Accuracy graph

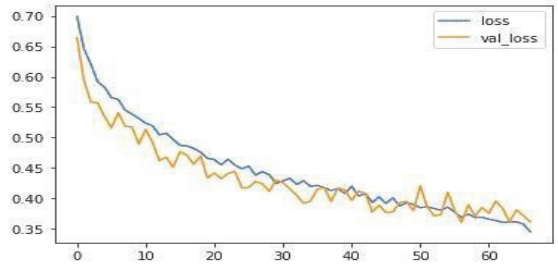

Fig. 6. Loss During Training

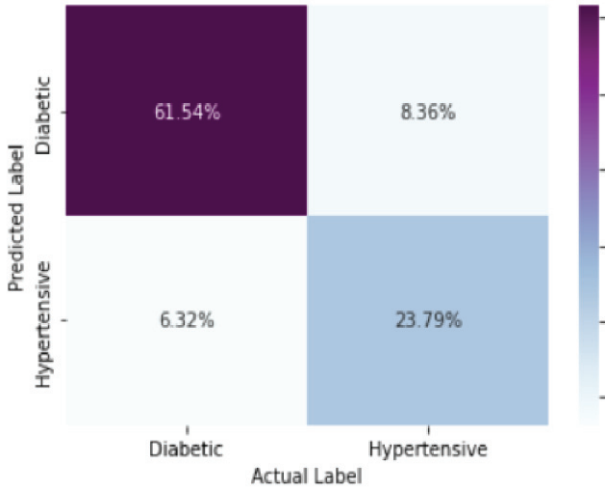

Fig. 7. Confusion Matrix of the CNN Model.

The fig 7 showing the confusion matrix of CNN model for Diabetic and Hypertensive Retinopathy. It shows percentage of Diabetic Retinopathy and Hypertensive Retinopathy Predicting correctly and incorrectly. For calculating the accuracies, we need to add the percentages of images predicted correctly. Let suppose we have two types of images then the formula of Accuracy is Percentage of Images of type1 predicted correctly and percentage of images of type 2 predicted correctly.

The accuracy after all the training and testing was around 85.33% which was tested on 1100 images for hypertension and 1900 images for diabetes.

VIII. CONCLUSIONS

As it has been shown above, we have proposed an efficient and highly accurate framework to detect and classify Diabetic retinopathy and hypertensive retinopathy by using Fundus Photography. We have designed the algorithm that can use different features like exudates, haemorrhage, cotton wool and many more to detect the disease and differentiates between Diabetic retinopathy and Hypertensive retinopathy, which helps the patient to diagnose and treat the disease efficiently and quickly.

ABSTRACT

The current research work focuses on the fabrication of carboxymethyl tamarind kernel gum/polyvinylpyrrolidone/polyacrylamide (CMTKG/PVP/PAM) based hydrogel and its loading was done with diclofenac sodium drug (DS) to obtain smart pH-responsive hydrogels. In addition, the effect of concentration of cross-linker- N, N′-methylene bis(acrylamide) (MBA), biopolymer (CMTKG), as well as initiator- potassium persulphate (KPS) on the swelling behavior of smart hydrogel was also analyzed. The synthesized hydrogels were characterized using Scanning Electron Microscopy (SEM), Powder X-ray Diffraction (PXRD), Thermogravimetry Analysis (TGA), and Attenuated Total Reflection-Fourier Transform Infrared spectroscopy (ATR-FTIR). ATR-FTIR confirms the successful formation of hydrogels, while PXRD and SEM indicate the amorphous and porous nature of the polymeric network. The TGA results indicate higher thermal stability for DS-loaded hydrogel than unloaded hydrogel. However, sol–gel analysis shows a rise in gel fraction, with increased concentrations of CMTKG, MBA, and KPS. The swelling ratio as well as the release of DS were found to be higher under slightly alkaline conditions. The result of drug loading and release indicates that PVP increases drug loading (%) and release (%). The drug release behavior of DS-loaded hydrogel follows the Fickian mechanism of diffusion with the Korsmeyer-Peppas model as the best-fitted one. The synthesized DS-loaded CMTKG/PVP/PAM hydrogels could be a promising substitute for prolonged delivery of sparingly soluble DS in pH 7.4.

1. Introduction

A drug delivery system (DDS) acts as a sustained release system that can alter the pharmacokinetics and biodistribution of the drug by enhancing several crucial properties of drugs i.e. solubility, in vivo stability, specificity, efficacy, etc [1]. Till today numerous materials have been explored in the drug delivery field, including nano-scale materials (nano-capsules, dendrimers, nanotubes, nano gels, and so on) [2,3], and inorganic-based DDS (layer double hydroxide, graphene oxide, metal oxides etc) [1,4,5]. However, conventional drug delivery systems do possess certain limitations i.e. poor bioavailability, low biocompatibility, high toxicity, burst drug release, and lesser hydrophilicity, resulting in reduced drug delivery efficiency. To address the above-mentioned issues, drug delivery systems based on hydrogels have been focused in recent decades owing to their easily tunable properties during synthesis, followed by controlled release, degradation, and efficiency to protect labile drugs [6].

Basically, hydrogels are highly hydrated 3D networks, derived from natural, semi-synthetic, or synthetic polymers having physical or covalent cross-linkage [7,8]. One of the most remarkable properties of hydrogel to be termed as smart or stimuli-sensitive hydrogels is their ability to adjust their volume in response to changes in physical and chemical stimuli such as pH, light, magnetic field, temperature, enzyme, ionic strength, etc [9,10,11,12]. The most notable among all are pH-responsive hydrogels, which provide an excellent drug administration system [11].

Polyacrylamide (PAM) is one of the most extensively used pH-sensitive polymers in drug delivery applications [13]. It is a synthetic, non-toxic polymer with excellent mechanical strength, and contains a cationic amine functional group that either protonates or deprotonates to show variation in swelling with a change in pH [14,15]. PAM has been widely combined with natural polymers such as gelatin, carboxymethyl tamarind kernel gum, collagen etc. to synthesize composite hydrogels [16,17]. The introduction of biopolymers imparts efficient drug release and also enhances the hydrophilicity, biodegradability, and biocompatibility of the hydrogel [11,18,19].

Tamarind kernel gum (TKG) is a biopolymer obtained from Tamarindus indica L., a typical African tree and carboxymethylation of TKG

results in the formation of carboxymethyl tamarind kernel gum (CMTKG) [20]. CMTKG possesses a high swelling capacity, high viscosity, and enhanced hydrophilicity compared to TKG [21]. It is a water-soluble polymer which contains glucose, xylose, and galactose in the molar ratio of 3:2:1 [22,23]. With variations in the pH of the medium, COO^- groups in this polymer undergo deprotonation or protonation, resulting in pH-dependent drug delivery [24].

Owing to the hydrophilic nature of hydrogels, they have been most commonly utilized for delivering hydrophilic drugs such as moxifloxacin hydrochloride, acyclovir [25,26,27]. To increase the compatibility of hydrophobic drugs with the polymer matrix, either the polymers capable of the formation of inclusion complexes such as cyclodextrin are introduced or various hydrophobic components are incorporated into the hydrogels. Polyvinylpyrrolidone, poly(lactic acid), nanoparticles, etc, are some of the hydrophobic components incorporated into the polymeric matrix [25]. Polyvinylpyrrolidone (PVP) is a non-toxic, and biocompatible polymer mainly used for drug delivery applications. It is an amphiphilic polymer containing a pyrrolidone ring, C = O, C-N, and CH_2 as a hydrophilic component and an alkyl group as a hydrophobic part [28,29]. The hydrophobic component of PVP interacts with the hydrophobic drug and increases drug loading capacity. Therefore, PVP is employed to deliver hydrophilic, hydrophobic as well as sparingly soluble drugs such as amoxicillin [30], acyclovir [31], diclofenac sodium [32], etc.

Diclofenac sodium (DS) is one of the most commonly prescribed nonsteroidal anti-inflammatory drugs (NSAIDs). It is sodium salt of o-(2,6-dichlorophenylamino)-phenylacetic acid and its antipyretic, analgesic, and anti-inflammatory actions help to treat rheumatoid arthritis and osteoarthritis. The DS half-life is relatively less (1–2 h) and so rapidly eliminated from the body. As a result, numerous doses of DS are required to provide sustained pharmacological action which causes unfavorable side effects such as ulcers and gastrointestinal bleeding. Therefore, a novel delivery system for DS release is required to decrease the complications and to ensure the prolonged delivery of DS [33,34].

In the present research work, first CMTKG/PVP/PAM-based hydrogel was synthesized and was then loaded using DS to obtain smart pH-responsive hydrogels for prolonged release of DS. Incorporation of PVP was done so as to improve the loading capacity of sparingly soluble DS drugs. The synthesized hydrogel was characterized using ATR-FTIR, SEM, PXRD, TGA, and to confirm the formation, surface morphology, crystallinity, and thermal stability of the developed hydrogel. A sol–gel study was conducted to evaluate the hydrogel's sol and gel portions. Finally, the impact of amounts of CMTKG, KPS, or MBA on swelling ratio was also examined for all DS-loaded hydrogels using pH 1.2 and 7.4 buffer. The work also emphasizes upon *in vitro* release of DS to estimate the DS release percentage. To contemplate the drug release mechanism, various kinetic models like Zero-Order, Hixson- Crowell, Higuchi, Korsmeyer-Peppas, and First-Order were employed.

2. Materials and methods

2.1. Materials

Acrylamide (CDH, New Delhi), Polyvinylpyrrolidone K-30 (CDH, New Delhi), Potassium persulphate (Fischer Scientific, Mumbai), and N, N′-methylenebis(acrylamide) (Merck, Germany), were used as supplied. Carboxymethyl Tamarind Kernel Gum was gratefully provided by Hindustan Gum and Chemicals Ltd., Haryana, India and Diclofenac sodium was provided by Unicure India Pvt Ltd, Noida, India.

2.2. Synthesis of CMTKG/PVP/PAM hydrogel and DS-loaded hydrogels

The novel hydrogel based on CMTKG, PVP, and AM was synthesized using a free radical mechanism by employing KPS (initiator) and MBA (cross-linker), shown in Fig. 1. The reaction was typically carried out by dissolving the desired quantity of CMTKG, AM, and PVP in distilled water on a magnetic stirrer for 1hr. To the resultant solution, KPS and MBA were added and stirred. Later, the solution was transferred into 20 mL test tubes and placed in a water bath at 60 °C for 1 h. The obtained hydrogel was cut into discs, dried at room temperature, and then in the oven at 60 °C till a persistent weight was attained [35,36]. For the synthesis of DS-loaded hydrogels, during the addition of KPS, and MBA, 50 mg diclofenac sodium dissolved in 1 mL ethanol was added to the mixture, however, the rest procedure followed the same as above. Table 1 summarizes the exact ratios of the KPS, MBA, CMTKG, PVP, and AM used during the synthesis of hydrogels [37].

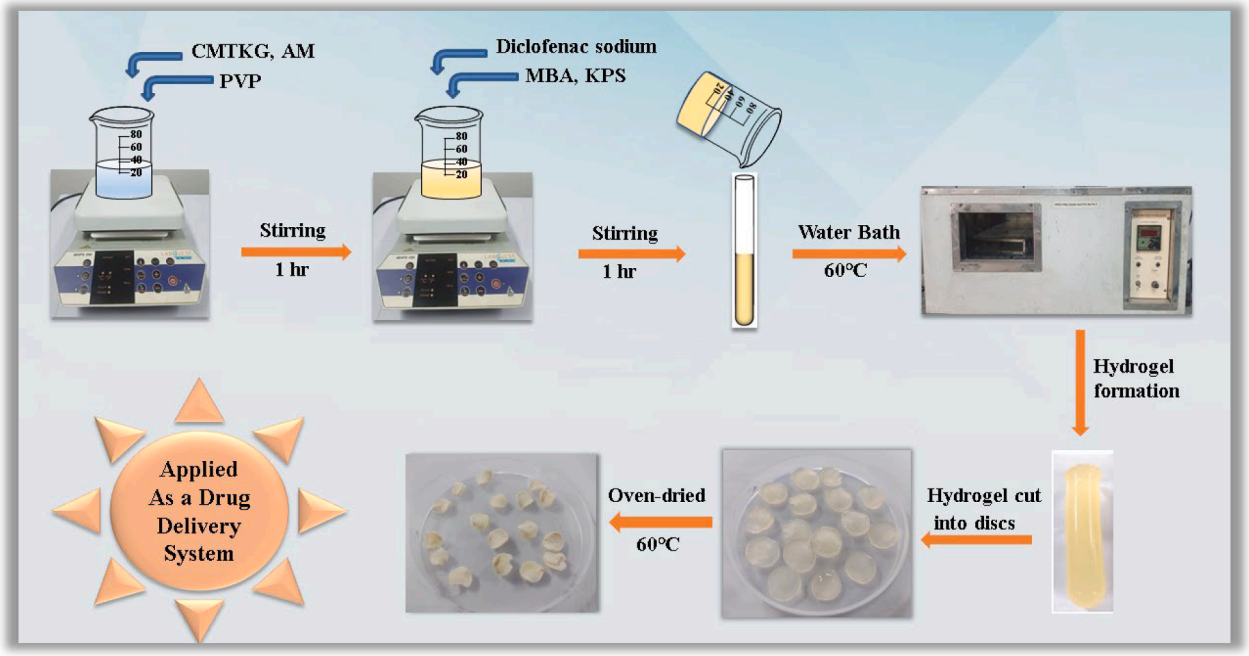

Fig. 1. Pictorial representation of the fabrication of DS-loaded CMTKG/PVP/PAM hydrogel.

Table 1
Different ratios of reagents required in the synthesis of the hydrogels and their swelling ratio.

Sample Code	CMTKG (g)	AM (g)	PVP (g)	MBA (mg)	KPS (mg)	DS (mg)	Swelling Ratio (%)		Gel fraction (%)

2.3. Swelling studies

Gravimetric analysis was carried out to analyse the swelling nature of the prepared DS-loaded hydrogels. First, dried hydrogels were weighed and soaked in pH 1.2 and 7.4 buffer solutions. After a regular interval, the swollen hydrogel disc was taken out, surface water was wiped using filter paper, and again, weight was noted [33]. The study was carried out in triplicate, and the swelling ratio was computed using the given equation.

$$\text{Swelling Ratio}\,(\%) = \frac{W_S - W_D}{W_D} \times 100 \quad (1)$$

Here, W_S refers to the weight of the swollen hydrogel at time t, whereas W_D refers to the initial weight of the dried hydrogel [38].

2.4. Sol-Gel analysis

Sol-gel analysis was done to discover the uncrosslinked portion of the synthesized DS-loaded hydrogel. A gel is the insoluble cross-linked portion of a hydrogel, and a sol implies the soluble uncross-linked portion of a hydrogel [33]. For this analysis, the dried hydrogel disc was weighed and processed to the soxhlet extraction method using distilled water as solvent at 100℃ for a duration of 4 hr. After 4 hr, the extracted hydrogel disc was dried at 45 °C in an oven till persistent weight was attained. The sol and gel fraction calculation was performed using the following equations.

$$\text{Sol Fraction} = \frac{W_i - W_F}{W_F} \times 100 \quad (2)$$

$$\text{Gel fraction} = 100 - \text{Sol fraction} \quad (3)$$

Here, W_i implies the weight of the initially dried hydrogel, and W_F implies the final weight of extracted dried hydrogel after being subjected to soxhlet extraction [39].

2.5. Drug loading and entrapment efficiency

The ideal candidate, hydrogel A-5, was selected for drug loading and entrapment studies on account of its highest swelling ratio of about 1128% and 967% at pH 7.4 and 1.2 respectively. The effect of PVP (amphiphilic polymer) on drug loading & entrapment efficiency was established by comparing formulation A-5 (CMTKG/PVP/PAM) that contains PVP to formulation A-14 (CMTKG/PAM) hydrogel, which lacks PVP. The drug loading (DL %) & entrapment efficiency (DEE %) was determined by placing the pre-weighed hydrogels (0.1 g) into a physiological buffer of pH 7.4 for 24 hr. The solution was withdrawn after 24 hr, and absorbance was noted at 276 nm with a UV–visible spectrophotometer (Model: Cary 300 UV–Vis). The amount of DS was estimated using a calibration curve. The below equations were used to establish the percent of drug loading and drug entrapment efficiency [40].

$$\text{DL}\,(\%) = \frac{\text{Drug amount in hydrogel}}{\text{Weight of hydrogel disc}} \times 100 \quad (4)$$

$$\text{DEE}\,(\%) = \frac{\text{Drug amount in hydrogel}}{\text{Theoretical Drug amount in hydrogel disc}} \times 100 \quad (5)$$

2.6. In vitro release study of diclofenac sodium

In vitro release analysis of DS was accomplished at physiological pH of 7.4 and 1.2 using DS-loaded CMTKG/PVP/PAM (A-5) and DS-loaded CMTKG/PAM (A-14) hydrogel to study the impact of the incorporation of PVP on drug release. The release study was done in an orbital incubator shaker by immersing 0.1 g of the DS-loaded hydrogel disc into 100 mL buffer of pH 1.2 and 7.4 at 37 °C, respectively [40]. After 1 hr, a 3 mL sample was extracted, and an equal amount of fresh buffer was made-up. Absorbance was recorded on a UV–visible spectrophotometer at λ_{max} 276 nm. The study was performed in triplicate and the drug content was evaluated using a calibration curve [41].

2.7. Release kinetics studies of diclofenac sodium

Several Mathematical models, such as the Zero-Order, Hixson- Crowell, Higuchi, Korsmeyer-Peppas, and First-Order, were used to identify the release mechanism of the drug. The release data were fitted to all the above-mentioned models, and regression coefficient (R^2) values were compared. The R^2 value must be closer to 1 for the model to be considered the best-fit model [42].

2.8. Characterization

PXRD was recorded using a Bruker D8 diffractometer within 2θ range of 5-70℃ using Cu Kα radiation. The ATR-FTIR analysis was done by an ATR-FTIR spectrophotometer (Model: PerkinElmer spectrum 2). The TGA was done by PerkinElmer TGA 4000 with an N_2 atmosphere in the range of 25 °C–900 °C at a rate of 10 °C/min. The surface morphology was investigated using SEM (Model: JEOL Japan Mode: JSM 6610LV).

3. Results and discussions

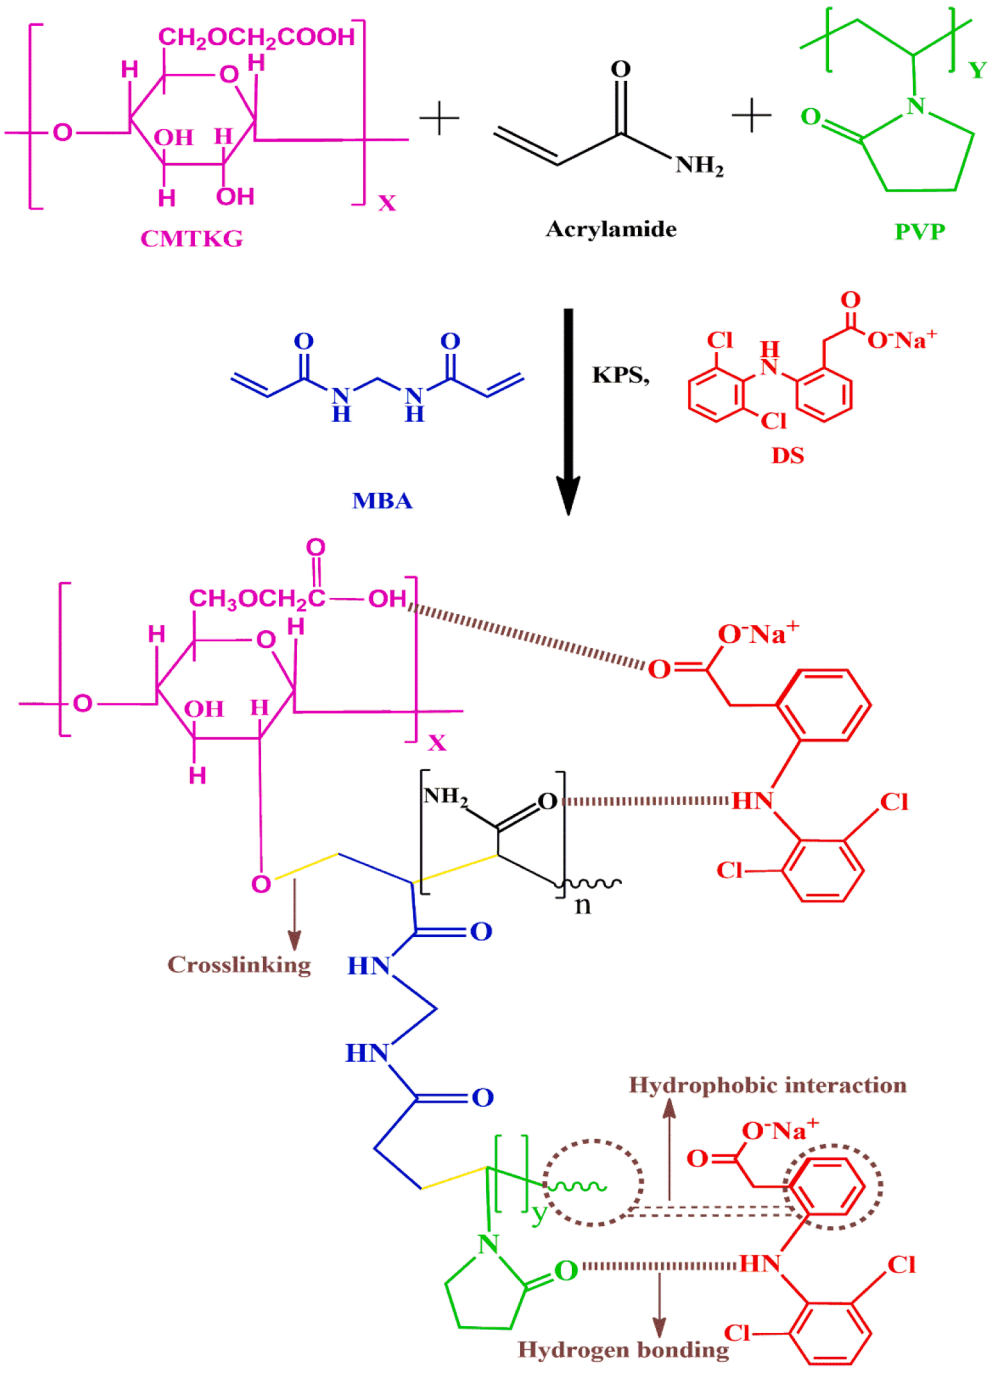
3.1. Mechanistic pathway followed for the formation of DS-loaded CMTKG/PVP/PAM hydrogel and their swelling studies

The details of various combinations (A-1 to A-13) of DS-loaded hydrogels attempted using a variable concentration of CMTKG, KPS, and MBA are given in Table 1. Here, KPS was used as an initiator, MBA was used as a cross-linker, and drug DS was loaded into the hydrogel. All the samples were fabricated with a varied amount of CMTKG (A1-A5), KPS(A6-A9), or MBA(A10-A13). The proposed mechanism involved during synthesis for hydrogel formation has been shown in Scheme 1. In the reaction, at first sulphate radical is formed by the decomposition of KPS (initiator) at 60 °C, which further leads to the polymerization of AM. While MBA acts as a cross-linker, the MBA helps in the formation of a crosslinked polymeric network based on CMTKG, PAM, and PVP. The hydrophobic interaction between the alkyl group of PVP and the aryl ring of DS, along with hydrogen bonding of DS with PVP, CMTKG and PAM, results in the synthesis of a tri-dimensional network of DS-loaded CMTKG/PVP/PAM hydrogel [43].

The swelling ratio of all DS-loaded hydrogels was examined using pH 1.2 and 7.4 buffer by varying amounts of CMTKG, KPS or MBA. The swelling ratio of all synthesized hydrogel were mentioned in Table 1.

3.1.1. Impact of biopolymer

The impact of concentrations of the CMTKG (biopolymer) on the swelling ratio, is presented in Fig. 2(a). The hydrogel swelling increases with an increase in the amount of CMTKG from 0.2 g to 0.4 g. Maximum



Scheme 1. Proposed mechanism for synthesis of DS-loaded CMTKG/PVP/PAM hydrogel.

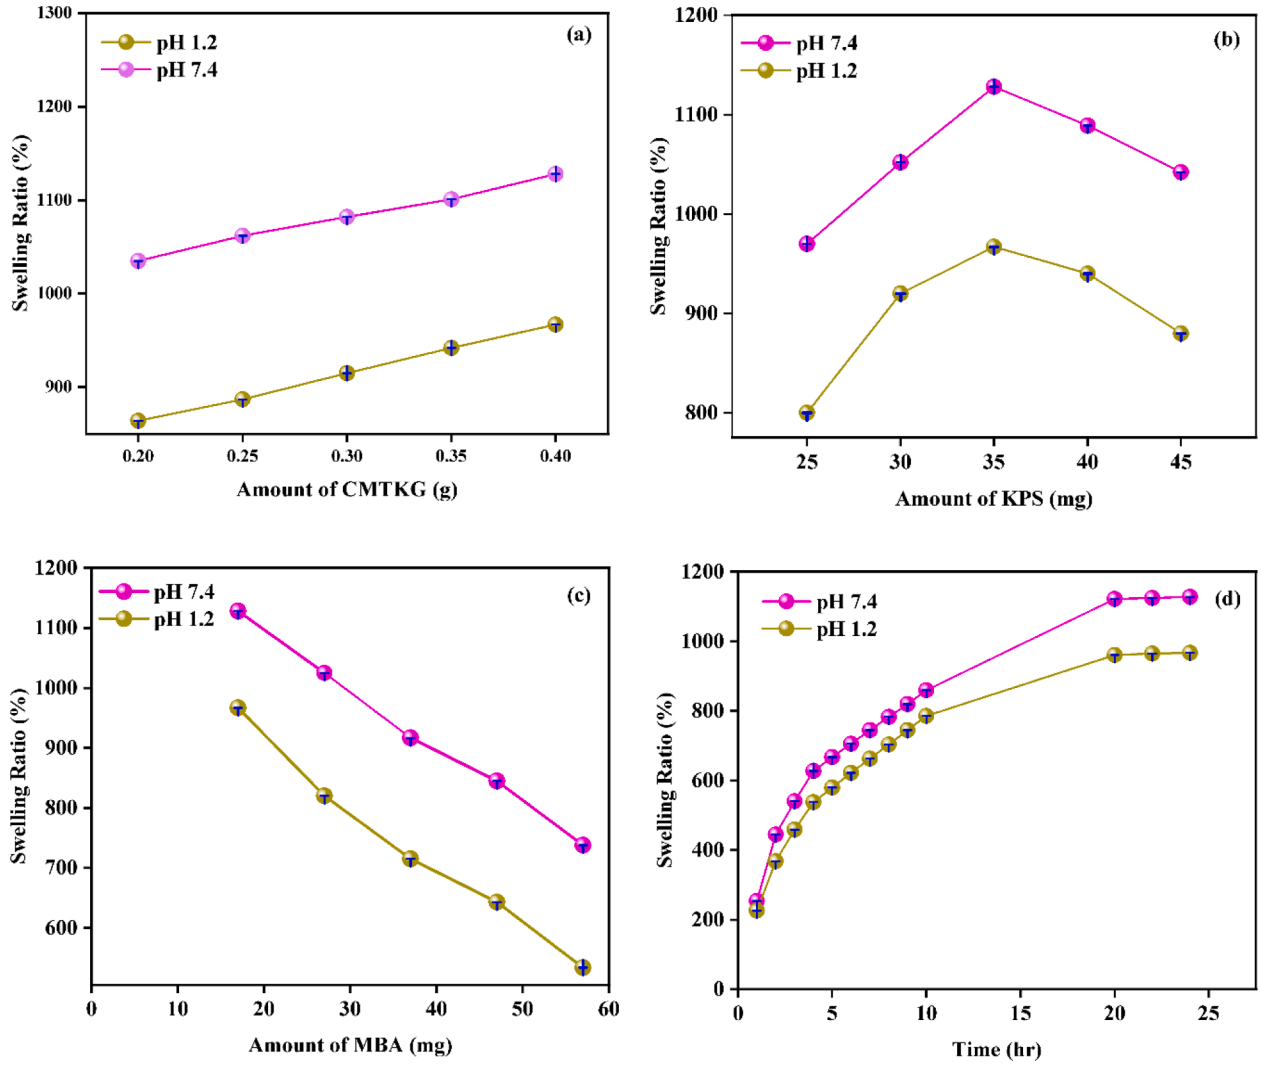


Fig. 2. Impact of the **(a)** CMTKG, **(b)** KPS, **(c)** MBA on swelling and **(d)** Rate of swelling of A-5 hydrogel in pH 1.2 and 7.4 with respect to time.

swelling of about 1128% was noticed at pH 7.4, while at pH 1.2, 967% swelling was recorded at 0.40 g of CMTKG. This may be associated with a greater number of carboxylate ions as the amount of CMTKG increases. The repulsion of carboxylate ion trigger chain relaxation and, as a consequence, swelling increases. However, attempts were made to process hydrogel with a concentration of CMTKG greater than 0.40 g but, the solution become highly viscous, and was challenging to stir [22].

3.1.2. *Impact of initiator*

Since the maximum swelling was observed at a biopolymer amount of 0.40 g, therefore it was kept constant. While the impact of altering the KPS concentration is shown in Fig. 2(b). As the KPS amount was elevated, the swelling percentage increased to a certain limit, and later increase in the KPS amount led to decreased water absorption capacity. At 35 mg of an initiator, maximum swelling of about 1128% was noticed in pH 7.4, while in pH 1.2, 967% swelling was reported. For the amount of KPS below 35 mg, the swelling ratio decreased to 723% at pH 7.4 and 620% at pH 1.2. This may be the consequence of a large quantity of unreacted soluble monomer, leading to a weak hydrogel network and reducing the swelling. When, the amount of KPS was increased beyond 35 mg, again swelling decreased because of the high collision between the free radicals. It leads to oligomer formation and increased cross-linking density; as a result, swelling decreases [22].

3.1.3. *Impact of cross-linker*

According to Flory's network theory, one of the significant factors that influence hydrogel swelling is cross-linking density. A slight variation in the cross-linker amount causes substantial changes in the swelling percentage, as presented in Fig. 2(c). Maximum swelling of about 1128% was noticed at pH 7.4. While at pH 1.2, maximum swelling of about 967% was reported at 17 mg of a crosslinker. When the amount of MBA is lesser than 17 mg, it was found that a jelly-like substance was produced due to a lack of a strong cross-linked network between polymeric chains [22]. The hydrogel swelling ratio decreased when the MBA concentration varied from 17 to 57 mg. A higher cross-linker amount reduces the free space inside the hydrogels and decreases the swelling of the hydrogels. Hence, the resulting rigid structure cannot expand, so water absorption decreases [34].

Among all the formulations attempted the greater swelling was noticed for A-5 hydrogel having CMTKG (0.40 g), AM (2.5 g), PVP (0.1 g), KPS (35 mg), MBA (17 mg), and DS (50 mg). However, for the A-5 sample, a higher swelling ratio was noticed in pH 7.4, than in pH 1.2, as shown in Fig. 2 (d). The greater swelling at alkaline pH is a consequence of the deprotonated carboxylate anion of CMTKG. This leads to anion-anion repulsion between COO^- ion, which further tends to polymeric chain relaxation and more free space resulting in fluid absorption [44]. While at pH 1.2, hydrogen bonding exists between PAM and CMTKG, causing shrinkage of the hydrogel network, thereby decreasing water absorption capacity [38].

3.2. Sol-Gel analysis

Sol-gel study for synthesized DS-loaded CMTKG/PVP/PAM hydrogel samples is shown in Fig. 3. An increase in gel fraction was noticed, with increases in the amount of CMTKG (A-1 A-2, A-3, A-4, A-5) and KPS (A-8, A-9). This is because more free radicals are generated and, therefore, there are more active sites for crosslinking, so the gel fraction increases. In addition, when KPS is further increased (A-6, A-7), a soluble oligomer chain forms, resulting in a greater sol fraction and a lesser gel fraction. As the concentration of MBA (A-10, A-11 A-12, A-13) increases, cross-linking density increases within the polymeric network, which causes an increase in gel fraction [33].

3.3. Characterization

PXRD was done to examine the crystallinity nature of hydrogel and the dispersion of the drug into the hydrogel matrix, as shown in Fig. 4. DS shows its characteristic peak at 2θ values of 6.2, 6.7, 8.6, 11.3, 15.2, 17.2, 20.3, 27.1, and 37.9 [43]. The sharp peaks in the DS reveal the crystallinity nature of the drug. However, the broad peak for CMTKG/PVP/PAM hydrogel indicated the hydrogel disc was amorphous and shows no long crystallographic order [38]. In the diffractogram of DS-loaded CMTKG/PAM/PVP hydrogel, no characteristic peak of DS was observed indicating uniform dispersion of DS in polymeric matrices [45], [46]. The increase in peak intensity was observed for DS-loaded hydrogel compared to unloaded hydrogel, which implies that the drug was effectively entrapped within the amorphous hydrogel matrices [33].

ATR-FTIR spectrum of CMTKG, AM, MBA, CMTKG/PVP/PAM, DS-loaded CMTKG/PVP/PAM (A-5) hydrogels and DS are presented in Fig. 5, and their ATR-FTIR data are presented in Table 2. In the FTIR spectra of AM, the peaks at 1665 cm^{-1} are assigned as -C = O asymmetric stretch, while in CMTKG/PVP/PAM and DS-loaded CMTKG/PVP/PAM hydrogel, moved to 1603 cm^{-1} and 1606 cm^{-1} respectively, validating the decrease in conjugation and confirmed the polymerization [35].

In the FTIR spectrum of MBA, the peaks at 1304 cm^{-1} correspond to C-N stretch, which in CMTKG/PVP/PAM and DS-loaded CMTKG/PVP/PAM hydrogel, moved to 1323 cm^{-1} and 1320 cm^{-1} respectively, indicate the lesser conjugation because of cross-linking. The peak at 1624 cm^{-1} represents the C = C stretch, which in CMTKG/PVP/PAM and DS-loaded CMTKG/PVP/PAM observed at 1659 cm^{-1} and 1660 cm^{-1}, confirming the cross-linking. This concludes that crosslinked CMTKG/PVP/PAM hydrogel has been successfully synthesized [43]. In

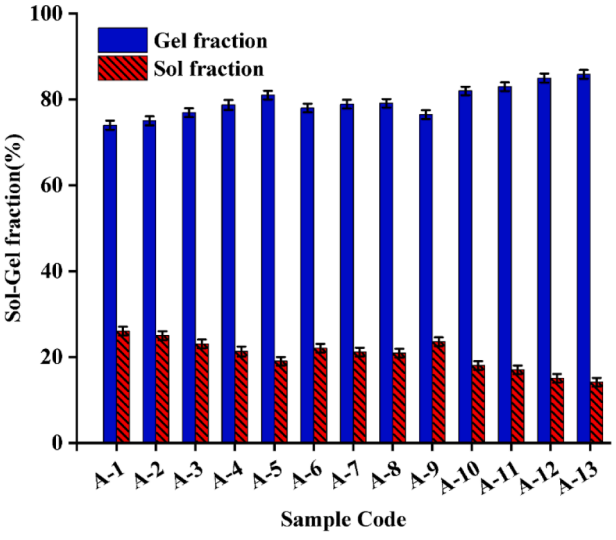

Fig. 3. Sol-Gel studies of synthesized formulations of DS-loaded CMTKG/PVP/PAM hydrogel.

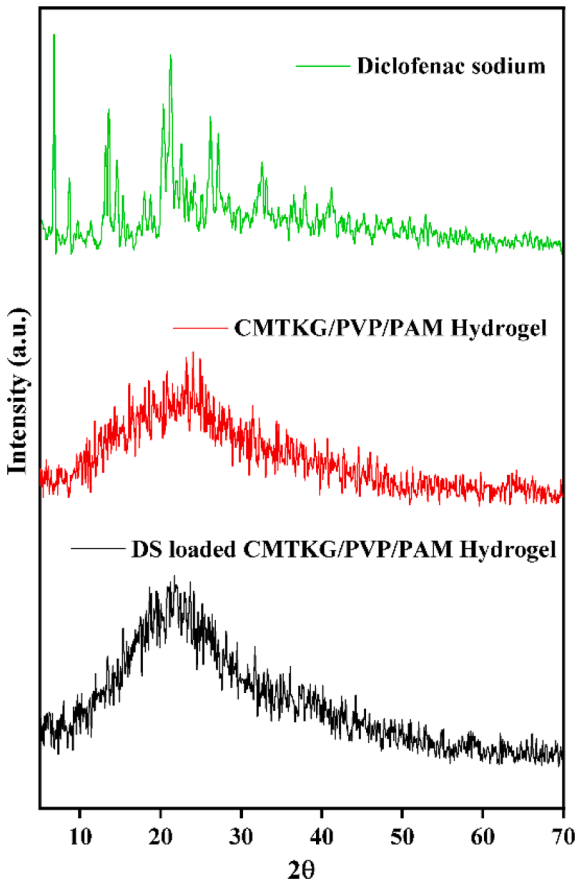

Fig. 4. PXRD pattern of DS, CMTKG/PVP/PAM hydrogel (A-15), DS-loaded CMTG/PVP/PAM hydrogel (A-5).

DS-loaded CMTKG/PVP/PAM, the new characteristic peak of DS is noticed at 2549 cm^{-1}, 2273 cm^{-1}, and 704 cm^{-1}. This signifies that drug is successfully encapsulated into the hydrogel matrix. There was no appearance or disappearance of additional peaks other than the drug noticed in DS-loaded hydrogel compared to unloaded hydrogel, which concludes that no chemical interaction exists, only physical interaction (hydrogen bonding) took place between the drug and polymeric network [38].

TGA was performed to analyse the thermal stability of hydrogel to understand the interaction existing between the drug and hydrogel, as presented in Fig. 6. In both CMTKG/PVP/PAM and DS-loaded CMTKG/PVP/PAM hydrogel (A-5), four step weight loss was noticed. The first stage is associated with the evaporation of H_2O molecule and initial decomposition of polymeric chain of CMTKG/PVP/PAM and DS-loaded CMTKG/PVP/PAM hydrogel, with a weight loss of 11.1% and 9.6% at 30–245 °C respectively. The second stage corresponds to the degradation of the polymer backbone, i.e. carboxymethyl and hydroxyl of CMTKG/PVP/PAM and DS-loaded CMTKG/PVP/PAM hydrogel, with the weight loss of 11% and 9.4% at 245–297 °C respectively. The third stage indicates the breakdown of crosslinking of the polymeric network, with weight loss of 31.8% and 31.1% at 297–385 °C. The fourth stage, corresponds to the complete degradation of the hydrogel, with weight loss of 40.2 % and 38.8% at 385–900 °C respectively [37].

The TGA thermogram of CMTKG/PVP/PAM hydrogel is almost the same as DS-loaded CMTKG/PVP/PAM hydrogel, which means DS shows very little or no impact on the thermal stability of the hydrogel indicating an absence of chemical interaction, but the presence of physical interaction (hydrogen bonding) between DS and the polymeric network.

The SEM images of CMTKG/PVP/PAM (A-15) hydrogel and DS-loaded CMTKG/PVP/PAM (A-5) hydrogel are displayed in Fig. 7. The

micrographs of CMTKG/PVP/PAM hydrogel reveal uneven surface morphology, and porous structure, indicating good water retention, and drug loading capacity of the hydrogel. However, micrographs of DS-loaded CMTKG/PVP/PAM hydrogel show a smooth surface with lesser pores. Hence, the drug got incorporated into the hydrogel matrix, therefore lesser interstitial void remains in the hydrogel [30].

3.4. Drug loading and entrapment efficiency

The percent drug loading (DL%) & entrapment efficiency (DEE%) was determined for DS-loaded CMTKG/PAM hydrogel (A-14) and DS-loaded CMTKG/PVP/PAM efficient swelling hydrogel (A-5) as illustrated in Table 3. It was noticed that DS-loaded CMTKG/PVP/PAM hydrogel showed greater DL% and DEE% in comparison to DS-loaded CMTKG/PAM hydrogel. This is due to the presence of aryl ring in the PVP molecule, creating more space or enlargement taking place in the network of DS-loaded CMTKG/PVP/PAM hydrogel as well as due to the hydrophobic-hydrophobic interaction existing among the alkyl group of PVP and the aryl ring of diclofenac sodium, which enhances the loading of the sparingly water-soluble diclofenac sodium.

3.5. In vitro release study of DS

In vitro release studies were performed for DS-loaded CMTKG/PAM hydrogel (sample code A-14) and DS-loaded CMTKG/PVP/PAM hydrogel (sample code A-5) in a simulated physiological buffer solution of pH 1.2 and 7.4, at 37°C for 24 hr, presented in Fig. 8. For both DS-loaded CMTKG/PAM and DS-loaded CMTKG/PVP/PAM hydrogel, the higher

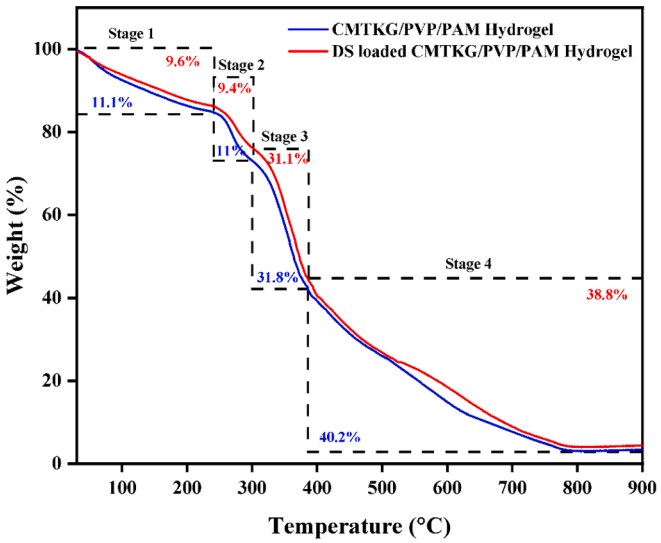

Fig. 6. TGA thermogram of CMTKG/PVP/PAM hydrogel and DS-loaded CMTKG/PVP/PAM (A-5) hydrogel.

percent of DS release was noticed at pH 7.4 because of the deprotonated COO^- anion of the CMTKG. Here, anionic-anionic repulsion among the carboxylate group causes an enlargement in network gaps. Therefore, the swelling ratio gets increases, which leads to rapid diffusion of diclofenac sodium from the polymeric matrix. However, at acidic pH, the carboxylate ion gets protonated, which results in the hydrogen bonding between PAM and CMTKG. As an outcome, shrinkage of the hydrogel took place, resulting decrease in swelling percentage as well as drug release [35]. The DS maximum release was reported to be 66.3% in DS-loaded CMTKG/PAM and 87.3% in DS-loaded CMTKG/PVP/PAM hydrogel at pH-7.4, while 22.9% and 26.3% in DS-loaded CMTKG/PAM and DS-loaded CMTKG/PVP/PAM hydrogel at pH-1.2. It was perceived that CMTKG/PVP/PAM hydrogel showed more excellent drug release compared to DS-loaded CMTKG/PAM hydrogel at pH 7.4 and 1.2. This is due to the presence of aryl ring in the PVP molecule, creating more space or enlargement taking place in the network and hydrophobic-hydrophobic interaction among the alkyl group of PVP and the aryl ring of diclofenac sodium, which causes a rise in the loading and release of the sparingly soluble diclofenac sodium. Hence, it can be concluded that the synthesized CMTKG/PVP/PAM hydrogel can be utilized as excellent material for the efficient delivery of sparingly soluble DS.

3.6. Release kinetic modeling of diclofenac sodium

The higher percent of drug release was noticed in the case of DS-loaded CMTKG/PVP/PAM hydrogel (A-5). Therefore, kinetic modeling was performed for A-5 hydrogel, using Korsmeyer-Peppas, First-order, Higuchi, Zero-order, and Hixson-Crowell models, as presented in Table 4. Based on the R^2 value for all the models, the best suitable model to explain the drug release mechanism was selected. The R^2 value for the Korsmeyer-Peppas model was the highest of the other models. The release exponent "n" suggested the type of diffusion. The R^2 value based on the Korsmeyer-Peppas model at pH 1.2 is found to be 0.9954, and the diffusion exponent value (n) value is 0.4848. In pH 7.4, the R^2 was 0.9931, and the n value was 0.3976. The kinetic graphs for this model are shown in Fig. 9. However, based on the n value, the diffusion mechanism was observed as Fickian at both pH values, which implies that drug release from the polymeric network is solely diffusion dependent.

3.7. Conclusion

This research work reports the successful synthesis of smart diclofenac sodium-loaded CMTKG-based hydrogel that can be used for the controlled release of sparingly soluble diclofenac sodium. Furthermore, the impact of the concentration of initiator, biopolymer, and crosslinker on the swelling nature of synthesized hydrogel was also studied. The swelling and drug release was examined in alkaline and acidic pH and found to be higher in alkaline condition, attributed to strong electrostatic repulsion between COO^- anion of the CMTKG. Sol-gel analysis was conducted by varying amounts of CMTKG, MBA, or KPS and shows an increase in gel fraction with the increase in the amount of reactant. The effect of the addition of PVP on drug loading and release was studied by comparing formulation (A-5), which contains PVP to formulation (A-14,) which lacks PVP. The result indicates that in the presence of amphiphilic polymer (PVP), a hydrophobic character imparts in the polymeric matrix, leading to increased drug loading and release capacity. The kinetics of drug release were effectively correlated with the

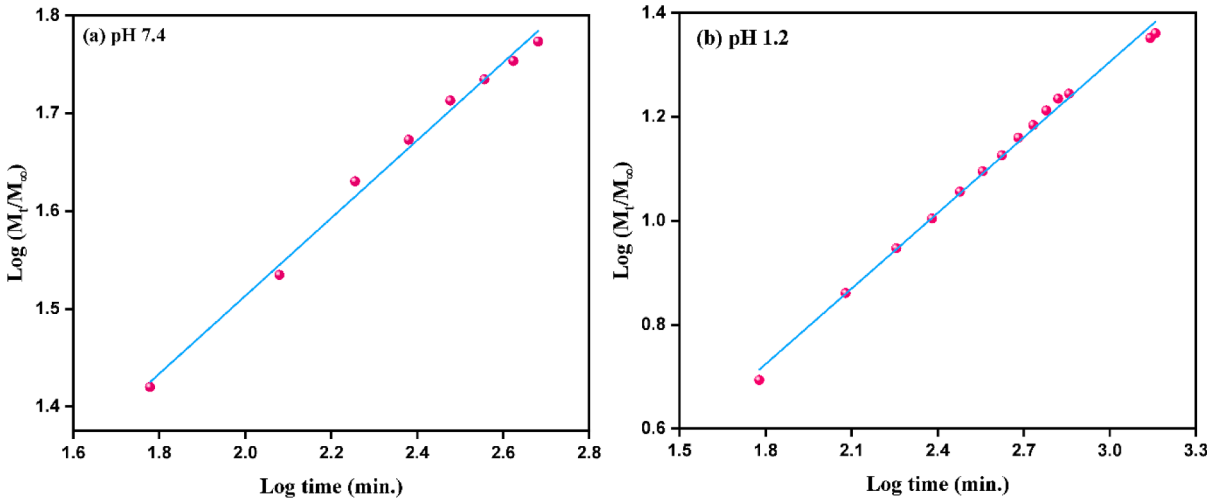

Fig. 9. Release kinetic of DS from CMTKG/PVP/PAM (A-5) hydrogel based on the Korsmeyer–Peppas model in **(a)** pH-7.4, **(b)** 1.2.

Korsmeyer-Peppas model, suggesting drug release from the hydrogel is purely diffusion dependent as it follows the Fickian diffusion mechanism. The above findings permit the utilization of DS-loaded CMTKG/PVP/PAM hydrogel as a feasible material for the pH-dependent release of sparingly soluble diclofenac sodium.

Development of flood susceptibility map using a GIS-based AHP approach: a novel case study on Idukki district, India

Zohaib Ahmed Khan and Bharat Jhamnani

Department of Civil Engineering, Delhi Technological University, Delhi, India

ABSTRACT

Flooding is a regular danger in the Idukki district of Kerala causing serious damage to life and property. An attempt has been undertaken in this research to identify crucial zones in the Idukki district that are more susceptible to flooding. The AHP technique was used to give relative weights to 12 flood contributing parameters. The resultant flood susceptibility map shows that 1346.4 km^2 of the total land in the Idukki district has a high to very high likelihood of flooding. Validation of the resultant map was achieved using the AUC-ROC approach, which showed good accuracy of 0.91.

KEYWORDS
Floods; analytical hierarchy process; susceptibility; mapping; remote sensing

1. Introduction

Flooding is a regular natural hazard that causes significant damage to people and property (Gabriels *et al*. 2022). Floods benefit the ecosystem in a number of ways at lower magnitudes, including by supplying water and nutrients to riparian corridors, eliminating pollutants from flood plain zones, recharging the groundwater table and enhancing soil fertility (Lyubimova *et al*. 2016, Zhang *et al*. 2017, Kraus *et al*. 2019, Abijith *et al*. 2020, Mahato *et al*. 2021). The lives, agricultural operations, residential areas, properties, roadways and natural ecosystems will all suffer enormous damage if the flood tolerance limit is exceeded (Pradhan and Youssef 2011, George *et al*. 2022). According to Kron (2005), this occurs due to heavy rain and melting of snow, which causes the river to overflow and stay momentarily stagnant, causing damage to the lands along the river. Flooding can be caused due to the overflowing of a river as well as other factors like abrupt cloudbursts in semi-arid locations, resulting in flash flood (Tehrany *et al*. 2013). Flooding is a very complicated occurrence that has always drawn researchers from all around the world to better understand and study different mechanisms for better management and avoidance of flood-related hazards. Several natural and human factors are to blame, all of which have the potential to cause a catastrophic flood disaster (Sholihah *et al*. 2020). There is an increase in frequencies of flood episodes and the causes are often associated with unsustainable industrial and farming practices such as cutting of trees, excessive utilisation of resources, improper planning of urbanised colonies and concretisation (Bradshaw *et al*. 2007).

Climate change has also been a significant impact in recent catastrophic flood episodes (Sampson *et al*. 2015). Climate-induced changes, according to (Charlton *et al*. 2006), can greatly affect an area's flood risk by changing land use patterns thereby creating an impervious surface, which increases the velocity of water. As the hydrological cycle becomes more intense due to climate change, flood-related hazards are anticipated to grow, posing a risk to people and property all over the world. Aside from climate, other elements influence flood occurrence, including a region's altitudinal features, vicinity to the main channel, slope, topographic curvature and geological variations (Lim and Lee 2017). Floods can also occur when the excess rainfall due to heavy downpour does not get routed in a particular time frame, which ultimately results in waterlogging of the region. Studies also indicate that increase in the flooding events over the years is due to the rapid increase in artificial surfaces such as roads and buildings in urban areas. Such artificial surfaces are highly impervious and do not allow water to infiltrate into the ground, which leads to floods and heavy waterlogging during events of extreme rainfall (Bronstert 2003).

India experiences a monsoon season spanning from June to September, wherein the country receives a substantial quantum of precipitation. Monsoons play a crucial role in facilitating agricultural practices; however, they can result in an overabundance of precipitation and consequent inundation (Saha *et al*. 2021). A number of regions in India are susceptible to flooding owing to various factors including but not limited to intense precipitation, insufficient drainage infrastructure, deforestation, urbanisation and suboptimal land utilisation practices. The management of floods in India is faced with additional challenges due to the effects of climate change and the swift process of urbanisation (Neumann *et al*. 2015). The alteration of precipitation distribution, increased magnitude of precipitation occurrences and intrusion upon indigenous water reservoirs intensify the susceptibility to flooding. The implementation of sustainable water management practices, resilient infrastructure, land-use regulations and long-term planning are essential. Several regions in India are highly susceptible to flooding, including Assam, Bihar, Uttar Pradesh, West Bengal, Odisha, Maharashtra, Kerala and Karnataka (Parthasarathy *et al*. 2021). Annually, floods in India have a significant impact on a vast number of individuals, reaching into the millions. Natural hazards have the potential to cause fatalities, displace communities, inflict harm on residential structures, devastate crops, impede transportation and communication infrastructure and propagate waterborne illnesses. The groups that are most susceptible to adverse impacts are those that are marginalised and reside in regions with low elevation or in close proximity to river banks (Abijith and Saravanan 2021). The occurrence of floods in India has noteworthy economic implications. The adverse consequences of this phenomenon extend to the structural integrity of various forms of infrastructure, including roads, bridges, railways and buildings, resulting in significant economic repercussions. The inundation of fields due to flooding can have a detrimental impact on the agriculture sector, leading to the destruction of crops and livestock, which in turn can have adverse effects on food production and the livelihoods of those involved in the industry. Industries situated in regions susceptible to flooding also encounter interruptions to their operations (Pramanick *et al*. 2022). The Indian government, at both the central and state levels, has been engaged in the development of flood management strategies and disaster response mechanisms. The endeavours encompass the establishment of flood control infrastructure, such as embankments, dams and reservoirs, along with the implementation of early-warning systems, rescue operations and relief measures for impacted

communities. The National Disaster Management Authority (NDMA) and State Disaster Management Authorities (SDMAs) are pivotal entities in the realm of disaster preparedness and response (Parthasarathy *et al*. 2021).

In recent years, India has had some of the most unusual severe precipitation occurrences, which have resulted in flooding and the loss of lives. For example, the Kosi River, commonly known as the 'Sorrow of Bihar', is renowned for its catastrophic floods in Bihar. The river in question has its source in Nepal and subsequently flows into Bihar, where it has been known to alter its course over time, resulting in devastating inundations. Due to the substantial amount of sediment transported by the river, it is susceptible to obstructions and embankment breaches, resulting in extensive flooding. The heavy precipitation in Uttarakhand in 2013 led to massive floods, killing over 6000 people and causing an economic loss of over 3.8 billion dollars ('Rapidly Assessing Flood Damage in Uttarakhand, India' 2013). The floods were predominantly triggered by extensive and uninterrupted precipitation throughout the monsoon period. The susceptibility of the region to landslides and flash floods was attributed to the combination of steep slopes, fragile geology and intense rainfall. According to Houze *et al*. (2017) the main cause of the disastrous flooding in Uttarakhand, India in June 2013 was the condition of deep convection which moistened the mountainsides, thereby making the region more vulnerable to floods. Flooding in Chennai was triggered by a major rain storm in 2015, which caused $3 billion in damage (Van Oldenborgh *et al*. 2016). The state of Assam experiences recurring floods on a yearly basis, resulting in substantial damage and displacement. Floods are typified by the inundation of extensive regions, the erosion of riverbanks, the breaching of embankments and the overflowing of rivers. The Brahmaputra River presents a considerable flood hazard owing to its substantial discharge and ever-changing characteristics. In India and other parts of the world, extreme rainfall occurrences and flooding have become among the most expensive natural catastrophes (The Human Cost of Natural Disasters 2015: A Global Perspective 2015). Flooding-related human losses are expected to increase by 70–80% if the global mean temperature rises over 1.5°C above pre-industrial levels (Dottori *et al*. 2018).

Catastrophic rainfall and extensive flooding in Kerala recently demonstrated the magnitude of India's extreme rainfall and large-scale floods. In August 2018, Kerala saw prolonged and excessive rains that impacted many elements of human life, including socioeconomic circumstances, transportation, infrastructure, agriculture and livelihood. The Kerala floods of 2018, which are probably the worst floods in a century, have already drawn the attention of the media, the scientific community and policymakers (Hunt and Menon 2020). According to preliminary estimates, the Kerala floods killed over 440 people and inflicted $3 billion of economic damage (Young *et al*. 2022). According to the India Meteorological Department (IMD), Kerala recorded the highest daily rainfall in six decades in 2021. This resulted in excess rainfall which flooded most of the agricultural areas, due to which crop production was adversely affected, which further impacted the livelihoods of farmers.

In recent decades, remote sensing and geographic information systems (GIS) have grown as instruments for management of natural hazards and geospatial mapping by employing different multi-criteria decision techniques (Das 2017, 2018). For instance, Chen *et al*. (2011) delineated flood susceptibility zones in the cities of Taiwan with the help of GIS coupled with the AHP approach. Kazakis *et al*. (2015) employed the AHP approach for delineating flood susceptible maps in Rhodope-Evros, which is a region in

Greece. The developed flood susceptible maps were validated with historical flood occurrence. Hsu *et al*. (2017) utilised the AHP and GIS approach to map flood-prone areas in the Fangshan district, China, employing nine flood conditioning factors, where six factors namely rainfall intensity, rainfall frequency, slope, elevation, river network density and impervious surface were considered in relation to hazard and three factors namely population, road network density and fixed assets were considered for vulnerability. The resultant map was successfully validated with the locations of historical flood events. Tran *et al*. (2017) developed flood susceptible zones in coastal lowland regions of central Vietnam in which they showed that factors such as elevation and distance to river play a significant part in the development of the final flood susceptibility map. Seejata *et al*. 2018 employed the AHP model for mapping of flooded regions of Sukhothai province in Thailand utilising six parameters, namely elevation, slope, rainfall intensity, land use patterns, soil permeability and channel density. Hamlat *et al*. (2021) employed the AHP method and remote sensing data along with the integration of GIS, and mapped the flood-hazard-prone regions in M'zi wadi basin in Algeria using seven parameters, namely elevation, rainfall intensity, flow accumulation, slope of the basin, drainage density, land use/land cover and type of soil present in the basin. The developed flood hazard map was successfully validated with help of pre-flood and post-flood satellite images of the basin.

Koks *et al*. (2015) utilised combined hazard, exposure and social vulnerability to enhance the detailed assessment of flood risk management strategies. Hadipour *et al*. (2020) employed GIS-based spatial multi-criteria decision analysis and developed a flood risk index due to coastal flooding and mapped it by integrating flood hazard, social vulnerability and exposure as risk components. Paranunzio *et al*. (2022) emphasised the importance of changes in rise in sea level, urban sprawl and land cover changes in the evaluation of coastal flood risk in the county of Dublin. Ghosh and Kar (2018) stressed the importance of including socio-economic parameters along with physical aspects to assess flood hazard and vulnerability through AHP-based approaches. Chakraborty and Mukhopadhyay (2019) signified the efficiency of coupled AHP and GIS approaches as a reliable tool for spatial flood risk distribution in regions where limited data are available. Over the last two decades, various methods for studying flood-prone areas have been developed, including the AHP approach (Dou *et al*. 2017), genetic algorithms and fuzzy logic (Nourani *et al*. 2014, Hong *et al*. 2018), decision tree models, multivariate statistics (Tehrany *et al*. 2013) and a hydrological forecasting system (Abbaszadeh 2016, Danandeh Mehr and Kahya 2017).

The flood susceptibility mapping makes extensive use of a variety of machine learning methods, including random forest, CART, support vector machines, XGBoost, gradient boosting machines and artificial neural networks (ANNs). ANNs have been used extensively in the past 10 years to map the susceptibility of natural hazards (Giovannettone *et al*. 2020, Jacinth Jennifer and Saravanan 2022), but they have shortcomings like under- and over-fitting, slow learning, the curse of dimensionality and slow convergence to a local optimum; in addition, their processing of complex hydrological phenomena has been insufficient (Krishnaraj and Honnasiddaiah 2022, Saravanan and Abijith 2022). The AHP model and geospatial approaches are the simplest way to predict flood susceptible zones by carefully examining multiple relevant components (Gupta and Dixit 2022). Inaccuracy in assigning weights to the different parameters can lead to an inconsistent spatial distribution of flood risk potentials. Over the years, the AHP in connection with GIS has gained more popularity for mapping floods (Pal and Ziaul 2017, Aslam *et al*. 2022).

Also, the outcomes of GIS-based statistical calculations showed more accuracy than using spatial data alone (Farhan Ul Moazzam *et al*. 2018, Swain *et al*. 2020). Several studies (Vimal *et al*. 2018, Singh 2019, Hunt and Menon 2020) have attempted to investigate and identify the flood-prone zones. The AHP technique is an approach for making decisions that aids in selecting different factors and criteria according to their relative relevance and may be used to the creation of comprehensive flood susceptibility models (Chakraborty and Mukhopadhyay 2019). Various studies (Dou *et al*. 2017, Pal and Ziaul 2017, Ghosh and Kar 2018, Vimal *et al*. 2018, Aslam *et al*. 2022) used only limited number of parameters with comparison to rainfall data. The utilisation of a restricted set of parameters in the mapping of flood-prone areas may heighten the likelihood of producing less precise flood susceptibility maps.

In the current study, we have used 12 parameters related to elevation and other conditions connected to terrain for accurate flood susceptibility mapping. Specifically, in the Idukki region of Kerala, where floods have been a constant phenomenon in the recent past, no study has attempted flood susceptibility mapping using 12 parameters and validated the maps using pre- and post-flood satellite images. One of the most important aspects of flood disaster research is flood susceptibility mapping (Tehrany *et al*. 2017, 2019, Bui *et al*. 2019, Das 2019, Band *et al*. 2020, Rafiei-Sardooi *et al*. 2021). As Idukki has been more prone to floods in recent years, a proper flood analysis has to be carried out to find the flood susceptibility region. Therefore, it is of utmost importance to develop flood susceptible maps in the Idukki district of Kerala. As a result, the objective of this article is to utilise remote sensing and geospatial analysis to examine the various influencing elements that are responsible for the frequent occurrence of floods in Kerala's Idukki District, as well as to demarcate flood-prone regions by constructing a flood susceptibility map.

2. Study area

The study region, Idukki District, is part of the Western Ghats and is characterised by rough hills and deep valleys. It is located in the southwest part of Kerala. It covers an area of 4358 km^2 and is located between 9°20′N and 10°20′N latitudes and 76°25′E and 77°25′E longitudes (Figure 1). The average annual rainfall is between 250 and 425 cm and the temperature varies between 21° and 29°C. Geology of the research area shows that recent sediments overlie Precambrian rocks, with no significant Phanerozoic representation other than a huge unconformity. Biotite gneiss, granite gneiss, charnockite, granite, hornblende biotite gneiss, calc granulite and quartzite are the Precambrian rocks found in the study region (GSI 2006). Clayey soil, fine loamy mixed soil and clayey-skeletal kaolinite soils are found in the studied region (NBSS 1996). Geomorphologically, the study region from east to west may be divided into three primary sections: the high escarpment of the Western Ghat, the mild plateau and the deep valley. Idukki District has elevation values which range from 15 to 2700 m above sea level. The research area is frequently flooded near the bottom of the Ghat region due to strong orographic rainfall during the monsoon season. Many tiny communities are located in such areas, and they are severely impacted both physically and economically.

The Idukki district is renowned for its hilly terrain and diverse range of flora and fauna. During August of 2018, Kerala experienced a catastrophic flood event, with the Idukki district being among the areas that were severely affected. In August 2018,

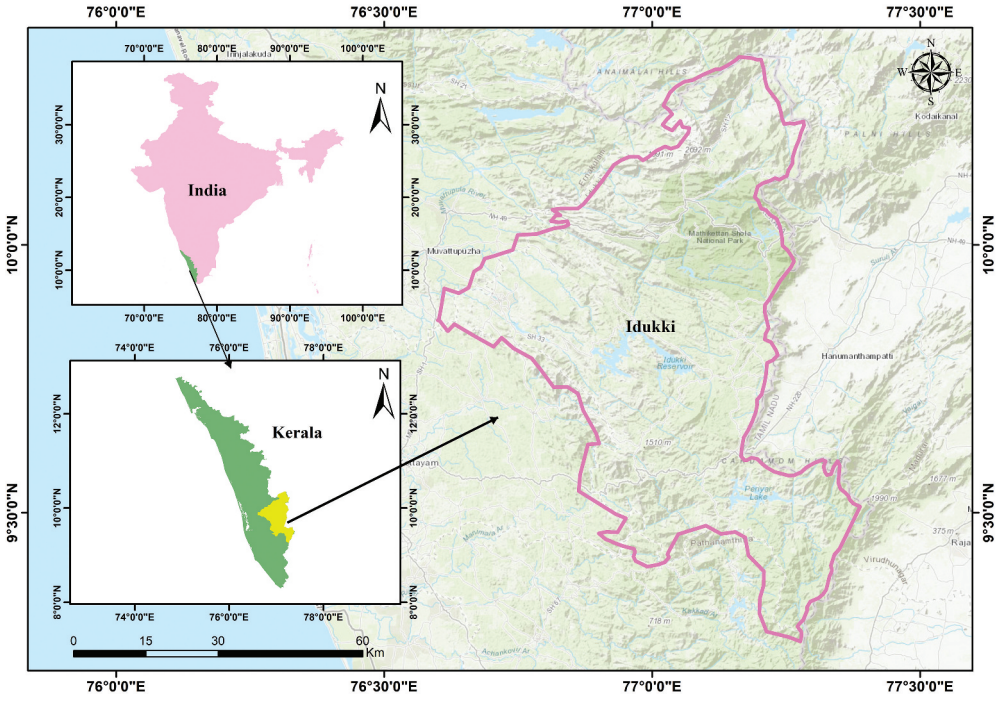

Figure 1. Location map of the study area.

a period of prolonged flooding was observed over multiple days. The precipitation of significant magnitude and consequent inundation were instigated by the southwest monsoon. The region experienced a significant amount of precipitation during the monsoon season, with approximately half of the total rainfall occurring within the initial 20-day period of August 2018. This resulted in a swift and excessive inundation of the area. Numerous regions located in the district encountered large quantities of precipitation, leading to a notable escalation in the water levels of rivers, lakes and reservoirs. As a result of the significant precipitation and the imperative to regulate the escalating water levels in the reservoir, the flood gates of the Idukki dam were opened, thereby contributing to the inundation of the lower-lying areas. The hydrological phenomenon of dam water release was a contributing factor to the extensive inundation observed in the district. The Idukki district suffered significant infrastructure damage as a result of the floods. The occurrence of landslides in mountainous regions exacerbated the situation by causing interruptions in transportation and communication infrastructures. The inundation that occurred in the Idukki district in 2018 led to a noteworthy fatality rate. Numerous individuals were left stranded and compelled to evacuate their residences as a result of the escalating floodwaters. The establishment of relief camps aimed to offer lodging, sustenance and healthcare aid to the impacted populace. The inundations had a significant effect on the agricultural sector and the means of subsistence in the region. The inundation of crops, encompassing paddy fields, plantations and horticultural lands, led to significant economic losses for agricultural producers. The livestock and fisheries sectors were also impacted.

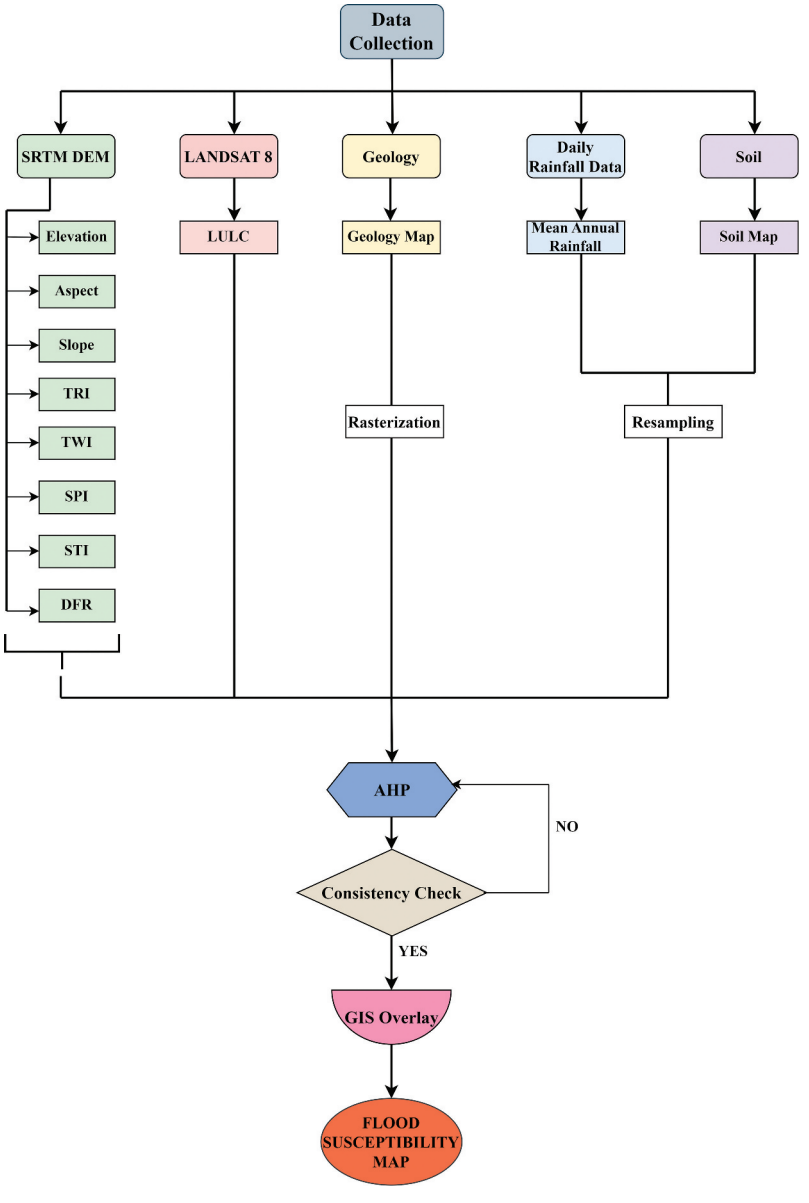

Figure 2. Methodology for preparing flood susceptibility map of Idukki district.

3. Material and methods

3.1. Methods for preparing flood thematic layers

The creation of the spatial flood model, which is frequently highly intricate and far from exact, necessitates a large amount of topographical and hydrological data. The flood susceptibility maps will be confirmed using scientifically defined metrics. As a result, one of the most important tasks is to identify the variables that cause flooding. The 12 flood-inducing parameters in the current study area were chosen based on the available flood

susceptibility literature which includes geology, elevation, distance from river, rainfall, land use, soil, topographic wetness index (TWI), slope, topographic roughness index (TRI), aspect, stream power index (SPI) and sediment transport index (STI) (Moghaddam *et al*. 2019, Paul *et al*. 2019, Sturzenegger *et al*. 2019). All of the influencing variables were transformed to a raster format with a spatial resolution of 30 metres by the resample tool in ArcGIS.

For flood modelling, topographic parameters are critical because they influence the hydrological properties of the studied region both directly and indirectly (Arabameri *et al*. 2020, Lei *et al*. 2020). Das and Gupta (2021) developed a flood susceptibility map for Subarnarekha River basin, India, and indicated that TWI, elevation, drainage density and slope are the most crucial factors for flood hazard mapping. In the first phase, the Shuttle Radar Topography Mission (SRTM) digital elevation model (DEM) for the research region was downloaded from Earth Explorer. This consists of 1 arc second 30 m resolution freely available DEM data widely used in various applications of remote sensing analysis. These data are re-projected to UTM zone 43 N in the projected coordinate system. The data are void filled, mosaicked and extracted by mask for further processing in the ArcGIS 10.2 environment. These pre-processed SRTM DEMs can provide more accurate and reliable elevation data for flood modelling. We used DEM to compute slope, aspect, curvature, sediment transport index (STI), topographic wetness index (TWI), stream power index (SPI) and topographic roughness index (TRI) in the ArcGIS environment. Each of the thematic layers were obtained from different sources as shown in the Table 1. The methodology for preparing flood susceptibility map of Idukki district is illustrated in Figure 2.

The most important aspect in flood modelling is elevation (Dodangeh *et al*. 2020). Flooding is inversely proportional to elevation. When heavy rainfall occurs, water flows quickly from higher-elevation regions such as mountainous and hilly areas to low-lying areas or flat regions of lower elevation, thereby making these low-lying areas more prone to flooding. (Chen *et al*. 2019, Veerappan and Sayed 2020). As a result, floods are more likely to occur on flat or lower-elevated areas. Figure 3(a) shows the elevation map of the study region. Another factor that influences the direction of flooded areas is aspect. This is derived from the DEM data spatial analyst tool in ArcGIS. It is considered to be a significant factor as it determines the direction of flow of water and hence assists in the evaluation of flooded regions (Rehman *et al*. 2021). As a result, the aspect has an indirect impact on floods. Figure 3(b) shows the aspect of the study area. The slope, which affects the flowing water's

Table 1. Database information of flood susceptibility mapping.

Data layers	Source of data	Data type	Resolution/ feature type
Rainfall	Indian Meteorological Department https://mausam.imd.gov.in/	Gridded	0.25°

Soil	National Bureau of Soil Survey and Land Use Planning https://www.nbsslup.in/	Raster	2.5 km
Digital elevation model (DEM)	SRTM https://earthexplorer.usgs.gov/	Raster	30 m
Land-use/land-cover	Landsat 8 OLI Image https://earthexplorer.usgs.gov/	Raster	30 m

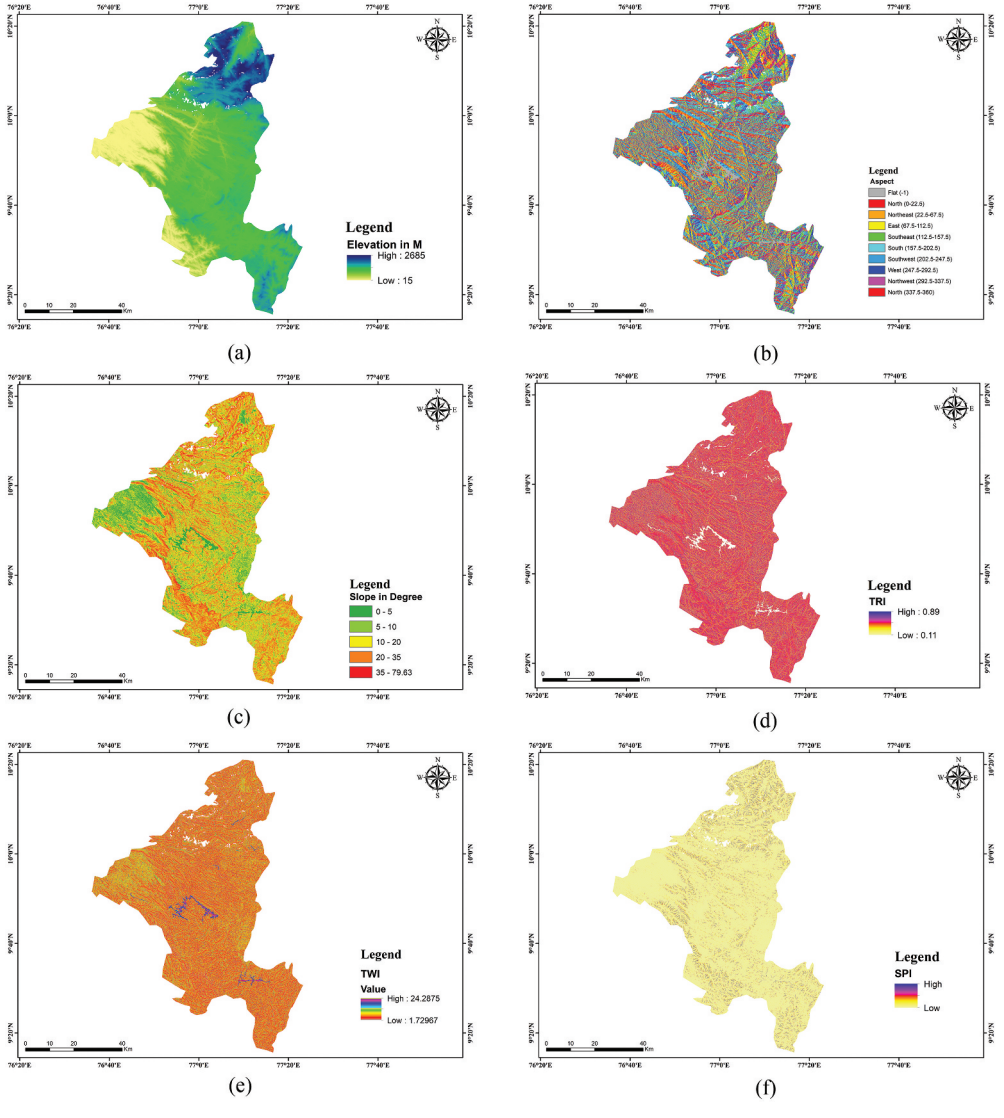

Figure 3. Thematic layers: (a) elevation, (b) aspect, (c) slope, (d) topographic roughness index, (e) topographic wetness index, (f) stream power index.

flooding pace, is another major aspect that influences the flood (Stevaux *et al*. 2020). Slope is derived from the DEM data using the spatial analyst tool in ArcGIS. In regions where the slope is steep, water flows with a high velocity during a rainfall event and hence disposes the surface runoff very quickly, whereas areas of flatter or gentle slopes are more prone to floods and water logging, as runoff gets stored over these regions for a longer time. Figure 3(c) demonstrates the slope of the study area. TRI is also a key contributing variable for flood episodes as it assists in investigating basin's local topography. It is calculated by deriving the focal mean, focal minimum and focal maximum of the raster in each pixel in the ArcGIS environment and using the following equation in the raster calculator.

$$TRI = \frac{(Focal\ mean - Focal\ minimum)}{(Focal\ maximum - Focal\ minimum)}$$

It describes the amount of difference in elevation between adjacent cells in a DEM. Higher magnitude of floods is always related to lower TRI values and a high value of TRI leads to low magnitude of floods (Talukdar *et al*. 2020). The TRI (topographic roughness index) map was preserved in stretch format in this investigation, with values ranging from 0.11 to 0.89 (Figure 3(d)). TWI (topographic wetness index) is also an important aspect in the occurrence of floods (Abdel Hamid *et al*. 2020), since it allows the difference in the wetness of a basin to be visualised spatially (Meles *et al*. 2020). This index depicts the water quantity present in each pixel of the area, and it is calculated using the following equation in the raster calculator in the ArcGIS environment.

$$TWI = \frac{ln(A_s)}{tan\beta}$$

A_s indicates the catchment area ($m^2\ m^{-1}$) and β represents local slope gradient (in degrees). Floods and high TWI levels are inextricably related. In the study region, the TWI value ranges from 1.72 to 24.28 (Figure 3(e)).

The stream power index (SPI) has a significant influence on the riverine system. A higher value of SPI is indicative of large erosion and heavy flowing water. SPI is calculated using the equation in the raster calculator in the ArcGIS environment.

$$SPI = A_s\ tan\beta$$

The specific catchment area is represented by A_s ($m^2\ m^{-1}$) and the local slope gradient is denoted by β (in degrees) (Wu *et al*. 2020). The SPI map is shown in Figure 3(f). The sediment transport index (STI) describes the topographical effect on loss of soil and erosive capacity of a terrain. It is derived from DEM using the following equation in the raster calculator in the ArcGIS environment.

$$STI = \left(\frac{A_s}{22.13}\right)^{0.6}\left(\frac{Sin\beta}{0.0896}\right)^{1.3}$$

where β denotes each pixel of the local slope (in degrees) and the area of the upstream region is denoted by A_s ($m^2\ m^{-1}$). The STI value ranges in this study were classed from low to high (Figure 4(a)).

Surface runoff and sediment transport are influenced by land use, which has a direct impact on the frequency of floods (Benito *et al*. 2010). Land use has a direct influence on surface runoff generation and infiltration, because metropolitan areas do not permit water to enter the ground, as a result of which flooding is more prevalent. In this work, we used the ArcGIS image classification approach to create a land use map from a Landsat 8 OLI image. The land use map was divided into seven categories: barren and fallow land, cropland, forest, grassland, plantation, settlements and waterbodies (Figure 4(b)). Supervised classification was employed to categorise land use. Supervised classification allows a user to select sample pixels in an image that are representative of specific classes and directs the image processing software to utilise these training samples as a reference for the classification of all other pixels in the image. Training samples are chosen based on the knowledge and expertise of the user. For instance, training areas for urban areas, vegetation and water bodies can be selected by drawing

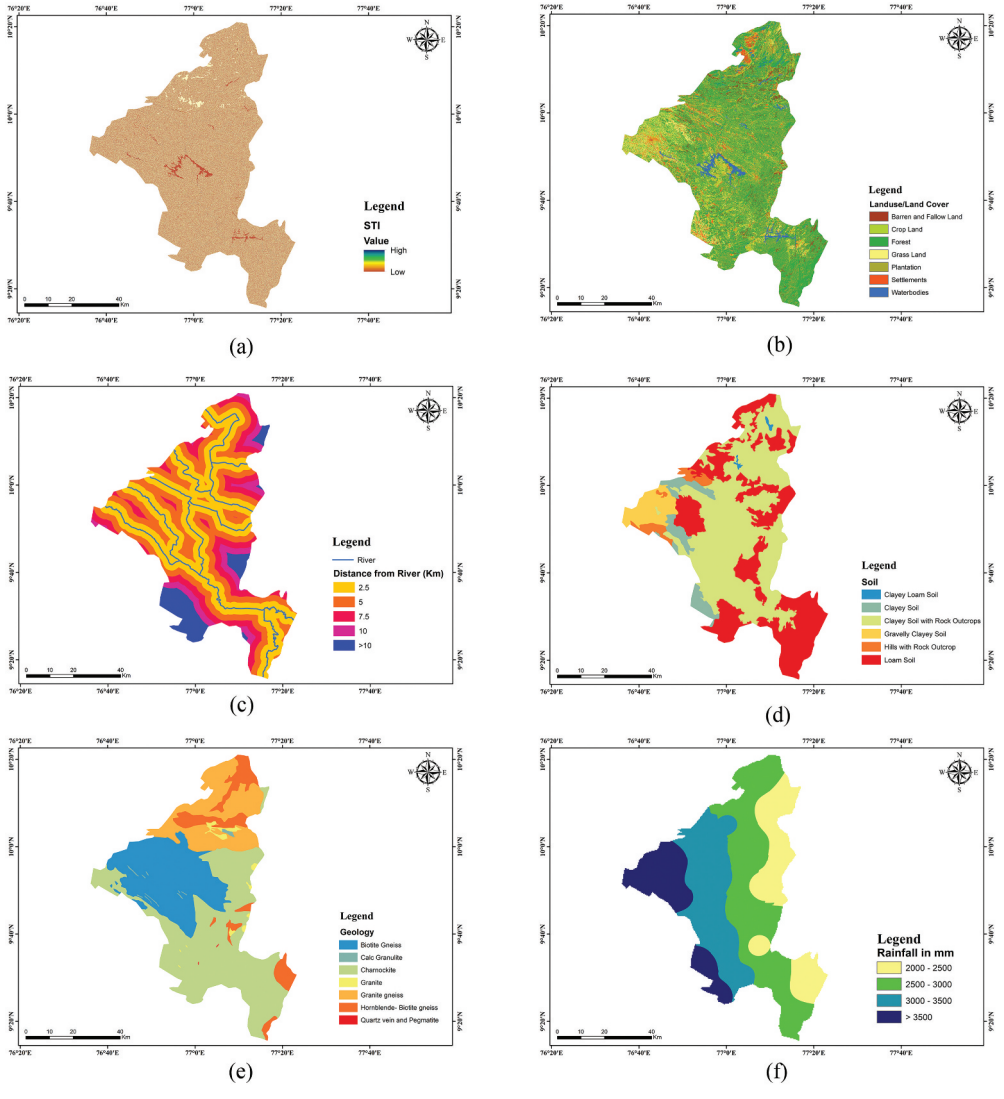

Figure 4. Thematic layers: (a) sediment transport index, (b) land use, (c) distance from river (DFR), (d) soil, (e) geology, (f) rainfall.

a polygon around them. After producing enough training samples for each class, signature files are generated in the ArcGIS software. Using the supervised classification tool, the study region is then classified into different land use features. The precision of the classification process is determined by selecting spatially balanced points within the research area and cross-referencing them with manually verified ground truth data obtained through the use of Google Earth Pro software. Subsequently, a confusion matrix was generated to evaluate the precision and reliability of the classified map. The results indicate an accuracy rate of approximately 83.35%, which is considered acceptable. Most flood-inundation areas are often located in the vicinity of a river or a stream. Distance from the river is a critical parameter for defining the areas of a basin that are prone to flooding because it governs the incidence of flooding and the river flow to river factor. The underlying concept is that the less the distance from the river,

the more likely it is that the region will get flooded. In the current study, we computed the distance to the river map using a 1:50,000 scale topographic map and Google Earth. The distance from the river chart is depicted in Figure 4(c). Soil types are one of the most important influencing elements in the rainfall-runoff process. Other variables such as local meteorological conditions and erosion regulate rainfall-runoff production, but soil qualities directly limit water infiltration, which determines rainfall-runoff generation. In the present study, we have used the National Bureau of Soil Survey and Land Use Planning (NBSS and LS) to prepare the soil map. Figure 4(d) shows the soil map of the study area. The lithological properties of a region influence porosity and permeability. Properties of a particular rock can also impact flood intensity to some extent because in the presence of impermeable rocks more flooding is bound to occur, while porous rocks will let more water infiltrate and hence lessen the chances of flooding. In the present study, the geology map was prepared using Geological Survey of India data (1:250,000 scale). Most of the study area is covered by charnockite followed by biotite gneiss, granite gneiss, etc (Figure 4(e)). Rainfall has been identified as one of the most important elements determining the incidence of floods because a large amount of rain in a short period of time might produce floods. Annual average rainfall data were collected from 15 Indian meteorological stations and with the help of the inverse distance weighted (IDW) interpolation technique, rainfall maps were created in the ArcGIS environment. IDW estimates the values of cells by averaging the values of sample data points in the neighbourhood of each processing cell. The closer a point is to the centre of the cell being estimated, the more influence it has in the averaging process. The disadvantage associated with IDW interpolation is that it is not suitable for territories having large orographic effects; however, due to the distribution of our rainfall data, this technique produced accurate rainfall maps. The annual rainfall ranges from 2000 to 3900 mm in the study area as shown in Figure 4(f).

3.2. Analytical hierarchy process (AHP) model

The analytical hierarchy process method is a versatile and well-structured technique for interpreting complex decision scenarios involving several factors (Saaty 1980). It is a well-established approach for solving complex decision-making problems. The advantage of using this method lies in the allotment of user-specified weights to a hierarchical structure of criteria and sub-criteria. Therefore, AHP assists the user to evaluate different parameters that are of utmost significance as per the requirement and to comprehend the problem statement with deeper understanding. Comparison of different parameters is done by assigning scores based on their relative influences and importance (i.e. 1 denotes equally significant; 3 denotes moderately more significant; 5 denotes strongly more significant; 7 denotes very strong more significant; 2, 4 and 6 are the transition scores) as shown in Table 2. In various problems such as flood susceptible mapping, landslide mapping and groundwater potential zone assessment, AHP is found to be a powerful and a beneficial tool having high accuracy (Mahmoud and Gan 2018, Surwase *et al*. 2019, Suthirat *et al*. 2020). The reason for the wide popularity of the AHP model is its capability to handle quantitative as well as qualitative data in assessing natural hazards like floods. Implementation of the AHP model has been successful in comprehending problems of various natural hazards such as assessment of flood and landslide susceptible regions (Danumah *et al*. 2016, El Jazouli *et al*. 2019).

Table 2. Saaty's 1987 1–9 scale of pairwise comparison matrix.

Numerical value	Description	Explanation
1	Equal importance	Two activities contribute equally to the objective
3	Slight importance of one over another	Experience and judgement slightly favour one activity over another
5	Moderate importance of one over another	Experience and judgement strongly favour one activity over another
7	Very strong importance	Activity is favoured very strongly over other
9	Extreme importance of one over another	Evidence favouring one activity over the other is of the highest importance
2, 4, 6, 8	Intermediate values	-

For investigating problems of flood modelling or susceptibility studies, the AHP model is used to estimate the weights and rankings of various factors. Steps involved in the AHP method for delineation of flood susceptibility zones in a region are described below:

- The first step of AHP is preparation of a pairwise comparison matrix of all the parameters affecting a system.
- The weights or values then are assigned to each parameter purely based on the knowledge or the expertise of the user in the pairwise comparison matrix. For instance, when rainfall is compared with elevation, a value of 4 is assigned which indicates intensity of importance for rainfall is 4 times more than that of elevation, as shown in Table 3.
- Similarly, when the same parameters are compared in the standard pairwise comparison matrix, for instance when slope is compared with slope, the assigned weight has a value equal to 1 as both the parameters hold equal importance, as shown in Table 3. This further explains the reason for assigning a value of 1 to all the diagonal elements in the pairwise comparison matrix in Table 3. Evaluation of all the attributes is generally performed on a 9-point scale, as explained by Saaty (1980), in Table 2.
- The second step is to sum all the assigned weights at the end of a column and then each assigned weight is divided by sum of all the assigned weights. The normalised principal eigenvector or priority vector is obtained by averaging all the weights and

Table 3. Each parameter's comparison matrix and relative score.

Parameters	Rainfall	Elevation	DFR	TWI	Slope	TRI	SPI	STI	LULC	Geology	Aspect	Soil

Aspect	0.12	0.13	0.18	0.25	0.22	0.25	0.33	0.50	0.50	0.50	1.00	2.00
Soil	0.12	0.14	0.14	0.18	0.20	0.33	0.29	0.40	0.25	0.33	0.50	1.00
Sum	3.27	7.88	11.35	14.36	17.24	17.82	20.72	31.57	33.75	33.33	44.50	52.00

a normalised value is obtained for each parameter. The priority vector indicates the final weights assigned to each parameter.
- To evaluate the consistency of weights with respect to one another, the consistency ratio is calculated.
- After the consistency check, the normalised weightage is then multiplied with rank of all individual parameter sub-classes to get the overall weightage of all thematic layers (Table 4).
- Finally, all the weightage values are attributed in the ArcGIS file to get the final flood susceptibility map.

A detailed mathematical expression of the AHP approach is given below.

Let X = {X_j| j = 1, 2 . . . . . n} be the arrangement of the model. The result of the pairwise comparison on n criteria can be done in a (n_n) assessment matrix A where each component a_{ij} (i, j = 1, 2 . . . n) is the range of the weight of the attribute, as given in the condition below

$$\mathrm{A} = \begin{bmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \dots & \dots & \dots & \dots \\ a_{n1} & a_{n2} & \dots & a_{nn} \end{bmatrix}, \; a_{ii} = 1, \; a_{ji} = \frac{1}{a_{ij}}, \; a_{ij} \neq 0$$

The weights or scores of pairwise comparison matrix are normalised to evaluate the standard pairwise comparison matrix through the method of weighted arithmetic mean. The weights of all the components are determined by the mean row method in the standard pairwise comparison matrix. The maximum characteristic root can be expressed as:

$A\ w = \lambda\max\ w$. Here A represents the standard pairwise comparison matrix, w is the eigenvector, λmax represents the matrix's principal eigenvalue.

To have a consistent pairwise comparison, the matrix A has rank equivalent to 1 and λmax is equivalent to n. Consistency of the pairwise judgements among the different parameters is of utmost importance as it regulates the accuracy of the results through the AHP model. The consistency of the AHP method is checked by employing the equation below (Saaty 1980):

$$CR = \frac{CI}{RI}$$

$$CI = \frac{\lambda\max - \mathrm{n}}{n - 1}$$

where CR represents consistency ratio, CI represents consistency index, RI represents random index, λmax represents the matrix's principal eigenvalue, and n denotes the number of parameters or factors. In Saaty's (1980) paper, a significant number of components are used to obtain RI values, as shown in Table 5. It has been discovered that RI is influenced by a variety of circumstances. According to Saaty's (1980) study, for instance, the comparable value of RI is 1.45 when the components are nine (Table 5). The consistency ratio (CR) is acceptable in this study if it is less than 10% or 0.10, which suggests a fair level for the pairwise comparison matrix.

Generally, for flood-related studies, previous research scholars generally utilise eight or nine parameters (Das 2018, Mandal and Mandal 2018, Saha and Agrawal 2020). In Idukki District, previous studies related to landslide susceptibility mapping have often been performed (Thomas *et al*. 2021, Jesudasan and Subbarayan 2022) to assess the risk-prone regions related to this natural hazard. However, studies related to floods have not yet been performed in Idukki District, and since it is one of worst affected districts in Kerala floods every year, it becomes essential to map the flood-prone areas of the district with accuracy. Hence, the present study has considered as many as 12 flood conditioning factors, which are elevation, slope, rainfall, topographic wetness index, topographic roughness index, stream power index, distance from the river, sediment transport index, land use, geology, aspect and soil for accurately identifying flood-prone zones using the AHP model in Idukki District. In earlier studies, only primary terrain attributes such as aspect, slope, elevation, soil types and geology were the main conditioning parameters in computing flood-prone areas. However, secondary terrain attributes or topo-hydrological aspects such as TWI, TRI, STI and SPI are also of paramount significance as they determine the effect of local topography, detailed undulations, overland flow and erosion risks. Hence the current study also includes the attributes of topo-hydrological parameters along with primary terrain attributes for calculation of flood-prone zones with utmost accuracy.

From consistency table and calculations, λmax denotes the principal eigenvalue, *n* refers to the dimension of the matrix and calculation of λmax and Consistency Index is given below:

$$\lambda\text{max} = 13.64416551$$

$$\text{Consistency Index} = \frac{\lambda\,\text{max} - 1}{n - 1}$$

$\text{Consistency Ratio} = \frac{\textit{Consistency Index}}{\textit{Random Index}} = 0.09706$, Here, the value of the Random Index (*RI*) is taken as 1.48 as there are 12 flood conditioning factors. Consistency ratio for the current study is less than 0.10 or 10%, hence weightages given to all the parameters are consistent with one another. This assists in having a preliminary quality assessment for the final map, as the resultant map is based on the assigned weights of the different parameters, hence inaccuracy in assigning weights would create bias in the results. It also implies that by employing these weights for the development of the flood susceptibility map, accurate assessment of the flood-prone areas can be performed for the Idukki district as all the flood conditioning factors are consistent with each other.

4. Results

All the thematic layers of 12 flood conditioning factors are prepared in the GIS interface as shown in Figures 3 and 4. After preparation of all the thematic layers, relative weights are given to all the flood conditioning parameters and a comparison matrix is made as shown in Table 3. The consistent weights are then calculated for every parameter in the standard pairwise comparison matrix. Since a lot of parameters are utilised for preparing a flood susceptibility map, a consistency check is of utmost importance to ensure that weightages given to parameters are consistent with each other.

The consistency check for all the flood conditioning parameters is evaluated, where the consistency ratio is found to be 0.09706. For maintaining consistency between parameters, the consistency ratio must be less than 10%, and hence the weightage given to each flood conditioning parameter is consistent with each other. AHP weightages for all the thematic layers, namely rainfall, elevation, distance from river, TWI, slope, TRI, SPI, STI, LULC, geology, aspect and soil ares 0.25, 0.15, 0.14, 0.10, 0.10, 0.06, 0.06, 0.04, 0.03, 0.03, 0.03 and 0.02 respectively. These weightage values are further multiplied with all the classes and ranks to determine the effect of each parameter and a final flood susceptibility map is developed, as shown in Figure 5.

The final flood susceptibility classes are ranged from 0.25 to 0.02 and are classified using natural break classification into five categories namely very low, low, moderate, high, and very high and these classes occupied areas of 609.0417 km^2, 1222.83 km^2, 1180.45 km^2, 950.48 km^2 and 395.9487 km^2 respectively (Table 6). More than 30% of the Idukki region is covered with high and very high flood susceptible zones (Figure 5). These very high and high flood risk zones were derived from the areas of low elevation, low slope area (less than 10°), distance from the river less than 2.5 km, highest topographic wetness index region (>15), very high rainfall region (3000–3500 mm), highest stream power and sediment transport index region and finally hard rock terrain and low permeability soil type region. Figure 5 displays the flood susceptibility map of the current study area. The very high and high flood-prone regions are in NW, central and SE regions of the study area.

From the flood susceptibility map shown in Figure 5, it is worthwhile to note that more than 30% of the area (1346.4 km^2) falls in the category of very high to high flood-prone zones (Table 6). Therefore, it becomes very important to assess the impact of these very high flood risk zones at subdivisional levels of Idukki. There are five taluks or subdivisions in Idukki, namely Devikulam, Udumbanchola, Idukki, Peerumade and Thodupuzha, as marked in Figure 6, which categorises the flood prone zones for every taluk separately. The developed flood susceptibility map indicates that majority of Thodupuzha town falls in very high flood-prone zones. This is because Thodupuzha lies in areas of lower elevation, low slope and high rainfall as seen from Figures 3(a,c) and 4(f). The distance from the river as shown in Figure 4(c) also reveals that Thodupuzha and Idukki have dense stream networks and major river flow through these districts, which become the paramount reason for having a high likelihood of flooding in these towns. During the Kerala floods of 2018, among all the towns Thodupuzha and Idukki were the worst affected. Seventeen villages constitute the Thodupuzha taluk or subdivision, which shows that people in these villages are at a very high risk of flooding and substantial damage due to floods in future could occur in these areas. Furthermore, the majority of the Idukki subdivision falls under high to very high flood-prone zones. This is because of the presence of the Idukki dam and a large number of

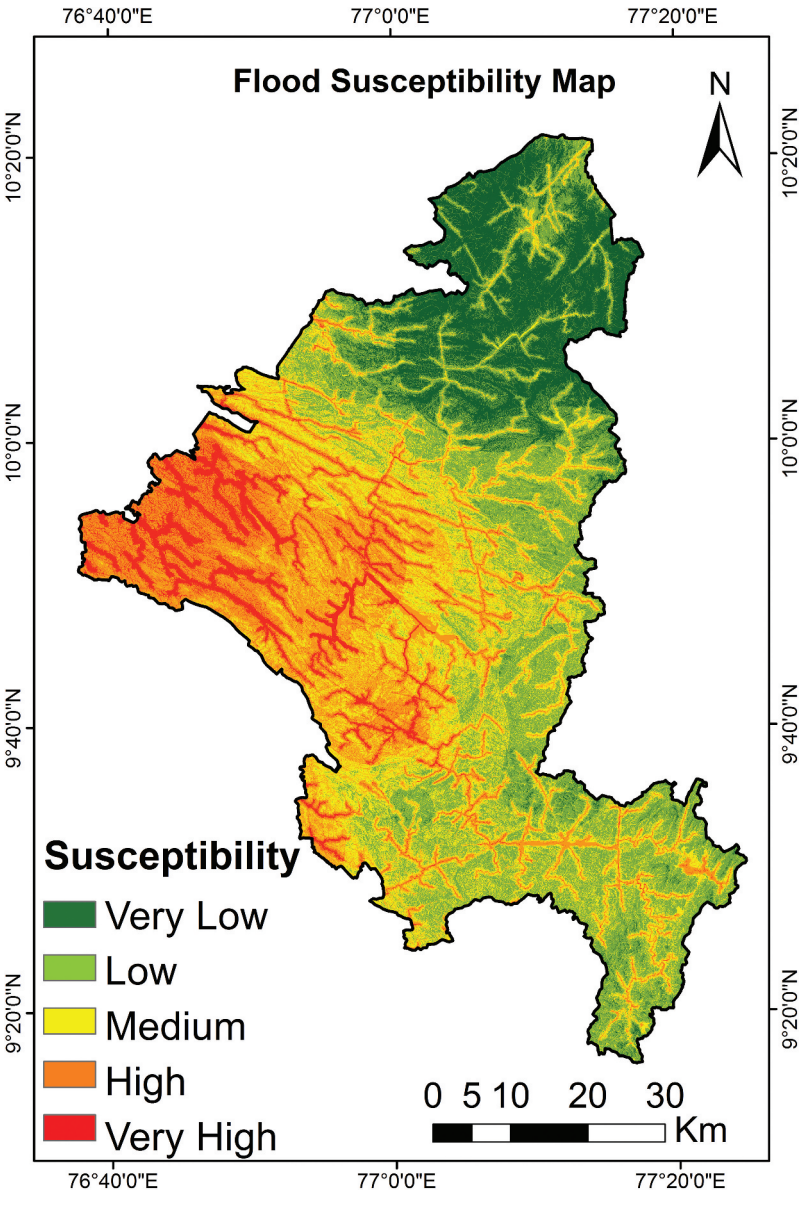

Figure 5. Resultant flood susceptibility map of Idukki district.

Table 6. Flood-prone zones.

S. No.	Flood-prone zones	Area (km^2)
1.	Very low	609.0417
2.	Low	1222.8336
3.	Moderate	1180.4571
4.	High	950.4855
5.	Very high	395.9487

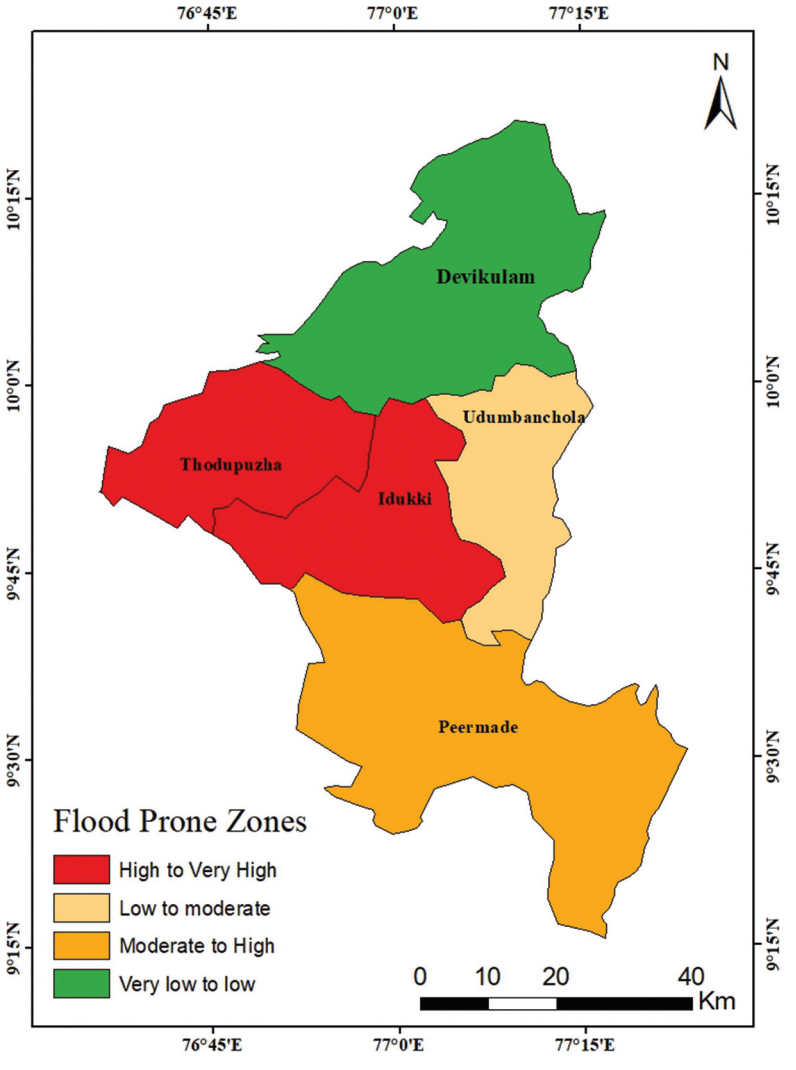

Figure 6. Categories of flood-prone zones in subdivisions of Idukki.

tributaries of the Periyar river. During the Kerala floods of August 2018, all five gates of the dam were opened by the authorities after 26 years, which caused a massive outflow of six lakh litres per second along the Periyar river and its tributaries. Due to this reason, the Periyar river and its tributaries flowed under spate conditions, which leads to flooding of the river banks causing damage to the people residing in these areas. Nine villages constitute the Idukki town and are home to many people, therefore inhabitants residing in these villages are at very high risk of flood-related natural hazards. Peermade subdivision, which is situated in the south east region of Idukki, falls under moderate to high flood prone zones, as shown in the developed flood susceptibility map in Figures 5 and 6. This region generally receives a considerable amount of rainfall in the monsoon season. During the Kerala floods of 2018 and 2021, this region received rainfall in the range 300–350 mm per day and some portion falls under low-lying areas, therefore the majority of the region falls under moderate

to high zones of flooding. Udumbanchola falls under low to moderate flood-prone zones as the region has a dense stream network, high TWI values and low rainfall. From the flood susceptibility map, it is clearly depicted that Devikulam taluk falls under low to very low flood-prone zones because of higher elevation values, a smaller number of streams, low TWI values and comparatively less rainfall than other subdivisions. The flood-prone zones in various subdivisions of Idukki, along with the taluks of maximum flood-prone regions and least flood-prone areas are shown in Figure 6. The process involves partitioning the vast majority of susceptible areas into distinct subcategories based on taluks. This measure is implemented with the aim of decreasing the affected population in that particular locality in the event of a disaster. The detailed impact of all 12 flood conditioning factors on the flood susceptibility map are also discussed below.

4.1. Impact of elevation

This largely influences floods in a region as low-lying areas are most likely to be affected by floods. As shown in the flood susceptibility map (Figure 5), it clearly indicates that subdivisions such as Thodupuzha, Idukki and Udumbanchola which are situated on comparatively lower elevation come under high- to very high-risk zones in flood susceptibility mapping (Xu *et al*. 2021).

4.2. Impact of slope

Another factor which largely influences and controls the flood is slope. In regions of higher slope, runoff flows with a high velocity and chances of water infiltrating through soil become much less and hence water stagnates in areas with small or flat slopes. This is evident as western and central regions of Idukki have low slope and hence are categorised in the areas of very high flood susceptibility (Figure 5). Though regions in the north of Idukki have comparatively higher slope, yet we still see medium flood risk in the flood susceptibility map (Figure 5). This is due to the presence of a large number of streams such as Pembar, Edamalaya and Muthirapuzha rivers, which overflow in events of heavy rainfall and hence make the region prone to flooding Hunt & Menon (2020).

4.3. Impact of TRI

Higher TRI indicates steep and rugged regions, whereas lower TRI indicates flatter areas. As Idukki is situated in a mountainous area factor, such as TRI in conjunction with slope assist in accurate assessment of flood mapping.

4.4. Impact of TWI

Topographic wetness index is an indicator of depth of surface and subsoil layers. Higher TWI indicates the presence of larger streams while lower values give an idea of ridge lines (Pourali *et al*. 2016). In the flood susceptibility map, higher values of TWI can be seen in the subdivisions of Thodupuzha and Peerumade and hence these regions fall in the category of high to very high flood-prone zones.

4.5. Impact of SPI

SPI is an indicator of the erosive power of surface runoff. It is a measure of flowing water's ability to perform a geomorphic task. Geomorphic tasks in relation to flood susceptibility studies would involve the occurrence of weathering, deposition and erosion processes over a land surface during events of heavy rainfall and flooding. Higher values of SPI can be seen in the northern regions of Idukki, which implies large erosion and heavy flowing water. This is because of mountainous regions, where water flows with a high velocity and causes erosion near the river bank. The resulting flood susceptibility map (Figure 5) reveals that low- to medium-risk flood zones are present in this area.

4.6. Impact of STI

Sediment transport index characterises the process of erosion and deposition. It is indicative of the effect of topography on soil loss. Higher STI values represent higher mobility of sediments while the lower values indicate the accumulation of sediments. It is used to describe the erosive capacity of a terrain and the possibility of changes in the channel bed geometry due to sediment deposition. Higher values of STI are found in the streams present in the Idukki district due to heavy flowing water, which helps in sediment deposition near the streams. Moreover, the flood susceptibility map also depicts very high risk of flooding in or near the streams. Therefore, STI develops a direct relation with the flood risk map. Lower STI values are present in the Idukki reservoir and Periyar lake, which is in sync with the flood susceptibility map. (Nones 2019, Siam *et al*. 2022)

4.7. Impact of LULC

LULC has identified seven major classes to quantify the impact of land use and land cover on floods. The capability of land cover types to either absorb rainfall or facilitate its infiltration into the soil varies. The presence of natural vegetation, such as forests or grasslands, has the potential to intercept rainfall and promote infiltration, thereby mitigating the volume of surface runoff. Conversely, urban regions or impermeable surfaces exhibit restricted infiltration potential, thereby leading to escalated surface runoff and expedited water flow towards streams and rivers, thereby augmenting the likelihood of inundation. Rough terrain, such as that found in wooded areas or open grasslands, can impede the velocity of water flow, thereby facilitating its infiltration or retention within the topography. Conversely, surfaces that are devoid of roughness such as roads tend to accelerate the flow of water, resulting in increased quantities of runoff and the possibility of inundation. The cutting down of forests or vegetation cover results in the disturbance of the natural equilibrium of water absorption and interception. The process of deforestation has been observed to have a negative impact on the hydrological cycle, as it leads to a reduction in the amount of rainfall that is intercepted by trees. Additionally, deforestation has been found to increase surface runoff and decrease infiltration capacity. In addition, in the absence of tree roots that provide soil anchorage, the likelihood of soil erosion is heightened. The erosion of soil has the potential to impede the flow of water in rivers, streams and drainage systems, thereby intensifying the occurrence of flooding. The presence of barren and fallow lands, small streams or rivers and urbanisation in the north of Idukki increases the chances of floods in

the region and the flood map suggests that the western region of Idukki, which constitutes high settlements, are high flood-prone areas.

4.8. Impact of distance from river

This parameter plays an important role in assessing flood-prone zones because Periyar river flows in Idukki District and is considered to have the largest discharge potential in Kerala. Because of very little distance from the river and dense drainage networks western and central regions of Idukki are under very high flood risk categories in the final flood susceptibility map (Figure 5).

4.9. Impact of soil

This parameter explains the reason for frequent floods in Idukki experienced in the past. As indicated in the soil map (Figure 4(d)), most of the study region is covered with clayey and loam soil, which has extremely low rates of permeability, due to which water is unable to infiltrate into the ground and hence the majority of the water flows as surface runoff, which further increases the chances of flooding.

4.10. Impact of geology

This parameter indirectly controls the water infiltration rates. Approximately 50% of the region is covered with charnockite rock, while other major rocks in the region are biotite gneiss and granite gneiss. Charnockite is a type of metamorphic rock which is an impermeable rock. Similarly, biotite gneiss and granite gneiss rocks belong to the family of metamorphic rocks and hence are treated as impermeable rocks. This is due to the impervious nature of these rocks which explains why the majority of the areas are high to very high flood-prone regions in Idukki District.

4.11. Impact of rainfall

Rainfall plays a major part in production of flood susceptibility maps. From the rainfall map, it is clearly depicted that Idukki and Thodupuzha received the highest annual rainfalls and hence both regions are very high flood-prone zones. Higher magnitude of rainfall results in more surface runoff and hence increases the chances of flooding in a region.

4.12. Impact of aspect

Factors such as aspect determine the path of floods in flood susceptibility mapping. The aspect map is created from the DEM and further classified into 10 classes. With this map, the direction of flow of water is determined, which further assists in the production of the flood susceptibility map accurately in the Idukki district.

5. Sensitivity analysis

Sensitivity analysis is performed to determine the key factors that have the greatest impact on the development of the flood susceptibility map. Sensitivity analysis is a method employed to ascertain the impact of changes or shifts in specific inputs or parameters of a given system on the resultant outputs or outcomes of that system. The evaluation of the strength and dependability of models is a prevalent practice in decision-making procedures. The goal of performing sensitivity analysis is to comprehend the interrelationships and interdependencies that exist between the input parameters and the resultant output of a given model or system. The outcomes of sensitivity analysis facilitate the identification of crucial variables or parameters that exert a significant impact. These data can be utilised to allocate resources effectively in data-gathering, concentrate on the most significant variables and enhance the decision-making procedures. Additionally, it has the potential to offer valuable perspectives on the hazards and unpredictability linked to the system under examination. The present investigation conducts a sensitivity analysis by utilising the final set of weights obtained from the AHP model. According to the sensitivity analysis as shown in Figure 7, parameters such as rainfall, elevation, distance from river, slope and TWI are the key contributing variables, while aspect, geology, LULC and soil are the least important variables among all the flood conditioning parameters.

6. Discussion

In the current study, a GIS-based AHP approach was employed to assess the flood-prone regions in Idukki District and the sensitive parameters that assist in

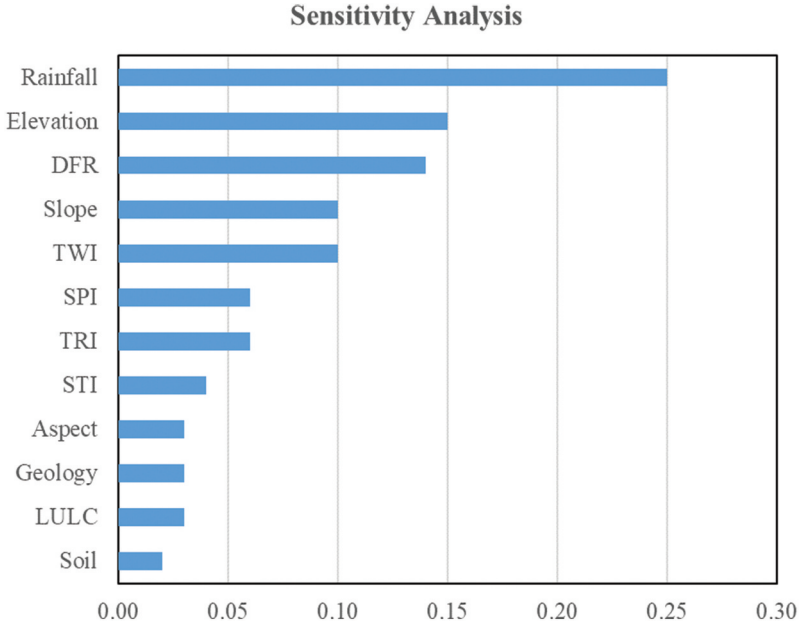

Figure 7. Variable importance of conditioning factors showing the sensitivity of each parameter.

development of an accurate flood susceptibility map. The efficacy and usage of the AHP model have been confirmed with several works in the domain of flood hazards and risk assessment (Liu *et al*. 2020, Pathan *et al*. 2022). Twelve flood conditioning parameters are utilised including topo-hydrological aspects such as TWI, TRI, STI and SPI in the delineation of the flood susceptibility map to perform detailed assessment on the different subdivisions or taluks of Idukki. Weighted parameters of different flood conditioning factors were used with the AHP model in the GIS platform in a linear way using geospatial technology. Sensitivity analysis shows the most influential parameters responsible for disastrous floods in the district. It is evident that rainfall is the primary factor contributing to flooding. The incidence of flooding can be attributed to the substantial rainfall, which is consistent with the sensitive parameter derived from the AHP model. Elevation is a highly significant parameter in the region, second only to rainfall. This is due to the presence of the Western Ghats, which influence the magnitude of floods by generating runoff from higher terrains. The distance from the stream is identified as a crucial factor for flood susceptibility, alongside the elevation. The areas adjacent to the streams are typically the first to experience flooding, and these regions are inundated and significantly impacted by the floods, as evidenced in the Idukki region. The areas in close proximity to bodies of water such as streams, rivers and reservoirs exhibited a higher degree of susceptibility to flooding.

The slope of a land surface plays a significant role in worsening the inundation process by enhancing the velocity of the water flow. Areas with steep slopes tend to produce floods with high velocity, while areas with gentle slopes are more susceptible to severe flooding, which can have a significant impact on the inhabitants of such terrain. Furthermore, the runoff originating from higher slopes can trigger landslides and transport substantial quantities of sediment to low-lying regions, exacerbating the socioeconomic conditions and normal livelihoods of affected communities. The development of TWI holds significant implications in the context of flooding, as it can impede the absorption of water into the ground in areas that have already been saturated with moisture due to precipitation, leading to surface runoff. This phenomenon will result in an amplification of the flood's magnitude. The SPI exhibits a direct correlation with flood events, as it serves as an indicator of the stream's potential energy where the flood velocity is expected to reach its peak during inundation. The TRI, STI and aspect parameters are utilised to assess the roughness of the terrain, transport of sediments and slope direction, respectively, which are indicative of the severity of flooding. The geology and LULC are subsequent factors in the analysis, as they provide insight into the permeability of a rock and the rate of infiltration that induce surface runoff and the land cover that may be significantly impacted during flooding, respectively, and the soil's porosity and permeability, which play a crucial role. The primary factor contributing to the occurrence of floods is excessive rainfall. However, the severity of the flooding is significantly amplified by the topographical characteristics of the area.

The importance of each sensitive parameter should be utilised by policy-makers as they contribute differently in preparation of a flood map. Das 2020 prepared the flood

susceptibility of whole of the Western Ghats using fewer parameters employing the AHP model, which indicates that the model is well suited for Indian states and districts.

Here are some key findings of the study:

- The AHP method was adopted to evaluate the flood-prone regions in the Idukki district of Kerala, India. It was observed that the AHP model was able to produce accurate results in development of a flood susceptibility map of Idukki. This also reveals the wide applicability of the AHP model in regions where heavy rainfall and floods occur every year (Khanday and Sujatha 2022).
- Twelve parameters are utilised to determine the flood-prone regions, which signifies that the model can handle a large number of parameters with accuracy and correctness.
- Results of the developed flood susceptibility map assisted in evaluating flood-prone regions in all the subdivisions of Idukki. Hence, accurate and detailed assessment of floods in the different taluks of Idukki District will help decision-makers to safeguard the livelihood of many inhabitants residing in these districts.
- The developed flood susceptibility map was validated using pre-flood and during-flood satellite images with the help of the AUC-ROC approach. This further consolidates the applicability of the AHP model in flood studies.

Though AHP is a flexible model for complex decision-making, sometimes calculations get cumbersome when the set of criteria is too large. Hence, the main limitation of the model involves the consistency check at each step to ensure the accuracy of the model. Another disadvantage associated with the model is that it does not allow one to add or remove a variable during the process of AHP.

7. Validation

The primary attribute of any proposed model is its ability to match with reality and produce significant outcomes. In order to validate the AHP flood susceptibility mapping, it is necessary to assess its success rate. The historic flood areas were compiled using information from the Survey of India, and pre- and post-flood Sentinel-1 images. For the validation procedure, one SAR image before the actual flood event (17 May 2018) and another SAR image during the flood event (21 August 2018) in VV polarisation were acquired. The Sentinel-1 images are subject to erroneous noise, which includes rigorous geometric and radiometric corrections, thermal effects and speckle. Prior to its application, any satellite data necessitate careful pre-processing. The pre-processing stage involves two key procedures: firstly, the correction of the orbital file to eliminate orbital noise; and secondly, the correction of thermal noise to eliminate noise in the data acquired by sensors during the satellite's data-collection process. The degradation of data quality in regions with low mean signal response detected by the Synthetic Aperture Radar (SAR) system, such as lakes, standing water and rivers, can be attributed to thermal noise. Radiometric calibration is employed to calibrate RADAR reflectivity (DN) to the backscattering coefficient (physical units) and is primarily utilised to compare SAR images obtained at different times. Terrain correction involves the conversion of Sentinel-1 SLC (Single Look Complex) data from slant range geometry to a map coordinate system and

the correction of distortions such as foreshortening, layover and shadowing effects. Following the pre-processing stage of Sentinel-1 VV SAR images, a speckle filter is implemented to achieve image smoothing for both before and during the flood event, as shown in Figure 8(a,b), respectively. To obtain the flooded region or points, both the SAR images are analysed using the image ratio technique with a threshold value of 1.2. The flooded SAR image is depicted in Figure 9, where white colour indicates flooded region and black indicates non-flooded areas. The obtained results are in coherence with the previous studies (Jacinth Jennifer *et al*. 2022, Parthasarathy *et al*. 2021) and are validated using the maps published by Kerala State Disaster Management Authority. This procedure assisted in acquiring actual historic flood locations of the Idukki district in a raster format. The data are then vectorised and transformed to a polygon, from which random points for both flooded locations and non-flooded locations are created using spatially balanced points in ArcGIS. The current study also aims to validate the performance and efficiency of the AHP model through the AUC-ROC technique (Figure 10). For validating the developed flood susceptibility map, the area under the curve - receiver operating characteristics (AUC-ROC) were plotted to validate the flood susceptibility mapping for the AHP model with that of the flooded points. In the AUC-ROC curve, the 'X' axis indicates the false positive rate and the 'Y' axis the true positive rate. Values of AUC-ROC vary from 0 to 1, where 0.50–0.60 indicates poor, 0.61–0.7 indicates average, 0.70–0.8 indicates good, 0.81–0.9 indicates very good and 0.91–1 indicates excellent sensitivity. AUC is useful as it assists in computing the performance of prediction accuracy

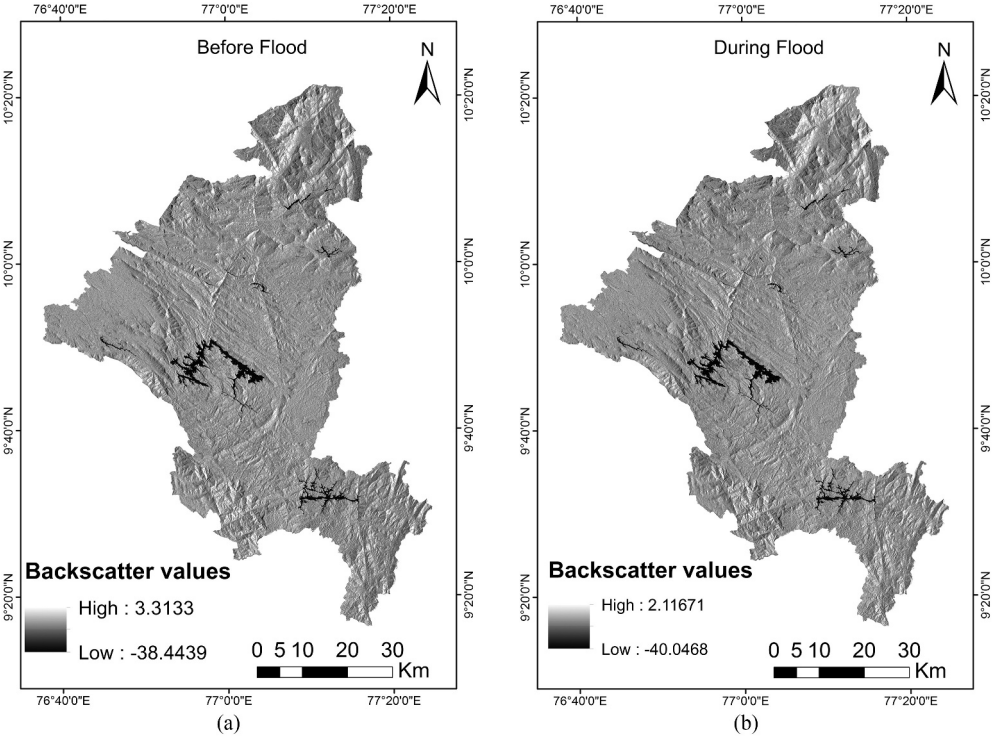

Figure 8. (a) SAR image before flood event. (b) SAR image during the flood event.

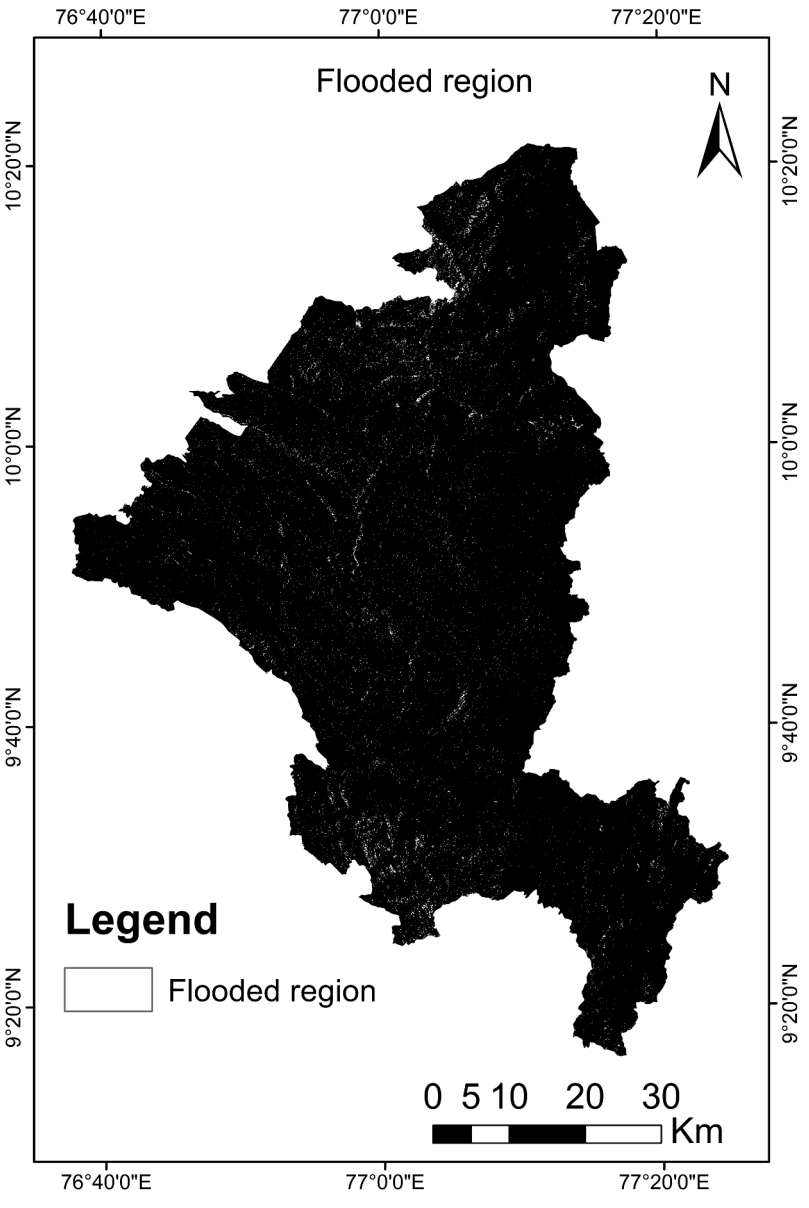

Figure 9. SAR image of flooded region of Idukki district.

and ROC is an effective method in assessing the performance of the model. The AUC value for the present study is evaluated as 0.91 or 91%, which is remarkably good accuracy for the employed spatial mapping model for flood susceptibility studies. This signifies that the adopted flood susceptibility approach can very well forecast the likelihood that a region will be flooded accurately. It seems that the proposed AHP approach can assist in developing flood susceptibility maps for other study areas also as this approach is not dependent upon the scale of the study region.

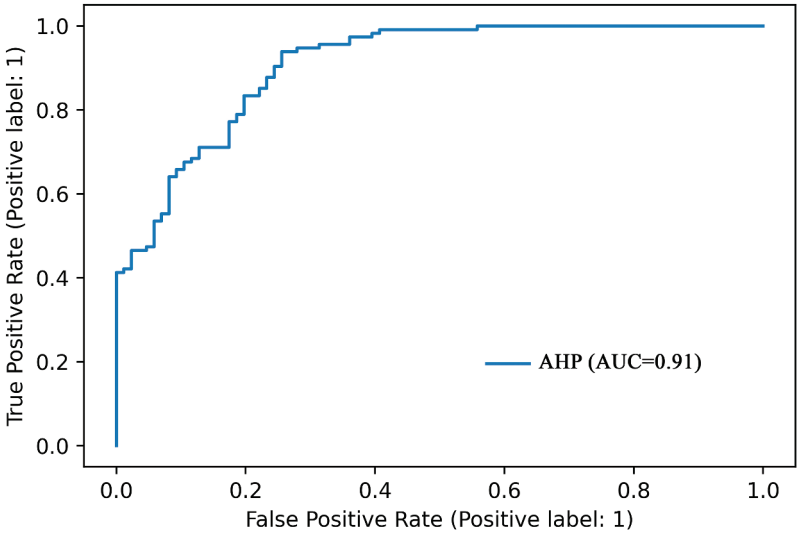

Figure 10. Validation of the flood susceptibility map using AUC-ROC curve.

8. Conclusion

The analytical hierarchy process (AHP) and geospatial techniques were utilised to demarcate flood-prone regions in the Idukki district of Kerala, resulting in a time-consuming and cost-effective methodology. Flood conditioning parameters such as slope, distance from the river, land use, topographic wetness index, topographic roughness index, rainfall, stream power index, sediment transport index, geology, elevation, aspect and soil map are all utilised in constructing a flood susceptibility map of the Idukki district in the ArcGIS platform. The developed flood susceptibility map reveals that about 1346.4 km^2 (~30% of the total area) was extremely susceptible to floods. These regions are mainly found in the western, central and southern sections of the Idukki district, where the slope grade rapidly changes and numerous minor streams join the main river. The accuracy of the AHP model was assessed with the help of the AUC-ROC approach, which indicated an accuracy of 91%. The approach utilised in this study has the potential to be used to provide flood-control recommendations in the study area.

Furthermore, the current study's future scope includes vulnerability and damage assessment of various subdivisions based on demographic criteria by assessing vulnerability index. The significance of each contributing parameter to floods and the optimum number of parameters to include in the AHP model should be tested against historic flood events of the region. For preparing susceptibility maps for flash floods, the AHP model has various benefits over other models, including fewer parameters, higher optimisation power and faster convergence. The utilisation of open-source data, like DEM, precipitation and soil characteristics, may present a limitation for the study due to their relatively low spatial resolution. The incorporation of high-resolution data, however, has the potential to enhance the understanding of flood dynamics and their corresponding variations in magnitude. Techniques for flood prevention have recently received more attention, particularly in Kerala, where flash

floods occur on an annual basis. Other basins and sites, on the other hand, have yet to undergo flood-control testing. As a result, the current study was conducted in the district of Idukki, employing AHP to give relevant information on ways that may be utilised to aid local governments and other parties in the implementation of successful flood mitigation measures and land-use policy planning.

Abstract

Sono-enzymatic biodiesel synthesis from different feedstocks has been significantly investigated in recent years, which reports the impact of ultrasound (US) on the structure of lipases. However, the links between alteration in the structure of lipases due to US and its activity enhancement have yet to be established. This study reveals the molecular mechanism of US-induced enhancement of lipase-catalyzed reactions in biodiesel synthesis. Using molecular simulations, we first analyzed the 3D structures and amino acid (aa) composition of the binding pockets of two lipases, viz. CALB and TLL. Next, docking analysis of different ligands (substrates and products of the reactions) with lipases was performed to reveal the interacting residues. We identified the US-induced alteration in the secondary structure of lipase from previous reports. Our analysis revealed that most binding pockets are located in the α-helix and random coil motifs, and binding interactions are mainly hydrogen bonding and hydrophobic interactions. We observed a rise in α-helix and random coils of lipase with sonication. The net effect of sonication is the widening of the catalytic cavity, thus easy substrate accessibility to the active site. Thus, enhanced enzymatic activity is manifested as faster kinetics of the reactions with higher yields.

Keywords Ultrasound · Lipase · Molecular docking analysis · Biodiesel · α-Helix · Random coil

1 Introduction

Biodiesel, derived from vegetable oils, animal fats, or waste cooking oils, is a renewable and sustainable alternative to conventional diesel fuel. It plays a crucial role in mitigating environmental concerns by reducing greenhouse gas emissions and emitting fewer pollutants [1, 2]. Biodiesel contributes to energy security and climate change mitigation by reducing dependence on fossil fuels and promoting a more sustainable energy future [3]. Recent research has focused on using microalgae as a sustainable feedstock for biodiesel production, addressing challenges in cultivation, harvesting, and extraction processes [3–5]. The combustion research of biodiesel and its model compounds has shown promising results in reducing emissions and improving combustion efficiency [6]. Techno-economic evaluations have highlighted the feasibility of biodiesel production using different catalyst technologies, with bulk calcium oxide catalysts being the most economically viable option [7]. These recent advancements in biodiesel research and technology provide valuable insights into the potential of biodiesel as a sustainable and environmentally friendly fuel source.

Conventionally, biodiesel is manufactured through an alkali-catalyzed transesterification process using vegetable oil or microalgal biomass as feedstock [2, 4, 8–10]. In the case of vegetable oils with a high free fatty acid content, acid-catalyzed esterification is also employed before transesterification. Enzyme-catalyzed biodiesel synthesis has also been explored in recent years [2, 11]. The most widely used enzyme for biodiesel synthesis is lipase.

Pallavi Patro, Unnati Raut, and Varsha Yadav contributed equally to this work.

Conventionally, lipase, a versatile commercial enzyme, finds applications in pharmaceutical industries for bioremediation and environmental processes [12]. Lipase has also synthesized biodiesel from various feedstocks using esterification, transesterification, and interesterification [12–14]. Despite the merits of feedstock flexibility, high yields, and selectivity, the kinetics of reactions catalyzed by lipases is relatively slow, a significant bottleneck in their commercial applications in biodiesel synthesis [15]. The multifaceted applications of lipase make it a vital enzyme. Thus, its activity enhancement is crucial for industrial purposes. Numerous techniques have been attempted to enhance the kinetics of lipase-catalyzed reactions. One of these techniques is sonication or ultrasound (US) irradiation, which has proven effective for intensifying all routes to biodiesel synthesis, viz., esterification, transesterification, interesterification, and hydrolysis [16]. Sonication is a physical technique and does not involve toxic chemicals or harsh conditions and thus can be termed a "Green Technology" for enhancement of lipase-catalyzed reactions [15]. Recent studies [13, 17, 18] have revealed that the lipase enzyme activity increases significantly after exposure to the US with a concurrent reduction in the activation energy of the reactions.

The previous authors [13, 19] have reported the impact of US on the structure of lipases. However, the links between alteration in the structure of lipases due to sonication and its activity enhancement (which essentially is manifested in faster reaction kinetics) have yet to be established. Such investigation would require elucidation of the exact nature of the interaction of the substrates/products with active site residues of the lipase enzyme on a molecular level.

This study presents a comprehensive investigation into the molecular mechanism of sonication-induced enhancement in the kinetics of lipase-catalyzed reactions for biodiesel synthesis. By combining three approaches—determining the structure of binding pockets of lipases, visualization of binding pockets in different secondary structure motifs, and docking analysis of ligands with lipases using hybrid quantum mechanics/molecular mechanics (QM/MM) computations—novel insights are gained into the exact nature of interactions between substrates/products and lipase enzyme on a molecular level. This research contributes to a deeper understanding of sonication's impact on lipase activity, providing a general framework for analyzing ultrasonic enhancement of reactions catalyzed by other enzymes.

2 Methodology

The schematic representation of workflow and steps followed in the present study for elucidation of the molecular mechanism of the sonication-induced enhancement in the kinetics of lipase-catalyzed reactions is given in Fig. 1. Detailed procedure in a step-by-step manner followed in this study is presented in following sections.

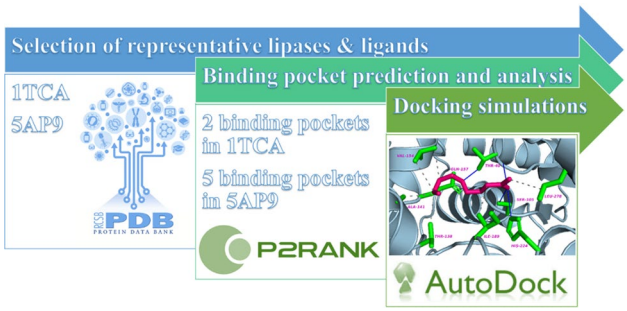

Fig. 1 Schematic representation of computational methodology followed in the present study

2.1 Selection of lipases and substrates for molecular docking experiment

For simulating esterification, transesterification, and hydrolysis reactions, we have chosen and imported two industrial lipases viz., *Candida antartica* lipase B (CALB; PDB ID: *1TCA*) and *Thermomyces lanuginous* lipase (TLL; PDB ID: *5AP9*), from the RCSB–PDB database [20]. These selected crystal structures were of good quality among others (judged based on the lowest atomic resolution and the Ramachandran scores provided in the PDB database). As per the requirement of ligands for molecular docking, we drew and optimized the chemical structure of the following compounds: methanol (MET), butanol (BOH), levulinic acid (LA), n-butyl levulinate (n-BL), aspirin methyl ester (AME), methyl salicylate (MSC), and oleic acid (OA) as representative substrates/products of esterification, transesterification, and hydrolysis reactions using density functional theory method in standalone Gaussian 16 software [21].

2.2 Sequence analysis and binding pocket prediction and molecular docking analysis

Before proceeding with molecular docking simulations, we first performed the sequence analysis and binding pockets prediction using 2StrctCompare (https://2struccompare.cryst.bbk.ac.uk/index.php) and PrankWeb (https://prankweb.cz/) software package of P2Rank web servers, respectively. The retrieved crystal structures (*1TCA* and *5AP9*) were visualized in PyMOL™ [22], and the secondary structure was compared using 2StrctCompare. The crystal structure of CALB and TLL was submitted to PrankWeb [23] to predict the

probable ligand-binding sites or binding pockets (BPs) in proteins. The high energies of CALB and TLL were eliminated using SWISS-PDB viewer (SPDBV) [24], and local minima closer to the native structure were achieved.

2.3 Molecular docking simulation and analysis

The molecular docking simulations of 7 ligands (described above) against both lipases were performed using Autodock v1.5.6 [22] linked with the MGLTools v1.5.6 viewer [23]. The ligand structure files were converted into "pdbqt" format using OpenBabel software. The procedure followed for molecular docking has been described in our earlier work [8]. The polar hydrogen ions and charges, such as Kollman and Gasteiger, were added to neutralize the system. A grid box was formed about coordinates for BP using the PrankWeb server. One hundred different docked conformations were generated using the Lamarckian Genetic Algorithm to investigate the optimal binding site of ligands to the lipases. These 100 docked conformations were ranked based on binding energies, and the best-docked conformation with the least binding energy was further analyzed in visualization software. The polar and non-polar interactions between protein–ligand complexes were studied in AutoDock, PyMOL™ version 2.4.1 [19] and PLIP webtool (https://plip-tool.biotec.tu-dresden.de/plip-web/). The 2D schematic representation of the enzyme-ligand complex's molecular interactions was analyzed using LigPlot + v.2.2 [24]. This protocol was reiterated for every ligand, and the final optimal conformation possessing the lowest binding energy among the hundred conformations procured for every operation was analyzed.

3 Results and discussion

3.1 Structural analysis and binding pocket characteristics

As outlined in the methodology section, the retrieved crystal structures of CALB and TLL were first visualized, and their sequences were compared using 2StructCompare. Both the lipases, CALB and TLL, are of α/β type fold and comprise 317 and 269 amino acid residues, respectively [25, 26]. DSSP (Database of Secondary Structure Assignments) algorithm for the prediction of secondary structures in CALB resulted in 37.5% helix (H), 12.3% extended sheets (E), and 50.2% random structure (R), which include turn and coils. On the contrary, TLL consists of 32% helix, 21.2% extended sheets, and 46.8% random structures.

The PrankWeb server identified the presence of two BP in CALB and five BP in TLL (refer to Table 1). The active site of CALB consists of SER_{105}-HIS_{224}-ASP_{187} with THR_{40}-GLN_{157} as an anionic hole contributing to the stabilization of the transition state. On the contrary, SER_{146}-HIS_{258}-ASP_{201} is present in active site in TLL. These active site residues are demonstrated in Fig. 2A(i, ii) in blue color. Figure 2A(i, ii) also demonstrate the residues in substrate/product BP in CALB and TLL, respectively. The amino acid composition of BP and results of 2D structure analysis using the DSSP algorithm are provided in Table 1. The minimap of secondary structure comparison produced using the 2StructCompare web server for CALB and TLL is provided in Fig. 2B.

Out of the multiple BPs in CALB and TLL, the pocket with the highest score was selected for molecular docking studies. We observed the presence of the glycine, leucine, valine, and

Active site amino acid residues are represented in blue color. **B** Minimap of secondary structure comparison produced using 2StructCompare web server for both CALB and TLL

serine amino acid residues in most BPs (Table 1). The other amino acid residues in the BPs are alanine, glutamine, histidine, isoleucine, phenylalanine, and tryptophan (Table 1). The PyMOL visualization of the BPs (shown in Fig. 2A) revealed that most of these residues are in the random coil region of the enzyme. Figure 2A shows the position of the most probable BP (i.e., BP with high scores) for substrate and product during esterification/transesterification reactions. Previous studies have reported that α-helices are mainly involved in protecting and activating the lid region of the lipase [12, 13]. In contrast, β (or extended)-sheets are primarily engaged in the structural integrity of the enzyme structure [12, 16, 27]. The secondary structural comparison of CALB and TLL is shown in Fig. 2B.

3.2 Molecular docking analysis shows central involvement of α-helix and random coil in complex formation

Molecular docking studies were conducted to get insight into the molecular mechanism of lipase-catalyzed esterification,

transesterification, and hydrolysis reactions. Protocols and steps followed for docking simulations are provided in Section 2.2. The results summarized in Table 2 and Fig. 3 reveal the significant interactions in the lipase-ligand (here, ligand represents either substrate or product of esterification/transesterification/hydrolysis reaction) complexes. These interactions are of type hydrophobic bonds, hydrogen bonds, and salt bridge interactions. Most of the interacting amino acids were present in the α-helix and random coil domain of the lipase, as seen in Table 2. Docking system indices (DSIs) in Table 2 correspond to the type of ligands (i.e., substrates and products) with which the docking analyses of lipase enzymes have been performed, which maps with Table 3 for respective lipase-catalyzed reactions.

As discussed in the introduction section of this study, biodiesel synthesis occurs majorly through esterification or transesterification reactions. The role of CALB and TLL in reversible catalysis of esterification/transesterification/hydrolysis reactions has been extensively studied for biodiesel synthesis [2, 13, 19]. Table 3 summarizes the types of reactions studied in the present research. Tables 2 and 3 show that DSIs A1, A2, and A3 represent levulinic acid's esterification with n-butanol. Similarly, DSIs (B0, B6) and (A0, A6) represent the transesterification reactions of mixed non-edible oils with methanol catalyzed by TLL and rapeseed oil with methanol catalyzed by CALB, respectively. The DSIs (A4 and A5) represent the hydrolysis reaction of aspirin methyl ester catalyzed by CALB.

It can be seen from Table 2 that for esterification and transesterification reactions, alcohol (i.e., methanol and butanol) substrates have higher binding energy compared to organic acid (levulinic acid and oleic acid) substrates. This suggests that alcohols have a lower binding affinity towards lipases than organic acid. Therefore, during the ping-pong bi-bi mechanism, organic acid will bind first with lipase, followed by the binding of alcohol after the release of the first product. Additionally, ester products (i.e., n-butyl levulinate and FAME) have a low binding affinity towards lipases compared to their substrates (i.e., alcohols and organic acids). Hence, they will be faster from the [E-P] complex. Similar trends were also observed in the hydrolysis reactions (DSIs: A4, A5, B4, and B5), where the substrate's binding affinity was lower than the product's binding affinity.

Figure 3(i–xiv) depicts ligands' binding and types of interactions in the respective lipases. It is observed from Fig. 3 that in the BP, two substrates (acid and alcohols) bind in the two distinct domains (i.e., alcohol-binding domain and acyl-binding domain). These

3.3 Sonication-induced structural and morphological changes in lipase

3.3.1 Preamble

Ultrasound is a longitudinal wave that passes through any compressible medium through compression/rarefaction cycles. This induces small amplitude and high-frequency oscillatory motion of the fluid elements of the medium. Such oscillatory motion generates intense micro-mixing in the medium. The passage of ultrasound waves also induces variation in the bulk pressure in the medium. The secondary effect of sonication is cavitation–nucleation, growth, volume oscillations, and implosive collapse of gas or vapor bubbles driven by pressure variation induced by the ultrasound waves. The volume oscillations of cavitation bubbles also produce intense micro-convection near the bubbles. In addition, cavitation bubbles also give rise to acoustic waves due to the reflection of the fluid elements from the bubble/fluid interface. These physical phenomena also contribute to intense mixing in the medium. A peculiar feature of the convection generated by ultrasound and cavitation is its tiny spatial and temporal scales, i.e., this convection is caused at the micro-level (only a few micrometers) and for a very short duration (for example, the period of 50 µs for an ultrasound wave of 20 kHz). Such convection can induce micro-level phenomena in the medium, such as the unfolding of the protein molecules, which also leads to the rearrangement of the secondary structure of the protein molecules [30, 31]. A representative literature summary on the US-assisted enhancement of lipase-catalyzed trans-/inter-/esterification reactions for the synthesis of biofuels or their chemical additives is provided in Table 4.

3.3.2 Secondary structural analysis of lipase before and after sonication

In the context of the present study, numerous biochemical reactions catalyzed by lipases are accelerated due to sonication. A summary of representative recent literature on the enhancement effect of sonication (in terms of faster kinetics

Table 4 Summary of the representative literature on ultrasound enhanced lipase-catalyzed reactions

Reaction	Experimental conditions	Results	Ref
Esterification	CALB and *RML*; $T = 40$ ℃; $f = 20$ kHz; Sub.: FFA and xylitol; no solvent	Efficient synthesis of xylitol fatty ester (95% yield), with xylitol monoacyl ester and xylitol diacyl ester appearing as the main products (greater than 96%)	[32]
	Novozyme 435; $f = 35$ kHz; $T = 50$℃; $P = 35$ W; Sub.: LA and BOH; Sol: BME	Application of 35-kHz sonication boosted n-butyl levulinate yield from 70.9 to 92.22%	[13]
	Novozyme 435; $T = 50$℃; $P = 32$ mW; Sub.: AA and isomylOH	Application of US for 20 min, the ester concentration increased by 27.4% with higher enzyme reusability	[17]
	Novozyme 435; $f = 28$ kHz; $T = 50$℃; $P = 1.75$ kW/m^2; Sub.: butyric acid-lauric acid	Improved synthesis efficiency of butyric acid-lauric acid designer lipid by 11.38% with application of US	[6]
Transesteri-fication	TLL; $T = 36$℃; Sub.: non-edible oils and MeOH; $(MR)_{MET/oil} = 7.64$; EL = 3.55%	US + water addition to the reaction mixture (10% v/v) boosted biodiesel yield from 90 to 94%	[2]
	BCL; $f = 37$ kHz; $T = 60$℃; $P = 500$ W; Sub.: castor oil, EtOH, $(MR)_{MET/oil} = 6$; EL = 12 g, US probe	FAEE yield of 83% in 72 h with an ethanol-to-oil molar ratio of 3:1 in the case of the US	[33]
	Novozyme 435; $f = 28$ kHz; $T = 50$℃; Sub.: DHA and EPA	99% conversion to FAEE with sonication at the condition of 1 ml/min flow rate	[34]
Interesterification	CALB; P = 165W; $f = 25$ kHz; $T = 60$℃; Sub.: Crambe oil, MeOH; $(MR)_{MET/oil} = 12$	The US reduced total reaction time and percentage of enzyme loading by 20 wt%	[35]

Table 5 Influence of ultrasound on secondary structures of lipase: a literature summary

Reaction type	Experimental Conditions	Observed enhancement	Changes in secondary structures	Ref
Esterification	Novozyme 435; $f = 35$ kHz; T = 50°C; $P = 35$ W; duty cycle = 20%, time = 1 h; ultrasonic bath; Sub.: LA and BOH	Boosted conversion of LA from 70.9% to 92.22%	Increased α-helix and random coil; concurrent decrease in β-sheets	[13]
Hydrolysis	CVL; $f = 25.8$, 26.2, 35.5, 36.5 kHz; $T = 25$°C; $P = 29$–349 W, time = 20 min; ultrasonic bath; Sub.: Olive oil with PEG	The half-life of PEG400-treated lipase was 27-fold higher than untreated	No change in the circular dichroism spectra of the secondary structure	[41]
Enzyme activity	CALB and TLL; $f = 22$ kHz; $T = 50$°C; $P = 35$ W; duty cycle = 50–67%, time = 20–30 min; probe sonicator	The activity of CALB and TLL enhanced by 1.3- and 1.5-fold, respectively	Increase the random coil by 25.99 and 21.54% in both lipases; the rest components decreased	[42]
Hydrolysis	PPL; $f = 60$ kHz; $T = 37$°C; $P = 138$ W; duty cycle = 50–67%, time = 240 min; probe sonicator; Sub.: coconut oil	Lauric acid yield increased in the presence of sorbitol and mannitol osmolytes	Increased α-helix and random coil; concurrent decrease in β-sheets	[43]
Transesterification	BCL; $f = 40$ kHz; $T = 40$°C; $P = 120$ W; duty cycle = 50–67%, time = 2 h; ultrasonic bath; Sub.: IL and methanol	The best reaction media for biodiesel yield is 82.22%. Anionic IL was the most effective	Increased α-helix, β-sheets, β-turns; concurrent decrease in random coil and turns	[44]
Hydrolysis	Immobilized *alcalase*, $f = 22$, 28, 33, 40, 68 kHz; $T = 60$°C; $P = 600$ W each, time = 30–150 min; ultrasonic bath; Sub.: rapeseed protein	In US assisted-hydrolysis, hydrolysis increased by 74.38% at the optimum conditions	The number of a-helix and random coil decreased by 10.7% and 4.5%, β -chain increased by 2.4%	[45]

and higher yields) on different lipase-catalyzed reactions with changes in the 2D structural composition of lipase is presented in Table 5. It could be observed that these reactions involve other feedstocks and lipases from various sources. Moreover, operating conditions of sonication (such as frequency, intensity, duration) have also varied. Nonetheless, enhancement is seen in all cases, although the extent of enhancement varies from case to case. The ultrasound-induced enhancement in the kinetics of lipase-catalyzed reactions is a manifestation of the enzyme's enhanced activity, which is a consequence of the modifications in the secondary structure of the enzyme.

Previous authors have deduced the changes in the secondary structure of lipase due to sonication using different techniques such as circular dichroism, X-ray crystallography, SEM, deconvolution of FTIR spectra, NMR, and fluorescence spectroscopy [13, 27, 36–38]. The results of previous literature showing the alteration in the secondary structure of lipase are summarized in Table 5. As can be inferred from Table 5, the changes in secondary structure are highly lipase specific and a vital function of the operational conditions of sonication, such as frequency, intensity, and duration. However, on a broader basis, the significant changes in the secondary structure of lipase induced by ultrasound can be identified as (1) a rise in alpha helix content and (2) a rise in random coils. Few studies have reported a reduction in alpha helix content with a concurrent increase in beta sheets and turn. Our previous study [13] revealed that sonication increased the α-helix content that enhanced the activity of immobilized CALB by opening the flapping lid and widening the catalytic cavity hosting the binding pockets. Sonication at 35 kHz also caused a rise in the random coil content of lipase. In a similar study on the lipase-catalyzed synthesis of sucrose fatty acid ester, Zhang et al. [39] reported an increase in alpha helices in the enzyme structure of CALB using circular dichroism analysis. This shift in the secondary structure of CALB contributed to a 75% reduction in the reaction time.

As per the results presented in Tables 2 and 3 for two representative lipase enzymes CALB and TLL, the binding pockets of all ligands (viz. methanol, butanol, levulinic acid, n-butyl levulinate, aspirin methyl ester, methyl salicylate, and oleic acid) are mainly present in α-helix and random coils. Thus, a rise in α-helix and random coil content of lipase widens the catalytic cavity and relaxes the enzyme structure [8, 9], resulting in easy access of substrates to BP. Additionally, a rise in random coil content favors the formation of enzyme-ligand complexes (with a possible reduction in inhibition and unfavorable dissociation of intermediate complexes), ultimately enhancing the reaction kinetics and product yield. Similar observations were also found in our previous study [13]. On the other hand, increased beta sheets and turns contents caused reduced lipase activity, as

observed through CD analysis by Sun et al. [40]. In addition, SEM studies by Liu et al. [31] and Zhang et al. [39] revealed the presence of extra holes in the enzyme morphology, which suggest a rise in the surface area. This feature also contributes to faster enzymatic reaction rates.

The ternary approach of binding pocket analysis and concurrent analysis of the molecular docking simulations (Tables 2 and 3 and Fig. 3) in the present study and the changes in 2D structure of lipase due to sonication reported in the literature (Table 5) provide mechanistic insight into the beneficial influence of ultrasound on lipase-catalyzed reactions. The ternary approach developed in this study to deduce the molecular mechanism of US-induced enhancement in lipase-catalyzed reactions for biodiesel synthesis is schematically depicted in Fig. 4.

3.3.3 Suggestions for future work based on the present study

The present study attempts to offer a theoretical explanation for the ultrasound-induced enhancement of lipase-catalyzed reactions based on the ternary approach of determining the physical and chemical characteristics of the binding pockets of lipases, deducing their locations in different structural motifs and molecular docking analysis of other ligands using QM/MM simulations. Although this analysis could be plausible effort, an experimental confirmation of the computation results presented in this work requires to be made. The experimental study would require the lipase enzyme in free form (unlike the most commercially available enzymes in immobilized form). This work will also require high-end analytical instruments like X-ray crystallography, NMR solution, and Cryo-electron microscopy. The scientific community in enzyme research with access to these facilities can take up the future research in this area. We believe that our computational study will be a useful tool for designing such an experimental endeavor but also analysis of the results.

4 Conclusions

This study has attempted to provide mechanistic insight into the influence of sonication on lipase-catalyzed reaction with a ternary approach of determining the physical and chemical characteristics of the binding pockets of lipases, deducing their locations in different structural motifs and molecular docking analysis of other ligands using QM/MM simulations. It has been observed that most of the binding pockets are located in either α-helix or random coils. The previous literature has reported significant modifications in the secondary structure of lipases after exposure to sonication such as rise in α-helix and random coil contents. The net consequence of sonication is thus widening the catalytic cavity and easy accessibility for substrate binding. This is manifested in a rise in enzyme activity and faster kinetics of the lipase-catalyzed reactions. Therefore, the results of present

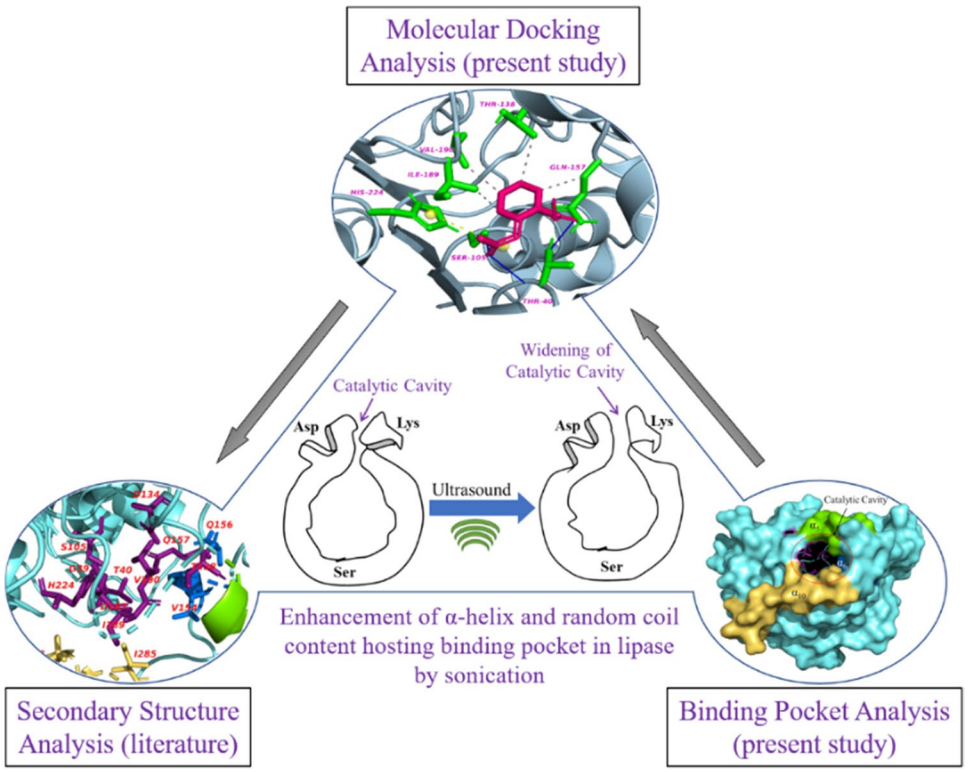

Fig. 4 Schematic depiction of the ternary approach to deduce the molecular mechanism of US-induced enhancement in lipase-catalyzed reactions for biodiesel synthesis

study have provided a mechanistic explanation to the previous literature on ultrasound-assisted intensification of esterification, transesterification, and hydrolysis reactions. Moreover, the methodology of ternary approach proposed in the present study also forms a general framework for analyzing the mechanism of ultrasonic enhancement of other enzyme-catalyzed reactions that are enhanced with sonication.

Abstract In software engineering, cross-project defect prediction is an important area in the field of defect prediction and change prediction. Software defect prediction aims for the identification of defects in the early stages of the software development life cycle. Defect prediction helps in optimizing the resources in terms of testing and reduction of maintenance efforts. Defect prediction works appropriately if a huge amount of data is available for training a prediction model. Nowadays, a sufficient amount of data is not available due to which we have to use different data for training and testing of a project. The cross-project defect prediction idea emerged when different projects are used as training and testing dataset for the identification of defects. To design a defect prediction model we have to consider only significant features out of all the features set. Feature selection techniques are categorized based on unsupervised and supervised learning. The major limitation of cross-project defect prediction is handling different data distributions of source and target projects. The experiment was conducted using AEEEM and ReLink software defect dataset. Moreover, five projects of AEEEM and three projects of ReLink with a maximum count of files in the selected projects are 1862 and 399. In this study, we have analyzed the effect of feature selection techniques in cross-project defect prediction. The results were analyzed using AUC. The significance of filter, wrapper, and swarm search-based methods for feature selection techniques was analyzed separately. There is a trade-off between computational complexity and the performance of feature selection techniques. Swarm search-based methods performed better than filter and wrapper methods in terms of computational cost and overall performance of the prediction modes. The results were statistically validated using Friedman test and Wilcoxon signed rank test.

Keywords Defect prediction · Cross-project · Feature selection · Filter method · Wrapper method · Swarm search-based techniques

1 Introduction

Nowadays, prediction model plays an important role in Machine Learning (ML). In software engineering, software defect prediction is a very crucial domain. Defect prediction aims at the identification of defects at the initial stage of development, i.e., SDLC (Herbold 2015). Defect prediction plays an important role in improving the quality of software in terms of maintainability, functionality, reliability, and testability. To release defect-free software, every developer must check it from the criterion to maintain the quality of the software in upcoming years also. For designing a defect prediction model, it must be ensured that a sufficient amount of training data is used for designing prediction model. Moreover, the predictive model does not perform efficiently for future data. Prediction models are useful for predicting unseen data or future data. However, the unseen data should have similar characteristics to use a pre-designed prediction model.

In the existing studies, it has been demonstrated that the software defect prediction models are trained with a sufficient amount of training dataset and work efficiently for testing on the same dataset having similar distribution (Zou

Published online: 27 July 2023

et al. 2023). However, such type of prediction modes come under the category of Within-Project Defect Prediction (WPDP). In WPDP, the training and testing of the prediction model are accomplished using the same dataset. Moreover, the collection of a sufficient amount of training data is a serious issue.

The objective of conducting this study is to analyze the efficiency of FS methods for Cross-Project Defect Prediction (CPDP) using filter, wrapper, and search-based FS methods. In the existing, the authors have analyzed the individual performance of FS methods. However, according to the observation swarm based performed best for CPDP. Furthermore, the filter method selected the best features based on ranking criteria while swarm search methods are exploring optimal solutions. Moreover, swarm search-based methods explore the best feature subset out of all the subsets to find out the optimal solution.

In recent years, CPDP gained popularity among researchers, academicians, and developers. The idea of CPDP emerged from the availability of a sufficient amount of training data. In CPDP, two different projects are used for training and testing. One project is considered as a source project for training and another project is considered as a testing project for testing. The features of both projects must be checked. If the features of source and target projects are same then it is termed a Homogeneous Cross-Project (HoGCP). If the features of both projects are different, then it is termed a Heterogeneous Cross-Project (HeGCP) (Pal and Sillitti 2022).

In the case of HeGCP, both source and target projects may contain different attributes. To design prediction models, the attributes must be correlated. Furthermore, the matching metrics are selected based on the amount of correlation between different pairs of source and target dataset attributes. Moreover, transfer learning work when a prediction model is used for testing on some other project which is having similar characteristics as training data (Pan and Yang 2010). Moreover, the prediction model was learned through the knowledge provided by the source project. There are various types of transfer learning settings based on the domain of source and target dataset. However, transfer learning works perfectly if we want to use our pre-trained model for future projects. Three types of learning come under transfer learning such as feature transfer, instance transfer, parameter transfer, and relational knowledge transfer.

In the prediction model, before starting with model development, we have to preprocess our dataset. In the next phase, we extract relevant features of our dataset using various techniques termed Feature Selection (FS) techniques. FS techniques are categorized into three methods such as filter method, wrapper method, and swarm search-based method. FS helps in selecting the features which are relevant for model development concerning output variables (Bhutamapuram and Sadam 2022). The main aim of conducting this study is to analyze the impact of various FS techniques on CPDP. Every method has a different criterion, different threshold, different parameter settings, and aspects to select relevant features.

In today's era, the speed of accumulating data warehouses and databases is increasing rapidly, and dimensionality reduction is considered a major problem (Liu and Yu 2005). In further years, dimensionality reduction become a major problem for ML algorithms. Negative effects are also observed due to the scaling of the dimensionality of a dataset. The presence of irrelevant and redundant features adds noise to the dataset, which leads to a problem of overfitting (Hawkins 2004). Thus, data mining algorithms are developed in various areas such as text mining, bioinformatics, medicine, image processing, engineering, financial estimation, and sustainability. However, the significance depends on the ability to convert large amounts of data into acceptable form.

The cause of the defects in a software module is difficult to determine (Czibula et al. 2014). Various ML classification techniques are developed and used for defect prediction. The authors conducted studies to analyze the impact of FS and feature reduction techniques (Lessmann et al. 2008), and various cross-validation techniques in WPDP (Tantithamthavorn et al. 2017). In some of the existing studies, benchmark ML-based models were also proposed for WPDP such as logistic regression, Support Vector Machine (SVM), neural networks, k-nearest neighbor, decision trees, naïve bayes, etc.

In this study, the impact of each FS technique is analyzed statistically using filter, wrapper, and swarm search-based methods. The importance of the three methods of FS techniques is studied for improving software quality in terms of maintenance and effort estimation. AEEEM and ReLink datasets are considered in this study for CPDP. The projects used in this study are having similar metrics concerning AEEEM and ReLink. Five projects of AEEEM and three projects of ReLink are used in pairwise combinations of source and target pairs. The source and target pairs are created by combining different projects. Thus, this study was performed for 20 pairs of AEEEM datasets and 6 pairs of ReLink datasets. In this study, we have done a comparison between different FS methods along with the impact on CPDP. The experiment was conducted using WEKA 3.9.6. In existing studies, FS methods are not analyzed for CPDP. Filter methods work on the concept of ranker while wrapper and swarm search-based methods working is based on the principle of greediness.

This study aims to evaluate the effectiveness of different FS methods in conjunction with object-oriented metrics for CPDP. Furthermore, this study explored the importance of each FS method individually. Furthermore, the study also

explored different settings of source and target projects concerning the FS methods. Furthermore, ML classifiers are used for building prediction models. The results of all the predicted models are statistically validated for determining the best FS method for CPDP. The Research Questions (RQs) addressed in this study are:

RQ1: What is the predictive capability of filter methods for CPDP using AEEEM and ReLink dataset?
RQ2: What is the predictive capability of swarm search-based methods for CPDP?
RQ3: What is the predictive capability of filter, wrapper, and swarm search-based methods for CPDP?

1.1 Paper organization

Section 2 presents existing studies discussion on CPDP, FS techniques for software defect prediction, and transfer learning. The dataset used for experiments in this study is presented in Sect. 3. The research methodology used in this study is discussed in Sect. 4. Section 5 stated a detailed analysis of the results obtained in this study. Section 6 summarized the conclusions along with future work.

2 Related work

Prediction models designed for defect identification are learned from source datasets that consist of actual values and predictive metrics. In the existing studies, various supervised classifiers are used such as logistic regression (LR), decision trees, SVM, etc. to detect defect-prone parts of a software using training data.

In the existing study (Faiz et al. 2023), the authors conducted a study for developing a solution to select the optimal set of features for multi-class data using search-based optimization for CPDP. Moreover, the study considered quantitative and explanatory research types for experimentation. The classifiers used for optimization in this study are KN filter, ANN filter, Random Forest Ensemble (RFE), and Genetic Algorithm (GA). Further, *ckloc* is investigated as the best feature for improving the efficiency of a prediction model for multi-class problems. However, search-based optimization for FS provided 30–60% better results for multi-class CPDP. The software metrics represent the independent variables signified by product and process properties. In today's era, prediction models seem more interesting for academicians, researchers, and software experts (Rahman et al. 2012). The authors have used deep learning models for generating a large number of features and a significant amount of memory for reducing the computation time required for processing those features (Pramanik et al. 2023). A hybrid Genetic Algorithm (GA) and Grey Wolf Optimizer (GWO) are used to develop a prediction model by reducing a large number of feature sets.

In the existing study (Zhao et al. 2022), the authors experimented to resolve the problem of multi-source projects for defect prediction. Further, in the existing study, the author developed a Multi-Source-Based CPDP (MSCPDP) model using AEEEM and PROMISE dataset. The performance of the MSCPDP model is compared with the existing six CPDP methods showed F1 performance improvement by3.51%, 3.92%, 36.06%, 0.49%, 17.05%, and 9.49%, and the ACU median is improved by − 3.42%, 8.78%, 0.96%, − 2.21%, − 7.94%, and 5.13%.

To improve software quality, the volume of the training dataset and representativeness has a major effect on the usability and maintainability of the prediction model. The existing authors faced the quality issue in training data (Bird et al. 2009; Bachmann et al. 2010). However, some of the studies proved that the quality of the prediction model is as per benchmarks if it is properly trained on the noisy data as well (Kim et al. 2011).

In current years, CPDP gained popularity among software testing researchers. In the research world, the first study (Briand et al. 2002) was conducted in 2002 on CPDP, which discussed whether CPDP is worth studying or not. The researchers found that CPDP is a challenging problem and observed that the results are not significant. Furthermore, Zimmerman et al. (2009) conducted a study on defect prediction considering 622 pairs of cross-projects and the results were not significant. Out of 622 pairs, only 3.4% of cross-project pairs had significant performance in terms of precision, recall, and accuracy. Moreover, researchers and academicians have proposed various methods for improving CPDP.

Nam et al. (2013) proposed the TCA + method for CPDP. In CPDP, the common problem is the spatial distribution of features. Thus, TCA + defines some rules, and standardization strategy, and it performed transfer component analysis on CPDP to make similar distribution of source and target dataset features. In the existing study (Ma et al. 2012), a novel CPDP method Transfer Naïve Bayes (TNB) is proposed, which assigns weights for each instance in candidate source projects by predicting the distribution of target data. Some of the authors (Yu et al. 2017) analyzed the significance of features, parameters, and instances in CPDP. Empirical studies are conducted on various FS methods, proposing various feature matching and transfer of knowledge across CPDP (Yu et al. 2016). In existing studies, a compositional method of HYDRA is proposed for CPDP (Yu et al. 2019). In some of the existing studies (Wu et al. 2018), a Semi-Supervised CPDP (SSCPDP) problem was studied and a cost-sensitive kernel-based technique was proposed.

CPDP considers two different projects for source and target. Thus, the selection of appropriate variables is most

important. Relevant features can be selected by using various FS techniques. FS techniques are categorized into filter method, wrapper method, and embedded methods. The motivation behind using FS techniques is to compute the predictive capability of features or feature subsets to proceed with class labels. The filter method does not use any mining algorithm for FS. The simple idea of picking up the subset of features is used in the filter method (Visalakshi and Radha 2014). Filters methods are based on the general aspects of distance, information gain, dependency, and consistency (Liu et al. 2010). However, filter methods use ranking criteria for selecting relevant features. The filter method is independent of any ML classifier. Furthermore, the filter method preferred ranking criterion due to its simplicity, effectiveness, and good results. Furthermore, the advantage of using the filter method is to avoid overfitting, reduction in computational amount, fast speed, scalability for large datasets, and ease to understand.

Some of the commonly used filter methods are removing constant features, information gain, chi-square, and pearson correlation coefficient (Visalakshi and Radha 2014). FS is a NP-hard problem, to select the best set of features that provides the optimal solution. Secondly, the wrapper methods require data mining algorithms alike filter methods. The wrapper method selects relevant features to improve the performance of the mining algorithm. Clustering is used to select features using predictive capability (Bai et al. 2014). In the wrapper method, the different sets of features are searched. The quality of the selected attribute set is measured with a classification algorithm. Thus, the relationship is established between the feature set and prediction model in the wrapper method. In comparison to filter methods, wrapper methods are computationally more demanding and suffer from overfitting issues (Liu et al. 2010).

In the existing studies, researchers worked on FS techniques concerning WPDP. Furthermore, the researchers explored the performance of a combination of FS techniques and ensemble approaches for defect prediction (Laradji et al. 2015). However, the forward FS technique performed successfully well for the defect prediction model build for PC2, PC4, and MC1 imbalanced datasets. Moreover, some of the studies used the automatic FS technique for feature selecting appropriate features out of all the software metrics (Vashisht and Rizvi 2020).

To reduce computational cost and a number of features, the FS technique plays an important role in designing a prediction model. The performance of the model is also improved with appropriate FS techniques. In the case of the HeGCP prediction model, the set of software metrics is different, However, to select similar features from both the source and target dataset, FS techniques are used (He et al. 2013). However, the authors developed a model in combination with FS techniques using four ML classifiers followed by instance selection (Pal and Sillitti 2022).

Meta-heuristic methods used for FS are based on optimization. Embedded methods are described by flexibility, low computational cost, and simplicity. Embedded methods consider the number of candidate solutions encountered for the optimization of the feature set. Some commonly used embedded methods for FS are LASSO and RIDGE. The above methods that are searched based on strategies are categorized into simple, complete, and sequential models.

The FS techniques are explored for multiclass data also using the CPDP model. The authors (Faiz et al. 2023) used explanatory and quantitative approaches for experimentation. However, search based optimizer is used to obtain the best features set for CPDP. Thus, the authors observed 30–50% significant results in comparison with Genetic Instance Selection (GIS). The CPDP models are also developed using transfer learning by considering different projects for training and testing (Malhotra and Meena 2022).

In the existing study, the authors (Khatri and Kumar 2023) proposed an approach to deal with the limitations of CPDP through knowledge transfer. The proposed strategy of the authors is based on FS using iterative and non-iterative approaches. In the first strategy, the authors selected the important features and similar data distribution. The second strategy is the iterative strategy, which selects features by optimization based on performance. The authors (Tong et al. 2023) proposed a high-performance CPDP FS method. The novel FS method for CPDP is named Adaptive Triple Feature-Weighted Transfer Naïve Bayes (ARRAY). Moreover, it is concluded that ARRAY improved AUC by 6.5% and performed better than baseline methods for CPDP. ARRAY also performed better than baseline methods according to the posthoc test.

In the existing study authors (Vashisht and Murtaza 2023) proposed a CPDP model using a feature extraction approach. The feature extraction was done using a stacking-based ensemble learning method and auto-encoder. Further, two techniques are used to deal with an imbalanced dataset and computed the correlation among the features. However, the proposed CPDP framework provided better results by reducing 50% features and the highest AUC of 0.8901. In some of the research studies (Lyu et al. 2023), the researchers explored that filter-based techniques are popularly used in research.

Many of the research experts also stated that FS plays a significant role in the development of prediction models. FS is widely used when a huge number of features are available in the dataset used for experimentation. In CPDP, similar data distribution is a major problem in heterogeneous CPDP. Thus, the authors developed a CPDP model using optimal transport theory for establishing similarity in data distribution between source and

target projects (Zong et al. 2023). The developed model firstly measures the distance between two metrics spaces by learning an optimal transfer matrix. Semantic feature learning is also explored for software defect prediction (Liu et al. 2023). The authors used extracted natural language text in combination with programming language code for semantic feature learning. In the existing studies, the ML techniques developed from 2018 to 2021 are explored for software defect prediction (Sharma et al. 2023).

A novel hybrid algorithm Negative Binary General (NBG) (Feng et al. 2023), is proposed in combination with oversampling and FS algorithm for improving the performance of imbalanced classification. Researchers have also analyzed the performance of the Negative Positive Synthetic Minority Oversampling Technique (NPSMOTE) for improving sample generation practicability. However, Binary Ant Lion Optimizer (BALO) algorithm outperformed by extracting the most relevant features for the classification problem. The authors have used a novel stochastic approximation approach for performing simultaneous k-best Features Ranking (FR) and FS based on Simultaneous Perturbation Stochastic Approximation (SPSA) (Akman et al. 2023).

The authors developed a novel technique based on filtration methodology named as Relevance Diversity Algorithm (RDA) for FS (Shaheen et al. 2023). RDA is based on two measures relevance and diversity. RDA provides a low set of features by minimizing the amount of search time for relevant features. The authors (Tang et al. 2023) developed a novel FS technique via multiple graph fusion and feature weight learning. Thus, instead of learning the feature coefficient matrix, researchers can directly gain the weights of various feature dimensions through the feature weight matrix, and the weighted features are projected into the label space. The methodology considers evaluation of features subset for all the features, and finds out the optimal set of features according to th evaluation criteria (Li et al. 2017).

In some of the existing studies, wavelet transform is also used for FS. In the existing studies, SVM is compared with multilayer perceptron and fuzzy inference systems for FS. In their work, the total number of seventeen features are getting extracted by using the wavelet transform. By using LDA only four features are getting selected. The performance of the selected feature subset is compared with all features and features selected by Principle component analysis (PCA) which results in the selected feature subset giving better performance among these. In this work, SVM is also compared with the Multilayer Perceptron (MLP) and the Fuzzy Inference System (FIS) which results in the SVM classifier giving better performance than other classifiers.

3 Dataset used

The dataset characteristics, variables of the dataset, and dataset sources are discussed in this section. Furthermore, the category of the dataset, count, types of metrics, and number of buggy files in each dataset are summarized.

3.1 Dependent and independent variable

This study aims to analyze the effectiveness of FS techniques for CPDP. Thus, the efficiency of selecting features in the case of CPDP using filter, wrapper, and swarm search-based (embedded) methods is analyzed. The dataset used consists of independent and dependent variables. The dependent variables indicate the presence and absence of defects in a specific module such as buggy or clean. If the output of the dependent variable is clean, it indicates that the module is free from defects. Moreover, if the output of the dependent variable is buggy, it indicates the module consists of defects. In this study, two projects are used such as AEEEM and ReLink. The AEEEM dataset consists of 61 attributes as independent variables and 1 attribute as dependent variable. ReLink dataset consists of 26 independent variables and 1 dependent variable. The independent variables of the AEEEM dataset are grouped into five categories such as Source Code-Based Metrics (SCM) (17), previous defect-based metrics (5), entropy-based metrics (5), entropy of SCM (17), and churn of SCM (17). Table 1 discussed the five categories of the AEEEM dataset (Tong 2019; Hu and Zhu 2023). In Table 1 the first column depicts the dataset type, the second column depicts the metrics name, the third column discussed the metrics, and the fourth column indicates the number of metrics combined into five categories.

3.2 Dataset description

The experiment has been conducted using AEEEM and ReLink datasets in this study. The project metrics of the dataset are summarized in Tables 2 and 3. Furthermore, a detailed description of the dataset is discussed (You et al. 2016). In Tables 2 and 3 first column represents s. no. corresponding to each project, the second column represents the project name (abbreviated name), the third column represents the type of project, the fourth column represents the total number of files in each project, the fifth column represents the percentage of buggy instances, and the sixth column represents no. of metric in each project. AEEEM and ReLink datasets are selected for experimentation in this study, to perform validation of FS techniques on different projects, validity of dataset, and most important varied feature sets.

Table 1 Statistic of AEEEM defect dataset

Category	Type	Description	# of metrics grouped into categories
Category 1	ck_oo_cbo ck_oo_numberOfLinesOfCode	Coupling based metrics Coupling-based metrics consider line of code	17
Category 2	numberOfBugsFoundUntil numberOfCriticalBugsFoundUntil	Defect based metrics Defect-based metrics consider critical security level	05
Category 3	CvsEntropy CvsLogEntropy	Change-based entropy metrics Change-based logarithmic entropy metrics	05
Category 4	LDHH_cbo LDHH_numberOfLinesOfCode	Linearly decayed entropy of CBO metrics Linearly decayed entropy of LOC metric	17
Category 5	WCHU_cbo WCHU_numberOfLinesOfCode	Coupling-based metrics consider weighted churn of CBO metric Consider churn of LOC metric	17

Table 2 Dataset statistics of the data collected from AEEEM

S. no.	Project	Type	Number of files	% of buggy files	# of metrics
1.	Equinox (P1_EQ)	OSGi framework	325	36.69	71
2.	Eclipse JDT Core (P2_JDT)	IDE development	997	20.66	71
3.	Apache Lucene (P3_LUC)	Search engine library	39,691	9.26	71
4.	Mylyn (P4_MYL)	Task management	1862	13.16	71
5.	Eclipse PDE UI (P5_PDE)	IDE development	1492	14.01	71

Table 3 Dataset statistics of the data collected from ReLink

S. no.	Project	Type	Number of files	% of buggy files	# of metrics
1.	Apace (P6_AP)	Web server	194	50.52	26
2.	Safe (P7_SA)	Security	56	39.29	26
3.	ZXing (P8_ZX)	Bar-code reader library	399	29.57	26

4 Research methodology

The steps followed to experiment with this study are discussed in this section. However, the dataset considered for experimentation is summarized in Sect. 3. The research methodology is further represented graphically in Fig. 1.

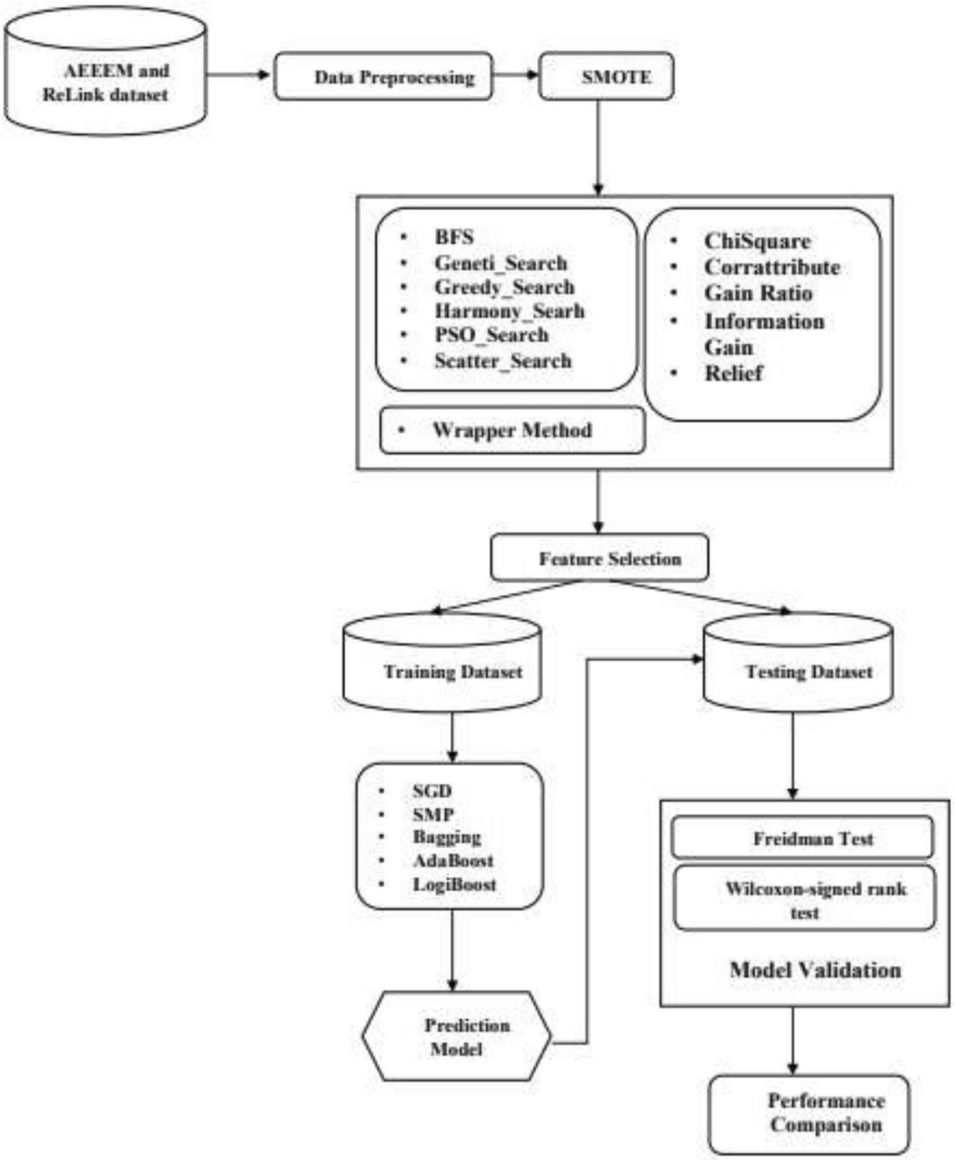
4.1 Data preprocessing techniques

In this study, the dataset is preprocessed before using for model development. For data preprocessing, missing values are handled, outliers are removed, null values are handled, and normalization of dataset techniques is performed. Firstly, the missing values or null values are replaced with the mean of the remaining values in the same column. Thus, the imputation of missing values by mean prevents information loss. Secondly, the outliers are handled using imputations. Moreover, the deletion of records due to outliers is not an advantage. In most cases, we try to retain the records by using some methods to prevent the loss of crucial information. However, the dataset needs to be normalized. However, normalization is a technique of converting data to a specified range of data. Furthermore, normalization techniques help in designing prediction models, statistical models, forecasting models, clustering models, and classification models. Thus, normalization is performed by converting all the numerical values in [0,1] considering the data used for normalization.

4.2 Imbalanced data

In a classification problem, when instances of one target class is more than the other class instances, this problem is termed an imbalanced dataset problem. There are various techniques exist to deal with imbalanced datasets such as SMOTE, oversampling, undersampling, and cost-sensitive learning. SMOTE is used in this study for balancing dataset. SMOTE is a technique, that oversamples the instances of minority class. Furthermore, new instances of minority class are synthesized from existing data only.

Fig. 1 Proposed methodology



4.3 Filter method

ChiSquare (FS1): It selects the relevant features based on ranking criteria. Furthermore, the chi-square test considers the independence of two events. Thus, the higher the value of chi-square, the attribute is depending on the outcome variable. Hence, the attribute will be selected by the chi-square test.

Correlation Attribute Evaluation (FS2): It selects the relevant attributes or features of a dataset using a correlation matrix. The correlation matrix predicts the amount of correlation between independent variables using pearson's correlation coefficient.

Gain Ratio (FS3): Gini ratio selects the relevant attributes by using a ranker. It assigns ranks to the features of high-dimension. Furthermore, the features with low ranks are removed and create reduces set of features. However, the K-anonymization privacy preservation techniques are used for both the original set of features and the reduced set of attributes.

Information Gain (FS4): Information gain is also used ranker for FS. Information gain provides the amount of useful information provided by each attribute for the outcome variable. It computes the gain of the attributes for the target variable. However, the feature with high gain is selected**.**

Relief Attribute Selection (FS5): The relief method is also based on the ranker criterion. It selects the relevant features according to the differentiation between instances that are near to each other. However, the relief method was designed for binary classification problems including non-metric data that is discrete or numerical features.

4.4 Wrapper method (FS6)

The selection of relevant features using the wrapper method follows a specific classifier that is used to develop a model. Unlike the filter method, wrapper method doesn't use a ranker. The wrapper method is based on the principle of greediness. It evaluates all the possible combinations for the selection of relevant attributes against the evaluation criterion. The evaluation measures for the regression problem are p-value and R-squared. The evaluation measures for classification problems are accuracy, precision, and recall. The commonly used wrapper methods are forward selection, backward selection, and bi-directional elimination.

4.5 Swarm search methods

In this study, six different swarm search methods are used for FS.

Best First Search (BFS) (FS7): BFS selects the attributes from an attribute set using search space. It selects the attributes by using greedy hill climbing augmented with a backtracking facility. Best first starts with an empty set of attributes and start searching for attributes in a specific direction by considering all possible combinations with additions and deletions.

Genetic Search (GENS) (FS8): GENS can be used for FS and hyperparameter optimization. It finds out the optimal set of attributes based on evolution.

Greedy Stepwise Search (GRS) (FS9): GRS selects the attributes using forward and backward search through the space of attributes subset. Starting criterion is either zero or all attributes or an arbitrary point in the feature space.

Harmony Search (HS) (FS10): It is inspired by the harmony improvisation process. HS method is considered a global optimization algorithm. In HS, at every iteration harmonies are generated termed as solution. Furthermore, these solutions are stored in harmony memory. HS method uses five parameters, three mandatory parameters, and two optional parameters.

Particle Swarm Optimization (PSO) (FS11): PSO method is an optimization approach based on the behavioral study of animals/birds. Furthermore, PSO performed better for FS for other techniques, Moreover, PSO has the capability of searching through large space, is computationally less expensive, and requires few parameters. The traditional PSO approach has some limitations. However, a new variant of PSO is developed. PSO (4–2) and BPSO overcome the limitations of the traditional PSO approach.

Scatter Search V1 (STS) (FS12): STS method uses an attributes subset for scatter search through the attribute space. However, it is starting with many significant attributes subsets and stops when the output is higher than a specified threshold or no further chances of improvement.

4.6 ML classifiers

In this study, five ML classifiers are used for designing CPDP such as Stochastic Gradient Descent (SGD), Sequential Minimal Optimization (SMO), AdaBoost (AB), Bagging (BNG), and LogiBoost (LB).

4.7 Statistical test

In this study, Friedman and Wilcoxon signed rank test (Liu and Xu 2022) are used for validating the difference among the performance of various FS techniques for CPDP. The results are validated using Friedman test and Wilcoxon sign rank test. However, the Wilcoxon sign rank test is used as a post hoc test in this study.

5 Results

The results and analysis are discussed in this section. We have collected eight projects of AEEEM and two projects of ReLink for experimentation. Furthermore, for experimenting all eight projects are combined to form different pairs for CPDP. However, these pairs are formed considering the size of the training dataset is low. Moreover, the model is not more efficient, if the amount of training data is less than the testing data. In the initial stage, 26 pairs are formed in this study, after extracting only those pairs having source data larger than the target data 13 pairs are selected. Furthermore, 12 methods are used for FS categorized as five filter methods, one wrapper subset method, and six swarm search-based methods. In this study, the FS techniques removed those features which are least relevant for the prediction of defects in the upcoming projects. In filter techniques, the features are ranked based on their contribution for defect prediction. Based on the number of features required for the prediction model, the relevant features are selected, and the remaining features are discarded. In the case of wrapper-embedded methods for FS, the cost function is optimized to find out the relevant features from both the source and target projects. Moreover, the features based on methods, attributes, and entropy are selected in the majority cases. Furthermore, five ML classifiers are used for the development of a prediction model with selected features.

In this study, 780 models were designed considering possible pairs of source and target datasets. The performance of each prediction model is analyzed according to the ML classifier for every attribute selection method. Each ML classifier takes a varied amount of time for the prediction model. The time complexity (Chen et al. 2020) of the SGD classifier is $O(r)$ where r is a number of records in the dataset, SMO classifier (Ouyang and Gray 2010) is $O(r^{2.3})$, BNG classifier (Zhao et al. 2020) is $O(Tt)$ where T refers to the number of

iterations and t is the average running time of an individual ML classifier, AB is $O(rlogr)$. However, the performance metric used in this study is AUC. AUC provides more generalized and unbiased results in case of an imbalanced dataset. This section interprets the results and answers to the RQs discussed in Sect. 1.

The existing FS algorithm is combined with a two-phase ensemble learning framework to improve the performance of software defect prediction models using SVM, random forest, and Enhanced Average Probability Ensemble (EAPE) technique. EAPE provided better results close to 0.9 for some of the datasets in comparison to SVM and random forest which are close to 0.7 and 0.8. Moreover, the specified FS techniques are used in the existing study using the same project for training and testing. The authors have used feature learning for CPDP using AEEEM and ReLink datasets with AUC values of 0.8 and 0.7 (Wu et al. 2018).

In the existing studies, authors have not analyzed the capability of filter, wrapper, and swarm search-based methods for FS. In the existing study, authors experimented with GA for CPDP. However, it is concluded that GA outperformed FS in comparison to the filtering technique (Hu and Zhu 2023). The authors also experimented with search-based FS techniques for CPDP with a KNN filter. Furthermore, the CPDP model using search based optimizer provided 30–40% better performance in comparison to the base paper. In this study, the performance of all the search-based FS techniques was analyzed with filter and wrapper techniques. However, it has been observed that search-based techniques outperformed for CPDP in comparison with the ranking and wrapper method. In the existing study, the FS methods are empirically validated for CPDP (Yu et al. 2019). The experiment is conducted using KNN and NB classifiers using feature subset selection and filtering techniques.

RQ1: What is the predictive capability of filter methods for CPDP using AEEEM and ReLink dataset?

In this study, CPDP models are developed successfully in conjunction with software metrics. Various filter methods are used for a selection of relevant attributes. Thus, filter methods are used with a ranker to select relevant features based on ranking. Null Hypothesis (H_o): There is no significant difference among the performance of filter methods used for FS. Alternate Hypothesis (H_a): There is a significant difference among the performance of filter methods used for FS. The predictive performance of filter methods was analyzed using the Friedman test for 325 CPDP models. Furthermore, the results obtained using filter methods are validated using Friedman test (Ma et al. 2023) at a significance level of 0.05. However, for five FS techniques and Degree of Freedom (DF) as 4, the obtained chi-square (χ^2) value is 7.520, and the p-value is 0.111. Moreover, the p-value is greater than the significance level which is 0.05. Thus, hypothesis testing proved that there is no significant difference among the performance of filter methods for five ML classifiers for the identification of defects in the CPDP. Hence, H_o is accepted and stated that filter methods performed similarly for FS with respect to HoGCP. The results are presented in Table 4.

RQ2: What is the predictive capability of swarm search-based methods for CPDP?

To answer this RQ, various swarm search-based methods are used for the selection of relevant attributes in this study. Thus, filter methods are used with correlation-based FS (CFS) to select relevant features. Null Hypothesis (H_o): There is no significant difference among the performance of six swarm search methods used for FS. Alternate Hypothesis (H_a): There is a significant difference among the performance of six swarm search methods used for FS. The results are presented in Table 5.

The predictive performance of swarm search-based methods analyzed using the Friedman test for 390 CPDP models. Furthermore, the results obtained using filter methods are validated using the Friedman test at a significance level of 0.05. However, for five FS techniques and DF as 4, the obtained χ^2 value is 7.353, and p-value is 0.196. Moreover, the p-value is greater than the significance level which is 0.05. Thus, hypothesis testing proved that there is no significant difference among the performance of six swarm search-based methods used with five ML classifiers for CPDP. Hence, H_o is accepted and stated that all the swarm search methods performed similarly for FS with respect to HoGCP.

RQ3: What is the predictive capability of filter, wrapper, and swarm search-based methods for CPDP?

To answer this RQ, the performance of the prediction model build using filter, wrapper, and swarm search-based methods is analyzed. Furthermore, the performance of 780 CPDP models are compared altogether using the Friedman test at a significance level of 0.05. H_o: There is no significant

Table 4 Average AUC values for filter methods and ML classifiers for CPDP (13 pairs of AEEEM and ReLink dataset)

ML classifier	Filter method				
	FS1	FS2	FS3	FS4	FS5
SGD	0.59	0.59	0.54	0.60	0.54
SMO	0.61	0.61	0.60	0.63	0.58
AB	0.75	0.75	0.75	0.68	0.65
BNG	0.64	0.64	0.66	0.62	0.63
LB	0.72	0.71	0.72	0.67	0.63

Table 5 Average AUC values for swam search-based methods and ML classifiers for CPDP (13 pairs of AEEEM and ReLink dataset)

ML classifier	Swarm search method					
	FS7	FS8	FS9	FS10	FS11	FS12
SGD	0.58	0.55	0.58	0.59	0.58	0.59
SMO	0.62	0.61	0.62	0.64	0.61	0.61
AB	0.73	0.74	0.73	0.73	0.73	0.74
BNG	0.7	0.72	0.7	0.69	0.69	0.70
LB	0.75	0.73	0.75	0.72	0.69	0.76

difference among the performance of filter, wrapper, and swarm search methods used for FS. H_a: There is a significant difference among the performance of filter, wrapper, and swarm search methods used for FS. However, for 12 FS techniques and DF as 11, the obtained χ^2 value is 23.185, and p-value is 0.017. However, the p-value is less than the significance level which is 0.05. Furthermore, the Friedman test resulted in the acceptance of an H_a, that is there is a significant difference among the performance of all three methods and 12 techniques used. Thus, H_a is accepted and stated that the performance of filter, wrapper, and swarm search-based FS methods differ significantly for HoGCP.

Furthermore, the results are validated using post hoc analysis with the Wilcoxon sign rank test. Wilcoxon sign rank test performed pairwise comparison among all the 12 techniques that formed 66 combinational pairs. Furthermore, out of 66 pairs, the Wilcoxon sign rank test resulted in the acceptance of the null hypothesis for 18 pairs presented in Table 6. Thus, there is no significant difference among the performance of 18 pairs of FS techniques. However, for the remaining 48 pairs Wilcoxon sign rank tests resulted in the acceptance of the alternate hypothesis presented in Table 7. Hence, there is a significant difference among the performance of 48 combinational pairs of FS techniques. Thus, the performance of swarm search-based methods is comparatively better than filter and wrapper methods.

FS12–FS11	0.042

6 Conclusion

The objective of conducting this study was to analyze the effectiveness of FS techniques for CPDP. However, in this study, the HoGCP model is designed, that considered source and target projects with similar features. In this study, three types of methods are explored for CPDP (i) Filter method (ii) Wrapper subset evaluation method, and (iii) Swarm search-based methods. Also, this study is evaluated using five ML classifiers for defect prediction in future projects with similar features to enhance the maintainability, reliability, and robustness of the software. Friedman and Wilcoxon sign rank test were used for statistical validation.

Five filter methods are compared based on ranking criteria. However, all the filter methods were performed on the same scale. However, for wrapper attribute subset evaluation, the principle of greediness is used to find out the global optimal subset of attributes with a specified ML classifier. However, the wrapper method is better than the filter method in most of the pairs. Furthermore, six swarm search-based methods are used for FS. However, the swarm method finds out the best attribute through attributes pairs search space and stops selecting the attribute according to the stopping criterion. Furthermore, swarm search-based methods outperformed with respect to filter and wrapper methods. Hence, conducting further experiments for CPDP swarm search-based methods are preferable. Furthermore, the FS techniques need to be explored for HeGCP defect prediction models on large datasets.

ABSTRACT

In the current study, 25% incorporating PVT hybrid CPC collector double slope solar still is using Al_2O_3 nanoparticles underwent energy matrices analysis and life cycle conversion efficiency (LCCE). With the aid of an analytical program fed into MATLAB, the analysis is conducted on an annual basis based on the atmospheric conditions in New Delhi. The IMD in Pune, India, provided weather input data needed for the numerical computations. The average annual energy output will be calculated using energy and exergy and later on evaluated EPT, EPF, and LCCE. This will reveal that the average annual yield is 8.5%, the average energy payback time is 16.16%, the average energy payback factor is 13.91%, and the average life cycle cost conversion efficiency is 7.15% higher compared to the previous research. Therefore, it is obvious the proposed system is better based on the following parameters i.e. (i). annual yield, (ii). energy matrices such as EPT, EPF, and efficiency of life cycle cost (LCCE). The proposed hybrid is a self-sustainable system that can also meet the future requirements of potable water as well as electricity.

Keywords: Energy matrices, Energy payback time, Energy production factor, Life cycle conversion efficiency, Al_2O_3 nanoparticles

INTRODUCTION

We can access a very low percentage of water from the ground. Therefore, there is a need to develop potable water and self-sustainable systems. Water purification is required due to polluted water to freshwater throughout the world. Consumption of polluted water is increasing death rates by increasing diseases in human beings. In present days, system availability is not self-sustainable. Electricity is needed which generates it causes pollution. Therefore, the better solution is a renewable energy source that can reduce the potable water problem. Lawrence and Tiwari [1] developed the empirical relations for the inside coefficients of heat transfer from the natural flow with a heat exchanger in a solar distiller unit. Popiel and Wojtkowiak [2] studied the thermo-physical properties of the base fluid. Pak and Cho [3] evaluated various correlations for different properties. G. N. Tiwari [4] studied the fundamental design of the solar still. Hwang et al. [5] analyzed the heat transfer coefficient for Al_2O_3 nanofluids.

Barden [6] improved the thermo-physical properties of the base fluid; the heat transfer coefficients could also be improved. Due to their superior thermo-physical characteristics, nanoparticles are easily deferred. The nanofluids are developing fluids with extremely quick heat transfer properties. Additionally, the base fluid's qualities could be enhanced by customizing the size and shape. Tiwari and Tiwari [7] expressed few merits of solar distillers over other distillation technologies such as filters, membranes, and batteries, no definitive resource of energy, and primarily low investment. Ho et al. [8] numerically analyzed nanofluids for natural convection in a square enclosure: effects due to uncertainties of viscosity and thermal conductivity. Otanicar and Golden [9] analyzed the enviro economic aspect of solar collectors using nanofluid and found it neutralizes 74 kg for a life span of 15 years. Patel et al. [43] analytically studied N^{th} identical photovoltaic thermal (PVT) compound parabolic concentrator (CPC) active double slope solar distiller with a helically coiled heat exchanger using C_uO Nanoparticles. Dharamveer, et al. [44] analyzed an N-identical active single-slope solar distiller with a helically coiled heat exchanger using CuO nanoparticles. Kumar and Singh, [45] compared single-phase microchannels for heat flow Experimental and using CFD. Subrit and Singh. [46] analyzed thermal of coal and waste cotton oil liquid produced by pyrolysis of diesel engine fuel was carried out by. Shahsavar et al. [47] Compared energy, exergy, environmental, exergoeconomic, and enviro economic analysis of building integrated photovoltaic/thermal, earth-air heat exchanger, and hybrid systems. Numerous studies on passive and active solar stills have been conducted, according to the current literature survey. However, not much investigation on active solar still filled with water-based nanofluids was studied. Based on energy and exergy, Dharamveer et al. studied a hybrid double slope. No scholars have examined the economic, and environmental, using nanofluid. Furthermore, no studies have been conducted for CPC, ETC double slope basin type solar distiller using nanofluid. Thus, the proposed study will examine the impacts of active solar still double slope with CPC and filled with water containing Al_2O_3 nanofluid on energy matrices based such as energy payback time, energy payback factor, life cycle cost conversion efficiency, and productivity, of solar desalination systems will be thoroughly examined. The effectiveness of the suggested approach will also be evaluated in comparison to the findings of past studies.

MATERIALS AND METHODS

To determine the following objectives the methodology is adopted as energy matrices analysis of hybrid solar distiller basin type double slope with heat exchanger using Al_2O_3 nanoparticles.

System Description

Working of double slope solar desalination incorporating PVT with CPC collector using nanoparticles (N-PVT-CPC-DS-HE) is shown. Representation of solar still is followed the greenhouse principle. The parameters used for the distiller unit are given in Table 1 and Table 2. The basin of the solar distiller is connected in series with N-CPC and incorporated with a helically coiled heat exchanger. Solar radiation received on the glass cover is transferred to the water surface and thereafter absorbed by the surface. Later on, reflected water received heat on the top cover and rest portion and then move to the liner where the maximum amount absorbed and liner temperature increased and transfer this heat to water. Thus the temperature of water in the basin is increased and water gets evaporated. Collectors also heat the water in the basin. Water is heated and evaporates in this manner. The distillate trickles forward to the passage attached to the bottom side as the vapor reaches the interior face of the condenser, where film-wise condensation takes place. Then, the beaker receives the distilled water that was siphoned off.

Fig. 1 represents 25% PVT incorporating hybrid solar still. Collectors are put south facing at an angle of 45° which are connected in series as the input of the second collector is attached to the first collector output. Radiation that falls on the collector directly gets absorbed and beam irradiation is reflected on the parabolic concentrator. Similarly, irradiation falls on PV modules that generate electricity which is further used for operating pumps (D.C) and access energy can be further used for any electrical appliances according to need. Table 2 represents the specifications of the proposed system. The inclination angle of the system is 30° and the orientation of the system is the southern face. The basin liner is absorbed maximum radiation which falls on the glass cover. The basin fluid gets heat from the heat exchanger through Al_2O_3 nanoparticles. As per a prior study, it is obvious that a helically coiled heat exchanger is more effective than any other design. The Al_2O_3 nanoparticles exchange more heat in active solar still because it covers more

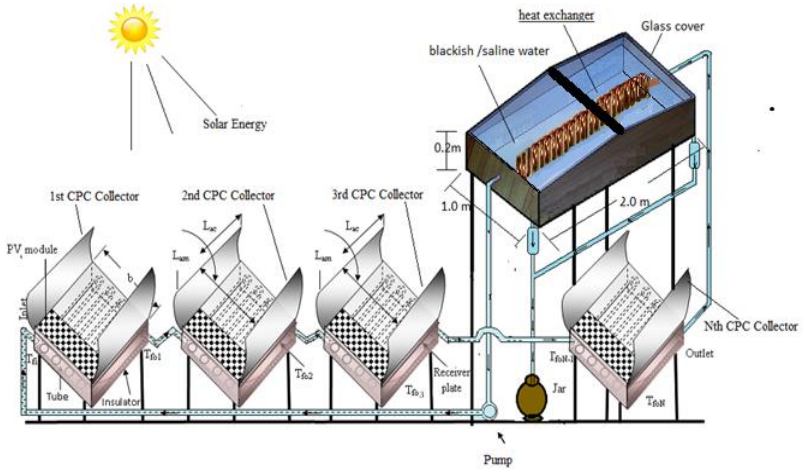

Fig. 1 active double slope solar still 25% incorporating N-PVT-CPC-DS-HE

surface area due to increasing volume due to heat exchanger. The system gets thermal energy via a combination of double-slope basins incorporating with PVT-CPC collector unit and it absorbs heat externally from a collector and internally from a basin. Basin water temperature increases via heat exchanger nanoparticles. Ultimately by releasing latent heat the vapor gets condensed, and collected at the lower end of the inclined glass cover of the basin.

This sort of system produced electricity as well as potable water. The other quality of this sort of system is i.e. low maintenance, easy to install, and useful for large and small demands of potable water as well as industrial purpose. Lot of advantages of such a system but in this work, we emphasize producing potable water only therefore according to making the system self-sustainable the PVT is provided otherwise 50%, 75%, and 100% can also be used.

Though, the proposed system-A is compared with the previous System-B based on basin water temperature, inside glass cover temperature, water outlet temperature, the overall thermal energy of collectors, overall exergy, overall electrical exergy, and potable water amount. Sedimentation possibility in nanofluid is more. Therefore nanoparticles size leads to a change in aggregation. The value of size matters to change in aggregation. Later on, more sophisticated equipment is needed to remove it.

Governing equations

To develop the characteristic equation, the following assumptions are:

i. Constant water level
ii. Negelectedohmic losses
iii. No leakage
iv. Over the entire surface film condensation
v. Steady-state partially covered active solar stills

The governing equations of the system are as follows:

a. East face

$$\alpha_g I_{SE} A_{gE} + h_{1wE}(T_w - T_{giE})\frac{A_b}{2} - h_{EW}(T_{giE} - T_{giW})A_{gE} = U_{cgaE}(T_{giE} - T_a)A_l \quad (1)$$

b. West face

$$\alpha_g I_{SW} A_{gW} + h_{1wW}(T_w - T_{giW})\frac{A_b}{2} + h_{EW}(T_{giE} - T_{giW})A_{gW} = U_{cgaW}(T_{giW} - T_a)A_{gW} \quad (2)$$

On solving Equations (1) and (2)

$$T_{giE} = \frac{A_1 + A_2 T_w}{p} \quad (3)$$

$$T_{giW} = \frac{B_1 + B_2 T_w}{p} \quad (4)$$

$$T_{goE} = \frac{\frac{K_g}{l_g} T_{glE} + h_{1gE} T_a}{\frac{K_g}{l_g} + h_{1gE}} \quad (5)$$

$$T_{goW} = \frac{\frac{K_g}{l_g} T_{glW} + h_{1gW} T_a}{\frac{K_g}{l_g} + h_{1gW}} \quad (6)$$

The unknown terms, A_1, A_2, B_1, B_2, and P in Equations 3, 4, 5, and 6 are mentioned in Appendix A,

c. Basin liner

$$\alpha_b(I_{SE} + I_{SW}) + 2h_{bw}(T_b - T_w) + 2h_{ba}(T_b - T_a) \quad (7)$$

d. Water equation

$$m_f C_f \frac{dT_w}{d_t} = \alpha_w(I_{SE} + I_{SW})\frac{A_b}{2} + 2h_{bw}(T_b - T_w)\frac{A_b}{2} - h_{1wE}(T_w - T_{giE})\frac{A_b}{2} - h_{1wW}(T_w - T_{giW})\frac{A_b}{2} + Q_{uN} \quad (8)$$

e. Energy balance equations for heat exchange and base fluid can be written for solar distillers as:

$$m_f C_f \frac{dT_w}{d_x} d_x = -(2\pi r_{11} U)(T_{HE} - T_w)d_x \quad (9)$$

Applying the limits Tw at (x = 0) = T_{woN} and Tw at (x = L) = T_{wi} on solving,

$$T_{wi} = T_{HE}\left[1 - \exp\left(\frac{-(2\pi r_{11} UL)}{m_f C_f}\right)\right] + T_{woN}\exp\left(\frac{-(2\pi r_{11} UL)}{m_f C_f}\right) \quad (10)$$

Where $U = \left[\frac{1}{h_{bf}} + \left(\frac{r_{11}}{k_1}\right)\ln\left(\frac{r_{22}}{k_1}\right)\left(\frac{1}{h_{bf}}\right)\right]^{-1}$

f. Energy balance for water collector N-PVT-CPC

$$T_{woN} = \left[\frac{(AF_R(\alpha\tau))_1(1 - K_p^N)}{m_f C_f(1 - K_p)}\right] I_b + \left[\frac{(AF_R(UL)_1)(1 - K_p^N)}{m_f C_f(1 - K_p)}\right] T_a + T_{wi} K_m^N \quad (11)$$

$$T_{woN} = \left[\left[\frac{(AF_R(\alpha\tau))1(1 - K_p^N)}{m_f C_f(1 - K_p)}\left(\frac{1}{(1 - e^z K_m^N)}\right)\right]\right] I_b +$$

$$\left[\frac{(AF_R(UL)1)(1-K_p^N)}{m_f C_f(1-K_p)}\left(\frac{1}{(1-e^z K_m^N)}\right)\right]T_a + T_{HE}\left(\frac{(1-e^z)K_m^N}{(1-e^z K_m^N)}\right)\Bigg] \quad (12)$$

Using this relation heat gain computed

$$Q_{uN} = m_f C_f (T_{woN} - T_{wi}) \quad (13)$$

The outlet temperature of water computed by these two equations 3.12 and 3.13,

$$T_{HE} > T_{wi} > T_w$$

$$Q_{uN} = [((\frac{(AF_R(\alpha\tau))1\,(1-K_p^N)}{(1-K_p)})\left(\frac{1}{(1-e^z K_m^N)}\right))I_b + \left(\left(\frac{(AF_R(UL)1)(1-K_p^N)}{(1-K_p)}\right)\left(\frac{1}{(1-e^z K_m^N)}\right)\right)T_a + m_f C_f (T_{HE}(\frac{(1-e^z)K_m^N}{(1-e^z K_m^N)}) - T_{wi})] \quad (14)$$

By putting

T_{giE}, T_{giW}, $2h_{bw}$ (T_b-T_w), and Q_{uN} from Equations (3),(4), and (9) in Equation (15)

$$\frac{dT_w}{dt} = -a_2 T_w + f_2(t) \quad (15)$$

The energy and exergy analysis has been done, respectively, based on the thermodynamics laws for the given entities.

$$E_{hourlyEn} = [h_{1wE}(T_w - T_{giE}) + h_{1wW}(T_w - T_{giW})](A_b) \quad (16)$$

$$E_{hourlyEx} = \{h_{1wE}[(T_w - T_{g\,iE}) - (T_a + 273)\ln\left(\frac{T_w + 273}{T_{g\,iE} + 273}\right) + h_{1wW}[(T_w - T_{g\,iW}) - (T_a + 273)\ln\left(\frac{T_w+273}{T_{g\,iW}+273}\right)]\}A_b \quad (17)$$

The constant 0.933 represents the solar irradiation exchange constant, per hour water production for the proposed system have been calculated using the following equation.

$$M_w = \frac{q_{ew}}{L_v}3600 = \frac{h_{ew}(T_w - T_g)}{L_v}3600 \quad (18)$$

Latent heat of vaporization is expressed as [43]:

L_v=3.162510^6+[1-(7.61610^{-4} T_v)] For T_v> 70 °C

L_v=2.493510^6 [1-(9.477910^{-4} T_v)+1.313210^{-7} (T^2_v)-4.797410^{-3} (T^3_v)]

For T_v< 70 °C

Thermophysical properties of vapor, base fluid from references [31-34], and Nanoparticles (Table - 3) [37- 42].

Analysis based on matrices and cost conversion based on the life span of hybrid active double slope solar distiller unit using Al_2O_3 nanoparticles -

Energy matrices inform about the time of energy payback (EPT), energy payback factor (EPF), and life cycle conversion efficiency for the lifetime period (LCCE) [27].

Energy Payback Time (EPT) [27]

The time duration needed to recover total exhausted energy in manufacturing material can be expressed as

$$EPT_{(e)} = \frac{\text{Embodied Energy}(E_{in})}{\text{Annual energy output}(E_{out})} \quad (19)$$

$$EPT_{(ex)} = \frac{\text{Embodied Energy}(E_{in})}{\text{Annual exergy output}(E_{out})} \quad (20)$$

Energy Production Factor (EPF) [27]

It is reciprocal of EPT an ideal value of EPF on an annual basis to express the overall performance of solar still can be expressed as

$$EPF_{(e)} = \frac{\text{Overall Energy Output}(E_{out})}{\text{Embodied Energy}(E_{in})} \quad (21)$$

$$EPF_{(ex)} = \frac{\text{Overall Exergy Output}(E_{out})}{\text{Embodied Energy}(E_{in})} \quad (22)$$

Lifecycle Conversion Efficiency (LCCE) [27]

$$LCCE_{(e)} = \frac{E_{out} \times n - E_{in}}{E_{sol} \times n} \quad (23)$$

Where, E_{sol} represents annual solar energy (kWh) and n is the overall lifetime period.

Table 3. Thermophysical properties of Al2O3 nanoparticles [43]

Economic analysis is required to determine of hybrid active double slope solar still using Al_2O_3 nanoparticles-

It is economically feasible for System-A and System-B for both systems.

Capital cost

Tables 5 and 6 provide the system's fabrication cost.

System's Lifespan

It is considered for 15, 20, and 30 years.

Salvage value (S)

Salvage value (s) = 0.2 × Principal capital (PCC) (24)

PCC stands for principal capital cost

Cost of annual salvaging (ASC)

Annually salvage = S × shrinkage in a fund (SFF) (25)

SFF is a factor used for shrinkage

Yearly maintenance (AMC)

Yearly maintenance (AMC) =0.15×FAC (26)

FAC stands for the first annual cost.

Factor for capital recovery (CRF).

At a fixed rate of interest, it shows the present cost as a constant annual cost across time.

$$CRF = \frac{i(1+i)^n}{(1+i)^n - 1} \quad (27)$$

Shrinking fund factor

$$SFF = \frac{i}{(1+i)^n - 1} \quad (28)$$

Firstly annual cot estimated

FAC=PCC×CRF (29)

Net annual cost estimated

TAC= FAC+AMC-ASC (30)

Cost of distillate per kg obtained

$$Cost/kg = \frac{TAC}{\text{yield in life}} \quad (31)$$

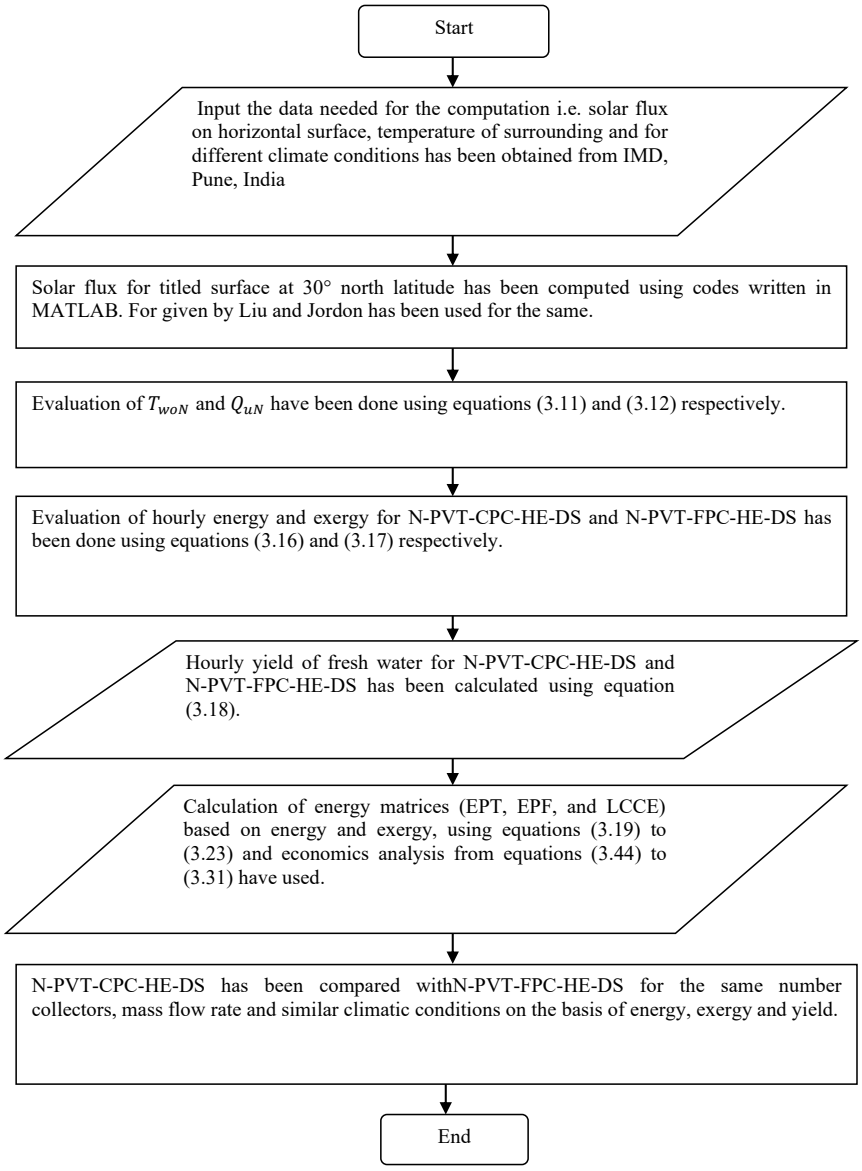

Fig. 2 Flow chart of the methodology adopted

Methodology to be Adopted

The following steps are included in the approach used to study the suggested system (Fig. 2):

Step-I

The proposed systems for the yearly are calculated using the Lui-Jordon formula for global and beam irradiation. Calculate daily solar radiation further by multiplying the number of days given in a month by the number of clear, hazy, hazy, cloudy, and cloudy days.

Step-II

The temperature of basin water is calculated based on hourly, monthly, and annual data, and all settings are tuned to maximize the collector's output temperature.

Step-III

Energy matrices such as efficiency of life cycle cost, Factor energy payback, energy payback time, and productivity have been evaluated.

Step-IV

Comparing proposed systems to the prior system using numerically computed values.

RESULT AND DISCUSSION

The solar irradiation on a flat area and surroundings temperature have been computed using

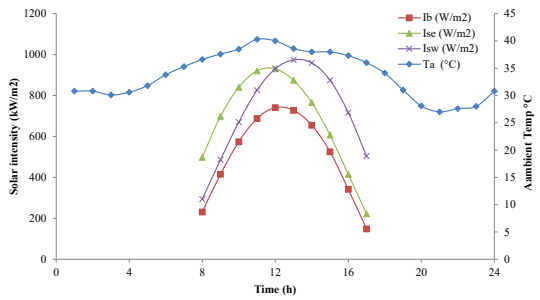

Fig. 3 Hourly variation in solar irradiation and ambient temperature for typical day of May

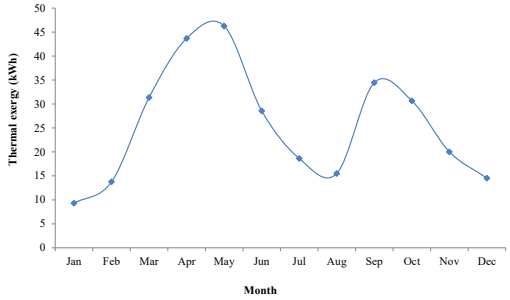

Fig. 4 Shows the thermal exergy of the proposed system-A

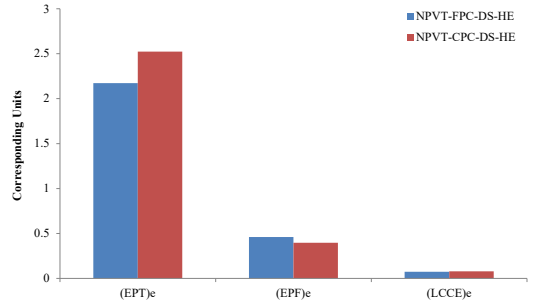

Fig. 5 Shows EPT, EPF, and LCCE for proposed and previous system for 15 years

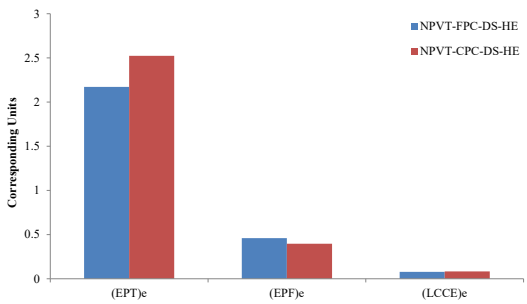

Fig. 6 Shows EPT, EPF, and LCCE for proposed and previous system for 20 years

IMD Pune data, India. By entering the pertinent data in MATLAB, the Liu and Jordan formula may be used to determine how much radiation was applied to N-PVT-CPCs. The values of beam radiation Ib, solar radiation Eastside ISE, Westside ISW, and ambient temperature Ta in kW/m^2 and ^{o}C, respectively, are shown in Fig. 3. Below Fig.4 shows a variation of the thermal exergy month-wise of proposed system-A.

Energy matrices and a life cycle cost conversion analysis are required for the hybrid active double slope solar distiller unit

Embodied energy (E_{in}), the conversion efficiency of the life cycle (LCCE), energy payback factor (EPF), and energy payback time for (N-PVT-DS-FPC-HE) and (N-PVT-DS-CPC-HE) are shown in Fig. 5, Fig. 6, and Fig. 7 for 15, 20 and 30 years respectively.

The number of energy matrices based on energy and exergy for proposed system-A is found that system-A is better to system-B. EPT based on energy and exergy is 16.16% and 17.84% higher, respectively. EPF based on energy and exergy is relatively less13.91% and 14.88%, respectively. LCCE based on energy and exergy is appreciably greater for system-A than system-B: 5.55%, 6.38%, and 7.15% for 15, 20, and 30 years of life considered, respectively.

Economic analysis is required to determine whether hybrid active solar still uses Nanoparticles (Al_2O_3)

It is economically feasible for system-A and System-B annually. Total yearly cost, fixed annual cost, yearly maintenance cost, and yearly water generation for system-A and system-B are shown during 30 years, at respective interest rates of 1%, 3%, and 5% respectively are represented in Fig. 8, and Fig. 9.

The cost of distillation relies on the rate of interest, as results over 30 years are shown in Fig.8. While the cost of distillate will reduce as system life increases, the price of distillate will climb annually as interest rates rise. For system-A and system-B, the cost of distillate is 0.69, 0.96, and 1.27 (/kg), and 0.72, 1.012, and 1.33 (/kg), respectively, over 30 years at interest rates of 1%, 3%, and 5%. According to the cost of distillation, it is concluded that the proposed system-A performs better than system B.

CONCLUSION AND FUTURE SCOPE

The proposed system and previous system performance have been studied using characteristic

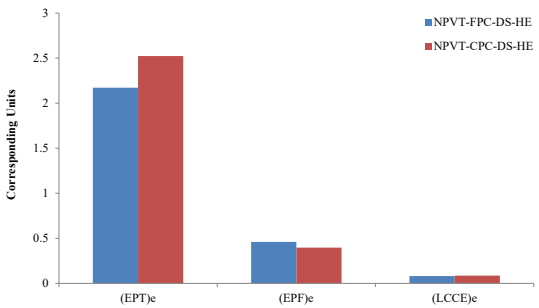

Fig. 7 Shows EPT, EPF, and LCCE for proposed and previous system for 30 years

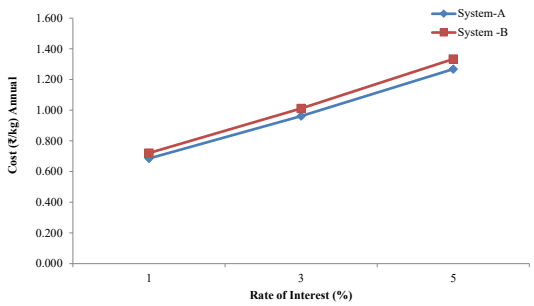

Fig. 8 Represents cost of distillate vs Interest rate

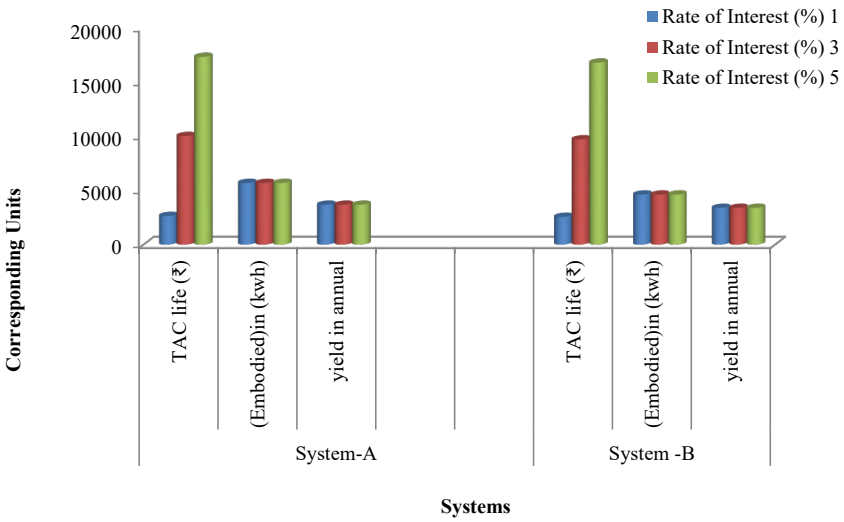

Fig. 9 Shows comparison for system-A and system-B based on TAC, Embodied Energy and Yield for 30 years

equations and Al_2O_3 nanoparticles and found better than the previous system.

Conclusions

The following conclusions are made by the annual analysis of the proposed systems with Al_2O_3 nanoparticles.

1. The proposed system-A gives better annual performance than system-B based on thermal exergy, energy, yield is 8.5%, and productivity 5.17% greater with Al_2O_3 nanoparticles.
2. Al_2O_3 nanoparticles-based system-A gives better results on annual performance and economics as compared to system-B.
3. Based on thermal energy, thermal exergy, energy, and exergy-based, Energy payback time (EPT) is 16.16%, Energy payback factor (EPF) is 13.91%, Efficiency of life cycle cost (LCCE) is 7.15% greater than the previous research, it is found that system-A outperforms system-B (previous).
4. System-A has a lower distillation cost than System B (previous). The yearly cost of distillate for systems A and B is 0.69, 0.96, and 1.27 (/kg), and 0.72, 1.012, and 1.33 (/kg), respectively, based on a 30-year basis at interest rates of 1%, 3%, and 5%. According to distillate cost, it is discovered that system-A performs better than system B.

Future scope

This work can be further expanded using research with PCM material in CPC up to a specific level.

1. Energy and exergy can be studied for different nanoparticles
2. energy matrices, EPT, EPF, and LCCE can be studied for different nanoparticles
3. Research on the environmental and economic benefits of various nanoparticles is possible. Different sizes, and shapes of nanoparticles can be investigated.
4. The partial covered 50%, 75%, and 100% can be studied.

U_{Lc} glazing to surrounding, overall heat transfer coefficient, in $(W/m^2\ K)$
U_{Lm} module to surrounding, overall heat transfer coefficient, in $(W/m^2\ K)$
U_{tca} solar cell to surrounding, overall heat transfer coefficient, in $(W/m^2\ K)$
U_{tpa} absorbing plate to surrounding, overall heat transfer coefficient, in $W/m^2\ K$
$U_{tc,p}$ solar cell to absorbing plate, overall heat transfer coefficient, in $(W/m^2\ K)$
X characteristic length, solar distiller unit, in (m)

Greek letters

α_g solar energy fraction absorbed by the condensing cover
α_b solar energy fraction absorbed by basin surface
α_f solar energy fraction absorbed by the fluid
α_c solar energy fraction absorbed by solar cell
β packing factor
β_p nanoparticles, coefficient of thermal expansion, in (K^{-1})
β_{nf} nanofluid coefficient of thermal expansion, in (K^{-1})
β_{bf} base fluid coefficient of thermal expansion, in (K^{-1})
$\emptyset_g$ nanoparticles fraction of volume, in (%)
μ_{bf} base fluid viscosity of dynamic, in (Ns/m^2)
μ_{nf} nanofluid viscosity of dynamic, in $(Ns/m^2))$
η_g collectors efficiency, in %
ρ_p nanoparticles density, in (Kg/m^3)
ρ_{nf} nanofluid density, in (Kg/m^3)
ρ_{bf} base fluids density, in (Kg/m^3)
τ_g transmitted fraction of glass cover

Subscripts

ABSTRACT

The combustion process has been successfully used to synthesize Ba_3MoTiO_8:-Sm^{3+} and Ba_3MoTiO_8:Sm^{3+}/Eu^{3+} co-doped phosphors for white light emitting diode (w-LED) applications. For the as-prepared phosphors, X-ray diffraction (XRD), scanning electron microscopy (SEM), fourier transform infrared spectroscopy (FT-IR), diffuse reflectance spectroscopy (DRS), and photoluminescence (PL) spectroscopy techniques have been used to investigate phase confirmation, morphological analysis, and PL properties. The PL emission spectra of singly Sm^{3+} doped and Sm^{3+}/Eu^{3+} co-doped phosphors recorded under 409 nm wavelength show intense emission in reddish–orange and red regions, respectively. For Sm^{3+}–Eu^{3+} co-doped phosphors, the intensity of Sm^{3+} peaks show a decrease with an increase in Eu^{3+} ion concentration, demonstrating the energy transfer from Sm^{3+} to Eu^{3+} ions. Quadrupole–quadrupole interaction is the mechanism responsible for energy transfer from Sm^{3+} ions to Eu^{3+} ions according to Dexter's hypothesis as applied to the PL spectra. This result is in consonance with the results of PL decay curves recorded under 409 nm excitation. The Commission Internationale de I' Eclairage coordinates calculated for singly Sm^{3+} doped and Sm^{3+}/Eu^{3+} co-doped phosphors show colour tunability from reddish–orange to pure red regions. All the results obtained finally revealed the utility of the titled phosphors as tunable red emitters needed to fabricate w-LEDs.

1 Introduction

In the current era, increasing human power consumption by humankind is taking a toll on natural resources. Most of the electricity produced is consumed by lighting devices and traditional lighting sources are being replaced by the white LEDs (w-LEDs), which are more efficient than the traditionally used incandescent and fluorescent lamps due to low power consumption, high brightness, compact

design, and longer lifetime [1–4]. Researchers working in the field of phosphors are fiercely searching for novel and more efficient phosphor materials for the replacement of traditionally used materials in LEDs. Blue chips made of InGaN and yellow phosphor (YAG: Ce^{3+}) are used to create the commercially available white LEDs [5, 6]. But the light produced through this method has some shortcomings, such as a poor colour rendering index, a high correlated colour temperature, and mismatched warm white light due to the deficiency of the red component [7, 8]. The introduction of red/orange emitting phosphors can improve these limitations. So another approach that can be used for white light generation is either a combination of blue LED chips coated with green and red phosphors or UV LED chips coated with orange and cyan emitting phosphors. So, an orange-emitting phosphor in combination with a cyan-emitting phosphor under UV excitation can be a promising choice for researchers [9].

Recently, rare earth (RE) doped phosphor/glasses materials have been finding immense attention in the scientific community because of their vast applications in the fields of solid-state lighting technology, display devices, solar cells, etc. [10–13]. RE ion doping is usually preferred in phosphors due to their magnificent properties like high solubility, high luminescence efficacy, and large Stoke shifts [14–18]. Commercially, the red phosphor is fabricated with the sulfide-based Y_2O_2S: Eu^{3+} material, which is excited in the near-UV range [19]. The material Y_2O_2S: Eu^{3+} is chemically unstable, decreasing its luminous efficiency [20]. Therefore, as a replacement for this, the development of a highly efficient red phosphor is required. The titanate-based phosphors have some distinct properties, like a high refractive index and a wide bandgap, because of which they have good emission properties and therefore can be preferred as a stable host compound among the other phosphor materials. In addition to this, low synthesis temperature, physical and thermal stability and the broad excitation band in the UV region of molybdenum (Mo) present in the host can also improve the luminous properties of the BMT phosphor [21–23]. Also, the chromaticity of the titanate phosphors can be varied with the doping elements in 3d and 4f systems. Recently, co-doping of RE's in host lattices has driven interest due to their attractive energy transfer mechanism and flexible colour tuning properties. Among all the RE ions, the Eu^{3+} and Sm^{3+} ions show promising results and give emission in the reddish–orange and pure red regions, respectively [20–23]. In a broad emission range that spans the UV to visible regions, they exhibit good electrical and optical properties. Here, optical transitions occur between a variety of f states, and the filled 5s and 5p subshells effectively shield the f electrons from their surroundings [11, 24–26]. The Eu^{3+} is an effective activator ion due to its high colour purity and its intense red emission (615 nm) corresponding to transition $^5D_0 \rightarrow {}^7F_2$ [24]. The Sm^{3+} ion can act as a good sensitizer because of the lower energy difference between Sm^{3+} ($^4G_{5/2}$) and Eu^{3+} ($^5D_0$) and can transfer its excitation energy to Eu^{3+}. So, co-doping of Sm^{3+}/Eu^{3+} ions in a host lattice can broaden the excitation bands and helps in enhancing the luminescence efficiency for the red color emission in w-LEDs. Sm^{3+} ions can also act as a good activator when doped singly in some host compounds and gives reddish-orange emission. Such singly Sm^{3+} ions doped phosphors are used in such devices where the emission corresponding to the reddish-orange regions is needed. Therefore, in this article, we have reported our work on singly Sm^{3+}doped and Sm^{3+}/Eu^{3+} co-doped barium molybdenum titanate (BMT) based host lattice Ba_3MoTiO_8.

XRD, SEM, and Energy Dispersive X-Ray Analysis (EDX) analysis have all been used to get the information relevant to structure and morphology. FT-IR studies were used to understand various functional groups present in the titled BMT phosphor. Diffuse Reflectance Spectral (DRS) studies were conducted to understand the band gap of Sm^{3+} and Sm^{3+}/Eu^{3+} co-doped BMT phosphors. The PL emission studies were conducted on Sm^{3+} and Sm^{3+}/Eu^{3+} co-doped BMT phosphors to understand the emission properties and color tunability possessed by the titled phosphor. Further PL decay studies were conducted to understand the energy transfer mechanism responsible for the enhancement of PL intensity and color tunability. The PL emission spectral information of Sm^{3+} and Sm^{3+}/Eu^{3+} co-doped BMT phosphors was further used to calculate the CIE chromaticity coordinates to understand the utility of the titled phosphors for w-LED applications.

2 Experimental method and characterization techniques used

The preparation of the BMT phosphor was done through the combustion method. In our previous work, we have reported the superiority of the combustion method used to prepare BMT phosphor because of relatively high luminescence efficiency, crystallinity, and better morphology [25]. This has prompted us to use the combustion method to prepare BMT phosphor co-doped with samarium and europium ions to study color tunability. The precursors like ammonium molybdate (CDH, 98%) and barium nitrate (Fisher Scientific, 99%) were dissolved in DI water in the stoichiometric ratio, individually as per the equation.

$$(105 - x - y)\ Ba(NO_3)_2 + 35\ C_{10}H_{14}O_5Ti + 5\ (NH_4)_6Mo_7O_{24} \times 4H_2O + 48\ C_2H_5NO_2 + 131\ H_2O + xSm(NO_3)_3 + yEu_2O_3 = 35\ Ba_3MoTiO_8 + 446\ CO_2 + 288\ NH_4.$$

At the same time, titanium (IV) oxyacetylacetonate (Sigma-Aldrich, 90%) was dissolved in methanol at 55 °C to obtain a clear solution. Subsequently, solutions for doping ions were prepared by adding Eu_2O_3 in HNO_3 (Sigma-Aldrich, 99.9%) at 75 °C and $Sm(NO_3)_3$ (Sigma-Aldrich, 99.9%) in DI water at room temperature, respectively. After this, all the above solutions were mixed together at 100 °C for 1 h. After homogeneous mixing, stoichiometric amount of glycine (Fisher Scientific, AR Grade) was added, and the mixture was stirred up continuously for 2 h. The obtained mixture was placed on a preheated hot plate at 500 °C for the dehydration process. As a result, the grey foamy powder was obtained after the release of a large number of gases. Finally, the foamy powder was crushed into the fine powder in an agate mortar, and the homogeneous powder was sintered at 1100 °C for 10 h to obtain a pure phase under normal conditions. After the sintering process, powder was grounded again for 15 min to make it fine and homogeneous. Figure 1 depicts the detailed steps involved in the synthesis process.

The phase identification and confirmation of all the as-synthesized BMT phosphors was determined by an X-ray diffractometer (Bruker D8 Advanced X-Ray Diffractometer) with Cu-Kα radiation (λ = 1.54 Å) in the range of 2θ = 20°–70°. To analyze the structural parameters, Rietveld refinement was done using FullProf Suite software. The surface morphology and elemental distribution were checked by SEM on a JEOL 7610F Plus operated at 5 kV. To determine the various vibrational functions and groups present in the system, FT-IR was performed by Perkin Elmer spectrum 2. The diffuse reflectance spectral (DRS) studies were conducted on a Jasco-made V-770 Spectrophotometer at room temperature. A Jasco FP-8300 spectrofluorometer was used to record the PL excitation and emission spectra with a Xenon lamp serving as the excitation source. On a Hameg Instruments HM 1507 digital oscilloscope operating at 150 MHz, PL decay curves were captured. The ocean optics setup was used to record the temperature-dependent PL experiments with a resolution of 0.1 nm under a Xenon lamp excitation source.

3 Results and discussion

3.1 Structural and morphological analysis

Figure 2(a) and (b) show the XRD patterns of un-doped, single-doped BMT: xSm^{3+} (x = 0.5, 1, 1.5, 2, and 2.5 mol%) and co-doped BMT: xSm^{3+}/yEu^{3+} (x = 1.5 mol%, y = 1, 2, 3, 4, 5, 6 mol%) phosphors along with standard JCPDS data (JCPDS No. 38-0254). From Fig. 2, it can be seen that all the diffraction patterns were in good agreement with the standard JCPDS patterns with rhombohedral crystal structure and space group R-3 m (166) without the formation of any secondary crystallite phase. This shows the successful incorporation of dopant ions into the host lattice and single-phase confirmation of all the phosphors. By zooming in on the main intense peak of the XRD data, it is found that there is some shifting in the peak position towards the higher angle side with the introduction of Sm^{3+} and Eu^{3+} ions in the host lattice when compared with the un-doped sample. This shifting may be caused by the difference in the ionic radii of the Ba^{2+} ions (ionic radii = 1.49 Å) in comparison to the dopant ions Sm^{3+} (ionic radii = 1.09 Å) and Eu^{3+}(ionic radii = 1.08 Å). Figure 3(a) and (b) shows the Rietveld refinement fitting for the xSm^{3+} (x = 1.5 mol%) and xSm^{3+}/yEu^{3+} (x = 1.5 mol%, y = 1 mol%) doped BMT phosphors using Full Proof suite software. In our earlier work, we performed Rietveld refinement on an un-doped BMT sample [23]. All the structural parameters extracted from the refinement fitting were listed in Table 1. The goodness of the fit (χ^2) value is less than

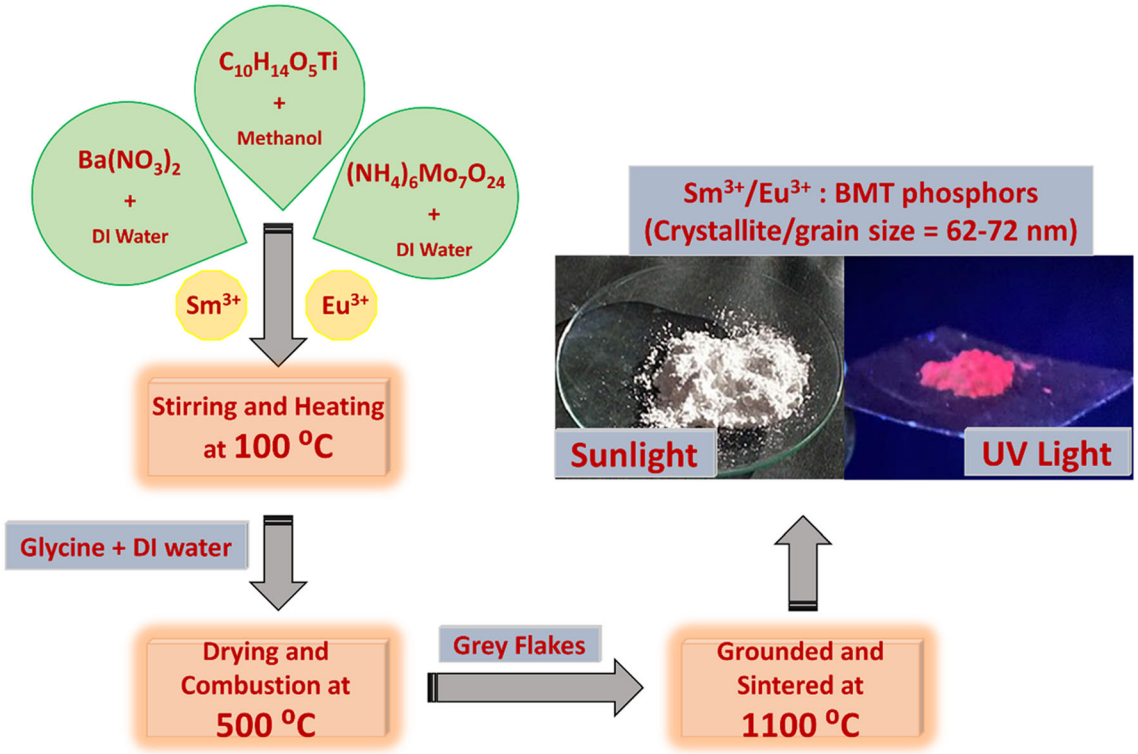

Fig. 1 Flow chart depicting synthesis steps involved in the combustion method

1, indicating no significant deviation in lattice parameters and the successful formation of single phase. The average crystallite size of the single and co-doped phosphors was calculated by the Debye–Scherrer formula given by:

$$D = \frac{s\lambda}{\beta_T \cos\theta},$$

where s, λ, β_T, and θ are shaping factor constant, the wavelength of X-rays, full-width at half maxima (FWHM), and diffraction angle of XRD peaks, respectively. Here D is the crystallite size. The crystallite size corresponding to the most intense peak calculated for single Sm^{3+} ion-doped phosphors lies in the 60–70 nm range, and for Sm^{3+}/Eu^{3+} co-doped phosphors, it lies in the range of 62–72 nm. As we know, the broadening of the XRD peak is due to the crystallite size in addition to the strain present in it. To calculate the lattice strain present in the crystal, a Williamson–Hall plot has been used using the equation [26]

$$\beta_T \mathrm{Cos}\theta = \frac{K\lambda}{D} + \varepsilon(4\mathrm{Sin}\theta).$$

The symbol ε represents the strain present in the lattice, and the other symbols have the exact same meaning as discussed above. A linear graph has been plotted between 4Sinθ and β_T Cosθ by considering the major peaks in the XRD data, as shown in Fig. 3(c) and (d). The slope of the fitted line gives the value of strain, and from the intercept value, we calculate the crystallite size. The average crystallite size for singly Sm^{3+} doped and Sm^{3+}/Eu^{3+} co-doped phosphors was found to be 98 nm and 88 nm, respectively. The value of strain was found in the range of 0.000170–0.000353 for Sm^{3+} doped phosphors, and for Sm^{3+}/Eu^{3+} co-doped phosphors, it lies in the range of 0.000267–0.0007.

Additionally, SEM and EDX have been performed to further investigate the microscopic morphology and elemental composition of the prepared phosphors. Figure 4(a) and (b) represent the SEM micrographs of single doped BMT: xSm^{3+}(x = 1.5 mol%) and co-doped BMT: xSm^{3+}/yEu^{3+} (x = 1.5 mol%, y = 1 mol%) phosphors. The particles of these phosphors are irregular in shape with much agglomeration. These irregularities in shape and size may be due to the unequal distribution of mass and temperature during the sintering as well as due to the

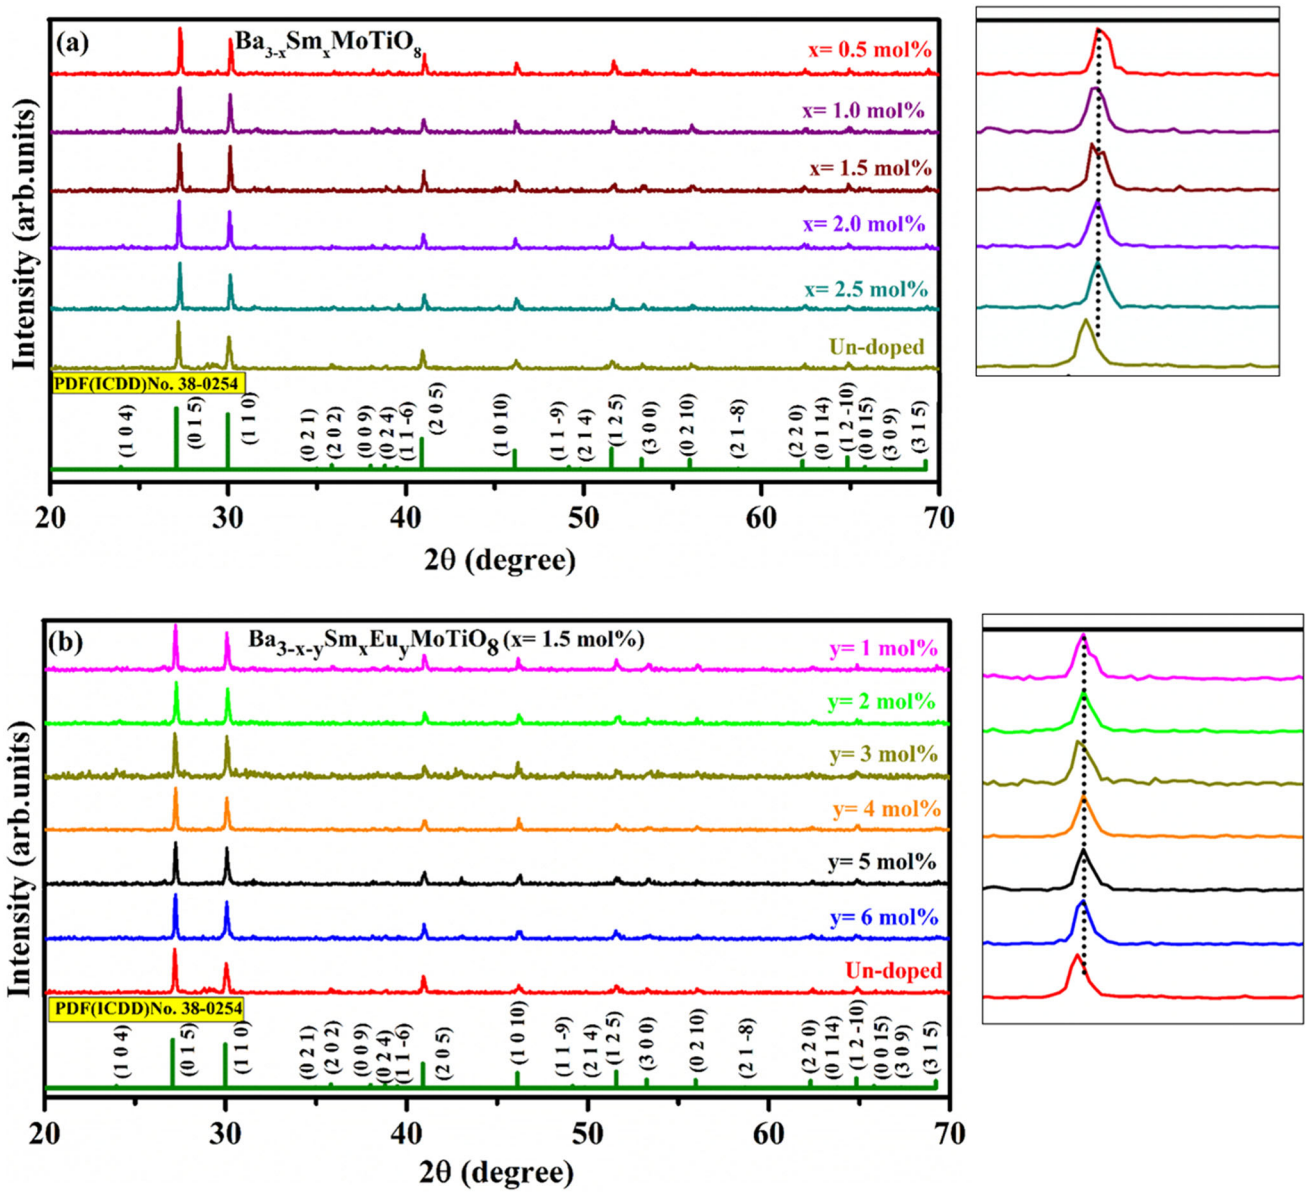

Fig. 2 (**a**), (**b**) XRD patterns of an un-doped, single doped BMT: xSm^{3+}(x = 0.5, 1.0, 1.5, 2.0 and 2.5 mol%) and co-doped BMT: xSm^{3+}/yEu^{3+} (x = 1.5 mol% and y = 1, 2, 3, 4, 5 and 6 mol%) phosphors with standard JCPDS

manual crushing of phosphor after sintering [27]. The size of particles for single-doped and co-doped phosphors are in the range of 0.5–5.0 μm and 0.1–6.0 μm respectively. Figure 4(c) and (d) demonstrate the corresponding EDAX images of these phosphors. It can be seen from both the EDX images that all elements are present in the phosphor lattice that have been used during synthesis.

Figure 5 shows the elemental mapping of co-doped BMT: xSm^{3+}/yEu^{3+} (x = 1.5 mol%, y = 1 mol%) phosphor. From the elemental mapping images, it was clear that barium, molybdenum, titanium, samarium, and europium elements were uniformly distributed in the particles, which shows the successful synthesis of phosphor.

3.2 FT-IR analysis

FT-IR spectra of un-doped, singly doped BMT: xSm^{3+} (x = 1.5 mol%) and co-doped BMT: xSm^{3+}/yEu^{3+} (x = 1.5 mol%, y = 1 mol%) phosphors were recorded in attenuated total reflectance mode (ATR), as shown in Fig. 6. The spectra were in the range 400–4000 cm^{-1} to analyse the different functional groups that are

present along with their stretching and bending vibrations. The infrared bands of all the phosphors occupy an almost similar position with or without doping. The absorption band at 530 cm^{-1} belongs to the stretching vibrations of Ti–O groups present in the system [22]. The bands at 678 and 818 cm^{-1} are due to the MoO_4^{2-} tetrahedrons ascribed to their Mo–O and Mo–O–Mo stretching vibrations [28, 29]. The bands at 1068 and 1421 cm^{-1} demonstrate C–N stretching and C=C stretching, respectively [30, 31]. The band at 1230 cm^{-1} describes the N–H bending absorption [32]. The two bands at 2897 and 2996 cm^{-1}

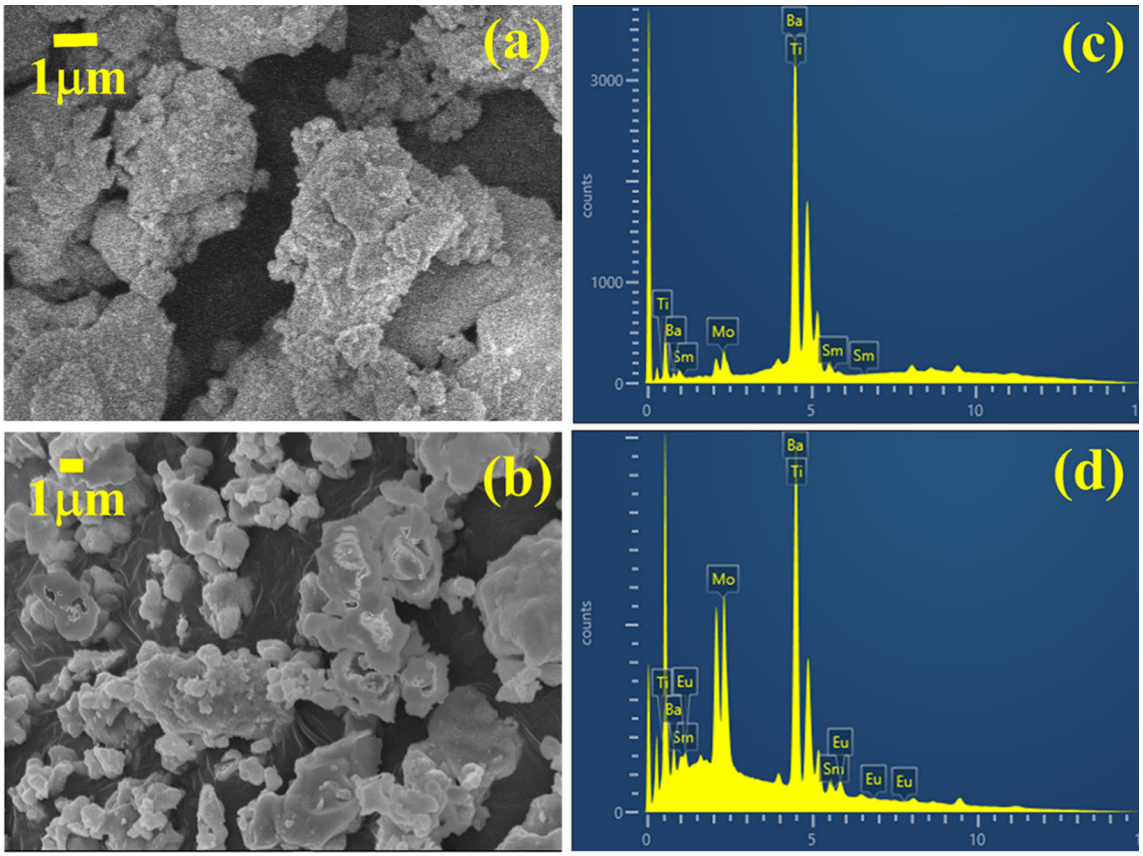

Fig. 4 Scanning electron microscope images (**a**), (**b**) of BMT: xSm^{3+} doped (x = 1.5 mol%) and BMT: xSm^{3+}/yEu^{3+} (x = 1.5 mol% and y = 1 mol%) co-doped phosphors and (**c**), (**d**) corresponding EDX images

represent C–H bonding [33]. The shortest absorption band at 3670 cm^{-1} can be assigned to the stretching mode of O–H groups in absorbed water molecules [34].

3.3 DRS spectra

Diffuse reflectance spectra were recorded for the BMT: xSm^{3+} (x = 0.5, 1, 1.5, 2 and 2.5 mol%) and co-doped BMT: xSm^{3+}/yEu^{3+} (x = 1.5 mol%, y = 1, 2, 3, 4, 5, 6 mol%) phosphors. To find the optical band gap, the Kulbelka–Munk function was applied to the DRS data given by equation [35]

$$F(R) = \frac{(1-R)^2}{2R} = \frac{A}{S}.$$

The Kulbelka–Munk function, reflectance coefficient, molar absorption coefficient, and scattering coefficient, respectively, are represented in this equation as F(R), R, A, and S. The relationship between the energy band gap (Eg) value and the absorption coefficient (α) was later determined using the Tau equation.

$$\alpha h\upsilon = C(h\upsilon - \mathrm{Eg})^n.$$

In this equation, n is a transition dependent constant with values of 1/2, 2, 1/3, and 3 for direct allowed, indirect allowed, direct forbidden, and indirect forbidden, respectively. Further, h stands for Planck's constant, C for an energy-independent constant and υ for the frequency of light.

Since F(R) is directly proportional to α, the above tauc equation becomes [36]

$$F(R)h\upsilon = C(h\upsilon - \mathrm{Eg})^n.$$

Now a graph was plotted between $[F(R)h\upsilon]^2$ vs. energy hυ for the n = 1/2 transition, as shown in Fig. 7. By extrapolating from the linear section of the figure, the intercept on the x-axis provides an approximation of the band gap value. The approximate band gap values for singly Sm^{3+} doped BMT phosphors lie in the range 3.3–3.5 eV, and for co-

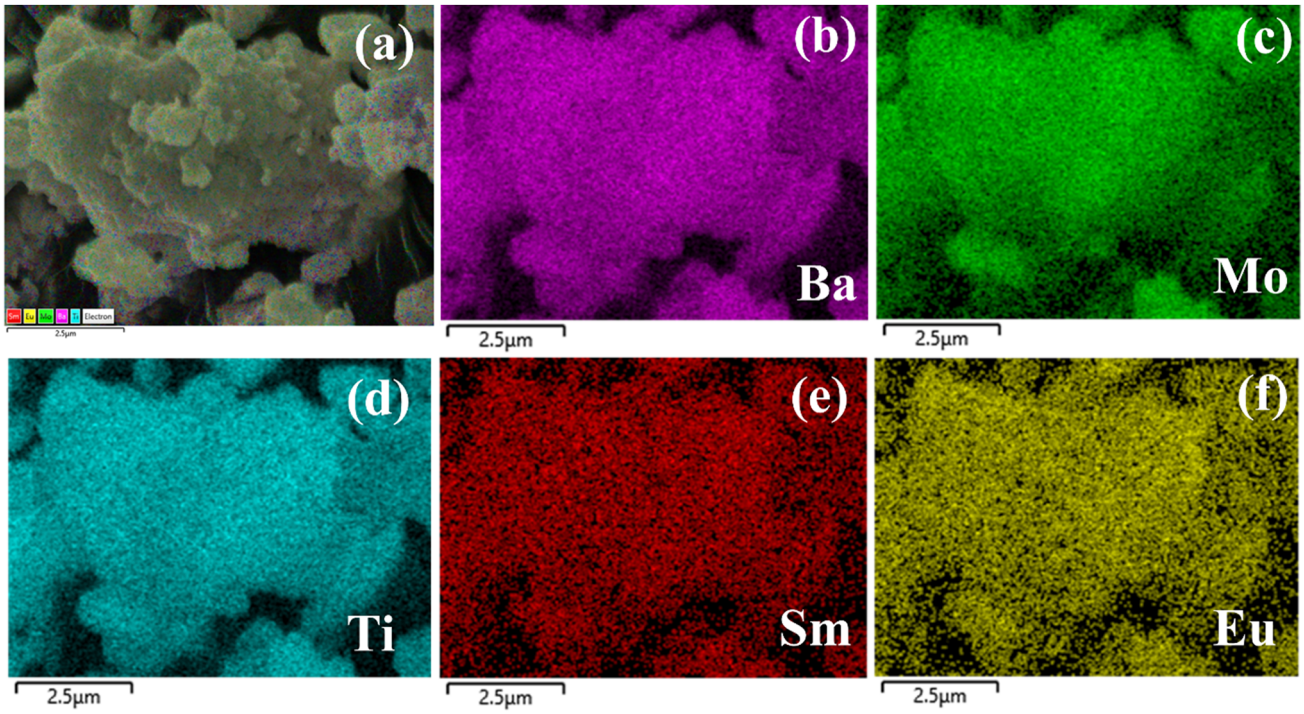

Fig. 5 Elemental mapping of BMT: xSm^{3+}/yEu^{3+} (x = 1.5 mol%, y = 1 mol%) co-doped BMT phosphor (**a**) mixed mapping (**b**–**f**) individual of Barium (Ba), Titanium (Ti), Molybdenum (Mo), Samarium (Sm) and Europium (Eu) elements

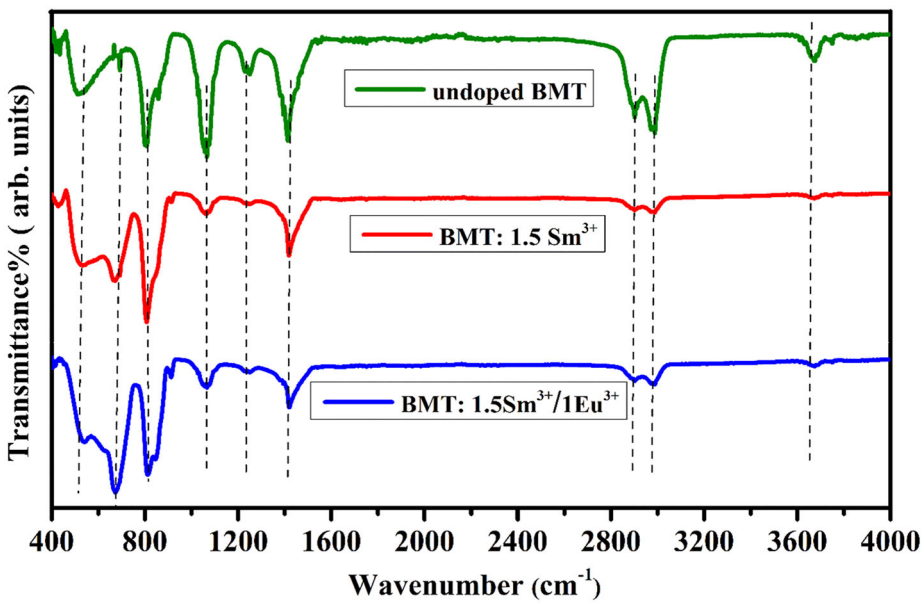

Fig. 6 FT-IR spectra of an undoped, xSm^{3+} doped(x = 1.5 mol%), and co-doped xSm^{3+}/yEu^{3+} (x = 1.5 mol%, y = 1 mol%) phosphors

doped BMT: Sm^{3+}/Eu^{3+} phosphors lie in the range 3.0–3.25 eV, respectively [37]. The band gap energy decreases with the addition of co-doping of Eu^{3+} ions. This results in more number of atoms getting excited to the upper states and thereby resulting a stronger emission when they are falling down to the lower energy states. The band gap values obtained in the present work are in consonance with the values reported for other phosphors doped with Sm^{3+} and Eu^{3+} ions [38, 39].

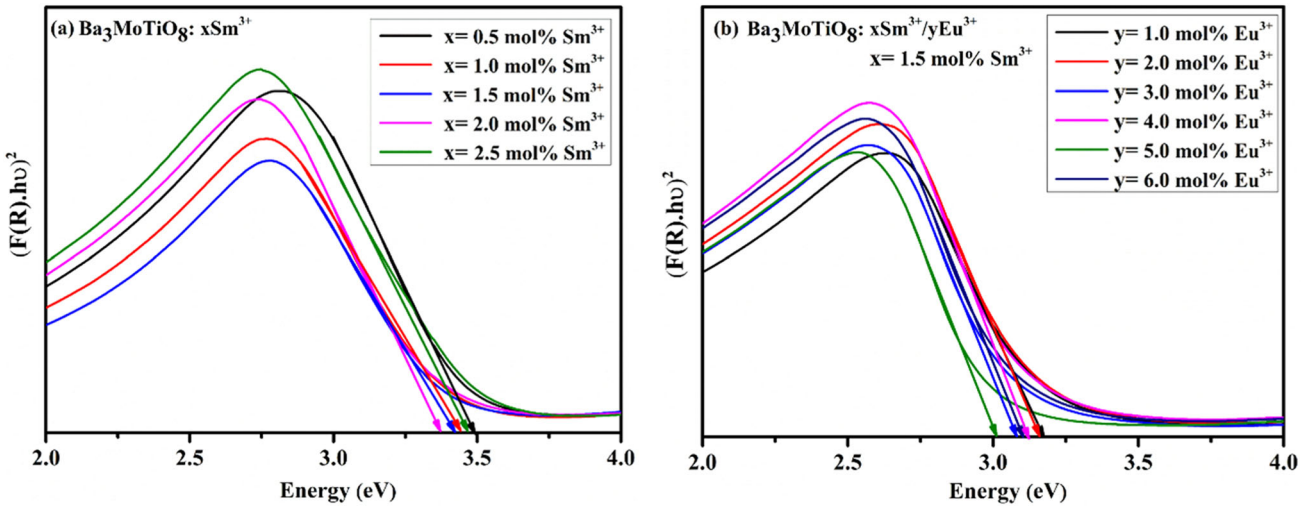

Fig. 7 $[F(R)hv]^2$ versus hν plot for optical band gap calculation of (**a**) BMT: xSm^{3+}(x = 0.5, 1.0, 1.5, 2.0 and 2.5 mol%) and (**b**) BMT: xSm^{3+}/yEu^{3+} (x = 1.5 mol% and y = 1, 2, 3, 4, 5 and 6 mol%) phosphors

3.4 PL studies

3.4.1 *PL studies of BMT: xSm^{3+}(x = 1.5 mol%) phosphor*

Figure 8(a) and (b) show the excitation spectrum and emission spectra of BMT: xSm^{3+}(x = 1.5 mol%) phosphor, respectively. A 596 nm emission wavelength was used to record the excitation spectra, which ranged from 325 to 500 nm. The spectrum comprises several peaks at 364, 381, 409, 421,442 and 465 nm corresponding to the transitions $^6H_{5/2} \rightarrow {}^4D_{3/2}$, $^6H_{5/2} \rightarrow {}^4D_{1/2}$, $^6H_{5/2} \rightarrow {}^4F_{7/2}$, $^6H_{5/2} \rightarrow {}^4M_{19/2}$, $^6H_{5/2} \rightarrow {}^4G_{9/2}$ and $^6H_{5/2} \rightarrow {}^4I_{11/2} + {}^4I_{13/2} + {}^4M_{15/2}$ respectively [21, 40–42]. Out of these peaks, the most intense peak in the excitation spectrum is at 409 nm, so we recorded the emission spectra for BMT: xSm^{3+}(x = 0, 1, 1.5, 2 & 2.5 mol%) series at this excitation wavelength. The emission spectra of this series recorded in the range of 540–700 nm comprise three bands at wavelengths 562, 596, and 643 nm corresponding to a transition from the excited state $^4G_{5/2}$ of Sm^{3+}ions to ground states $^6H_{5/2,}{}^6H_{7/2}$ and $^6H_{9/2}$ respectively [43, 44]. The intensity of emission peaks increases with Sm^{3+}ions concentration up to 1.5 mol%; beyond that, emission intensity decreases, which is attributed to the phenomenon of concentration quenching. Concentration quenching is the phenomenon in which if we increase the activator ions higher than a certain value, the number of non-radiative transitions rises through cross-relaxation processes and results in low PL intensity. In the present work, it was observed that, 1.5 mol% of Sm^{3+} ions produce concentration quenching as shown in Fig. 8(b). The most intense band at 596 nm wavelength corresponds to reddish–orange emission under UV excitation. So Sm^{3+} doped BMT phosphors can be used with cyan-emitting phosphors by coating them with UV LED as reddish–orange colour emitting devices, and by co-doping them with Eu^{3+} ions, they can be used to obtain pure red emission.

3.4.2 *PL studies of single doped Eu^{3+} and Sm^{3+}/Eu^{3+} co-doped BMT phosphors*

The PL excitation and PL emission spectra of BMT: yEu^{3+}(y = 1 mol%) phosphor were reported in Fig. 8(c) at λ_{em} = 615 nm and λ_{ex} = 395 nm, respectively. The excitation spectrum recorded in the range 300–550 nm comprises peaks at wavelengths 306, 360, 381, 395, 415, and 465 nm corresponding to the charge transfer band (CTB), $^7F_0 \rightarrow {}^5D_{4,}{}^7F_0 \rightarrow {}^5L_{7,}{}^7F_0 \rightarrow {}^5L_{6,}{}^7F_0 \rightarrow {}^5D_{3,}$ and $^7F_0 \rightarrow {}^5D_2$ transitions of Eu^{3+} ions respectively [45]. The emission spectrum was recorded using the most intense peak of the excitation spectrum (λ_{ex} = 395 nm) in the range of 550–750 nm. The emission spectrum consists of five peaks at wavelengths 579, 596, 615, 653, and 701 nm corresponding to the transition of Eu^{3+} ions from excited state $^5D_0$ to $^7F_{0,}{}^7F_{1,}{}^7F_{2,}{}^7F_{3,}$ and $^7F_4$ states, respectively [46]. The transition $^5D_0 \rightarrow {}^7F_1$ is a magnetic dipole (MD) in nature, whereas $^5D_0 \rightarrow {}^7F_2$ is an electric dipole (ED). In the emission graph, if the ED transition is ruling over the MD transition, that means the

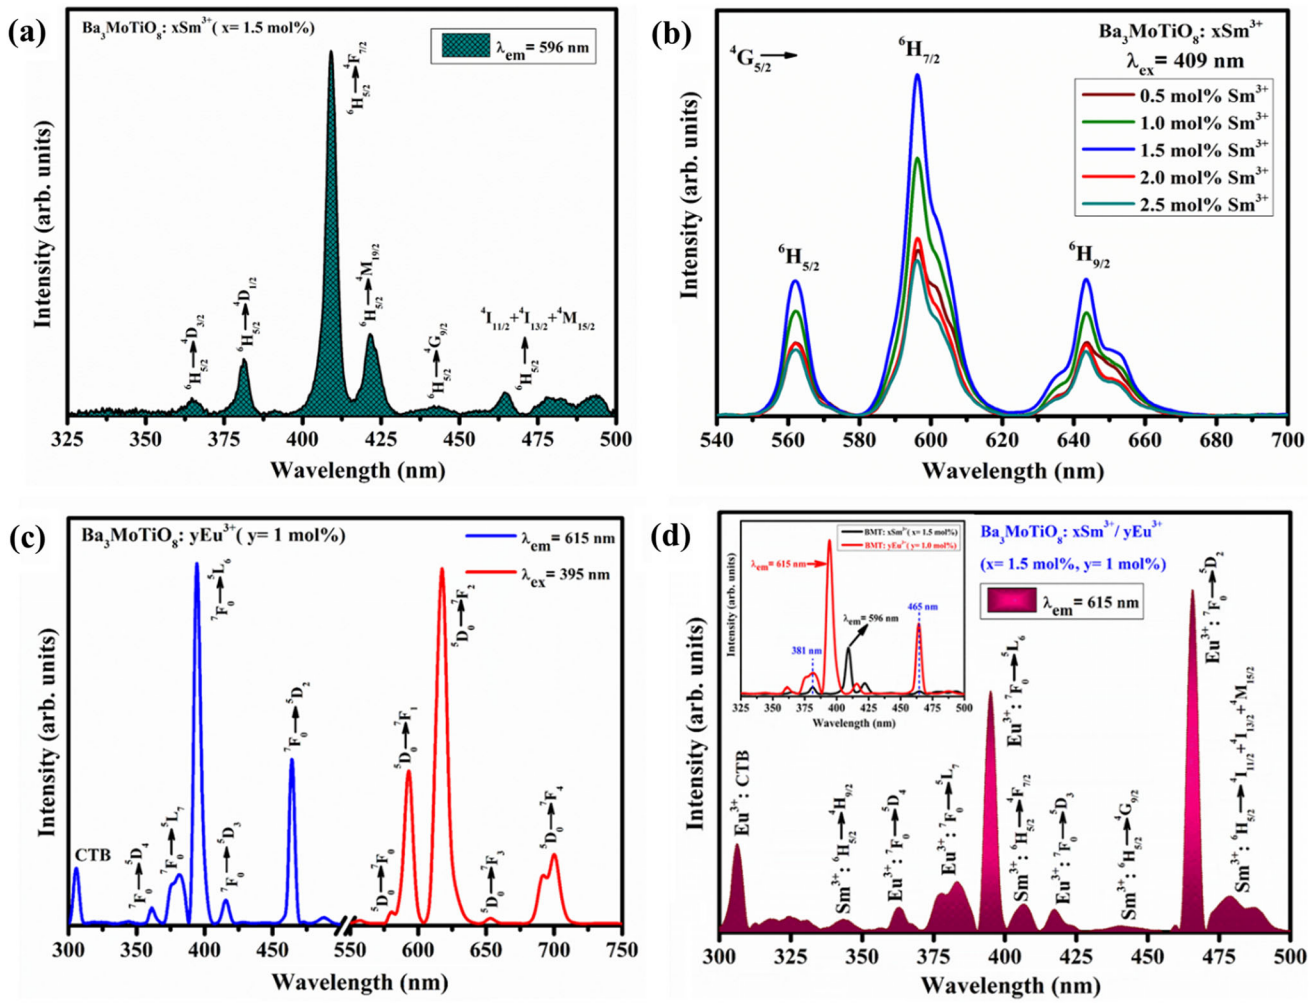

Fig. 8 (**a**) PL excitation spectrum of BMT: xSm^{3+}(x = 1.5 mol%) under 596 nm emission (**b**) emission spectra of BMT: xSm^{3+}(x = 0.5,1.0,1.5,2.0 and 2.5 mol%) phosphors under 409 nm excitation wavelength, (**c**) PL excitation and emission spectrum of BMT: yEu^{3+}(y = 1.0 mol%) phosphor under 615 nm emission and 395 nm excitation wavelengths, respectively and (**d**) PL excitation spectrum of BMT: xSm^{3+}/yEu^{3+}(x = 1.5 mol%, y = 1 mol%) phosphor under 615 nm emission wavelength (inset figure shows the overlapped excitation spectrums of singly Sm^{3+} doped and Sm^{3+}/Eu^{3+} co-doped phosphors at emission wavelengths 596 and 615 nm respectively)

Eu^{3+} ion occupies anti-inversion symmetry and gives red emission corresponding to transition $^5D_0 \rightarrow {}^7F_2$ with high colour purity [47].

The PL excitation spectrum of BMT: xSm^{3+}/yEu^{3+} (x = 1.5 mol%, y = 1 mol%) co-doped phosphor is shown in Fig. 8(d) in the wavelength range 300–500 nm by keeping λ_{em} = 615 nm. In the spectrum, the highest number of peaks are due to Eu^{3+} ions, and some peaks are due to Sm^{3+} ions. The Sm^{3+} ion peaks at 343, 406, 440, and 480 nm are due to the transitions $^6H_{5/2} \rightarrow {}^4H_{9/2}$, $^6H_{5/2} \rightarrow {}^4F_{7/2}$, $^6H_{5/2} \rightarrow {}^4G_{9/2}$ and $^6H_{5/2} \rightarrow {}^4I_{11/2} + {}^4I_{13/2} + {}^4M_{15/2}$ respectively. Eu^{3+}ion peaks are present at 306, 362, 382, 395, 417, and 465 nm, corresponding to transitions CTB, $^7F_0 \rightarrow {}^5D_4, {}^7F_0 \rightarrow {}^5L_7, {}^7F_0 \rightarrow {}^5L_6, {}^7F_0 \rightarrow {}^5D_3$ and $^7F_0 \rightarrow {}^5D_2$ respectively. The inset of Fig. 8(d) shows the excitation spectrum of BMT: xSm^{3+} (x = 1.5 mol%) and BMT: yEu^{3+} (y = 1 mol%) by keeping the emission wavelengths at 596 and 615 nm, respectively. By taking into account this inset of Fig. 8(d), the emission spectra of BMT: xSm^{3+}/yEu^{3+} (x = 1.5 mol%, y = 1, 2, 3, 4, 5, and 6 mol%) co-doped phosphors were recorded at three different excitation wavelengths (381, 409 and 465 nm). Here, 409 nm is the Sm^{3+} ion (sensitizer) excitation wavelength, and 381 and 465 nm are the overlapping wavelengths of Sm^{3+} and Eu^{3+} ions.

Figure 9(a), (b) and (c) show the emission spectra of co-doped BMT: xSm^{3+}/yEu^{3+} (x = 1.5 mol%, y = 1, 2, 3, 4, 5 and 6 mol%) phosphors at λ_{ex} = 381, 409, and 465nm respectively. The emission spectra at λ_{ex} = 381 nm show seven peaks. Out of these seven peaks, two peaks at 562 nm ($^4G_{5/2} \rightarrow {}^6H_{5/2}$) and 644 nm ($^4G_{5/2} \rightarrow {}^6H_{7/2}$) correspond to the Sm^{3+} ion transitions, and the other five peaks at 581 ($^5D_0 \rightarrow {}^7F_0$), 594 ($^5D_0 \rightarrow {}^7F_1$), 615 ($^5D_0 \rightarrow {}^7F_2$), 652 ($^5D_0 \rightarrow {}^7F_3$) and 700 nm ($^5D_0 \rightarrow {}^7F_4$) due to the Eu^{3+} ion transitions [48]. The spectra given in Fig. 9(a), (b) and (c) show that with increasing concentration in Eu^{3+} ions, the emission intensity of Eu^{3+}ion peaks increase while Sm^{3+} ion peak intensity decreases. The emission spectra given in Fig. 9(b) were recorded at λ_{ex} = 409 nm. With an increased concentration of Eu^{3+} ions, the emission intensity of Sm^{3+} peaks decreased, and Eu^{3+} ion peaks increased up to 4 mol%. This confirms the energy transfer mechanism of Sm^{3+} ions to Eu^{3+} ions. After a 4 mol% concentration of Eu^{3+} ions, the energy transfer mechanism becomes constant, i.e., it attains saturation. This may be due to the phenomenon of concentration quenching. Figure 9(d) shows the increase in Red to Orange (R/O) emission intensity with different Eu^{3+} ion concentrations at λ_{ex} = 409 nm. The R/O ratio is increasing up to 4 mol% concentration of Eu^{3+} ions. Increasing R/O ratio is a clear indication of energy transfer from Sm^{3+} to Eu^{3+} ions [49]. To explain that energy transfer mechanism via multipolar interaction, Dexter's formula, along with Reisfeld's approximation, was applied as [50].

$$\frac{\eta_0}{\eta} \propto C^{n/3},$$

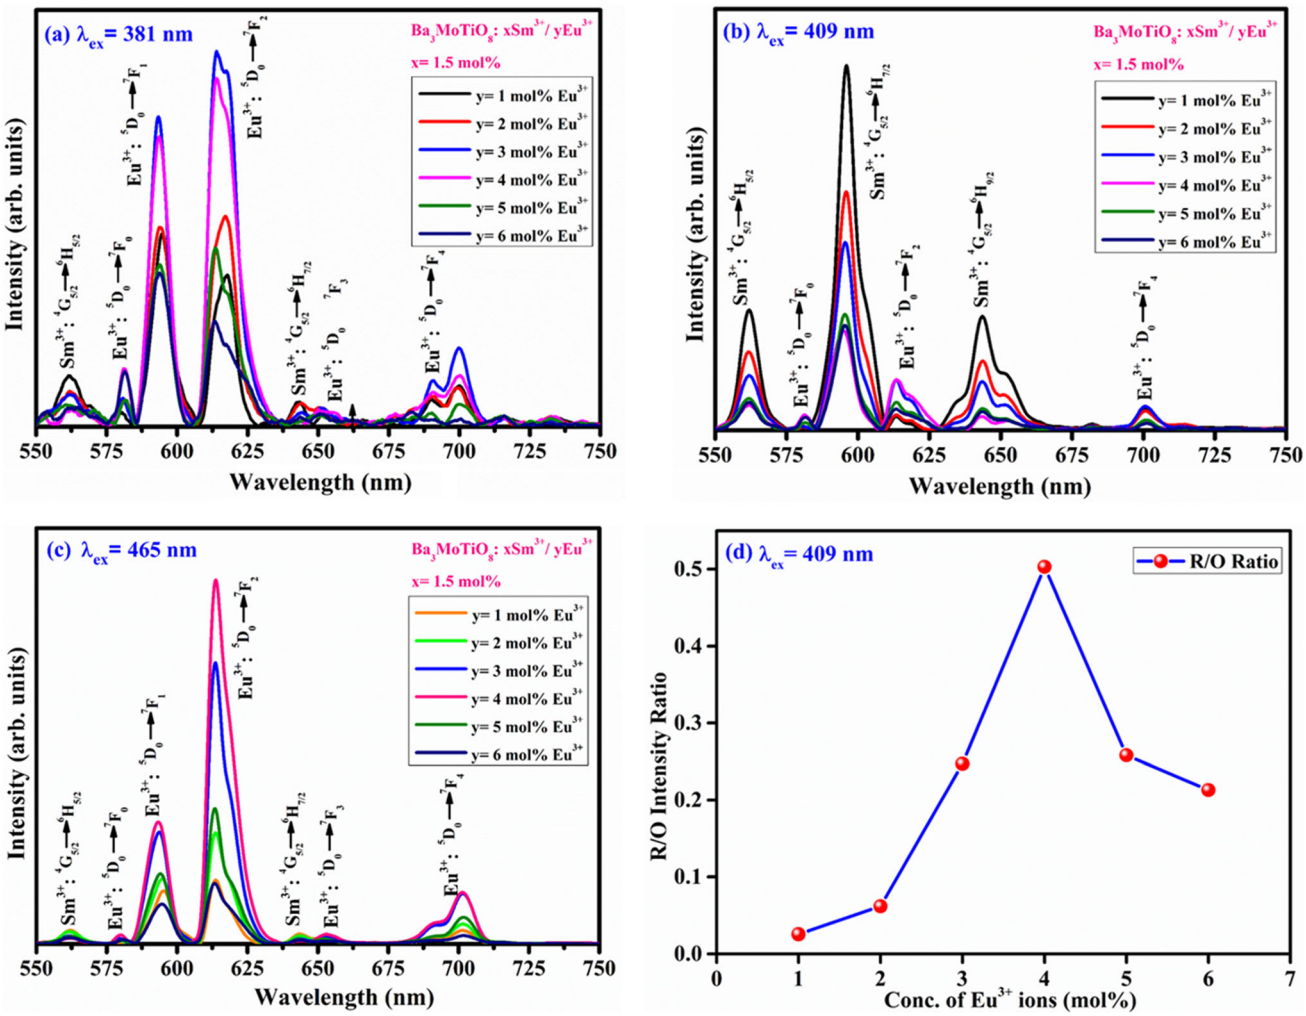

Fig. 9 PL emission spectra of BMT: xSm^{3+}/yEu^{3+} (x= 1.5 mol%, y= 1, 2, 3, 4, 5 and 6 mol%) co-doped phosphors under excitation wavelengths (**a**) 381 nm, (**b**) 409 nm and (**c**) 465 nm respectively and (**d**) plot of R/O ratio vs conc. of Eu^{3+} ions under l_{ex}= 409 nm

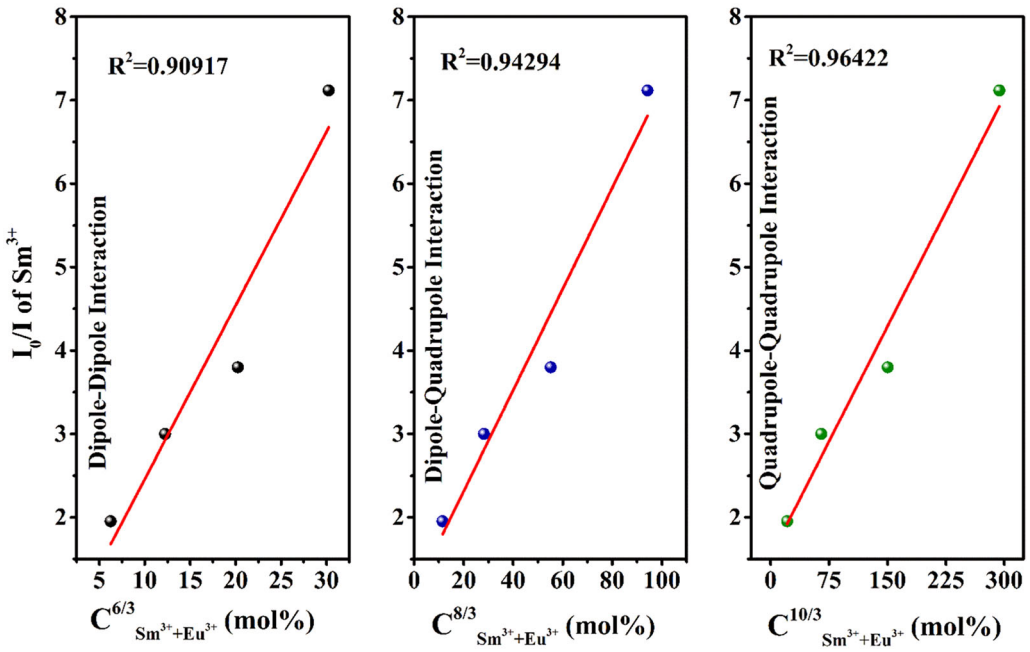

Fig. 10 Variation of I_{SM}/I_{SU} of Sm^{3+} ion w.r.t. $C^{6/3}$, $C^{8/3}$ and $C^{10/3}$ for BMT: xSm^{3+}/yEu^{3+} (x= 1.5mol%, y= 1, 2, 3, 4, 5 and 6 mol%) co-doped phosphors under 409 nm excitation wavelength

where η_0 and η represent the luminescent quantum efficiencies of Sm^{3+} ions without Eu^{3+} ion doping and with Eu^{3+} ion doping, respectively, C is the sum of the concentration of activator (Eu^{3+}) and sensitizer (Sm^{3+}) ions, and n is a number that indicates the type of multipolar interaction (n = 6, 8 and 10 for dipole–dipole, dipole–quadrupole, and quadrupole–quadrupole interaction, respectively). The ratio of luminescence intensities can be used to roughly calculate the ratio of quantum efficiencies [51, 52].

$$\frac{I_{SM}}{I_{SU}} \propto C^{n/3},$$

here I_{SM} is the luminescence emission intensity for the Sm^{3+} ion-doped sample, and I_{SU} is the luminescence emission intensity for the Sm^{3+}/Eu^{3+}co-doped sample. A graph was plotted between I_{SM}/ I_{SU} versus $C^{n/3}$ by taking n = 6, 8, and 10 under λ_{ex} = 409 nm in Fig. 10. The best linear regression was found in the case of n = 10, which shows that quadrupole-quadrupole interaction is responsible for energy transfer mechanism from Sm^{3+} to Eu^{3+} ions [42].

Figure 11 shows the energy level diagram of Sm^{3+} and Eu^{3+} ions to display the energy transfer mechanism between these two ions. There is a very small energy difference between the energy level $^4G_{5/2}$ of the Sm^{3+} ion and the $^5D_0$ level of the Eu^{3+} ion. Due to this, the Sm^{3+} ion can act as an efficient sensitizer for Eu^{3+} ions [53].

3.5 PL decay studies

The PL decay curves of BMT: xSm^{3+}/yEu^{3+} (x = 1.5 mol%, y = 1, 2, 3, 4, 5, and 6 mol%) phosphors excited under a 409 nm wavelength have been shown in Fig. 12. The PL decay curves show best fitting for a non-linear bi-exponential function given by [40, 54]-

$$I = I_0 + A_1 exp.\left(\frac{-t}{\tau_1}\right) + A_2 exp.\left(\frac{-t}{\tau_2}\right).$$

where I_0 and I are the luminescence intensities at t = 0 and some moment of time t, respectively. For bi-exponential fitting, A_1 and A_2 are fit constants, while τ_1 and τ_2 are the rapid and slow decay components, respectively. The average lifetime values for bi-exponential curve fitting given by [21, 55].

$$\tau_{avg.} = \frac{A_1\tau_1^2 + A_2\tau_2^2}{A_1\tau_1 + A_2\tau_2}.$$

The average lifetime values of the co-doped BMT phosphors are listed in Table 2 [40, 56, 57]. The lifetime values of the Sm^{3+}/Eu^{3+} co-doped BMT phosphors initially decrease up to 4 mol% of Eu^{3+} ions

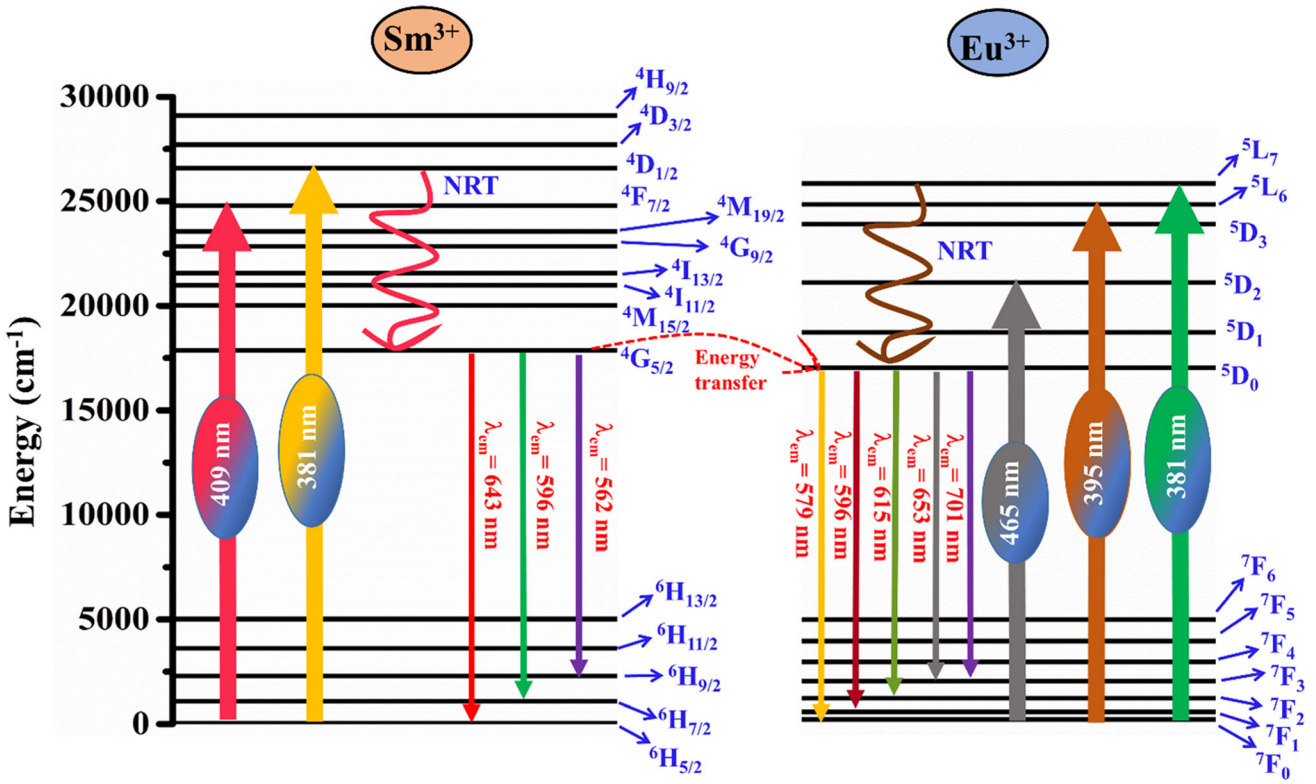

Fig. 11 Schematic energy level diagram of Sm^{3+} and Eu^{3+} ions and their energy transfer mechanism

and reach saturation beyond. This indicates energy transfer from a donor (Sm^{3+} ions) to an acceptor (Eu^{3+}) ion, up to 4 mol% of Eu^{3+} ions in the BMT phosphors. This result is in consonance with the information given by the PL spectral data of Sm^{3+}/Eu^{3+} co-doped BMT phosphors. The PL intensity of the co-doped BMT phosphor increases up to 4 mol% of Eu^{3+} ion concentration and decreases further [47, 56]. After that concentration, energy transfer saturates and results in an intensity decrement in the PL spectra due to the phenomenon of concentration quenching. As a result of it, lifetime decay curve behaviour also changes.

3.6 Temperature-dependent PL studies

Thermal stability is an important parameter for phosphor utilisation in SSL and wLED applications. To check the thermal stability of BMT: xSm^{3+}/yEu^{3+} (x = 1.5 mol%, y = 4 mol%) co-doped phosphor, temperature-dependent PL spectra have been recorded by taking the 409 nm excitation wavelength. Figure 13(a) shows the PL spectral curves by varying the temperature from 303 to 453 K. With variation in temperature, a decrease in the luminescence intensity of the phosphor has been observed without any change in the emission profile. This decrement in intensity may be due to the thermal quenching effect, which increases the non-radiative electronic transitions and results in low luminescence intensity. Up to the 423 K, the phosphor retains approximately 65% of its luminescence intensity, showing the thermal stability of this phosphor. The activation energy of the co-doped phosphor can be calculated using this equation [51].

$$I_T = \frac{I_0}{1 + C\,exp.\left(\frac{-E}{K_B T}\right)}.$$

where I_0 and I_T represent the luminescence intensities at room temperature and at a certain temperature, respectively. Here, C is an equation constant. Figure 13(b) shows a graph plotted between $\ln(I_0/I_T - 1)$ and $1/K_BT$, and linear fitting in this plot gives the value of the slope. The activation energy (ΔE = 0.306) calculated from the slope was compared with the

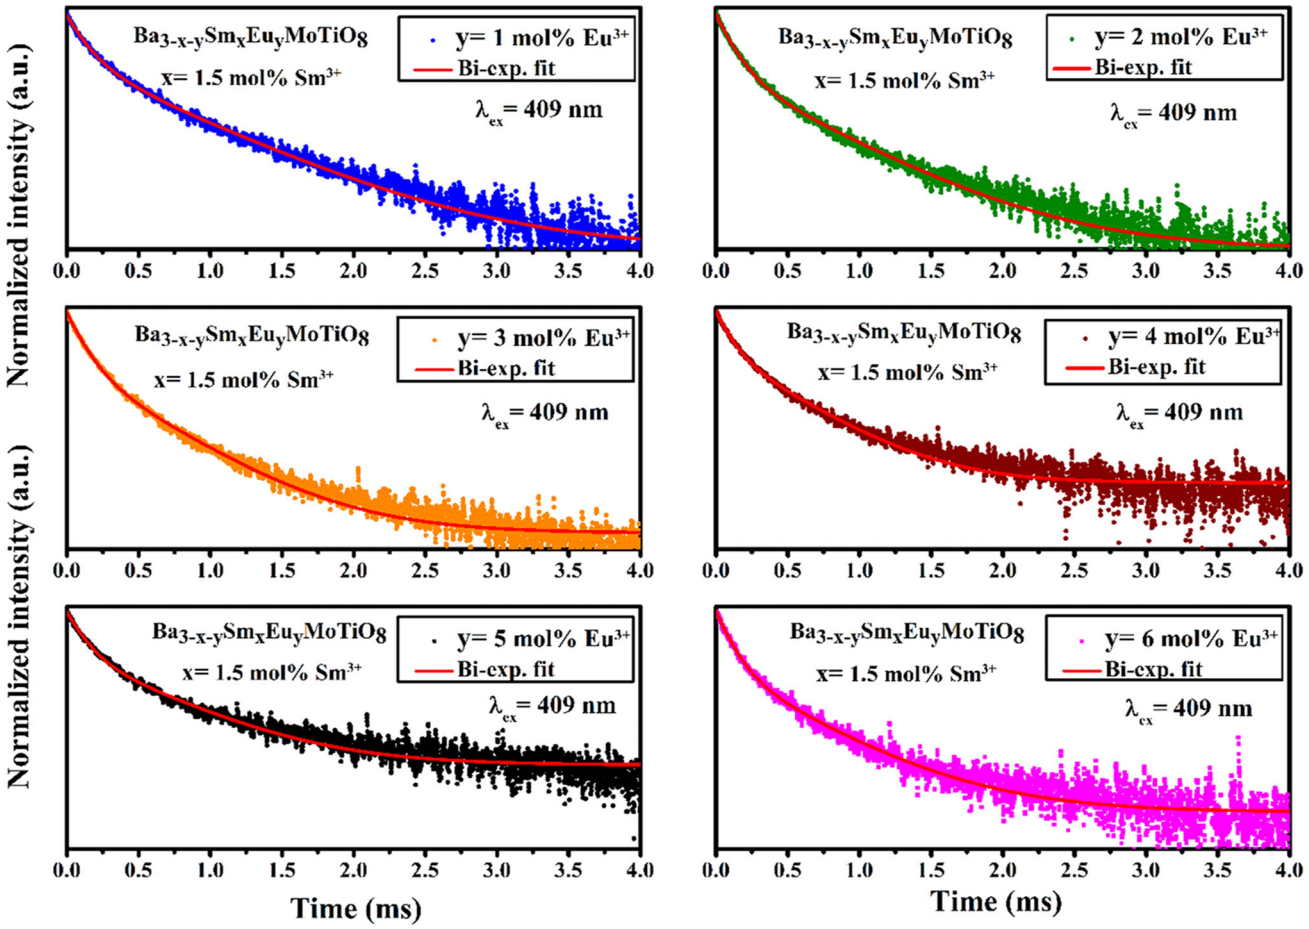

Fig. 12 PL lifetime curves of BMT: xSm^{3+}/yEu^{3+} (x=1.5 mol% and y=1, 2, 3, 4, 5 and 6 mol%) phosphors under 409 nm excitation

Table 2 Lifetime decay values of BMT: xSm^{3+}/yEu^{3+}(x = 1.5 mol%, y = 1,2,3,4,5 and 6 mol%) co-doped phosphors for λ_{ex} = 409 nm

Sample ID (Sm^{3+}/Eu^{3+}series) (mol%)	Lifetime values (ms)
y = 1	0.60 References [40, 56, 57].
y = 2	0.448
y = 3	0.257
y = 4	0.205
y = 5	0.273
y = 6	0.311

previously reported work and showed the good thermal stability of the co-doped phosphor [58].

3.7 CIE performance

Using PL emission spectral data, CIE coordinates were determined for the optimised single- and co-doped BMT phosphors, as shown in Fig. 14. The CIE coordinates for the optimised single Sm^{3+} ion (1.5 mol% concentration) doped BMT phosphor were (0.582, 0.416) under the 409 nm excitation wavelength, which lie in the orange- reddish region. CIE co-ordinates for the BMT: xSm^{3+}/yEu^{3+} (x = 1.5 mol%, y = 4 mol%) phosphor were calculated to be (0.632, 0.36), (0.598, 0.40) and (0.650, 0.349) under 381 nm, 409 nm, and 465 nm excitation wavelengths,

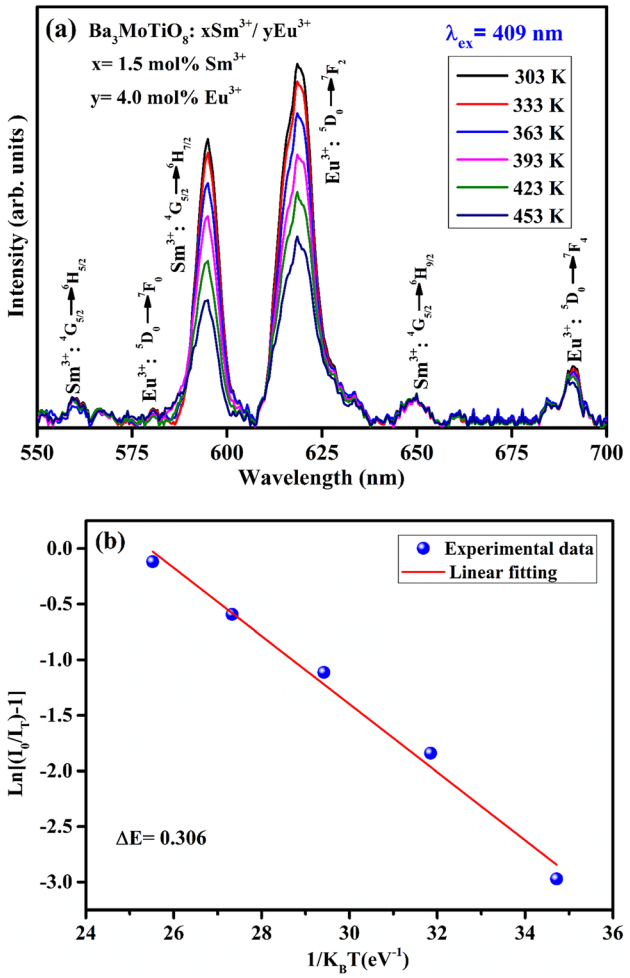

Fig. 13 Temperature-dependent PL emission spectra (**a**) of BMT: xSm^{3+}/yEu^{3+} (x= 1.5 mol%, y= 1, 2, 3, 4, 5 and 6 mol%) co-doped phosphors under excitation wavelengths 409 nm and (**b**) graph of $Ln(I_0/I_T-1)$ vs. $1/K_BT$ for activation energy

respectively. All the CIE coordinates for co-doped phosphors lie in the pure red region.

4 Conclusion

A series of singly Sm^{3+} doped BMT: xSm^{3+} (x = 0.5, 1, 1.5, 2 and 2.5 mol%) and co-doped BMT: xSm^{3+}/yEu^{3+} (x = 1.5 mol%, y = 1, 2, 3, 4, 5 and 6 mol%) phosphors were successfully synthesized by combustion method. The single-phase confirmation of these singly doped and co-doped phosphors was done by XRD patterns. All the phosphors show sharp XRD peaks without any impurities. Through SEM, morphological analysis has been performed, and particle size was calculated to be in the micrometer range. All the elements were uniformly distributed over the surface of the crystal, and that has been confirmed by EDX. FT-IR spectra recorded for an undoped, single Sm^{3+} doped, and Sm^{3+}/Eu^{3+} co-doped phosphors show similar vibrational and absorption bands. The optical band gap obtained from the DRS study lies in the range of 3.0–3.5 eV for all the concentrations of Sm^{3+} and Sm^{3+}/Eu^{3+} co-doped phosphors. PL spectra recorded under the 409 nm excitation wavelength for the singly Sm^{3+} ion doped phosphors show reddish-orange emission at the 596 nm wavelength, corresponding to transition $^4G_{5/2} \rightarrow {}^6H_{7/2}$. Sharp red emission at 615 nm corresponding to transition $^5D_0 \rightarrow {}^7F_2$ is visible in PL spectra for co-doped BMT phosphors that were taken at three distinct excitation wavelengths (409, 381, and 465 nm). The intensity of the Eu^{3+} peaks increases with an increase in Eu^{3+} ion concentration, while the Sm^{3+} peaks decrease under the 409 nm excitation wavelength, according to PL spectral analysis of co-doped phosphors. This shows the energy transfer mechanism from Sm^{3+} ions to Eu^{3+} ions in the co-doped phosphors. Quadrupole–quadrupole interaction is the basis for this energy transfer process, according to Dexter's theory applied to it. CIE coordinates calculated for optimized single Sm^{3+} ion-doped phosphors lie in the reddish–orange region, and for co-doped phosphors lie in the red region, demonstrating the energy transfer induced colour tunable behaviour from the reddish-orange to red region, respectively. These studies show the application of prepared phosphors in orange and red color-emitting LED devices.

Acknowledgements

The Delhi Technological University provided the facilities required to enable the current research endeavour, for which the authors are quite grateful. Additionally, we would like to express our gratitude to Dr. Manju Srivastava and Dr. Shyama Prasad of the Chemistry Department at the Dayalbagh Educational Institute of the Deemed University of Agra for providing all the assistance necessary to take FESEM images of the samples and record the EDAX data.

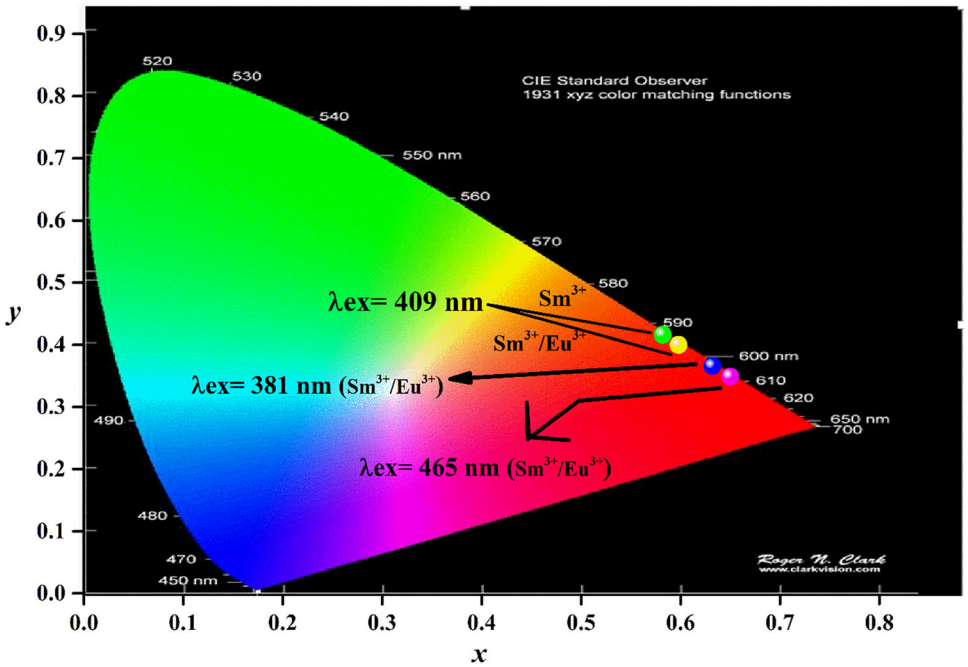

Fig. 14 CIE plot of optimised single Sm^{3+} doped (under 409 nm excitation) and Sm^{3+}/Eu^{3+} co-doped phosphors (under 381, 409, and 465 nm excitation), respectively

Author contributions

PR: experimental, calculations, analysis, writing. ASR: work plan, validation of results, manuscript corrections.

Funding

One of the author Pooja Rohilla is thankful to the Delhi Technological University for providing Senior Research Fellowship (SRF) to support this research work.

Data availability

The data that support the findings of this study are available on request from the corresponding author Prof. A.S. Rao. The data are not publicly available due to restrictions, e.g., their containing information that could compromise the privacy of research participants.

Declarations

Competing interest The authors declare that they have no known competing financial interests or personal relationships that could have appeared to influence the work reported in this paper.

ABSTRACT

Copper zinc tin sulfide solar cell (CZTS), Cu_2ZnSnS_4-based solar cells have shown promising conversion efficiency because of their ease of variation in configurations. In this work, the architecture of a ZnO–Al/i–ZnO/n–CdS/CZTS/Mo solar cell was optimized by using Silvaco Atlas simulation software. In this simulation study, the thickness and defect density of the CZTS layer has been varied to achieve the highest efficiency of 26.58%, with Isc = 36.64 A and Voc = 0.909 V at a defect density of 1.8×10^{12} cm^{-3}. Increase in the layer thickness of CZTS improves the photon absorption and cell efficiency. This study has evidenced the impact of defect density on the absorber layer, including photo-generation rate, recombination rate, and solar cell efficiency. By optimizing the device parameters, it has achieved a fill factor of 79.74% under AM 1.5 illumination, demonstrating the potential for low-cost, highly efficient CZTS solar cells.

K. C. Devendra and Deb Kumar Shah have contributed equally to this work.

1 Introduction

In recent decades, human energy consumption has dramatically increased due to rapid scientific and technological advancements. This increase is primarily fueled by our reliance on finite fossil fuels, such as coal, oil, and natural gas, to power our homes, businesses, and transportation infrastructure [1, 2]. However, burning these fuels produces large volumes of carbon dioxide and other greenhouse gases that contribute to global warming [3–7]. Consequently, there has been a global push to transition to cleaner, energy sources such as solar, wind, hydropower, capacitors, fuel cell, batteries, hydrogen, etc., which are abundant, widely accessible, and have a significantly smaller carbon footprint [8–20]. To this end, researchers have focused on developing new solar energy systems that are highly efficient, require less investment, and emit less pollution [21–23]. Among these, thin-film solar cells have generated immense interest among researchers due to their promising potential as a renewable energy technology. In particular, the development of highly efficient absorber materials for solar energy has been a key area of innovation [24–26].
