PREFACE

This is the **One Hundred Thirty Eight** Issue of Current Awareness Bulletin started by Delhi Technological University, Central Library. The aim of the bulletin is to compile, preserve and disseminate information published by the faculty, students and alumni for mutual benefits. The bulletin also aims to propagate the intellectual contribution of Delhi Technological University (DTU) as a whole to the academia.

The bulletin contains information resources available in the internet in the form of articles, reports, presentations published in international journals, websites, etc. by the faculty and students of DTU. The publications of faculty and student which are not covered in this bulletin may be because of the reason that the full text either was not accessible or could not be searched by the search engine used by the library for this purpose.

The learned faculty and students are requested to provide their uncovered publications to the library either through email or in CD, etc. to make the bulletin more comprehensive.

This issue contains the information published during **June, 2023**. The arrangement of the contents is alphabetical. The full text of the article which is either subscribed by the university or available in the web is provided in this bulletin.

Central Library

CONTENTS

1. A Comparison of Transfer Learning Inspired CNN Architectures for 2D Image Workout Recognition, ***7.Aman Rehman***, ***3.Shailender Kumar*** and ***8.Lakshya Verma***, CSE, DTU

2. A Fractional-Order Meminductor Emulator with Applications in Chaotic Oscillator, Shireesh Kumar Rai, ***7.1.Bhawna Aggarwal*** and Rupam Das, Electronics, DTU

3. A Graded Index Hybrid Photonic Crystal Fiber for Supercontinuum Generation using AsSe2- As2S5, ***6.Drishti Singh Tomer*** and ***3.Ajeet Kumar***, A Physics, DTU

4. A lightweight convolutional swin transformer with cutmix augmentation and CBAM attention for compound emotion recognition, ***6.Nidhi*** and ***3.Bindu Verma***, IT, DTU

5. A Machine Learning and Augmented Reality based Framework for Multilingual Product Identification in Retail using Mobilenets and Vuforia, ***3.Geetanjali Bhola***, ***8.Amogh Bansal***, ***8.Divij Aggarwal*** and ***8.Gagan Kishor Upadhyay***, IT, DTU

6. A Metaheuristic Approach based Feasibility Assessment & Design of Solar, Wind and Grid Powered Charging of Electric Vehicles, Fayez Alanazi, ***6.1.Mohd Bilal***, Ammar Armghan and Md Reyaz Hussan, Electrical, DTU

7. A metasurface based close-proximity two-port circularly polarized MIMO antenna for mid-band sub-6 GHz 5G applications, ***6.Suresh Angadi***, ***3.Yashna Sharma***, ***3.N.S. Raghava*** and Thennarasan Sabapathy, ECE, DTU

8. A Novel Enhancement Mode GaN HEMT with MIS and p-GaN structure, ***6.Tanvika Garg*** and ***3.Sumit Kale***, Electronics, DTU

9. A novel nature-inspired nutcracker optimizer algorithm for congestion control in power system transmission lines, Vivek Kumar, R Narendra Rao, ***3.Ajendra Singh***, Vineet Shekher, Kaushik Paul, Pampa Sinha, Thamer AH Alghamdi and Almoataz Y Abdelaziz, Electrical, DTU

10. A novel software defect prediction model using two-phase grey wolf optimisation for feature selection, ***3.Ruchika Malhotra*** & ***6.Kishwar Khan***, Software Engineering, DTU

11. A Single Bitline Highly Stable, Low Power With High Speed Half-Select Disturb Free 11T SRAM Cell, ***6.LOKESH SONI*** and ***3.NEETA PANDEY***, Electronics, DTU

12. Adaptive control strategy for isolated renewable energy-based generation system with intermittency, Sombir Kundu, Ashutosh K. Giri, ***3.Madhusudan Singh*** and Sunil Kadiyan, Electrical, DTU

13. An Empirical Study to Enhance Leadership Qualities among Students by Improving the Social Intelligence Level of School Teachers: A Study of Select Schools in Delhi and NCR, Dr. Deepa Bisht and ***3.Dr. Meha Joshi***, DSM, DTU

14. Analysing Customer Satisfaction Towards Personal Loans: Evidence from Banking Industry, Divya, ***3.Deepti Aggrawal*** and Adarsh Anand, USME, DTU

15. Analysis of renewable energy and economic growth of Germany, ***6.Akanksha Singh*** and ***3.Nand Kumar***, Humanities, DTU

16. Analytical modeling of nucleation and growth of graphene layers on CNT array and its application in field emission of electrons, ***6.Shruti Sharma*** and ***3.Suresh C Sharma***, Applied Physics, DTU

17. As38 Se62 based segmented clad-graded index photonic crystal fber for supercontinuum generation covering 3–9.5 μm with moderate peak power, ***6.Akash Khamaru*** and ***3.Ajeet Kumar***, Applied Physics, DTU

18. BEACOMP: A Novel Textual Adversarial Attack Architecture for Unveiling the Fragility of Neural Text Classifiers, ***8.Rishabh Sharma***, ***8.Aatish Ghosh***, ***6.Ashish Bajaj*** and ***3.Dinesh Kumar Vishwakarma***, Electrical and IT, DTU

19. Bio Synergize: Microbial Synergy Driving Simultaneous Bioremediation and Nanoparticle Synthesis, ***7.Arif Khan***, ***7.Suman Yadav*** and ***3.Jai Gopal Sharma***, Biotechnology, DTU

20. Buildings of Distinct Plan Shapes Under Wind Load: Wind Interference Effects, Supriya Pal, ***3.Ritu Raj*** and , Alfia Bano, Civil, DTU

21. CDME-GAT: Context-Aware Depression Detection Using Multiembedding and Graph Attention Networks in Social Media Text, ***3.Minni Jain***, Siddh Jain, Amita Jain and Bhavuk Garg, CSE, DTU

22. Concentration of betanin from model beetroot extracts by using nanofiltration: parameter estimation and sensitivity analysis, ***6.Ashwani Kumar Tiwari*** and ***3.Manish Jain***, Applied Chemistry, DTU

23. Constraining Variable Generalized Chaplygin Gas model in Matter Creation Cosmology, ***7.Yogesh Bhardwaj*** and ***3.C. P. Singh***, Applied Mathematics, DTU

24. Control With Style: Style Embedding-based Variational Autoencoder for Controlled Stylized Caption Generation Framework, ***6.Dhruv Sharma***, ***3.Chhavi Dhiman*** and ***3.Dinesh Kumar***, Electronics, DTU

25. Cooperative MAC Protocol based on Best Data Rate (CMAC-DR), Nagesh R, M. N. Sree Rangaraju, ***6.N. R. Kushar Gowda*** and Vinayak Shekharappa Antin, DTU

26. Deep learning in neglected vector-borne diseases: a systematic review, ***8.Atmika Mishra***, ***8.Arya Pandey*** and ***3.Ruchika Malhotra***, Software Engineering, DTU

27. Deep learning-empowered intrusion detection framework for the Internet of Medical Things environment, ***3.Prashant Giridhar Shambharkar*** & ***6.Nikhil Sharma***, CSE, DTU

28. Design and analysis of a rectangular core refractive index-based PCF sensor for bio-sensing application, ***7.Neeraj Singh***, ***6.Akash Khamaru*** and ***3.Ajeet Kumar***, Applied Physics, DTU

29. Design of Dual-Band 4-Port Flexible MIMO Antenna for mm-Wave Technologies and Wearable Electronics, Rakesh N. Tiwari, Deepti Sharma, ***7.1.Prabhakar Singh*** and Pradeep Kumar, Electronics, DTU

30. Determination of Residual Stresses and Surface Roughness Using Chemical Assisted Ball End Magnetorheological Finishing, ***6.Anand Sharma*** and ***3.Mahendra Singh Niranjan***, Mechanical, DTU

31. Dy3+ doped KCa(PO3)3 phosphor for white light generation: structural and luminescent studies, ***7.Deepti***, ***7.Sandip Maurya***, ***6.Sheetal Kumari***, ***6.Pooja Rohilla***, Aman Prasad and ***3.A S Rao***, Applied Physics, DTU

32. Dynamic Resource-Aware Federated Framework for Secure and Sustainable Learning in Data Sensitive Applications, ***6.Manu Narula***, Jasraj Meena and ***3.Dinesh Kumar Vishwakarma***, IT, DTU

33. Dynamics of Phase Transition in Quark-Gluon Plasma Droplet Formation under Magnetic Field, Agam K. Jha and ***8.Aviral Srivastava***, DTU

34. EFFECT OF AGRICULTURAL TRADE LIBERALIZATION ON FARM INCOME IN INDIA: AN EMPIRICAL ANALYSIS USING ARDL APPROACH, ***6.Hariom Prakash Verma*** and ***3.Nand Kumar***, Humanities, DTU

35. Evaluating the Environmental Impact of a Home Appliances: A Life Cycle Assessment with a New Green Product Design Framework, ***6.Mohd Tayyab***, ***3.Ranganath M Singari*** and Peer M Sathikh, Design, DTU

36. Examining the Dynamics of India's Major Exchange Rates Using Fourier Nonlinear Quantile Unit Root Test, Khyati Kathuria and ***3.Nand Kumar***, Humanities, DTU

37. Examining the structural viability of recycled fine aggregates in sustainable concrete, ***6.Harish Panghal*** and ***3.Awadhesh Kumar***, Civil, DTU

38. Exploring Biomedical Named Entity Recognition via SciSpaCy and BioBERT Models, Aman Jolly, Vikas Pandey, Indrasen Singh and ***6.Neha Sharma***, DTU

39. Fabrication of rGO-decorated hBNNS hybrid nanocomposite via organic–inorganic interfacial chemistry for enhanced electrocatalytic detection of carcinoembryonic antigen, ***6.Kanika Sharma***, ***3.Nitin K. Puri*** and ***3.Bharti Singh***, Applied Physics, DTU

40. Fe(III)-modified bamboo biochar for the removal of phosphate from synthetic and field stormwater runoff, ***6.Shivani Yadav***, ***7.Harsh Pipil***, ***3.A. K. Haritash*** and Krishna R. Reddy, Environmental, DTU

41. Fingerprint-Enabled ATM Network, ***8.Pragati Agrawal***, ***8.Rohan Saxena***, ***8.Saksham Agrawal*** and ***3.R.K. Singh***, Mechanical, DTU

42. FLOLSTM: Fuzzy logic-driven optimized LSTM for improved malicious traffic detection in hypervisor environments, ***6.Anumukonda Naga Seshu Kumar***, ***3.Rajesh Kumar Yadav*** and ***3.Nallanthighal Srinivasa Raghava***, CSE, Electronics, DTU

43. Harris Hawk Optimized CLAHE and Novel Score Level Fusion of Lightweight CNNs for Multimodal Biometric Recognition, ***3.Indu Singh***, ***8.Tanvi Singh***, ***8.Sunaina Luthra*** and ***8.Shruti Khatri***, CSE, DTU

44. IRIS: Intelligent Responsive Interface Solution, a promising Desktop Assistant for Differently-Abled, ***8.Aryan Karkra***, ***8.Raavi Singh*** & ***3.Dinesh K. Vishwakarma***, IT, DTU

45. Key Factors in Automobile Design: Expert Views on Enhancing User Experience during New Product Development, ***6.Shahid Ahmadm***, ***3.Ranganath M Singari*** and S.L. Bhandarkar, Design, DTU

46. Laboratory simulation to study the nonlinear evolution of right-hand circularly polarised wave in laser-produced plasmas, ***6.Aditya***, ***3.Suresh C Sharma***, Indraj Singh and R P Sharma, Applied Physics, DTU

47. LetsTalk: Understanding Social Media Usage of Self-Harm Users in India, ***3.Garima Chhikara*** and Abhijnan Chakraborty, DTU

48. Leveraging MediaPipe and YOLO Keypoint Detection in Ensemble Approaches for Workout Pose Recognition, ***7.Aman Rehman*** and ***3.Shailender Kumar***, CSE, DTU

49. Link chain driven reversible data hiding in encrypted images for high payload, ***6.Ankur***, ***3.Rajeev Kumar*** and Ajay K. Sharma, CSE, DTU

50. Machine learning: an advancement in biochemical engineering, ***8.Ritika Saha***, ***8.Ashutosh Chauhan*** and ***3.Smita Rastogi Verma***, Biotechnology, DTU

51. Magnesium oxide Nanoparticle synthesis using Rhizophora lamarckii plant extract and its characterization, ***8.Ankit Kundu*** & ***3.Jai Gopal Sharma***, Biotechnology, DTU

52. Meta-Learning-Based Physics-Informed Neural Network: Numerical Simulations of Initial Value Problems of Nonlinear Dynamical Systems Without Labeled Data and Correlation Analyses Worrawat Duanyai, Weon Keun Song, Thanadol Chitthamlerd and ***3.Girish Kumar***, Mechanical, DTU

53. Modified clustering and incentivized stable CH selection for reliable VANET communication, ***6.Ashish Kumar***, ***3.Shailender Kumar*** and Ram Shringar Raw, CSE, DTU

54. Modified-generative adversarial networks for imbalance text classification, ***6.Poonam Rani*** and ***3.Om Prakash Verma***, CSE and Electronics, DTU

55. Multimodal Architecture for Sentiment Recognition via employing Multiple Modalities, ***8.Samridhi Kapoor***, ***8.Shubham Gulati***, ***8.Sumit Verma***, ***8.Ananya Pandey*** and ***3.Dinesh Kumar Vishwakarma***, IT, DTU

56. Navigating the Web of Disinformation and Misinformation: Large Language Models as Double-Edged Swords, ***8.SIDDHANT BIKRAM SHAH***, SURENDRABIKRAM THAPA, ASHISH ACHARYA, ***8.KRITESH RAUNIYAR***, SWETA POUDEL, SANDESH JAIN, ANUM MASOOD AND USMAN NASEEM, CSE, DTU

57. Numerical modeling of microstructure of slag incorporating cement paste, ***6.Andualem Yadeta***, ***3.Pradeep Goyal*** and ***3.Raju Sarkar***, Civil, DTU

58. Numerical modelling for triple hybrid gate optimization dielectric modulated junctionless gate all around SiNWFET based uricase and ChOX biosensor, Rishu Chaujar and ***6.Mekonnen Getnet Yirak***, Applied Physics, DTU

59. Numerical simulation of flow characteristics in nonprismatic compound channels, ***6.Vijay Kaushik***, ***3.Munendra Kumar*** and Bandita Naik, Civil, DTU

60. Optimization of battery/ultra-capacitor hybrid energy storage system for frequency response support in low-inertia microgrid, ***6.Philemon Yegon*** and ***3.Mukhtiar Singh***, Electrical, DTU

61. Performance analysis of LaFeO3 perovskite solar cells: A theoretical and experimental study, ***6.Rahul Kundara*** and ***3.Sarita Baghel***, Applied Physics, DTU

62. Performance Assessment of Underwater-to-Air Optical Wireless Communication System With the Effect of Solar Noise and Sea Surface Conditions, ***7.1.BHOGESWARA RAO ANGARA,*** PALANISAMY SHANMUGAM HARISHANKAR RAMACHANDRAN AND CHAVAPATI GOUSE SANDHANI, Electronics, DTU

63. Photonic Spin Hall Effect based AQI sensor: Effect of concentration of PM2.5, ***6.Lokesh Ahlawat***, ***3.Kamal Kishor***, Monu Nath Baitha and ***3.Ravindra Kumar Sinha***, Applied Physics, DTU

64. Physicochemical evaluation of polyvinyl alcohol films crosslinked with saturated and unsaturated dicarboxylic acids: A comparative study, ***6.Leela Gautam***, ***3.Sudhir G. Warkar*** and ***3.Manish Jain***, Applied Chemistry, DTU

65. Predicting Wealth Score from Remote Sensing Satellite Images and Household Survey Data Using Deep Learning, Shashank SHEKHAR, Pratibha SINGH, ***6.Rashmi MISHRA*** and Sunil KUMAR, CSE, DTU

66. Pressure-dependent bandgap characteristics in photonic crystals with sensing applications, ***6.Varnam Sherawat***, ***3.Renuka Bokolia*** and ***3.Ravindra Kumar Sinha***, Applied Physics, DTU

67. Probabilistic multiplicative unbalanced linguistic game using linguistic cloud model, ***6.Parul Chauhan*** and ***3.Anjana Gupta***, Applied Mathematics, DTU

68. Radially polarized femtosecond laser interaction with unmagnetized plasma slab and symmetric modes for enhanced terahertz field generation, ***6.Himank Sagar*** and ***3.Suresh C. Sharma***, Applied Physics, DTU

69. Role of polymers in encapsulation and shapestabilization of phase change materials (PCMs) for thermal energy storage applications: an overview, ***6.Surya Tanwar*** and ***3.Raminder Kaur***, Applied Chemistry, DTU

70. Shallowfake and deepfake image manipulation localization using noise and RGB-based dual branch method, ***6.Deepak Dagar*** and ***3.Dinesh Kumar Vishwakarma***, IT, DTU

71. Short-term aggregate electric vehicle charging load forecasting in diverse conditions with minimal data using transfer and meta-learning, Shashank Narayana Gowda, ***8.Keshav Nath***, Chen Zhang, Rohan Gowda and Rajit Gadh, Mechanical, DTU

72. Synthesis of Graphene Quantum Dots (GQDs) from Paddy Straw for Bilirubin Detection, ***6.Isha***, ***6.Aneesha*** and ***3.Mohan Singh Mehata***, Applied Physics, DTU

73. Text mining based an automatic model for software vulnerability severity prediction, ***3.Ruchika Malhotra*** and ***7.Vidushi***, Software Engineering, DTU

74. The Influence Of Color On Visual Psychology And Cognitive Behavior: A Study In Paediatrics Hospital Environment, ***6.Monica Singh***, ***3.Ranganath M Singari*** and Mihir Bholey, Design, DTU

75. The rise of passive investing: a systematic literature review applying PRISMA framework, ***3.Priya Malhotra***, USME, DTU

76. Towards Optimal Resource Allocation: A Multi-agent DRL based Task Offloading Approach in Multi-UAV-Assisted MEC Networks, MUHAMMAD NAQQASH TARIQ, JINGYU WANG, SALMAN RAZA, ***7.1.MOHAMMAD SIRAJ***, MAJID ALTAMIMI and SAIFULLAH MEMON, Computer, DTU

77. Train Length and Service Frequency Optimization: Passenger Health Expense Perspective, ***7.Manish Kumar Sharma*** and Manvendra Singh, Electrical, DTU

78. Up-Conversion Luminescence in Sr9Y2W4O24:Ho3+, Yb3+ Phosphors for applications in Temperature Sensing and w-LEDs, ***6.Sheetal Kumari***, Aman Prasad, ***3.A. S. Rao*** and ***3.R. K. Sinha***, Applied Physics, DTU

79. Visual Sentiment Recognition via Popular Deep Models on the Memotion Dataset, ***6.Bhavana Verma***, ***3.Priyanka Meel*** and ***3.Dinesh Kumar Vishwakarma***, IT, DTU

80. Weighted voting ensemble of hybrid CNN-LSTM Models for vision-based human activity recognition, ***8.Sajal Aggarwal***, ***3.Geetanjali Bhola*** and ***3.Dinesh Kumar Vishwakarma***, IT, DTU

81. Workload dynamics implications in permissioned blockchain scalability and performance, ***6.Anita Thakur***, ***3.Virender Ranga*** and ***3.Ritu Agarwal***, IT, DTU

82. Zinc-Copper-Nickel Mixed Metal Oxide as Heterogeneous Catalytic Material for the Reductive Degradation of Nitroarene and Azo Dye, ***6.Jigyasa Pathak*** and ***3.Poonam Singh,*** Applied Chemistry, DTU

2024 IEEE 9th International Conference for Convergence in Technology (I2CT) | 979-8-3503-9447-4/24/$31.00 ©2024 IEEE | DOI: 10.1109/I2CT61223.2024.10543597

***Abstract*—Physical exercise is a key part of a healthy lifestyle, encompassing a wide array of activities from dance and aerobics, to weightlifting and sports. Proper form and posture are critical to ensure the safety of these exercises as well as making them effective. Accurate assessment of workout poses can provide invaluable feedback to individuals and fitness professionals alike. Performing exercises correctly also reduces the risk of injury, especially for people new to exercises. Additionally, fitness professionals can utilize this to remotely guide clients in virtual training sessions. Such systems can also act as a guide for people working out without any assistance. Deep learning approaches have been extensively used in computer vision as they show exceptional performance across a range of tasks. This may be used to automate the process of evaluating body postures during workouts. By leveraging these architectures, the aim is to develop an efficient and accurate system capable of precise pose identification. For this, we have taken a2D image dataset of 20 different workout postures. Weexperiment using 9 CNN architectures. EfficientNetB0 was found to have the greatest test accuracy of 91%.**

Keywords—deep learning, transfer learning, computer vision, pose detection

I. INTRODUCTION

Exercise routines are a vital part of staying in good physical health, reduce the risk of chronic illness, increase our energy, help us feel content and revitalize our body and mind. It takes proper form and skill to get the maximum benefit from any exercise.The same exercise may result in harm if carried out improperly. Especially when many individuals like to workout at home, or are traveling, or neither own a gym membership nor have access to a qualified trainer. The injuries caused due to improper form and guidance during exercises can do long-term damage. So, the attempt is to develop techniques that allow individuals to perform exercises safely. Here, we focus on realistic still images to develop machine learning models to do this task. There are video-based action recognition systems too, but in contrast, it may be more challenging for still images since they lack spatiotemporal information. There are several datasets which are used to perform exercise pose recognition from still images. However, we use a custom dataset as based on existing work, different papers have used different number of categories for different datasets and a wide variety of exercises. But, currently to our best knowledge, the number of categories we are including is higher than most related work. Also, there are inconsistencies in some and unavailability of some datasets. There is a need for a dataset that is less resource heavy, has different poses, people, lighting conditions, backgrounds and angles. Our dataset attempts to capture this wide variety.

Architecturally, implementing popular CNN architectures, specificallyVGG16, VGG19, ResNet50, DenseNet121, DenseNet201, MobileNetV2, InceptionV3, Xception and EfficientNetB0 via transfer learning are used to extract features from the images.Next, the models are adjusted to the subtleties of pose identification by training, hyperparameter tuning, and fine-tuning specific layers or the network as a whole.Finally, deploying the best model and continuously checking its performance allows possible improvement in accuracy and reliability in real-world applications.

II. RELATED WORK

Research on the identification of actions in still photos has regularly been conducted. Every study that pertains to the following makes use of still pictures. A residual neural network is used in Sreela et al. [1]'s image action recognition model to extract features efficiently. Succeeding in 15 Pascal VOC action courses, the model showed sensitivity to contextual changes and real-world imagery. By utilizing a residual neural network and a support vector machine classifier, the enhanced model achieved 66.1% accuracy in identifying human activities in a two-layer classification model.The research[2] uses ResNet as a feature extractor to identify human actions in still photos with accuracy of 61.07%. Activity recognition is augmented by approximating postures, and classification is handled by SVM. But these systems suffer in nuanced positions, truncations, and occlusions in complex situations.The two-stream convolutional neural network described in study[3] improves action recognition by using long-term fusion pooling to capture the temporal complexity of actions. Their method, called STDDCN, combines a knowledge distillation module with dense connectivity and multiscale information. Though it is successful in comprehending actions, it suffers from difficulties with computational load and large memory needs because of frame processing, even though it achieves great performance with fewer parameters. Their model yields an accuracy of 92.1%. Jose et al.[4] achieved 85% accuracy using the VGG-16 model to recognize 10 distinct yoga poses in still photos.

The study[5] used a neural network for sports picture classification across 6 categories using a pre-trained InceptionV3 for feature extraction. In sports picture categorization, their method yielded 96.64% accuracy rate.Podgorelec et al. [6]presented a CNN architecture based on the VGG-19 model with differential evolution method for classifying images. The CNN model's hyperparameters are optimized using the DE(differential evolution) approach after the training data has been fine-tuned using the TL method prior to classification. With 4 sports categories in their

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 18,2024 at 09:31:17 UTC from IEEE Xplore. Restrictions apply.

unique dataset, they achieved 81.31% accuracy. There is room for improvement in accuracy.In order to identify workout actions, [7]suggests using a deep learning-based model called WorkoutNet. With 2796 photos representing 10 distinct exercise stances, the approach demonstrated an impressive validation accuracy of 92.75%. Using MediaPipe, Pham et al. [8] were able to extract skeletal sequences from RGB footage that was taken using a commercial camera. The DD-Net deep architecture is utilized for action recognition in the assessment section. The model's average accuracy is 98.33%.

Das et al.[9] developed a system that counts repetitions, analyzes comfort using heart rate data, and recognizes activities performed at home and at the gym. For indoor exercise recognition, they employed k-NN, SVM, and decision trees. They achieved remarkable accuracy of 99.4% for counting repetitions and 95.3% for activity detection. This technique is effective for usage in the gym or at home since it assists in selecting the proper weights for workouts.Using decision trees as the underlying classifier, Zhou et al.[10] used the confidence-based AdaBoost algorithm. They used inertial pressure sensors to detect motion during a variety of sports-related activities, with an emphasis on leg exercises. After six participants participated in twenty-four leg workouts, they achieved an accuracy of 81.7%. The utilization of sensor-based technologies in this technique shows potential for precise monitoring and analysis of leg exercises.The study's authors stressed the possibility of precisely measuring exercise time spent on routine tasks. They used Support Vector Machines (SVM) and Random Forest (RF) to reach an accuracy of about 96.2%. [11]speciallymade use of data gathered from wearable wristband sensors, demonstrating the potential to identify workout periods.

Nunavath et al. [12] have classified various physical activities using sensor data, especially accelerometer data. On the UCI-HAR dataset, they applied sensor-based methods such as Deep Neural Networks (DNN) and Recurrent Neural Networks (RNN). Based on the gathered sensor data, their efforts yielded an accuracy of 84.89% in classifying these activities.Farhad et al.[13] used a pre-trained VGG-16 model to categorize a set of 18 distinct categories in a custom sports picture dataset. With this approach, they were able to classify these sports photos with 93% accuracy.A CNN-based technique for predicting human exercise postures shown in 2D photos was proposed by Haque et al. [14] used a carefully selected dataset with five distinct workout courses to achieve this. Their model properly identified these exercise postures with an accuracy of 82.68%.

III. Proposed Approach

The process used to complete the given task consists of multiple phases. To put it another way, as figure 1 illustrates, it includes gathering data, preparing it, choosing a model, training and honing it, assessing and then possibly deploying it.

A. Dataset Collection

We have taken variousexercise categories each containing 2D pose images which were pulled manually from Google search engine using Kaggle [15] as a reference. Thus, our dataset contains 1058 photos in total, divided into 20 classes, each with 55–60 images.As described above, the dataset attempts to capture a wide variety of exercises and different people performing them in various settings. The 20 exercise categories are as follows: Benchpress, bow, bridges, child's pose, cobra, crane pose, crunches, cycling, deadlift, donkey kicks, downdog, flutterkicks, lat-pulldowns, leg-extensions, plank, pullup, shoulder press, squat, standing toe reach andtricep-pushdown. The exercises are chosen to incorporate a variety of bodyweight and weight training exercises as well as stretches.

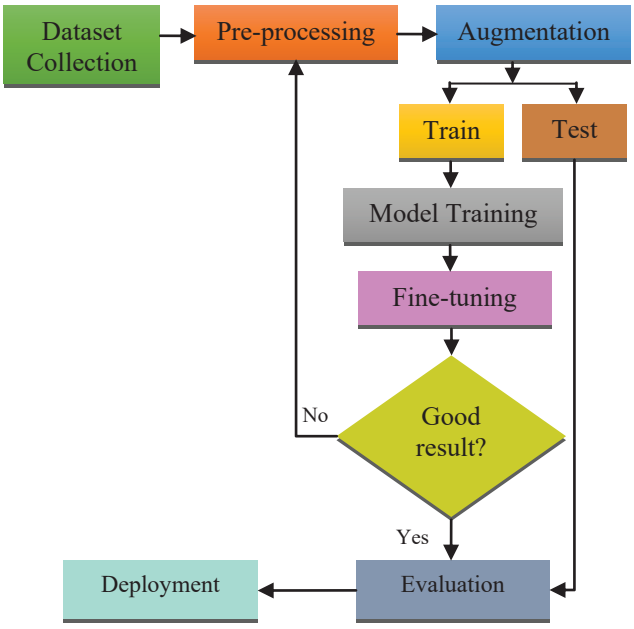

Fig. 1. Workflow

B. Data Processing and Augmentation

Images are loaded using Tensorflow and a standard size of 224x224 pixels is maintained. To avoid class-imbalanced splits, each image—labeled according to the exercise in the directory structure—is shuffled. The dataset split is 80:20 where 80% of the data is used for training, and the remaining 20% is used for testingafter normalizing to [-1, 1]. Before an image is fed into the models, it undergoes a predetermined set of augmentations, such as contrast and brightness fluctuation, random rotation, zooming, and flipping of the horizontal and vertical axes, to increase variability and facilitate generalization.

C. Model Architecture and Training

Multiple deep learning CNN architectures have been used to conduct a thorough study. ImageNet pre-trainedmodels were downloaded from Tensorflow. The advantage is that we can use the information already learnt by these models.To reduce spatial dimensions and focus attention on significant features, Global Average Pooling (GAP) layers were introduced.Also dropout layer is added to avoid overfitting.Later, dense layers are added with softmaxactivation function.The models are then trained and evaluated using accuracy metric.Categorical cross entropy loss function was used along with Adam optimizer.

D. Model Evaluation and Fine-Tuning

Model evaluation is performed on the test set. For a detailed analysis, we have used multiple methods on each model. We calculated the accuracy, the confusion matrices, class-wise accuracy and generated classification reports for each model.Training and testing accuracy and loss curves

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 18,2024 at 09:31:17 UTC from IEEE Xplore. Restrictions apply.

were plotted to analyse the models for overfitting or underfitting. For the process of fine-tuning, we unfroze some of the pre-trained layers. After unfreezing, the parameters associated with those layers also become part of the training process. Multiple tests with different number of frozen layers were performed. After this, the models are further trained for more epochs. Varying improvement in accuracy was observed.

E. Comparative Study

A comparative study was done to obtain a more thorough understanding of the performance of each model best. Then, the best-performing model with the highest test accuracy was chosen, and its weights were saved for deployment later.

IV. Experimental Analysis

A. Model Architecture

For VGG16, the 16 layers are divided into 3 fully connected and 13 convolutional layers. It is often recommended for its simplicity and uniform structure. It uses small 3x3 convolutional filters throughout the network. For our task, we had a total of 14,724,948parameters and all of them were kept trainable.VGG19 is a larger variant of VGG16, with 3 additional convolutional layers. There are total of 20,034,644 parameters and all of them were kept trainable.

ResNet-50 introduces residual learningwith 50 layers, including GAP, fully connected, and 48 convolutional layers. Residual blocksuse a bottleneck design, consisting of a series of 1x1, 3x3, and 1x1 convolutions whichpreserves representational strength and decreases computational complexity.There are a total of 23,628,692 parameters, out of which 23,575,572 were kept trainable.

DenseNet contains densely connected layers, which ensure that each layer gets information directly from all layers before it. This promotes the reuse of features and eases information transfer across the network. For DenseNet121, there were a total of 7,633,108 parameters out of which 6,047,572 were kept trainable. For DenseNet201, there were a total of 20,995,604 parameters out of which 6,475,092 were kept trainable.

MobileNetV2 introduces depth-wise separable convolutions. Because of its reduced computation and parameter counts, it is ideal for mobile and edge devices and real-time applications with constrained processing capacity.There were a total of 2,283,604 parameters out of which 2,249,492were kept trainable.

InceptionV3 aims to capture multi-scale features efficiently using inception modules.They incorporate convolutions of varying filtersizes and concatenate feature maps. There were a total of 21,843,764parameters out of which21,809,332were kept trainable.

In Xception,depth wise separable convolutions are used. This minimizes the amount of parameters while capturing spatial interdependence efficiently and encouragingbetter information flow. The total number of parameters were20,902,460 out of which 20,847,932were kept trainable.

EfficientNet introduces the concept of compound scaling. This means that it scales the network's depth, resolution and width uniformly by a factor which can be learned. This guarantees a computationally efficient model which balances efficiency and complexity, improving performance under various resource restrictions. We have used EfficientNetB0 model whose architecture (figure2) consistently demonstrates good performance on benchmark datasets when it comes to image classification. We added our own GlobalAveragePooling2D layer, dropout layer (at 20% rate)and dense layers with softmax activation for20 exercisecategories. There were a total of 4,075,191 parameters out of which 4,033,168were kept trainable.

B. Requirements and Specification

Python version 3.10 was used to carry out the experiments. Hardware requirements include an Nvidia RTX 3080 GPU, a8-core Intel i7 processor, 64GB DDR4 RAM and Google ColabGPU for faster processing.

C. Result and Analysis

For all the 9 models, we have kept a learning rate of 0.001 with Adam optimizer while fine tuning with different number of layers and using categorical cross entropy loss.

We conducted an analysis of all the models used in our study for workout image recognition. Table 1's benchmark results demonstrate EfficientNetB0's superior performance, with the model attaining the maximum accuracy of 91% for top-1 classification. Among the best performers, DenseNet201 stood out with a 99.05% accuracy rate for top-5 classification closely followed by EfficicentNetB0 with 98.9%. We also present information on each model's precision, recall and F1 score.

TABLE I. BENCHMARK RESULT OF 9 T-L MODELS

	Before fine-tuning	After fine-tuning				
Models	**Initial Accuracy**	**Top-1 Accuracy**	**Top-5 Accuracy**	**Precision**	**Recall**	**F1-Score**
VGG16	70.62%	79.62%	97.16%	0.88	0.81	0.81
VGG19	81.52%	83.89%	98.10%	0.85	0.84	0.84
ResNet50	76.30%	81.99%	97.16%	0.84	0.82	0.81
DenseNet121	66.35%	85.31%	98.00%	0.87	0.87	0.86
DenseNet201	72.51%	86.73%	**99.05%**	0.89	0.88	0.88
MobileNetV2	72.64%	76.42%	92.92%	0.81	0.76	0.75
InceptionV3	73.11%	84.43%	95.75%	0.85	0.84	0.83
Xception	76.30%	81.52%	96.68%	0.84	0.83	0.82
EfficientNetB0	86.73%	**91.00%**	98.90%	0.92	0.92	0.91

In the first training phase of EfficicentNetB0, the best model discovered, took place across 25 epochs, yielding an initial testing accuracy of 86.73% and a testing loss of 0.43. After then, the 150th layer was the focus of 10 more epochs of fine-tuning at a lower learning rate of 0.0001. With the use of checkpointing and optimal accuracy monitoring mechanisms, the procedure produced an astounding 99.65% fine-tuning training accuracy and 0.012 fine-tuning loss. Testing accuracy for the optimized model was 91.00%, and testing loss was 0.43, which was the same as during the first training phase. The model's accuracy was significantly increased overall through the fine-tuning procedure, indicating the success of the modifications made at this stage. The accuracy and loss curves in figures 3 and 4 graphically illustrate the model's development with fine-tuning; they show a clear tendency towards improved accuracy and lower loss.

In order to provide a more nuanced view of exercise-specific accuracy, we have included Table 2 that shows EfficientNetB0's accuracy for each workout class. The model performs well in a variety of exercises, with accuracy levels ranging from 69.23% to 100.00%. Most exercises yield greater than or equal to 80%, only tricep-pushdown shows a low performance of 69.23%. Examining the AUC-ROC curve as shown in figure 5 offers a thorough evaluation and shed light on the model's discriminative ability in this multi-class situation. The model's competency is demonstrated by notable precision, particularly the 100.00% accuracy for classes like Bow, Bridges, Child's Pose, Cobra, Crane Pose, Cycling, FlutterKicks and Pullup.

A breakdown of classifications is given by the confusion matrix(figure 6). Examining measures relevant to each class, such as precision and recall, we obtain detailed understanding of how well the model understands different types of exercises. Diagonal elements show the model correctly predicting poses. The off-diagonal elements point out areas that require improvement. It shows which incorrect class the model predicts for each exercise. The same follows for all the classes. This could be of interest as it may indicate similarity of movement or range of motion between exercises which may require more discriminating data to distinguish classes. This method provides a detailed insight of the strengths and limitations of the model.

TABLE II. POSE-WISE ACCURACY OF EFFICIENTNETB0 MODEL

Workout Pose	Accuracy
Benchpress	91.66%
Bow	100.00%
Bridges	100.00%
Child's Pose	100.00%
Cobra	100.00%
Crane Pose	100.00%
Crunches	90.00%
Cycling	100.00%
Deadlift	80.00%
Donkey kicks	90.00%
Downdog	84.61%
FlutterKicks	100.00%
Lat-pulldowns	88.88%
Leg-extensions	93.33%
Plank	82.35%
Pullup	100.00%
Shoulder Press	90.90%
Squat	90.00%
Standing toe reach	90.00%
Tricep-pushdown	69.23%

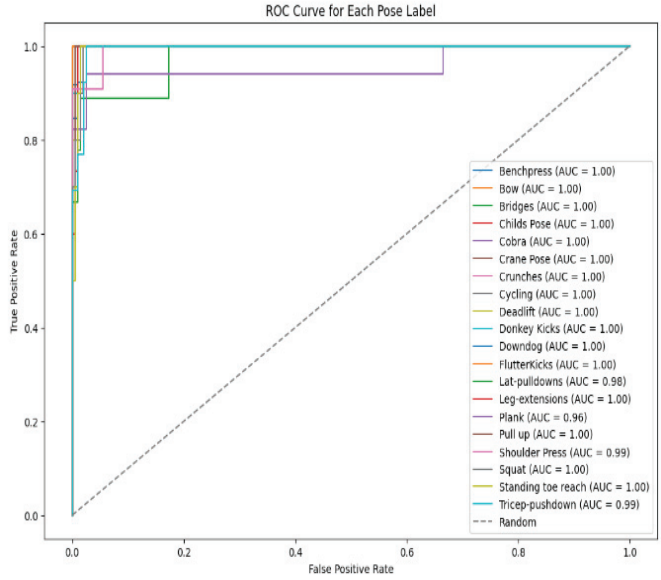

Fig. 5. AUC-ROC curve of EfficientNetB0 model

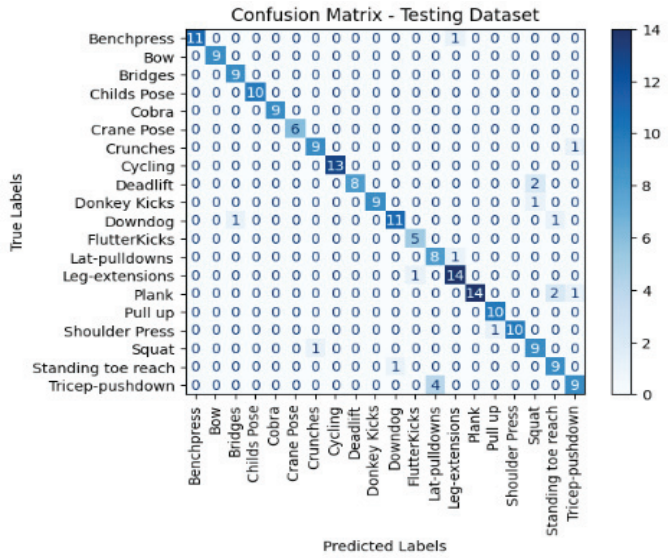

Fig. 6. Confusion-matrix for EfficientNetB0 model

D. Output

Figure 7 shows the true and predicted labels for images of different workout stances from the testing dataset. As demonstrated in the confusion matrix, there are incorrect predictions in the result as well. For classes where lower accuracy is obtained, it is useful to analyze possible similarities between images which may cause confusion.

Fig. 7. Actual vs Predicted pose of some test images

V. Conclusion

The presented experimental results reveal insights into the performance of prominent CNN architectures—VGG16, VGG19, ResNet50, DenseNet121, DenseNet201, MobileNetV2, InceptionV3, Xception, and EfficientNetB0 on workout pose detection. The dataset provides a challenging and diverse set of visual data for training and evaluation. The observed variations in test accuracies across models and epochs underscore the influence of architectural differences. EfficientNetB0 has demonstrated the strongest performance, achieving top 1 accuracy of 91%. Architectures like DenseNet121 and DenseNet201 notably performed worse than EfficientNetB0. These findings highlight the importance of selecting architectures that balances model complexity with the complexity of the problem, taking into account the diversity of exercises and the context of application.

A. Future work

Several avenues for future research exist. Firstly, the exploration of ensemble methods holds promise for further improving the overall accuracy. Combining predictions from multiple models can enhance generalization. Secondly, the integration of transformer-based models for vision, which is the latest development in computer vision tasks also holds promise. Specifically, vision transformers[14] have shown to beat previous state-of-the-art set by CNN architectures on multiple tasks. Furthermore, attention to data augmentation techniques could enhance model generalization. Specifcally, investigating results through an augmentation technique called RandAugment[13]. We may also attempt to improve model performance by incorporating keypoints. Finally, an exploration of explainability and interpretability may contribute to the transparency of the system and facilitate user trust and acceptance. Overall, the findings from this study lay the foundation for further advancements in workout

pose detection, encouraging the integration of novel architectures and methodologies to address the inherent challenges.

Abstract: This paper introduces a fractional-order meminductor emulator (FOMI) with both grounded and floating configurations, showcasing its applications in a chaotic oscillator. It employs one voltage differencing inverted buffered amplifier, a current follower, a fractional-capacitor, and a conventional capacitor. The transient analysis, pinched hysteresis loops, and non-volatile characteristics obtained for the suggested FOMI serve as clear indicators of the circuit's effective operation. The variations in pinched hysteresis loops with changes in the fractional-order (α) and frequency also support the theoretical concepts. The circuit's robust performance has been assessed by analyzing simulation results under varying conditions of temperature and supply voltage. The analysis also involves examining the impact of varying capacitor values on pinched hysteresis loops. Monte Carlo and corner analyses support the robust behaviour of the circuit. The suggested FOMI's potential use has been demonstrated using the chaotic oscillator circuit.

Keywords: Pinched hysteresis loop, chaotic oscillator, memristor, meminductor, memcapacitor, fractional-order.

1. Introduction

The exploration of novel circuit components and architectures is a continuous pursuit in the field of electronic design, leading to advancements with applications across diverse disciplines. While traditional approaches focus on integer-order differentiation and integration, the potential of non-integer, or fractional-order, calculus has gained significant interest due to its ability to model real-world phenomena more accurately. This branch of mathematics, known as fractional calculus, offers greater flexibility by introducing the concept of fractional-order derivatives and integrals. Its impact has transcended boundaries, finding applications in various scientific and engineering fields, including material science, biology, and control theory [1].

To take the advantages offered by fractional calculus, in circuit theory, fractional-order capacitors (FOCs) have been realized. These elements, denoted as C_α where α lies between 0 and 1, are also known as constant phase elements (CPEs). Their impedance characteristic, $1/s^\alpha C_\alpha$, introduces a constant phase shift of $-\alpha\pi/2$. However, due to the absence of readily available physical components exhibiting fractional-order behaviour, various techniques based on RC networks have been developed to approximate FOCs through continuous fraction expansion [2, 3]. Notably, Foster and Cauer networks utilize resistors and capacitors to achieve this approximation, with a trade-off between network complexity and accuracy. While higher-order networks provide better approximations, they also require more components. The foster form of fifth order is often realized with the help of six resistors and five capacitors.

The potential of fractional-order elements extends beyond capacitors, finding application in the recently discovered memristor. Unlike traditional capacitors and inductors that store energy, memristors possess the unique ability to store information, making them highly attractive for low-power neuromorphic computing applications. Their capability to retain and process information within a compact footprint further enhances their appeal. While conventional circuit components lack the captivating features of memristors, these were first envisioned by Prof. Leon Chua in 1971 [4] and eventually physically realized using Titanium dioxide (TiO2) by HP labs after a 37-year gap [5]. Today, they are readily available as commercial components. However, memristors' counterparts, memcapacitors and meminductors, are not yet widely available, prompting researchers and engineers to develop emulator circuits that replicate their expected characteristics. While numerous integer-order memcapacitor and meminductor emulator designs exist, research on their fractional-order counterparts remains scarce.

The motivation for this paper stems from this noticeable gap in research concerning fractional-order meminductors. In addition to the fact that fractional-order meminductors remain underexplored as compared to their integer-order counterpart, it has been analyzed that the existing fractional-order meminductor designs are often intricate, limiting their frequency responses to the kHz range. *This paper addresses this critical gap by introducing a simplified circuit for a FOMI with a superior frequency response.* Unlike existing fractional-order meminductors, the proposed design directs for a more straightforward architecture, ensuring broader applicability across broad frequency ranges. Beyond overcoming the

limitations of existing designs, the untapped potential of fractional order meminductors has been explored compared to their integer-order counterparts. Specifically, in chaotic circuits, fractional-order meminductors hold immense promise for generating complex dynamics and offering greater flexibility in controlling chaotic behavior. To achieve these objectives, a new design of meminductor emulator has been realized that leverages two well-established active building blocks: a voltage differencing inverted buffered amplifier (VDIBA) and a current follower (CF). Additionally, the design incorporates both a fractional-order capacitor and a conventional capacitor. The resulting circuit demonstrates robust performance, as verified through simulations conducted under varying temperature and supply voltage conditions. Finally, to showcase the versatility of the proposed fractional-order meminductor emulator (FOMI), its potential application in chaotic oscillator has been demonstrated.

A comparison summary of the suggested FOMI with existing ones are presented in Table 1. The observations of Table 1 are provided below:

1. For fractional meminductor emulators described in the literature [6-13], the greatest frequency for PHLs is restricted up to kHz only. In comparison, the suggested FOMI operates till 7MHz.
2. The suggested circuit is free from the requirement of memristors. This is in contrast to the known meminductor emulators [6], [7], and [12] that require memristors for their proper functioning.
3. The meminductor emulators [6], [11], and [13]) involve multipliers, active building blocks, along with a lot of passive components, nonetheless, the proposed FOMI has a fairly simple architecture and only requires a few components.

The content of the paper is arranged into seven sections which start from the first section of the introduction. The short review is given in Section 2 for the ease of readers. Section 3 presents the traits of active building blocks (ABBs) and their CMOS realizations. Section 4 discusses the operational concept and mathematical formulations of the proposed FOMI. Section 5 presents the simulation results. Applications of the proposed floating meminductor emulator namely chaotic oscillator is given in Section 6. Section 7 contains the paper's conclusion.

2. Short review of FOMI

Fractional meminductors extend the concept of traditional inductors and capacitors by incorporating fractional calculus principles. The application of fractional calculus principles

enables the analysis of time-domain behaviour and fractional-order dynamics, thereby enhancing modelling capabilities for these devices and offering potential solutions across a range of applications. In fractional calculus, the fractional derivative of a function is expressed in terms of the differentiation of non-integer order. Similarly, the fractional integral is an integration of non-integer order. FOMI is a device that exhibits memory effects in its current-flux relationship, similar to a traditional inductor, but with the inclusion of fractional-order derivatives. The FOMI's fractional nature enables it to capture more intricate and non-linear system behaviours. The FOMI can be tuned to have particular memory characteristics and frequency responses, allowing for more flexibility in system design and analysis.

The fractional derivative of a function *f(t)* with respect to time *t* of order α, denoted by D_t^{α}, is defined using the Caputo or Riemann-Liouville fractional derivative operators. The Caputo fractional derivative operator is commonly used and is defined as follows:

$$D_t^{\alpha} f(t) = \frac{1}{\Gamma(n-\alpha)} \int_0^t \frac{f^{(n)}(\tau)}{(t-\tau)^{\alpha+1-n}} d\tau \quad (1)$$

where, $\Gamma(.)$ is gamma function and $n\text{-}1 \leq \alpha \leq n$ is the fractional order.

In the case of fractional meminductors, the fractional derivative term is incorporated into the constitutive relation between the current (I) and flux (φ) of the meminductor. The fractional-order derivative of current (I) with respect to time (t) is related to the fractional-order derivative of voltage (V) by a constant fractional-order meminductance (L^{α}) [14]:

$$I(t) = L^{-\alpha} \cdot D^{\alpha-1} V(t) \quad (2a)$$

here, $D^{\alpha-1}$ represents fractional derivative. Considering the fact that flux is time integral of voltage, Equation (2a) can be re-written as:

$$I(t) = L^{-\alpha} \cdot D^{\alpha} \varphi(t) \quad (2b)$$

The fractional order α, which controls the memory characteristics, frequency response, and dynamic behaviour of the device, affects the distinct characteristics and behaviour of fractional-order meminductors. The desired characteristics of meminductors can be attained by choosing suitable values for α.

3. Overview of ABBs

VDIBA and CF have been used in the designing of the proposed FOMI.

3.1 VDIBA

The VDIBA is a four-terminal amplifier, as illustrated in Fig. 1 (a). The positive and negative high-impedance input voltage terminals are denoted as V+ and V-, respectively. The output voltage terminal W- has a low impedance, while the intermediate terminal 'Z' exhibits high impedance. In terms of implementation, its input stage comprises an OTA with a differential input and a single output. This OTA converts the differential signal into a corresponding current at the 'Z' terminal. The voltage at the W- terminal of the output stage unity-gain inverting voltage buffer is the inverse of the voltage observed at the 'Z' terminal. An additional biasing terminal V_B can be used to control the transconductance parameter (G_m). Applications requiring resistor-less and electronically regulated circuits encourage the use of VDIBA because its G_m may be electronically controlled by a biasing voltage.

The equations defining the port characteristics of VDIBA are given as:

$$I_{V+} = I_{V-} = 0 \tag{3}$$

$$I_Z = G_m\left(V_{V+} - V_{V-}\right) \tag{4}$$

$$V_{W-} = -\beta V_Z \tag{5}$$

$$G_m = \frac{K}{2\sqrt{2}}\left(V_B - V_{SS} - 2V_{th}\right) \tag{6}$$

where K is a technological parameter and its value is given by $\mu_n \cdot C_{ox} \cdot W/L$, with μ_n representing the mobility of charge carriers, C_{ox} is per unit area capacitance due to the oxide layer, W is the width and L is the channel length of the symmetric MOSFETs constituting differential pair of OTA. V_{SS} is the negative supply voltage used for biasing of VDIBA and V_{th} is the threshold voltage of the MOSFETs that govern the gain of the amplifier. β denotes the gain of 'W-' terminal in the non-ideal case and is ideally unity. The CMOS circuit of VDIBA depicting all its port terminals is shown in Fig. 1 (b).

3.2 CF Block

The current at the output terminal follows the input current in a traditional CF, which has a low input impedance and a very high output impedance. The number of output terminals and their current polarity can be adjusted by using different combinations of current mirrors. The block diagram and CMOS circuit of a four-terminal CF are shown in Figs. 2 (a) and (b), respectively.

Here ‘X’ is a low-impedance input current port, Z_{1+} and Z_{2+} are two high-impedance output ports with positive current polarity, and Z- is a high-impedance output port with negative current polarity. The port equations describing the current at various ports of CF are given as:

$$V_X = 0 \tag{7}$$

$$I_{Z1+} = I_{Z2+} = \gamma \cdot I_X \tag{8}$$

$$I_{Z-} = -\gamma \cdot I_X \tag{9}$$

here, γ is the current gain of non-ideal CF and has a value equal to unity in case of the ideal output.

4. Proposed FOMI

Electronic components called fractional-order meminductors have fractional-order dynamics in terms of memory effects and nonlinearity. Fractional-order dynamics can offer greater flexibility and control for simulating memory effects in the context of meminductor emulators. The fractional meminductor emulator can simulate a variety of meminductive behaviours, including varied degrees of memory and nonlinearity, by varying the order of the fractional calculus operator. A few designs [6-13] are available for floating-order meminductors. It is well-known that fractional-order meminductor provides many advantages over integer-order meminductors such as better control over pinched hysteresis loops, complex chaos generation in chaotic oscillators for secure communication, and additional variable (α) available for controlling many circuit parameters, etc. Therefore, in this paper, a FOMI has been proposed. This meminductor is designed using VDIBA and CF as active blocks. Along with active blocks, the proposed emulator employs a fractional capacitor and a conventional capacitor. The fractional capacitor (C_α) is connected to VDIBA's ‘Z’ terminal to produce the fractional behaviour. The VDIBA is used in view of charging C_α and its internal buffer helps in copying the voltage generated at the ‘Z’ terminal to the ‘W-’ terminal. The proportional voltage produces a current I_X for the CF that is utilized to charge the capacitor C_2. The capacitor C_2 is used to remember the state of the circuit. The voltage across C_2 is further utilized to control the fractional meminductance of the proposed FOMI.

4.1 Proposed grounded FOMI

The complete circuit of the suggested grounded FOMI designed using VDIBA and CF has been presented in Fig. 3(a). The depiction of the Foster-I realization employed for the

implementation of C_α is illustrated in Fig. 3(b). The order of the RC network shows a significant compromise between the accuracy of the achieved fractional capacitor and the intricacy of the design. In the presented implementation, a 5th order RC network has been selected for the realization of the fractional capacitor. This choice has been governed by the fact that a 5th order Foster-I RC network offers a precise emulation of fractional capacitors across a broad frequency spectrum.

In the proposed meminductor of Fig. 3(a), the incremental configuration is obtained by connecting the V- terminal to the input and the V+ terminal to the ground (ⓐ → ⓓ and ⓑ → ⓒ). In order to obtain decremental configuration, the input is connected to V+ while V- terminal is grounded (ⓐ → ⓒ and ⓑ → ⓓ). The fractional capacitor C_α is charged by the voltage reflected at the 'Z' terminal. The 'X' terminal of the CF draws current from 'W-' and is reflected to 'Z_{1+}', 'Z_{2+}', and 'Z-' terminals. The capacitor C_2 is charged by the current drawn from 'W-' terminal. The voltage developed across C_2 biases the VDIBA and controls the transconductance G_m as per Equation (6). The feedback mechanism created by the charge stored at C_2 provides the basis for memory in this meminductor.

To verify the working of the circuit, a detailed mathematical analysis of the incremental meminductor is carried out as follows:

Using Equation (4) and analyzing from Fig. 3(a) that $V_{V-} = V_{in}$ and $V_{V+} = 0$, the expression obtained is:

$$I_Z = G_m\left(-V_{in}\right) \tag{10}$$

Using Equation (5), the voltage across C_α can be written in s-domain as:

$$V_Z\left(s\right) = \frac{1}{s^\alpha C_\alpha}\cdot I_Z = -\frac{G_m V_{in}}{s^\alpha C_\alpha} \tag{11}$$

where α is the fractional order of C_α.

Since, the flux at the input is represented as: $\phi_{in}(s) = \frac{V_{in}}{s}$, Equation (11) gets modified as:

$$V_Z\left(s\right) = \frac{-G_m}{s^{\alpha-1} C_\alpha}\cdot \varphi_{in}\left(s\right) \tag{12}$$

Direct analysis of Fig. 3(a) yields the current drawn by CF as:

$$I_X = \frac{V_{W-}}{R_1} \tag{13}$$

where R_1 is the parasitic resistance seen between 'W-' and 'X' terminals and is given as:

$$R_1 = R_{W-} + R_X I_X \tag{14}$$

here, R_{W-} and R_X denote the parasitic resistances at 'W-' and 'X' terminals, respectively. The voltage across the capacitor C_2 ($V_{C2}(s)$) is given by:

$$V_{C2}(s) = V_B(s) = \frac{1}{s \cdot C_2} \cdot I_{Z2+} \tag{15}$$

Using Equation (8) and Equation (13), Equation (15) can be rewritten as:

$$V_B(s) = \frac{\gamma}{s \cdot C_2} \cdot \frac{1}{R_1} \cdot V_{W-} \tag{16}$$

Substituting V_{W-} from port Equation (5) and V_Z from Equation (12), Equation (16) can be expressed as:

$$V_B(s) = \frac{\gamma \cdot \beta \cdot G_m}{s^{\alpha} R_1 \cdot C_{\alpha} \cdot C_2} \cdot \varphi_{in}(s) \tag{17}$$

Since, $\frac{\phi_{in}}{s} = \rho(s)$, where $\rho(s)$ is the time domain integral of flux, Equation (17) can be redefined as:

$$V_B(s) = \frac{\gamma \cdot \beta \cdot G_m}{s^{\alpha-1} R_1 \cdot C_{\alpha} \cdot C_2} \cdot \rho(s) \tag{18}$$

The transconductance parameter (G_m) of VDIBA is dependent on biasing voltage V_B, as seen in Equation (6). Substituting value of V_B from Equation (18) in Equation (6) yields:

$$G_m(s) = \frac{K}{2\sqrt{2}} \left(\frac{\gamma \cdot \beta \cdot G_m}{s^{\alpha-1} R_1 \cdot C_{\alpha} \cdot C_2} \cdot \rho(s) - V_{SS} - 2V_{th} \right) \tag{19}$$

From Fig. 3(a), $I_{in} = -I_{Z+}$. Further combining Equations (5), (9), (12) and (13), we get:

$$I_{in}(s) = \frac{\gamma \cdot \beta \cdot G_m \cdot \varphi_{in}(s)}{s^{\alpha-1} R_1 \cdot C_{\alpha}} \tag{20}$$

Substituting the value of G_m from Equation (19) in Equation (20), yields:

$$I_{in}(s) = \frac{\gamma \cdot \beta}{s^{\alpha-1} R_1 \cdot C_{\alpha}} \frac{K}{2\sqrt{2}} \left(\frac{\gamma \cdot \beta \cdot G_m}{s^{\alpha-1} R_1 \cdot C_{\alpha} \cdot C_2} \cdot \rho(s) - V_{SS} - 2V_{th} \right) \cdot \varphi_{in}(s) \tag{21}$$

The relation between current and induced flux in meminductor in terms of meminductance (L_M) is given as:

$$I(s) = L_M^{-1} \cdot \varphi(s) \tag{22}$$

Considering Equations (21) and (22), the inverse meminductance of the proposed meminductor is expressed as:

$$L_M^{-1} = \frac{\gamma \cdot \beta}{s^{\alpha-1} R_1 \cdot C_\alpha} \frac{K}{2\sqrt{2}} \Bigg(\underbrace{V_{SS} + 2V_{th}}_{\text{fixed part}} - \underbrace{\frac{\gamma \cdot \beta \cdot G_m}{s^{\alpha-1} R_1 \cdot C_\alpha \cdot C_2} \cdot \rho(s)}_{\text{variable part}} \Bigg) \tag{23}$$

where α is fractional order, β is the voltage gain of VDIBA and γ is the current gain of CF. Equation (23) shows that the meminductance of the proposed meminductor can be controlled by fixed parameters (supply voltage and threshold voltage) and variable parameters (input flux). The fractional power (α) helps in precise control of the meminductance. The circuit shown in Fig. 3 (a) can be used in decremental mode by connecting ⓐ → ⓒ and ⓑ → ⓓ. A similar mathematical analysis as carried out for incremental configuration, yields meminductance for decremental configuration as:

$$L_M^{-1} = \frac{\gamma \cdot \beta}{s^{\alpha-1} R_1 \cdot C_\alpha} \frac{K}{2\sqrt{2}} \Bigg(\underbrace{V_{SS} + 2V_{th}}_{\text{fixed part}} + \underbrace{\frac{\gamma \cdot \beta \cdot G_m}{s^{\alpha-1} R_1 \cdot C_\alpha \cdot C_2} \cdot \rho(s)}_{\text{variable part}} \Bigg) \tag{24}$$

From Equation (24) it can be observed that both fixed and variable components are negative, leading to decremental behaviour of the proposed fractional meminductor.

4.2 Proposed floating FOMI

The suggested floating type FOMI is shown in Fig. 4. When the circuit of Fig. 4 is subjected to the same mathematical analysis that was done for the grounded type, the relationship obtained between flux and current for incremental configuration is provided below:

$$L_M^{-1} = \frac{\gamma \cdot \beta}{s^{\alpha-1} R_1 \cdot C_\alpha} \frac{K}{2\sqrt{2}} \Bigg(\underbrace{V_{SS} + 2V_{th}}_{\text{fixed part}} + \underbrace{\frac{\gamma \cdot \beta \cdot G_m}{s^{\alpha-1} R_1 \cdot C_\alpha \cdot C_2} \cdot \rho(s)}_{\text{variable part}} \Bigg) \tag{25}$$

By flipping the switch as indicated in the figure, the proposed emulator shows decremental behaviour and its meminductance can be expressed as:

$$L_M^{-1} = -\frac{\gamma \cdot \beta}{s^{\alpha-1} R_1 \cdot C_\alpha} \frac{K}{2\sqrt{2}} \Bigg(\underbrace{V_{SS} + 2V_{th}}_{\text{fixed part}} + \underbrace{\frac{\gamma \cdot \beta \cdot G_m}{s^{\alpha-1} R_1 \cdot C_\alpha \cdot C_2} \cdot \rho(s)}_{\text{variable part}} \Bigg) \tag{26}$$

In the proposed FOMI, Equations (23) to (26) show that the fractional s-domain factor of $s^{\alpha-1}$ offers greater flexibility in modelling complex systems. This aids in capturing a broader range of system behaviours that integer-order models are unable to faithfully capture. Additionally, it offers greater accuracy and increased adaptability in simulating real-world

systems, particularly those displaying non-linear and non-integer behaviours. However, fabricating such emulators with precise fractional-order characteristics is a complex task, leading to increase in manufacturing costs. Additionally, fractional-order circuits are generally more sensitive to variations in component values compared to their integer-order counterparts. Even minor discrepancies in resistance, capacitance, or other parameters can significantly affect the behaviour of the emulator, posing challenges in practical implementations. Furthermore, commercially available components specifically designed for fractional-order circuits are limited compared to those readily available for integer-order circuits. Furthermore, existing circuit design methodologies, simulation tools, and standard components are primarily tailored for integer-order circuits making the analysis of these circuits a challenging task.

5. Simulation results

Simulations using the LTspice tool have been performed to test the operation of the proposed fractional-order meminductor circuit. The blocks VDIBA, and CF have been simulated with supply rails of ±0.9V utilizing TSMC's 180nm technology parameters. Table 2 displays the size of the MOSFETs utilized in the active blocks. The capacitance value C_2 is set to 10 pF in order to achieve pinched hysteresis lobes. A fifth-order Foster-I form is used to implement C_α linked to the 'Z' terminal of VDIBA, as displayed in Fig. 3(b). The values of R and C for the Foster-I form have been calculated using MATLAB [15]. These values for C_α = 10pF, for different values of α have been presented in Table 3. Unless otherwise stated, all the simulated results have been plotted with α = 0.5 for the sake of simplicity.

5.1 Simulation results of proposed floating FOMI in incremental configuration

The curves representing transient analysis of the proposed floating FOMI for α = 0.5, plotted with a 100kHz sinusoidal signal have been displayed in Fig. 5. This analysis reveals intricate details of the proposed floating FOMI's temporal behaviour showcasing the unique relationship between voltage, flux, and current waveforms. In this figure it can be observed that the voltage waveform leads the flux and current waveforms. This is a characteristic that is observed in inductive circuits. The non-sinusoidal nature of the current waveform is attributed to the dynamic fluctuations in the inductance value over time, providing a comprehensive understanding of the circuit's transient response. To check the non-volatile behaviour of the proposed emulator, a step signal with 15µs period and 1µs ON time is

applied at the input terminal and the observed response is shown in Fig. 6. The figure illustrates a key aspect of the emulator's behavior. Specifically, during the ON time of the step signal, the emulator's meminductance value increases. Meminductance is a property similar to inductance but with memory effects, implying that the device "remembers" its previous states. What is particularly noteworthy is that when the pulse train is turned OFF, the emulator retains its meminductance value from the previous ON state. This persistence of the meminductive property during the OFF state demonstrates the non-volatile behaviour of the proposed emulator. This ensures that the emulator has the ability to "remember" and maintain its meminductive state even after the input signal is no longer actively applied. This characteristic is a crucial element of non-volatile memory, where information or states persist even in the absence of power or input stimuli.

To understand the behaviour of the circuit across different frequency ranges, sinusoidal signals with varying frequencies are applied. The corresponding hysteresis loops obtained are presented in Figs. 7(a) and 7(b). Fig. 7(a) displays the PHL curves obtained for frequencies ranging from 1kHz to 7kHz. In this figure, the curves are plotted with frequency varying in steps of 2kHz. Fig. 7(b) demonstrates the curves for frequency varying from 1MHz to 7MHz in steps of 2MHz. The capacitance of C_2 has been suitably modified to produce PHL curves with zero-crossing for the given range of frequencies. An additional crucial aspect of a meminductive device is the PHL lobes' area decreasing with frequency. This characteristic can be effectively visualized in the PHL curves shown in Fig. 7.

Additionally, to explore the maximum operating frequency of the proposed FOMI, the circuit underwent testing with high-frequency sinusoidal signals. Fig. 8 displays the results analyzed for an input signal of 10MHz frequency for different values of the fractional order parameter (α = 0.2, 0.5, and 0.8). As evident from the figure, PHL curves for all tested α values exhibit the dumbbell hysteresis shape, confirming the FOMI's functional operation even at a high frequency of 10 MHz. However, these curves are observed with slight shift in pinched point.

5.2 Simulation results of proposed floating FOMI in decremental configuration

The proposed floating FOMI presented in Fig. 4 is simulated in decremental mode. The circuit behaved satisfactorily, as shown by the results of the non-volatility test and transient analysis. The PHL curves observed for a sinusoidal signal with frequency varying from 100kHz to 7MHz are depicted in Fig. 9. All these curves have been plotted for α = 0.5. From Fig. 9, it can be visualized that the size of the lobes reduces as frequency increases, this

confirms the satisfactory behaviour of the proposed emulator in the complete range of frequencies for the decremental mode of configuration.

To analyze the effect of the variations in α on PHL curves, the circuit has been simulated for α varying from 0.2 to 0.8 under the stimulation of a sinusoidal voltage signal. The curves obtained are displayed in Fig. 10. The slight modifications in the shape of loop demonstrate the control of the fractional order in meminductance of the designed emulator.

5.3 Simulation results of the proposed grounded FOMI

In the presented grounded FOMI circuit illustrated in Fig. 3, a sinusoidal signal with a phase difference of 90^0 has been applied at the input. This sinusoidal input serves as a dynamic stimulus to assess the performance of the grounded FOMI across a range of frequencies. The frequency of the applied signal has been systematically varied, spanning from 100kHz to 7MHz. For the evaluation of the meminductive behaviour under these varying frequencies, the R and C values are configured according to the Foster-I form with a specific fractional order, in this case, α = 0.5. This choice of α is significant, as it represents a balanced fractional order that influences the circuit's meminductive characteristics.

The resulting responses of the grounded FOMI are captured in curves presented in both Fig. 11 and Fig. 12. Fig. 11 illustrates the behaviour in the incremental mode, where the meminductive response is observed during the increasing phase of the applied signal. On the other hand, Fig. 12 displays the response in the decremental mode, focusing on the meminductor's behaviour during the decreasing phase of the signal. These curves validate the proper functioning of the proposed grounded meminductor across the entire frequency range for both incremental and decremental configurations. The fact that the curves exhibit consistent and reliable behaviour throughout this frequency spectrum affirms the robustness and effectiveness of the grounded FOMI circuit.

5.4 Analysis of the proposed meminductor subjected to environmental conditions

In reality, a device will experience a variety of non-ideal environmental and manufacturing conditions, which will affect its behaviour. It is necessary to analyze a device's characteristics, when subjected to practical conditions, to determine its tolerance in a real-world environment. In this section, the impact of the variations of various parameters on the behaviour of the proposed FOMI has been investigated.

5.4.1 Temperature variation analysis

The performance characteristics of the proposed meminductor have been thoroughly investigated by examining its behaviour across a temperature range spanning from -50°C to +50°C. The analysis involves the generation of PHL curves for the floating FOMI under both incremental and decremental configurations. The outcomes of this investigation are represented in Fig. 13(a) for incremental mode and Fig. 13(b) for decremental mode.

In these figures, the meminductor's behaviour is assessed for $\alpha = 0.5$, a choice that represents a balanced configuration for the meminductor. The PHL curves plotted in these figures depict the slight deviations in the meminductive response under varying temperatures.

The observed slight deviations in the PHL curves do not compromise the overall operation of the proposed meminductor. Instead, they confirm the meminductor's ability to maintain functionality and stability across a defined temperature span. This resilience is indicative of the suggested meminductor's capability to withstand temperature variations without substantial impact on its performance, making it a reliable and robust component for applications that may be subjected to temperature fluctuations within the specified -50°C to +50°C range.

5.4.2 Supply voltage variations

The impact of supply voltage variations on the performance of the proposed FOMI has been systematically examined by subjecting the circuit to an approximate 10% fluctuation in the supply voltage. The resulting PHL curves, obtained by simulating the suggested meminductor with a sinusoidal signal of 100 kHz frequency and $\alpha = 0.5$, are presented in Fig. 14. The depicted waveforms in Fig. 14 illustrate the PHL curves in the φ vs. i plane, showcasing the meminductive response to variations in supply voltage. Specifically, the curves are generated for supply voltage fluctuations ranging from 0.81V to 0.99V for V_{DD} and from -0.81V to -0.99V for V_{SS}.

Despite the variations in supply voltage within the specified range, the suggested meminductor demonstrates satisfactory performance. The observed PHL curves reveal only slight modifications in lobe shape, indicating that the meminductive behavior remains stable even under supply voltage variations of 10%.

5.4.3 Variations due to capacitance tolerance:

During the fabrication process, achieving exact component values is often an impossible task. In reality, component values are inherently prone to certain tolerances or variations, which can potentially lead to circuit failure or suboptimal performance. Recognizing this inherent variability, an examination of the suggested meminductor's behaviour in the φ vs. i plane has been conducted by varying capacitor values. This investigation aims to understand how fluctuations in capacitance values influence the meminductive response.

Fig. 15 visually presents the PHL curves for the floating FOMI for both incremental and decremental configurations. These curves are generated for different values of capacitance, where C_2 is set at 5pF, 10pF, and 20pF. This variation in capacitance values provides insight into how the meminductive behaviour adapts to different component tolerances.

5.4.4 Monte-Carlo Analysis:

In the practical development of a MOSFET-based circuit, factors such as the aspect ratio and threshold voltage of the MOSFET can undergo variations due to fabrication imperfections. To assess the impact of these variations on the properties of the proposed meminductor, Monte Carlo (MC) analysis has been employed. The Gaussian distribution function has been used to perform the MC analysis with 5% variations in the MOSFET's aspect ratio and threshold voltage. Figs. 16 (a) and 16 (b) show the MC plots of PHL curves for a 100 kHz sinusoidal signal, considering threshold modifications for incremental and decremental meminductors, respectively. Each curve in these figures represents the outcome of the MC analysis for a specific run, with a total of 100 runs being conducted. These MC plots serve to demonstrate the robustness of the proposed circuit's meminductive behaviour across a range of mismatch scenarios.

The observed PHL curves in the MC plots affirm the circuit's ability to maintain meminductive functionality over the entire range of mismatch induced by variations in MOSFET specifications. Despite the inherent variations in the aspect ratio and threshold voltage, the form of the PHL curves remains consistent, with only minor modifications. This resilience is crucial for real-world applications where fabrication-induced variations are inevitable, ensuring that the proposed meminductor reliably preserves its intended behaviour despite variations in MOSFET properties.

5.5 Quantification of error in fractional-order capacitance using Foster-I form

As mentioned in Section 1, commercially available fractional capacitors are not readily accessible. Hence various continuous fraction expansions utilizing RC networks have been proposed in the literature to approximate their values. The s-domain equation that characterizes the impedance of a CPE is expressed as follows [15]:

$$Z(s) = \frac{1}{C_\alpha s^\alpha} \tag{27}$$

here, C_α represents normalized capacitance expressed in Farad/sec$^{(1-\alpha)}$ (F/sec$^{(1-\alpha)}$). The value of this capacitor which depends both on frequency and order, is represented as:

$$C_\alpha = C\omega_0^{1-\alpha} \tag{28}$$

where, C is the capacitance value for which the fractional capacitor is designed. The phase (θ) of the impedance $Z(s)$ of CPE is expressed as:

$$\theta = -\alpha\pi/2 \tag{29}$$

In this paper, a fifth-order Foster-I network has been employed to realize the fractional capacitor (C_α) required in the proposed design. There exists a trade-off between the network order and the exact value of fractional impedance. The 5th order network was chosen in this work, as it enables the attainment of a highly accurate value of fractional capacitor impedance across several decades centered around the central frequency.

In this work, a capacitance C=10pF centred at f_0 = 100 kHz ($|Z|$ = 159.15kΩ) has been chosen for the realization of the fractional capacitor through 5th order Foster-I form. The impedance of the fractional capacitor, implemented using the network illustrated in Fig. 3(b) with the component values specified in Table 3, have been examined. The resulting impedances for various values of alpha are plotted in Fig. 17(a). In this figure, the impedance corresponding for α = 0.2, 0.4, 0.6 and 0.8 have been plotted for a frequency range of 10^3 Hz to 10^7 Hz (4 decades). The waveforms depicting % error as compared to the impedance obtained through Equation (27) have been plotted in Fig. 17(b). These waveforms show that near centre frequency, the 5th order Foster-I form accurately realizes the fractional capacitance. The error in impedance magnitude is almost negligible in the frequency range of 20kHz to 500kHz and increases beyond this range.

The waveforms showing phase response of fractional capacitance realized through Foster-I RC network and the corresponding error related to different values of α have been plotted in Fig. 18(a) and 18(b) respectively. These plots have also been drawn for a frequency range of 4 decades (10^3 Hz to 10^7 Hz). Fig. 18(b) depicts that error in phase response is almost negligible for 2 decades of frequency variation (from 10kHz to 1MHz).

Figs. 17 and 18 confirm the validity of the 5^{th} order Foster-I RC network for implementing the desired fractional capacitor.

6 Applications of the suggested FOMI as a chaotic oscillator

This section introduces a chaotic oscillator implemented using the proposed FOMI. The incorporation of FOMI in chaotic oscillator design introduces additional degrees of freedom, resulting in more intricate and diverse dynamical behavior. The fractional order, denoted by 'α', offers precise control over the system's dynamics, facilitating customization of the oscillator's behavior to meet specific requirements [14, 16]. Despite the advantages of fractional-order chaotic oscillators, including richer dynamics and enhanced controllability, their implementation entails increased complexity and challenges.

In the suggested implementation of Chua's oscillator, the fractional order model is exclusively applied to the meminductor flux characteristic, while the remaining states are maintained as integer order. Fig. 19 illustrates the basic configuration of Chua's oscillator, where the traditional nonlinear element (M_L) is replaced with the proposed VDIBA and CF based meminductor. The oscillator includes one inductor (L), two capacitors (C_1 & C_2), a resistor (R_1), an OPAMP-based negative impedance converter (-R_2), and one meminductor (M_L).

The four state variables of this oscillator are: current through the inductor (I_L), the capacitor node voltages (V_X & V_Y), and flux (φ_{MI}) and integral of flux (ρ_{MI}) of meminductor. This meminductor-based oscillator's state space dynamics can be expressed with the help of 1st order differential equations as shown below:

$$\left.\begin{aligned} C_A\frac{dV_X}{dt} &= \frac{V_X}{R_B} - I_L \\ C_B\frac{dV_Y}{dt} &= I_L - I_{ML} \\ L\frac{dI_L}{dt} &= V_X - V_Y - I_L\cdot R_B \\ \frac{d\varphi_{MI}}{dt} &= V_Y \\ \frac{d\rho_{MI}}{dt} &= \varphi_{MI} \end{aligned}\right\} \qquad (30)$$

In above analysis, C_A, C_B, L, R_A and R_B represent the values of the respective elements (capacitance, inductance, or resistance) in the chaotic oscillator. To model the current through the meminductor, the equation $I_{LM} = (A+B\rho_{MI})\varphi_{MI}$, as derived in Equation (21), can be employed. In this equation, α is considered to be equal to unity for the sake of simplicity (α = 1 for an ideal capacitor). Under this assumption, the parameters A and B are characterized by Equation (31).

$$\left.\begin{aligned} A &= \frac{\gamma \cdot \beta}{R_1 \cdot C_\alpha} \frac{K}{2\sqrt{2}} \left(V_{SS} + 2V_{th}\right) \\ B &= \frac{\gamma^2 \cdot \beta^2}{R_1^2 \cdot C_2 \cdot C_\alpha^2} \cdot \frac{K \cdot G_m}{2\sqrt{2}} \end{aligned}\right\} \tag{31}$$

A set of equilibrium points can be derived by setting all derivatives of Equation (30) equal to zero. This set of equilibrium points considering, $\dot{V}_X, \dot{V}_Y, \dot{I}_L, \dot{\varphi}_{MI}, \dot{\rho}_{MI} = 0$, is defined as:

$$E = \left\{ \left(V_X, V_Y, I_L, \varphi_{MI}, \rho_{MI}\right) | V_X = V_Y = I_L = \varphi_{MI} = 0, \rho_{MI} = m \right\} \tag{32}$$

where, *m* is a constant real number. At equilibrium point given by Equation (32), the Jacobian matrix (*J*) is defined as:

$$J = \begin{bmatrix} \frac{1}{C_A R_B} & 0 & -\frac{1}{C_A} & 0 & 0 \\ 0 & 0 & \frac{1}{C_B} & -\frac{1}{C_B}\left(A + Bm\right) & 0 \\ \frac{1}{L} & -1 & \frac{-R_A}{L} & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \end{bmatrix} \tag{33}$$

The dynamics of the Chua's oscillator (Fig. 19) can be analyzed by finding the characteristic equation associated with the Jacobian matrix expressed Equation (33). This equation which gives the eigenvalues of the matrix is defined as:

$$Det\left(J - \lambda I\right) = 0 \tag{34}$$

here, λ represents the eigenvalues and are crucial for determining the stability of the Chua's oscillator at the equilibrium point specified by Equation (32). Using MATLAB, the eigenvalues of the system are calculated as:

$$\lambda^5 + a_1\lambda^4 + a_2\lambda^3 + a_3\lambda^2 + a_4\lambda = 0 \tag{35}$$

here, coefficients a_1, a_2, a_3, and a_4 are defined by Equation (36).

$$\left.\begin{aligned} a_1 &= \frac{R_A}{L} - \frac{1}{C_A R_B} \\ a_2 &= \frac{1}{C_B}\left(1 + A + Bm\right) + \frac{1}{C_A L}\left(1 - R_A \big/ R_B\right) \\ a_3 &= \frac{1}{C_B}\left\{\left(A + Bm\right)\left(\frac{R_A}{L} - \frac{1}{C_A R_B}\right) - \frac{1}{C_A R_B}\right\} \\ a_4 &= \frac{1}{C_A C_B L}\left(A + Bm\right)\left(1 - R_A \big/ R_B\right) \end{aligned}\right\} \tag{36}$$

Using the characteristic equation given by Equation (34), the eigen values can be obtained for the chaotic circuit of Fig. 19. From Equation (35), it can be easily realized that Jacobian matrix '*J*' has a zero value and four nonzero values. Since, the coefficients a_1, a_2, a_3, and a_4 are all nonzero, if the real parts of all eigenvalues of Equation (35) (except $\lambda = 0$) are negative, the system is stable. As per Routh–Hurwitz criterion the system is stable only when, $\Delta_1 = a_1$, $\Delta_2 = (a_1a_2 - a_3)/a_1$, $\Delta_3 = a_3-(a_1^2a_4)/(a_1a_2 - a_3)$, and $\Delta_4 = a_4$, all are positive. Otherwise, the system is unstable, and chaotic response can be generated. Fractional-order systems exhibit significantly more complex behavior than their integer-order counterparts due to the challenging nature of fractional-order calculus. The previous analysis was conducted assuming an ideal capacitor with $\alpha = 1$. Interestingly, when considering a fractional capacitor ($0 < \alpha < 1$), the chaotic behavior remains at least as stable as the integer-order system [17]. However, maintaining chaos in the fractional system depicted in Fig. 19 requires the same number of eigenvalues to remain within the unstable region. The essential condition to achieve unstable eigenvalues is outlined below:

$$\alpha > \frac{2}{\pi}\tan^{-1}\left(\frac{\left|\mathrm{Im}(\lambda)\right|}{\mathrm{Re}(\lambda)}\right) \tag{37}$$

The behavior of the chaotic oscillator, as illustrated in Fig. 19 and implemented with the recommended fractional-order meminductor with $\alpha = 0.5$, has been explored through LTspice simulations. The negative resistance ($-R_2$) is achieved by the OPAMP-based negative impedance converter when $R_a = R_b = 2$k. The rest of the elements are set to have the following values: L=120mH, C_1=65nF, C_2=10nF, and R_1=200. Fig. 20 shows the 2-D projection plots that are observed for the different state variables. These plots validate the chaotic dynamics exhibited by the system when utilizing fractional values of α.

7 Conclusion

In this paper, the feasibility of designing grounded/floating FOMI based on a few active blocks has been investigated. VDIBA and CF blocks have been selected for their straightforward construction, differential capabilities, and inherent tuning options. Verification tests, including meminductor fingerprints, PHL with zero-crossing, and non-volatility tests, have all been employed to ensure the intended functionality of the proposed circuit. The circuit's ability to operate in both incremental and decremental modes was demonstrated using a simple switch connected to the input terminals. LTspice simulation results indicate the circuit's effectiveness up to 7MHz. Temperature variations (-50°C to

+50°C), capacitance changes (5pF to 20pF), and supply voltage fluctuations (10%) were considered in PHL curves, affirming the circuit's practicality in real-world scenarios. Additionally, the proposed fractional-order meminductor's realization was validated through a Monte Carlo study. The paper illustrates the successful implementation of a chaotic oscillator using the suggested fractional-order floating meminductor emulator.

Shireesh Kumar Rai received the B. Tech. degree in electronics and communication engineering from the Noida Institute of Engineering and Technology, Gr. Noida in 2008, the M.Tech. degree in VLSI Design from the YMCA University of Science and Technology, Faridabad, in 2012, and the Ph.D. degree from the Netaji Subhas Institute of Technology (University of Delhi), New Delhi, in 2017. From 2008 to 2010, he was a Lecturer at the Galgotias College of Engineering and Technology, Gr. NOIDA. From 2012 to 2013, he was a Sr. Lecturer at Echelon Institute of Technology, Faridabad. In 2013, he joined as a Teaching Cum Research Fellow with the Netaji Subhas Institute of Technology (University of Delhi). Since 2017, he has been an Assistant Professor with the Thapar Institute of Engineering and Technology, Patiala. He has authored/co-authored 43 research papers in SCI journals, 5 research papers in Scopus journals, and 6 research papers in international conferences. His research areas include mem-elements emulator circuits, chaotic circuits for cryptographic applications, analog integrated circuits for signal processing, and bandgap reference circuits.is currently working as Associate Professor, ECE Department, Netaji Subhas University of

Bhawna Aggarwal Technology, Dwarka, New Delhi, India. She has a total work experience of 20 years and received her PhD. from NIT Kurukshetra, Haryana, India in the year 2016. She received her M.E. in Electronics & Communication Engineering from Delhi College of Engineering, New Delhi in 2006 and B.Tech. in Electronics & Communication Engineering from Indira Gandhi Institute of Technology, Delhi in 2002. Low power design techniques, Mem-element circuits and Fractional order filters are her areas of research. She is a Senior Member of IEEE and an active member of IETE, ISTE and Vibha Societies. She has published 30+ research papers in SCI/SCIE journals and more than 30 papers in reputed international conferences.

Rupam Das received his B.Tech. Degree in Electronics & Communication Engineering in 2006 and M.Tech. Degree in VLSI & Microelectronics in 2008 from West Bengal University of Technology, West Bengal, India. He has completed his Ph.D from Indian Institute of Technology (Indian School of Mines), Dhanbad, India in 2021. Currently he is working as an Assistant Professor in Electronics and Communication Engineering at Asansol Engineering College, Asansol, India. He has published many papers in the reputed international journals and conferences. His main research interest is in the area of current mode analog integrated circuit design and mixed signal circuit design.

Abstract
We design and simulate an especially engineered photonic crystal structure. $AsSe_2$ as the solid core and As_2S_5 in graded-index hybrid cladding. Hybrid cladding region with inner cladding as a graded helical structure and outer cladding is a hexagonal structure. We have tailored the structural parameters to obtain nearly zero flat-top dispersion profile with all normal dispersion profile. The dispersion at 5 μm is -53.13 ps/nm-km with effective mode area of the fundamental mode as 4.18 μm^2. Proposed PCF is suitable for the generation of an ultra-broadband supercontinuum spectrum from 1 μm to 11 μm in MIR domain when pumped with the peak power of 0.75 KW at 5 μm with 50 fs pulse width. Proposed PCF design holds potentiality for applications like early cancer diagnostics, gas sensing and food quality check.

Keywords Photonic crystal fibers · Supercontinuum generation · Nonlinear optics · Photonic integrated circuits

Introduction

In recent years, research in mid-infrared (MIR) supercontinuum has gathered significant attention [1, 2]. Supercconntinuum generation (SCG) is the process where amalgamation of various nonlinear phenomena including stimulated Raman scattering, self-phase modulation (SPM), cross-phase modulation (XPM), and four-wave mixing takes place (FWM). They work together on an intense pump beam, leading to a significant amount of spectral broadening compared to the original pump beam in an optical fiber. This concept of SCG was first introduced in 1970 [3]. It involves interplay between Raman effect, Kerr effect and dispersion properties of the fiber. Among fibers we have a special class of fibers called holey fibres (HFs) or the microstructured fibers (MOFs) or photonic crystal fibers (PCFs) due to their exclusive linear and nonlinear properties they have been a good choice among researchers [4]. The reason for such fascination is their properties such as dispersion management, large mode area with endlessly single-mode operation, higher birefringence, SCG and high power delivery. When compared to traditional optical fibers, PCF requires lesser initial peak power of the input laser pulses. It results in a huge spectral broadening at a very mimimal peak power this fact can be utilized in applications like frequency metrology [5].

The fiber of choice has traditionally been the silica PCF because it can be made endlessly single-mode, its dispersion can be tailored and its zero-dispersion wavelength (ZDW) can move down into the visible region [6]. Chalcogenide glasses have wider transmission range and a greater nonlinear coefficient in a MIR waveband when compared to silica (non-transparent beyond 2.5 μm), sulfur, fluoride and telluride glasses (long wavelength spectrum is limited at 5 μm) [7].The chalcogenide materials are preferred for broadband SCG because of the lower peak power requirement and high nonlinearity. Compared to single glass chalcogenide fibers, step-index fibers with hybrid-glasses offer several benefits. Firstly, they exhibit a higher refractive-index (RI) difference between the fiber core and cladding, enhancing the effectiveness of light confinement in the core and reducing loss. Secondly, the fiber's numerical aperture is increased due to the higher RI difference, facilitating the collection of light into the core during coupling. Lastly, effective controlling over the chromatic dispersion can be achieved by using

Published online: 15 June 2024

multiple glasses. Consequently, a hybrid fiber composed of two types of chalcogenide glass proves to be well-suited for supercontinuum (SC) generation, especially in extending to the M-IR band [8].

Photonic crystals, waveguides, and photonic crystal fibers all leverage the control of light propagation through structural design and material choice. They share foundational principles such as the use of periodic structures and photonic bandgaps, while differing in their specific forms and applications [9–18]. Several theoretical and experimental studies have documented the exploration of silica, tellurite, fluoride, and chalcogenide glasses in the context of step-index fibers, photonic crystal fibers (PCFs), and waveguides for (SCG) [1, 19–29]. The experimental demonstration of the broadening in SC spectrum from 2.1 to 3.1 µm has been performed by Shaw et al. using a PCF in As_2Se_3 chalcogenide glass [19]. The bandwidth of SCG is maximized by Hu et al. using As_2Se_3 chalcogenide PCF for input pulse at the wavelength of 2.5 µm [22]. Petersen et al. reported a Mid-IR SC spectra, spanning 1.4–13.3 µm by using a chalcogenide step-index fiber [9]. To achieve high nonlinearity at 1.55 µm a composite PCF of As_2Se_3 glass and tellurite is modeled by Liao et al. [10]. Saini et al. presented a triangular core graded-index (GI) PCF for SCG [23]. The SCG of bandwidth 1–6 µm has been computationally analyzed by Seifouri et al. in a PCF made up of As_2Se_3-MgF_2 composition [24]. An equiangular spiral shaped PCF structure is theoretically presented by Saini et al. to generate the SC spectrum, spanning 1.2–15 µm [25]. Salem et al. have done the numerical investigation of a tapered As_2S_3 PCF design using a pulse energy of 100 pJ pumping at 4.7 µm for generation of ultra-broadband SC spectrum [26]. Numerical modeling of an As_2Se_3 rib waveguide is reported by Saini et al. for SCG [27]. In our previously published work, we have done numerical modelling of a parabolic core waveguide for SCG [2]. Using a Ge-Sb-S chalcogenide based waveguide, nonlinear characterization is carried out by Choi et al. for the demonstration of the SC spectrum [28]. A Ga-Sb-S based PCF has been studied for coherent SCG by injecting a laser pulse of 50 fs pulse width and 20 kW peak power in 1 cm fiber length at 4.5 µm [29]. The numerical simulations with an experimental extensive study has been performed by Xing et al. to generate SCG spanning, 1.9–2.34 µm at −20 dB power level in a 2 cm long fiber [20]. A 150 mm long $Ge_{11.5}$ As_{24} $Se_{64.5}$ based PCF is numerically simulated for effective SC spanning, 1.4–10 µm using 85 fs input laser pulse at 3.1 µm with peak power of 5 kW [21].Recently, the maximum SC range covering one octave in a chalcogenide step-index fiber with $AsSe_2$ core and As_2S_5 cladding from 1550 to 3300 nm is obtained with 20 cm long fiber at 2000 nm pulses in normal dispersion region [1].

Among the well-known chalcogenides the transparency range of the $AsSe_2$ core glass extended from approximately 0.83 to 18.9 µm, surpassing that of the conventional materials like As_2Se_3 (0.8–10 µm) [30]. In this study, we devised and produced an innovative photonic crystal fiber (PCF) structure by combining $AsSe_2$ and As_2S_5 materials, resulting in a significant difference in refractive indices. The $AsSe_2$-As_2S_5 composition was carefully chosen for their admirable compatibility during the drawing process to prevent interface cracking. Also, the significant contrast between their refractive index facilities efficient control over chromatic dispersion [31].

In our reported design we are experiencing higher supercontinuum broadening at a low input pump power. Also the tradeoff between broadening and coherence has been efficiently addressed. The generated supercontinuum source can be used to discern chemicals, inspect food quality, detect explosives and hazardous gases, ulcer and cancer diagnosis, frequency comb generation, optical imaging, and optical coherence tomography. This paper includes five segments in total. First segment provides the brief introduction and overview of the work. While, the second segment includes about the PCF designing and its importance. In the third segment, provides the extensive illustration of the analytical methodology used. Fourth segment comprises of results and its discussion. At the end, conclusion of the entire work has been provided in section five followed by references.

In this work, we report a mid-IR supercontinuum spectrum extending form 1 –11 µm at 5 µm using a 4 mm long fiber pumped with 50 fs laser pulses of 750 W. In comparison to recently reported result in Table 1 we obtained broader coherent mid-IR supercontinuum spectrum with comparatively lower peak power of input laser pulse.

Table 1 Value of parameters in the design

		Inner cladding region		Outer cladding region
1st helical ring diameter(µm) (d_1)	2nd helical ring diameter(µm) (d_2)	3rd helical ring diameter (µm) (d_3)	δD(µm) ($=d_1-d_2=d_2-d_3$)	Diameter of hexagonal air holes(µm) (d_4)
0.50	0.50	0.50	0.00	0.70
1.10	0.80	0.50	0.30	0.70
1.30	0.90	0.50	0.40	0.70
1.50	1.00	0.50	0.50	0.70

Design principle of PCF

Figure 1(a) shows the cross-sectional view of proposed PCF. The core is structured using $AsSe_2$ with diameter d_{core}. Cladding is hybrid with two regions, inner cladding and outer cladding. Inner cladding is a graded helical structure around a fixed core. Outer cladding is a hexagonal structure. As_2S_5 is used as a cladding material in combination with air holes. The cladding comprises of 6 layers of hexagonal structured air-holes, where the first 3 layers of air holes have been eliminated from the center to design inner graded helical structure. The inner cladding structure consists of 8 helical patterns and each pattern comprises 3 air holes that are positioned at $r_k = r_{k-1} + 1.5*d$ from the center. The angular variation is given as $\theta_k = (k * 360^\circ) / (2 * K)$ and K reflects the number of spherical rings (K = 3 in our case) as shown in Fig. 1(c) &1(d). For effective detention of light and its propagation through the core forked shift of air holes along with grading is presumed. First three layers of the proposed graded – index (GI) helical shape are arranged with diameter of 1st, 2nd and 3rd ring as $d_1 > d_2 > d_3$,. The value of d_3 is constant as 0.50 µm but d_1 and d_2 has been changed. The distance from the center of the first ring is constant and represented as r_0, which is 2.0 µm. The pitch (Λ= spacing between two air holes) in other rings is optimized. Λ is changed from 1.8 µm to 2.2 µm with a period of 0.2 µm. Grading has been done in a systematic manner where 1st ring diameter is varied as (d_1 = 1.10 µm, 1.30 µm, 1.50 µm), 2nd ring diameter (d_2 = 0.80 µm, 0.90 µm, 1.00 µm), 3rd ring diameter (d_3 = 0.50 µm), core diameter is also varied as (d_{core} = 1.2 µm, 1.4 µm, 1.6 µm, 1.8 µm). Amount of successive grading ($\delta D = d_1 - d_2 = d_2 - d_3$ = 0.30 µm, 0.40 µm, 0.50 µm). The next three rings which forms the outer cladding region have a hexagonal shape of constant diameter (d_4 = 0.70 µm). The distance of first hexagonal ring from the center is 5.6 µm. The distance between the consecutive hexagonal rings is kept constant which is 1 µm. The value of structural parameters have been shown in Table 1 for better understanding. The cylindrical PML is applied at the periphery of the cladding for eradicating the reflection effect occurring at the boundary. Here, the thickness of perfectly matched layer is fixed [23, 32, 33].

Achieving a profile with all-normal dispersion (ANDi) as well as nearly zero dispersion is the purpose of fabricating such a structure. Since, it helps in achieving broader SCG and low noise. Simulated electric field distribution of traversing mode in proposed PCF design has been illustrated in Fig. 1(b). From the fabrication point of view, the reported PCF structure can be fabricated using the well-known rod in tube fabrication technique [34].

Analytical methodology

Linear characteristics

The PCF structure and the effective mode index (n_{eff}) of the fundamental mode is determined using COMSOL software which uses full-vectorial finite element (FEM) method. The wavelength dependent refractive index of $AsSe_2$ chalcogenide glass and As_2S_5 materials was calculated by using the Sellmeier equation and the constant values for $AsSe_2$ ($B_1=6.751$, $B_2=0$, $B_3=0.1768$, b_1^2 0.1034 μm^2, b_2^2 = 153.7990 μm^2, b_3^2 = 10^{-32} μm^2) and As_2S_5 ($B_1=2.1361$, $B_2=0.0693$, $B_3=1.7637$, $b_1^2=0.0954$ μm^2, $b_2^2=225.0001$ μm^2, $b_3^2=2.1783\times10^{-7}$ μm^2) are known [35, 36]

$$n^2(\lambda) = 1 + \sum_{k=1}^{N} \frac{B_k \lambda^2}{\lambda^2 - b_k^2} \tag{1}$$

For Arsenic selenides the wavelength range for sellmeier equation to be valid is typically 1 –14 μm and in some cases it has been further extended up to 0.6 –15 μm [37].

The comprehensive dispersion profile of the intended PCF framework is assessed by employing the following relationship

$$D(\lambda) = -\frac{\lambda}{c}\frac{\partial^2 Re(n_{eff})}{\partial \lambda^2} \tag{2}$$

Re (n_{eff}) denotes the real component of the effective mode index and c is the speed of light in free space. Using the following equation, the effective mode area (A_{eff}) of the propagating mode has been conducted [38]

$$A_{eff} = \frac{\left(\iint_{-\infty}^{\infty} |E|^2 dxdy\right)^2}{\left(\iint_{-\infty}^{\infty} |E|^4 dxdy\right)} \tag{3}$$

Where, the amplitude of the electric field of the light is represented by E.

3.2. Nonlinear characteristics

In the simulations, the initial input laser pulse considered is a hyperbolic secant, as depicted in the equation below.

$$\mathrm{A}(0,\mathrm{T}) = \sqrt{\mathrm{P}_0}\mathrm{sech}\frac{\mathrm{T}}{\mathrm{T}_0} \tag{4}$$

The equation introduces various components: The pulse envelope A (0, T), characterizes the shape of the pulse. P_0, the peak power of the input pulse. T_0 is full-width-at-half-maxima (FWHM) divided by 1.7627, specifically tailored for hyperbolic secant pulses. T is the concurrent frame associated with the group velocity (GV) of the pulse envelope.

The following generalized nonlinear Schrödinger equation is solved using Split-Step Fourier method to obtain the widening of the spectral range observed in the generated SC within the PCF structure [39]

$$\frac{\partial \tilde{A}'}{\partial z} = i\tilde{\gamma}(\omega)\exp\left(-\hat{L}(\omega)z\right) \mathcal{F}\left\{\bar{A}(z,T)\int_{-\infty}^{\infty} R(T')\left|\bar{A}(z,T-T')\right|^2 dT'\right\} \tag{5}$$

Where, $\tilde{A}'$ is envelope or the covering of the output pulse which represents its modulation amplitude or shape, $\bar{A}(z,T)$, the envelope at distance z at time t. $\bar{A}(z,\omega)$, the Fourier transform of $\bar{A}(z,T)$. The frequency-dependent nonlinear coefficient $\bar{\gamma}(\omega)$ is obtained by taking into account its dependency on the frequency

$$\bar{\gamma}(\omega) = \frac{n_2 n_0 \omega}{c n_{eff}(\omega) A_{eff}^{1/4}(\omega)} \tag{6}$$

n_2 corresponds to the nonlinear refractive index, which is specifically 2.3×10^{-17} m^2/W for $AsSe_2$ chalcogenide glass [40]. The symbol n_0 represents the glass refractive index at the wavelength needed to calculate n_2 and c being the speed of light in free space (vacuum). The expression for the altered variables are stated as

$$\tilde{A}'(z,\omega) = \tilde{A}(z,\omega)\exp(-\hat{L}(\omega)z) \tag{7}$$

The following equation shows the linear operator $\hat{L}(\omega)$as

$$\hat{L}(w) = i(\beta(\omega) - \beta(\omega_0) - \beta_1(\omega_0)[\omega-\omega_0]) - \frac{\alpha(\omega)}{2} \tag{8}$$

β, propagation constant; β_1, the inverse of the group velocity of pulse envelope; α, the total loss and; ω_0, the reference frequency, within the PCF design. The Raman response function$R(t)$ is defined as

$$R(t) = (1-f_R)\delta(T) + f_R\frac{\tau_1^2+\tau_2^2}{\tau_1\tau_2^2}\exp\left(-\frac{T}{\tau_2}\right)\sin\left(\frac{T}{\tau_1}\right)\mathrm{H}(\mathrm{T}) \tag{9}$$

Here, H (T) being the Heaviside step function depends on T. For the $AsSe_2$ glass, Raman parameters f_R,τ_1,τ_2 are known [35].

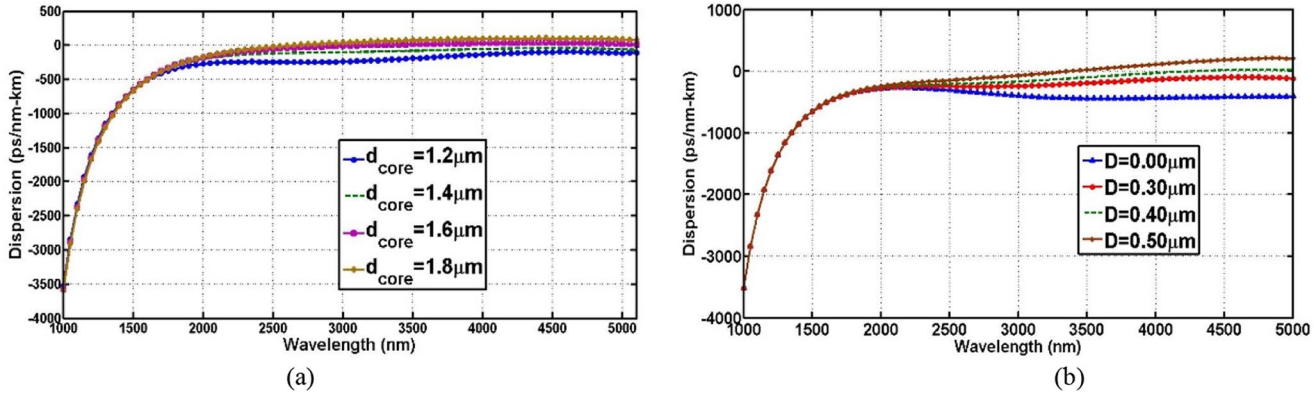

Fig. 2 (**a**) Effect of core Width "d_{core}" on dispersion characteristic of the PCF with $d_1 = 1.10$ μm, $d_2 = 0.80$ μm, $\delta D = 0.30$ μm and $\Lambda = 2.2$ μm ; (**b**) Effect of grading on the dispersion characteristic of the PCF for $d_{core} = 1.6$ μm and $\Lambda = 2.2$ μm

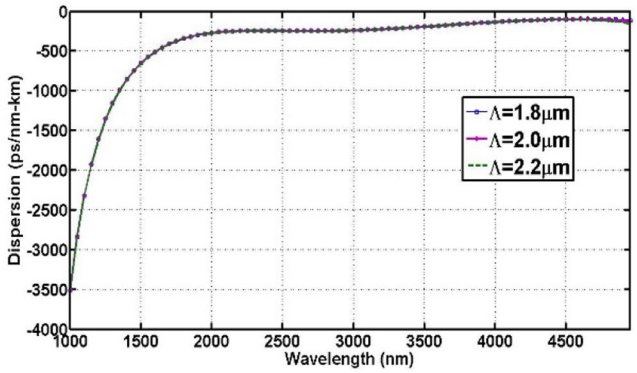

Fig. 3 Effect of pitch on the dispersion characteristic of the PCF for $d_{core} = 1.6$ μm and $\delta D = 0.30$ μm

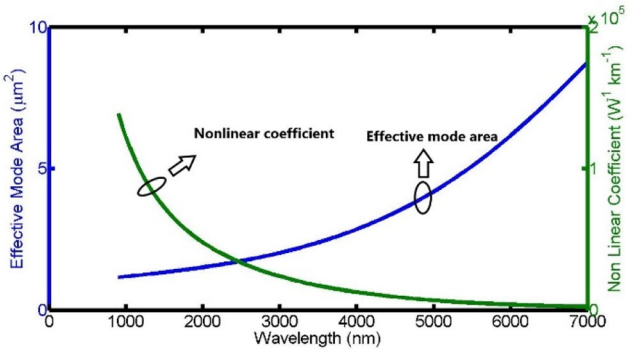

Fig. 4 The spectral changes in the effective mode area and nonlinear coefficient are depicted with respect to wavelength for PCF

Results and discussion

For a PCF structure the broadening in the supercontinuum spectrum primarily depend upon the nonlinearity of material and the dispersion characteristics [13].We have optimized the core diameter of the proposed design for d_{core} (1.2 μm, 1.4 μm, 1.6 μm and 1.8 μm) as shown in Fig. 2(a). Dispersion profile shows all normal dispersion behavior for all d_{core} except for 1.8 μm. Soliton fission process along with the emission of the dispersive waves is responsible for the broadening in the supercontinuum spectrum if pumped in the anomalous dispersion region. The SCG by the process of soliton fission is vulnerable to the laser shot noise which makes supercontinuum unstable.

As depicted in Fig. 2 (a) with 1.6 μm as the core diameter, $d_1 = 1.10$ μm, $d_2 = 0.80$ μm, $\delta D = 0.30$ μm and pitch = 2.2 μm the profile is more flat and all normal with minimum value of dispersion around 4.8 μm as compared to rest of the core diameters. So, we have opted for 1.6 μm as a core diameter. Further, the air holes in the inner cladding region has been graded in the decreasing order of diameter. Figure 2(b) shows dispersion for δD (amount of grading). Among the evaluated δD (0.00 μm, 0.30 μm, 0.40 μm and 0.50 μm) it has been found that both $\delta D = 0.00$ μm(non-graded) & $\delta D = 0.30$ μm is showing all normal dispersion profile whereas others have both normal and anomalous dispersion regime. But between these two, we have considered $\delta D = 0.30$ μm, along with being all normal it is having less dispersion. So it will result in more broadening as well as good coherency. Figure 3 shows that on changing the pitch (Λ) of the air holes in the inner cladding region there is no significant change in the nature of the profile. On changing pitch the effective refractive index of the profile has not changed much which could possibly affect dispersion curve, since it is same so the profile is also same for different pitch values. Considering the availability of a commercial available laser source we have taken 5 μm as a pump wavelength. At 5 μm the dispersion is -53.13 ps/nm-km for 1.6 μm core diameter, $\delta D = 0.30$ μm and $\Lambda = 2.2$ μm. In Fig. 4, effective mode area vs. nonlinearity shows the obvious trend when plotted against wavelength. At 5 μm effective mode index, effective mode area and nonlinearity has been evaluated and found to be 2.278, 4.18 μm^2 and 6900 $W^{-1}Km^{-1}$ respectively.

The complete loss is sum of both material and confinement loss in a fiber. The value of confinement loss is less in comparison to the material loss of the $AsSe_2$ chalcogenide glass, which shows absorption peak in the loss curve around 2.9 μm due to the OH impurity in the chalcogenide glass, and other absorption peak around 12.7 μm because of the Se-OH bonds [41]. The confinement loss was very less in comparison to the material loss and its value is 1.19×10^{-2} dB/m at 5 μm.

SCG has been evaluated at pump wavelength of 5 μm for various values of fiber length, pulse width and peak power with 1 kHz repetition rate. The maximum broadening is observed for 4 mm fiber length, 750 W peak power and 50 fs pulse width. Figure 5 shows variation of intensity with length from 2 mm to 8 mm, it is seen that the broadening is very less below 4 mm and above 4 mm noise is increasing. Similarly, in Fig. 6 the length variation in a spectrum from 4 mm to 8 mm depicts that on increasing the length at-40 dB power level the spectrum is experiencing a shift towards longer wavelength region. In the beginning the broadening has occurred due to SPM which is later dominated by (OWB) optical wave breaking. Further increase in length add undesirable fluctuations in the supercontinuum spectrum and deteriorate coherence. So we have considered 4 mm as optimum fiber length. Also, from Fig. 7 it is evident that on increasing length the coherency is also getting disturbed.

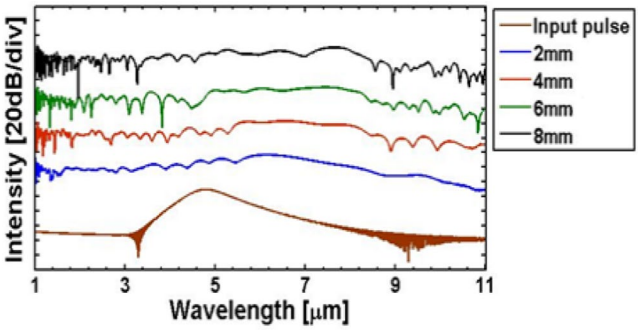

Fig. 5 The advancement of spectral SC broadening along the length of the PCF, induced by 50 fs laser pulses with 750 W pump power at 5.0 μm

In Fig. 8, as the pump power is incremented from 750 W to 2750 W the spectrum gets shifted towards the longer wavelength region. As the pumping power was further

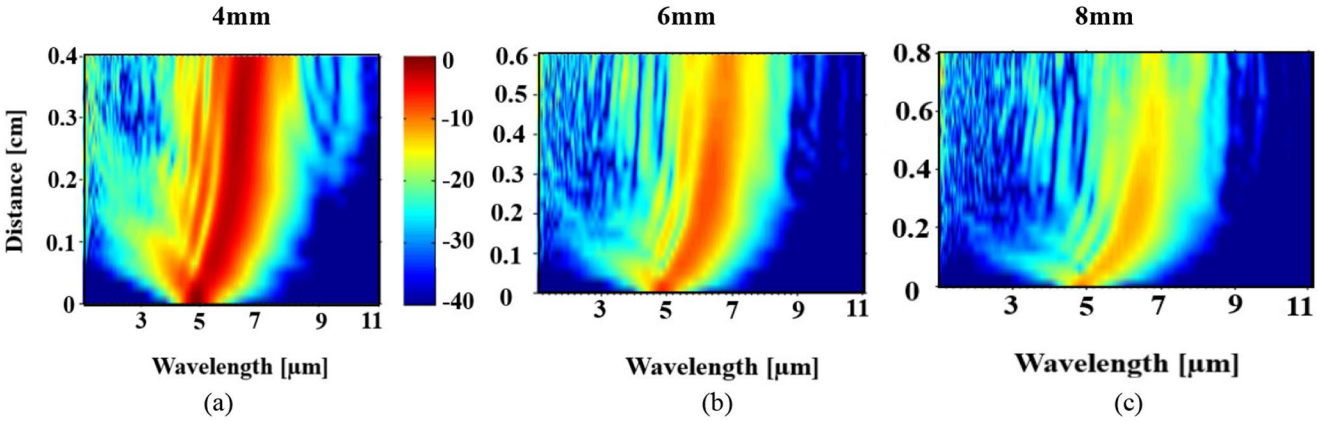

Fig. 6 The advancement of spectral SC broadening along the length (**a**) 4 mm; (**b**) 6 mm; (**c**) 8 mm of the PCF, induced by 50 fs laser pulses with 750 W pump power at 5.0 μm

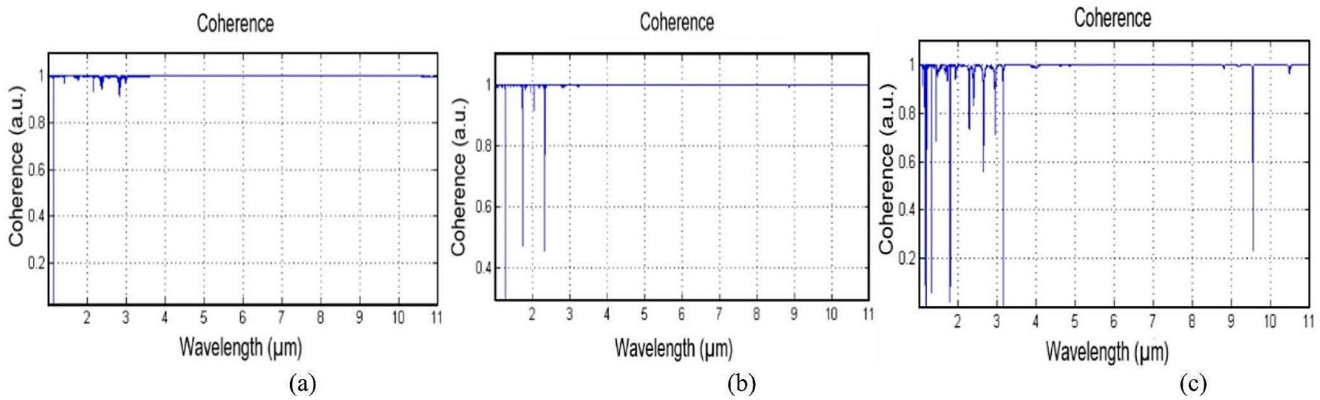

Fig. 7 The changes in the coherence evolution at 5 micron in response to the input pulse peak power 750 W,50 fs pulse width along the length of the fiber (**a**) 4 mm; (**b**) 6 mm; (**c**) 8 mm

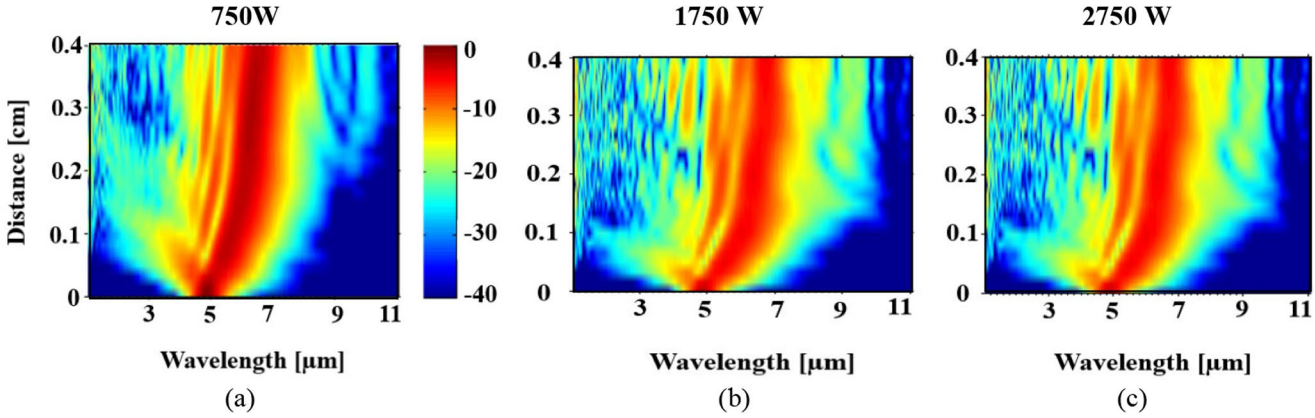

Fig. 8 The advancement of spectral SC broadening with the pump power, (**a**) 750 W; (**b**) 1750 W; (**c**) 2750 W; induced by 50 fs laser pulses with 4 mm fiber length at 5.0 μm

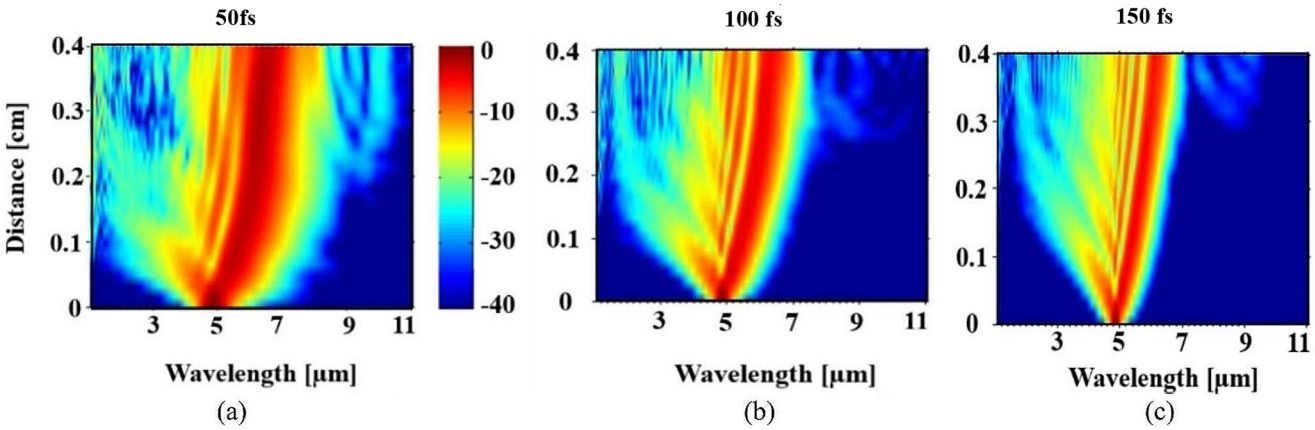

Fig. 9 The advancement of spectral SC broadening at 5 μm induced by (**a**) 50 fs; (**b**) 100 fs; (**c**) 150 fs laser pulses at 4 mm fiber length ,750 W pump power

increased the SC started to degrade due to absorption at the coating [42] In Fig. 9, it can be observed as the value of T_{FWHM} is increased from 50 femtosecond to 150 femtosecond the resultant spectra began to get (thinner) narrow down. This is due to the Self phase modulation effect. It is worth noting that shorter pulses tend to get broader SC spectra. Hence, 50 fs pulses are giving stable spectrum.

For 50 fs laser pulse at 5 μm, β_2 is 1.15×10^{-25} ; ($T_0 = T_{FWHM}/1.763$) ; the nonlinear length ($L_{NL} = (\gamma P_0)^{-1}$) and dispersion length ($L_D = (\beta_2/T_0^{\,2})^{-1}$) for proposed PCF are 1.9×10^{-4} m and 2.17×10^{-2} m respectively. In order to achieve a broader supercontinuum generation, it is desirable to have a nonlinear length that is comparable to or shorter than the dispersion length. This ensures that nonlinear effects play a significant role in shaping the spectrum of the input pulse, while dispersion does not excessively broaden the pulse before nonlinear effects can take place. The soliton order, $N \approx L_D/L_{NL} \approx 10$ and the soliton fission length, $L_{fiss} = L_D/N \approx 2.17$ mm is evaluated using these relations. In the starting phase of pulse propagation, self -phase modulation (SPM) is responsible for spectral broadening whereas at longer wavelength optical wave breaking is responsible for broadening.

Within the range of 1.3–1.7 μm, it is advantageous to modify the probing wavelength in order to enhance the imaging capabilities of optical coherence tomography (OCT) systems for biological tissue [41]. Additionally, near-to-mid-IR supercontinuum pulses that are repeatable from shot to shot are crucial for enhancing image penetration depth and regaining a 10 dB signal-to-noise ratio [43]. In this paper, we concentrate on the extensive range of SC spectra achieved with minimal pump power within a short length of the suggested PCF structure. Further, to explore the degree of coherence (DoC) of the obtained spectra, we have calculated coherence in Fig. 7 for length 4 mm, 6 mm and 8 mm respectively. The first-order DoC is given as

$$|g_{12}(\lambda(t_1 - t_2)| = \frac{|< E_1^*(\lambda, t_1)E_2(\lambda, t_2) > |}{(|< E_1(\lambda, t_1)^2 < \left|E_2(\lambda, t_2)^2\right| >)^{1/2}} \tag{10}$$

Table 2 Comparison against previously documented outcomes of SC spectrum in chalcogenide PCFs

References	Chalcogenide type	Pump Wavelength (μm)	Fiber length	Peak power (kW)	SCG bandwidth (μm)
[44]	$As_{38.8}$ $Se_{61.2}$ PCF	3.7	5 cm	0.88	2.9–4.575
[45]	As_2S_5 – Borosillicate PCF	2.5	4 mm	28.16	1–5
[46]	As_2Se_3 PCF	2.5	10 mm	20	1–10
[29]	$Ga_8Sb_{32}S_{60}$ PCF	4.5	1 cm	20	1.65–9.24
[42]	$GeSe_2$-As_2Se_3-PbSe PCF	3.1	10 mm	0.95	1–11
Proposed work	$AsSe_2$- As_2S_5 PCF	5.0	4 mm	0.75	1–11

Electric fields of independent SCG pairs are given by $E_1(\lambda, t_1)$ and $E_2(\lambda, t_2)$. These electric fields pertains to immediately consecutive generated SCG spectra with the angular brackets indicating an average over the entire pulse ensemble. To center on the wavelength dependence of the coherence, $\Delta t = t_1 - t_2 = 0$ was adopted.

The DoC function is bounded as $0 \leq |g_{12}(\lambda, t_1 - t_2)| \leq 1$. The value 0 signifies completely incoherent spectrum while the maximal value 1 represents perfect spectral coherence. We have computed the DoC function especially to examine the wavelength dependence of the coherence [42].

Finally we conclude that our proposed structure is able to generate broader and comparable SCG bandwidth with lower pump power in comparison to previously reported work, mentioned in Table 2.

As can be inferred from the table $As_{38.8}$ $Se_{61.2}$ PCF [44] and As_2S_5 – Borosillicate PCF [45] has a limited broadening up to 5 μm, As_2Se_3 PCF [46] and $Ga_8Sb_{32}S_{60}$ PCF [21] has broadening around 1 to 10 μm but the peak power used is quite high around 20 kW. In $GeSe_2$-As_2Se_3-PbSe PCF [42] the broadening is comparable but the peak power used is higher as 0.95 kW with 10 mm fiber length as compared to 0.75 kW and 4 mm fiber length in our case.

Since the focus of this work is to produce greater broadening with low peak power as it offers several advantages in SCG. It can reduce nonlinear effects which can distort the spectrum and limit the bandwidth of the supercontinuum.It leads to better performance in applications where spectral stability is crucial, such as optical coherence tomography (OCT) and spectroscopy. With lower peak power, the supercontinuum spectrum tends to be more stable over time. It enhances Signal-to-Noise Ratio which improves the quality of measurements and imaging in various applications. It reduces photodamage. Also, it often corresponds to longer pulse durations, which can be beneficial for certain applications that require longer interaction times with the sample, such as material processing and biomedical imaging.

Overall, using lower peak power in supercontinuum generation can result in more stable, high-quality spectra with reduced nonlinear effects and improved safety for sensitive samples.

Conclusion

In summary, the especially designed graded index hybrid PCF structure with $AsSe_2$- As_2S_5 offers all normal dispersion (ANDi) at pump wavelength of 5 μm. The essence of this work lies in the generation of mid-IR supercontinuum an efficient broadband coherent mid-IR SC spectrum extending from 1 to 11 μm is reported in a 4 mm long PCF when subjected to 750 W, 50 fs laser pulse at a wavelength of 5 μm. From an application standpoint, the utilization of a PCF-based broadband coherent NIR to MIR SC light holds great significance in various critical domains, including early cancer diagnostics, food quality control, security, sensing, and the recognition of a sustained optical frequency comb for enabling high-precision spectroscopy and optical coherence tomography. Additionally, the reported PCF, which generates NIR to MIR SC light, has the potential to significantly expand the range of functionalities achievable in future photonic integrated circuits.

Abstract
Facial emotion recognition has become a complicated task due to individual variations in facial characteristics, as well as racial and cultural variances. Different psychological studies show that there are complex expressions other than basic emotions which are made up of two basic emotions like"Happily Disgusted", "Happily Surprised", "Sadly Surprised", etc. Compound emotion recognition is challenging due to very less publicly available compound emotion datasets which are imbalanced too. In this paper, we have proposed an LSwin-CBAM for the classification of compound emotions. To address the problem of the imbalanced dataset, the proposed model exploits the cutmix augmentation technique for data augmentation. It also incorporates the CBAM attention mechanism to emphasize the relevant features in an image and swin transformer with fewer swin transformer blocks which leads to less computational complexity in terms of trainable parameters and improves the overall classification accuracy as well. The experimental results of LSwin-CBAM on RAF-DB and EmotioNet datasets show that the proposed transformer-based network can well recognize compound emotions.

Keywords Swin transformer · CutMix augmentation · CBAM · Compound emotion recognition

1 Introduction

Face expressions are an efficient way for people to communicate their emotions. It gives the spectator a plethora of social cues, such as the viewer's focus of attention, emotion, motivation, and intention and brings out 55% of the conveyed message, which is relatively higher than the part communicated by the combination of voice and language [1]. Research done in social psychology explains that facial expression helps in coordinating the conversation between speaker and listener that can perceive the interest of the listener [2, 3]. In most of the studies, macro-expressions (happiness, surprise, sadness, anger, fear, and disgust) are subjects of concern that are most commonly observed in most cultures. But, sometimes humans can express mixed emotions. For example, a person can have feelings of "sad" and "surprise" components together which forms a compound emotion named "Sadly Surprised". The combination of two or more emotions is represented by a compound emotion where one emotion is dominant and the other is complementary. Face recognition in the real environment is a challenging task due to the variation in head orientation, illumination conditions, and head poses. For compound emotion recognition where dominant and complementary emotions need to be recognized, the task becomes more difficult [4].

Authors usually focus on seven basic emotions: 'Surprise', 'Anger', 'Happiness', 'Contempt', 'Fear', and 'Disgust'. But there is a need to examine more detailed and precise facial expressions. Some authors tried to find out detailed facial expressions because of recent developments in the area of compound emotions [5, 6]. To examine a person's emotional state in greater detail using facial emotion expression analysis, compound emotion categories have been proposed [7]. Such studies contribute in the context of compound emotion recognition which comprehends and identifies fine-grained facial expressions.

Transformers [8] are greatly used in Natural Language Processing (NLP) tasks. Research efforts to adapt transformers for vision tasks have been driven by the tremendous achievement of transformers in NLP. Due to its original transformer architecture and promising performance in vision

tasks, Vision Transformers (ViTs) [8] received a lot of attention from AI researchers. Apart from its promising performance, there are a few limitations encountered in ViTs. The computational complexity of ViTs is quadratic to image size, which is why it particularly faces difficulties with high-quality input images. Moreover, the variable scale visual features in vision tasks make it unsuitable as it processes the fixed scale tokens.

Liu et al. [9] developed the swin transformer which is possibly the most intriguing concept of research following the original ViT. Swin transformer addressed the limitations of ViT by introducing these key concepts: hierarchical feature maps and shifted windows. The key idea behind the swin Transformer is to divide the input image into non-overlapping patches and organize them hierarchically. Unlike traditional vision transformers that operate on fixed-size patches, the swin Transformer employs shifted windows, which means that each patch is constructed by shifting a fixed-size window across the image. This allows the model to have a larger receptive field without increasing the computational complexity significantly. It outperforms ViTs in image classification by identifying fine-grain features in an image where each pixel is labeled as in semantic segmentation. The deep swin transformer model is modified by including a single stage only with additional modules which improves the classification accuracy with minimal computational overhead. The adoption of lightweight machine learning models offers several significant benefits for real-time applications. Lightweight models are designed to have fewer parameters and require less computational power compared to heavy models with more computation. Due to their reduced complexity, lightweight models often have faster inference times, allowing for real-time processing of facial expressions. Training lightweight models typically requires less time and resources compared to training larger models. This can accelerate the development and deployment process, allowing for quicker adaptation to changing requirements or datasets.

Next, the absence of significant, publicly available labeled datasets for compound emotions is one of the major barriers to advancing research on the automatic recognition of compound emotions. To overcome the above-mentioned problem, the CutMix data augmentation technique has been used in the model which increases the training set and solves the problem of information loss and inefficient behavior of other regional dropout methods. The Cutmix technique picks random patches from the training images and ground truth labels are combined in the ratio corresponding to the area of patches in the images. The neural network's ability to focus on specific regions, eliminate irrelevant information, and effectively extract essential features from images is made possible by using attention mechanisms. In the proposed model, the convolutional block attention module (CBAM) attention mechanism [10] has been used which sequentially combines the channel attention module to exploit the inter-channel relationship by giving varying significance to the channels of feature maps and spatial attention module to determine which parts of a feature map are more imperative. The key points of the proposed framework are as follows:

- *T*o design a lightweight compound emotion recognition model named LSwin-CBAM that is based on a streamlined swin transformer exploiting CutMix augmentation technique and CBAM attention mechanism to improve the classification rate of compound emotions.
- *C*BAM attention mechanism is incorporated to enable the network to focus on relevant regions resulting in pertinent feature extraction and introduces a trade-off between model accuracy and parameter count in the proposed model.
- *A*dditionally, an analysis of the computational efficiency and model complexity of LSwin-CBAM is conducted, providing insights into its practical applicability.

The organization of the manuscript is as follows: Section 2 reviews the state-of-the-art methods in the field of compound emotion recognition. Section 3 includes the architectural and formulation overview of the proposed method. The experimental setup and results of the proposed method are depicted in Section 4, At last, the manuscript is concluded in Section 5.

2 Literature survey

Humans can easily recognize emotions accurately, but making a fully automated machine to recognize facial expressions is still challenging. If this capability of emotion recognition can be empowered in robots or computers then robotic applications can be developed to understand the emotions of a human with a limited understanding of the relationship between emotional expressions and body movements [11]. The facial expression recognition method is developed by deforming a few control points of the FACS-based facial motion proposed by Ekman [12]. Many studies exist [13–16] which focused on seven basic expressions but to enrich more details of human emotions, compound emotions came into the picture. Jarraya et al. [17] developed a system for compound emotion recognition for autistic children in a time of meltdown crisis. Researchers assessed deep spatio-temporal geometric features of involuntary facial expressions in the time of meltdown crisis. They analyzed the relevance of different feature selection methods like filter methods, Wrapper methods, and (Neighborhood component analysis) NCA method and observed to achieve the best accuracy i.e. 85.5% using RNN classifier and Information Gain feature

selection method [17]. Guo et al. [4] compared the top winner's methods (used CNN) from FG 2017 workshop on an iCV-MEFED dataset for the recognition of compound emotion and observed that Ist model given by [18] has performed better with less misclassification rate (0.793 for validation set and 0.802 for test set). Li et al. [19] proposed a deep locality-preserving convolutional neural network (DLP-CNN) approach which seeks to maximize inter-class dispersion while maintaining local relationships to improve the discriminative ability of deep features. The performance of DLP-CNN was evaluated on the RAF-DB dataset [19] (includes basic and compound emotions) and other different benchmarks datasets.

Kaminska et al. [20] proposed a two-stage recognition model for compound emotion. The first stage introduces coarse recognition that merges appearance-based features extracted using DCNN and facial-point features and the second stage introduces fine recognition using a binary classifier. Authors [20] further tried the ensemble model which includes a one-stage and two-stage model and eventually improves the recognition rate from 19.28% to 21.83%. Shaila et al. [21] used the MobileNet model with depthwise convolution operation for compound emotion recognition. Liang et al. [22] proposed a fine-grain dataset named "FG-Emotions" to draw a more detailed analysis of facial emotions. FG-Emotions dataset has 33 fine-grained emotion classes. Authors [22] developed a "two-stream multi-scale AU-based Network (MSAU-Net)" for the prediction of fine-grained emotions. Pons et al. [23] proposed a Selective Joint Multitask approach (SJMT) which considers selective loss function (sigmoid cross-entropy) for each dataset. This approach [23] is beneficial while dealing with different datasets containing unlabeled images. The proposed loss function is incorporated with ResNet-50 and VGG16 model and found more effective when applied to datasets collected in an unconstrained environment (Oulu-Casis, SFEW) and compound emotion recognition (EmotioNet) as compared with the individual ones. Kirillov et al. [24] proposed a foundation model SAM (Segment Anything Model) using prompt engineering which solves downstream segmentation challenges on unseen data during training.

Dosovitskiy et al. [25] introduced a vision transformer that allows models to understand image structure independently as input images and are depicted as sequences and predict the class labels for the given image. The input images are processed as a sequence of patches, where each patch has been flattened into a single vector, further concatenated by the channels of all of its pixels before projecting them linearly to the defined dimension of input. Mu et al. [26] proposed a model based on visual transformers with feature fusion which is tested on in-the-wild expression datasets like RAF-DB, AffectNet, and FERPlus. Lian et al. [27] assessed GPT-4 with vision for Generalized Emotion Recognition (GER) tasks including tweet sentiment analysis, facial emotion recognition, visual sentiment analysis, micro-expression recognition, multimodal emotion recognition, and dynamic emotion recognition. Zhu et al. [28] proposed a unified framework based on a multi-branch vision transformer for multi-task facial emotion recognition and mask-wearing classification. Dong et al. [29] introduced a novel loss function called bi-center loss, which is an extension of center loss. This new function is designed to capture compound emotion features by utilizing the centers of basic emotions. Xue et al. [30] used the vision transformer model to produce relation-aware local representation and the relation between them whereas Multi-head Attention Dropping (MAD) is also incorporated in the proposed model to drop the attention maps. Multi-head self-attention joins the relevant features using information subspaces at various locations. But different self-attention may produce identical relations which can be alleviated using Multi-head Self-attention Dropping (MSAD). Vision transformer performed well for image classification tasks but has some limitations such as higher computational complexity as it computes self-attention operation globally, and creates feature maps of a single low-resolution image. Liu et al. [9] developed a Swin transformer that merges image patches in deeper layers to produce hierarchical feature maps and it computes self-attention operation within the local window which leads to linear computational complexity. Zhao et al. [31] proposed a swin transformer-based model that accepts multimodality inputs to recognize the micro-expressions. Xue et al. [32] proposed a Coarse-to-fine Cascaded Network (CFC) with Smooth Predicting (SP) and improved the classification rate by extracting both unique and universal features and by ensembling swin transformer with ResNet for the training of the model. The proposed LSwin-CBAM framework is based on a lightweight swin transformer which consists of only two consecutive swin transformer blocks with CBAM attention mechanism which improves the recognition capability of the network with very less computational overhead.

3 Proposed work

Compound emotions are the composite of basic emotions that gives a detailed understanding of a person's feeling. Transformers performed tremendously well for natural language processing (NLP) tasks. So researchers [25] developed a variant named "Vision Transformer" based on transformer architecture which can be applied for vision tasks. However, there are some limitations as it works on a constant scale. In contrast, the scale of visual entities in the given images can have large variations and computational complexity is quadratically increasing with image size. So, these above-mentioned limitations forced researchers [9] to develop the

Swin transformer model to extract dense information from the given images. Swin transformer works on each pixel and forms a hierarchical feature map that initiates with small-sized patches and progressively merges with neighboring patches as moves down in deeper transformer layers.

In our work, we proposed a transformer-based model for compound emotion recognition which used a streamlined swin transformer with a CBAM attention module. Swin transformer is taken as the base model with some architectural modifications. The general architecture of the Swin transformer (ST) [9] has 4 stages where the ST block is preceded by a linear embedding layer in the first stage and a patch merging layer in the last three stages which leads to a heavy deep model that increases computational overhead with 6M parameters on experimentation. To optimize the base model, a reduced number of stages (single stage) are included, resulting in minimal computational overhead with 0.15M parameters. The adoption of a lightweight model is suitable for real-time applications. Moreover, the CBAM (Convolutional Block Attention Module) attention mechanism is integrated, introducing a trade-off between model accuracy and parameter count in the proposed model. Additionally, the utilization of CutMix augmentation enhances the classification performance, surpassing that of the base Swin model while utilizing fewer parameters (0.15M). By carefully integrating these components, the LSwin-CBAM model achieves enhanced performance in recognizing compound emotions, surpassing the capabilities of individual methods.

The proposed architecture of LSwin-CBAM is shown in Fig. 1 that accepts the images as input which are forwarded to the cutmix augmentation module because imbalance data is a very common problem in facial expressions datasets which affects the performance of the model. The augmented dataset is fed to the Conv2D layer to produce a feature map which is given as an intermediate map to the CBAM attention module to enhance the feature representation of relevant features. CBAM is followed by a patch partitioning module to produce patches that are flattened to form a feature vector which will go through a linear embedding layer to convert it to an arbitrary dimension C. This intermediate feature map is further fed to the streamlined swin transformer block (consisting of a single stage only) and followed by a patch merging operation to merge two adjacent patches for downsampling of the feature map. After patch merging, global average pooling and dense layer are applied to produce the classified emotion as an output. Below we have discussed each steps of proposed work.

3.1 Input data and augmentation

Input to the proposed model is a compound emotion RGB images. Cutmix augmentation is applied to increase the training samples. Data augmentation is considered as one of the important steps of data pre-processing as it greatly enhances the variety of data accessible for training our models, all without the need to gather additional data samples. Basic techniques such as flipping, random cropping, and random rotation are frequently employed to train extensive models, particularly effective for smaller datasets and simpler problems. However, significant shifts and corruptions in data can occur when faced with the complexities of real-world scenarios. So, there are advanced augmentation techniques available like cutout [33], mixup [34], and cutmix [35]. In Cutout augmentation [33], a square-shaped region is eliminated from the image and substituted with either black or grey pixels, or filled with Gaussian noise. The eliminated regions

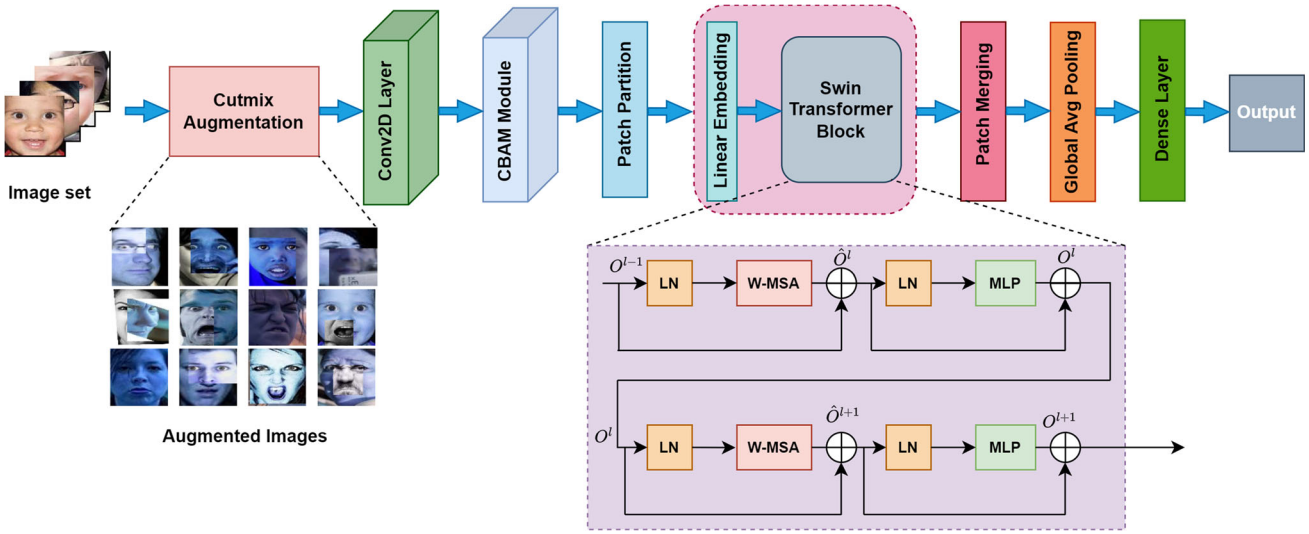

Fig. 1 Proposed model architecture integrating cutmix augmentation, CBAM attention, and lightweight Swin transformer module for compound emotion recognition

are typically zeroed out or populated by random noise [33] which drastically lowers the extent of informative pixels in given images. With mixup augmentation [34], a linear interpolation is employed between two randomly selected images. Nevertheless, the resulting images exhibit a degree of unnaturalness that can confuse the model. So, to utilize the deleted regions, Yun et al. [35] proposed the cutmix augmentation strategy. It uses a patch from a different image to restore the missing regions rather than just eliminating pixels as shown in Fig. 2. Additionally, the ground truth labels are combined in accordance with the total number of pixels in the merged images. The additional patches make the model recognize the object from a partial context, which improves the localization capability even further.

Cutmix augmentation technique [35] is applied on the given training images which produce the output images shown in Fig. 2. The training image is indicated by $x \in I^{W \times H \times C}$ where H, W, and C represent the height, width, and channels of an image respectively. Cutmix aims to produce a new training instance $(\tilde{x}, \tilde{y})$ by mixing any two given training samples (x_i, y_i) and (x_j, y_j). The model is trained using the original loss function of generated training sample $(\tilde{x}, \tilde{y})$. The combining or mixing operations are defined in (1) where $B_m \in (0, 1)^{W \times H}$ represents binary mask which suggests the pixels to keep and drop from two images.

$$\tilde{x} = B_m \odot x_i + (1 - B_m) \odot x_j,$$
$$\tilde{y} = \delta y_i + (1 - \delta) y_j, \tag{1}$$

The cutmix method will produce a cutmix-ed augmented sample $(\tilde{x}, \tilde{y})$ by combining any two randomly picked training samples in each iteration as shown in Fig. 2.

3.2 CBAM attention mechanism

The origination of simulating human attention in computer vision is to improve the model's performance for image processing tasks with minimized computational complexity. Attention mechanisms concentrate on particular sections of the images instead of the complete picture and improve the interest representation, which has gained popularity in deep learning. The convolution function extracts relevant features by incorporating spatial and cross-channel information together. The convolutional Block Attention Module (CBAM) module sequentially infers attention maps along

Fig. 2 Samples of images post-CutMix augmentation

the two distinct dimensions of channel and spatial from an intermediate feature map and then multiplies the attention maps by the input feature map to refine the adaptive feature. As a universal and lightweight module, it can be seamlessly integrated with any CNN-based architecture with minimal overhead (Fig. 3).

CBAM accepts an intermediate feature map represented by $M \in I^{C\times H\times W}$ and applies a single-dimensional channel attention map $A_c \in I^{C\times 1\times 1}$ and two-dimensional spatial attention map $A_s \in I^{1\times H\times W}$ in a sequential manner. The attention operation can be formulated in (2). In element-wise multiplication, the channel and spatial attention values are copied along spatial and channel dimensions respectively, and give M''as the final output. The visualization of learned attention weights using CBAM attention mechanism is shown in Fig. 4 to show how CBAM highlights the relevant facial features in an original image. Brighter regions indicate greater attention weights, signifying the relevance of those regions for subsequent processing.

$$\begin{aligned} M' &= A_c(M) \odot M, \\ M'' &= A_s(M') \odot M', \end{aligned} \tag{2}$$

3.3 Swim Transformer

Swin transformer [9] is developed as a general-purpose transformer-based architecture for vision tasks. It performs local self-attention within distinct windows and attains linear computational complexity. The streamlined architecture of the swin transformer used in the proposed model is illustrated in Fig. 5. Firstly, attentive features extracted from CBAM attention undergo patch partitioning process which splits input images into non-overlapping patches with a patch size of 2×2. Each patch is considered a "token," where its feature is configured as a concatenation of the pixel values of an RGB image. Each feature with dimension $2 \times 2 \times 3$ will be flattened and converted into a vector of length 12. The vector is projected to an arbitrary dimension (C) using a linear embedding layer. On these patch tokens, two swin transformer blocks (within a single stage only) with modified self-attention mechanisms are used, and maintain the number of tokens $(H/2 \times W/2)$. A transformer block with a linear embedding layer is referred to as stage 1 in Fig. 5.

3.3.1 Swin transformer block

The Swin Transformer block has a hierarchical structure, which allows it to process images of varying sizes. So, to create the Swin Transformer, the conventional multi-head self-attention (MSA) module in a transformer block is replaced with an SW-MSA module (Mutli-head attention with shifted windows) to compute the self-attention within local windows, while other layers remain the same. It includes shifted-window-based multi-head self-attention

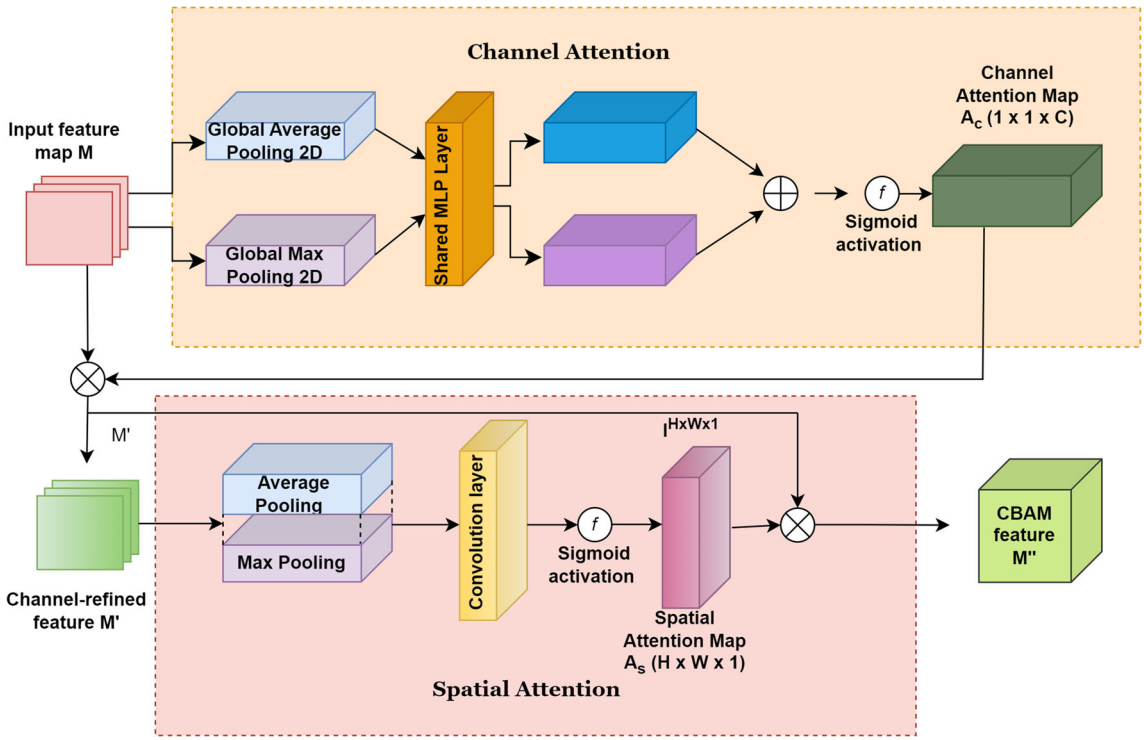

Fig. 3 Architecture of Convolutional Block Attention Module (CBAM) [10]

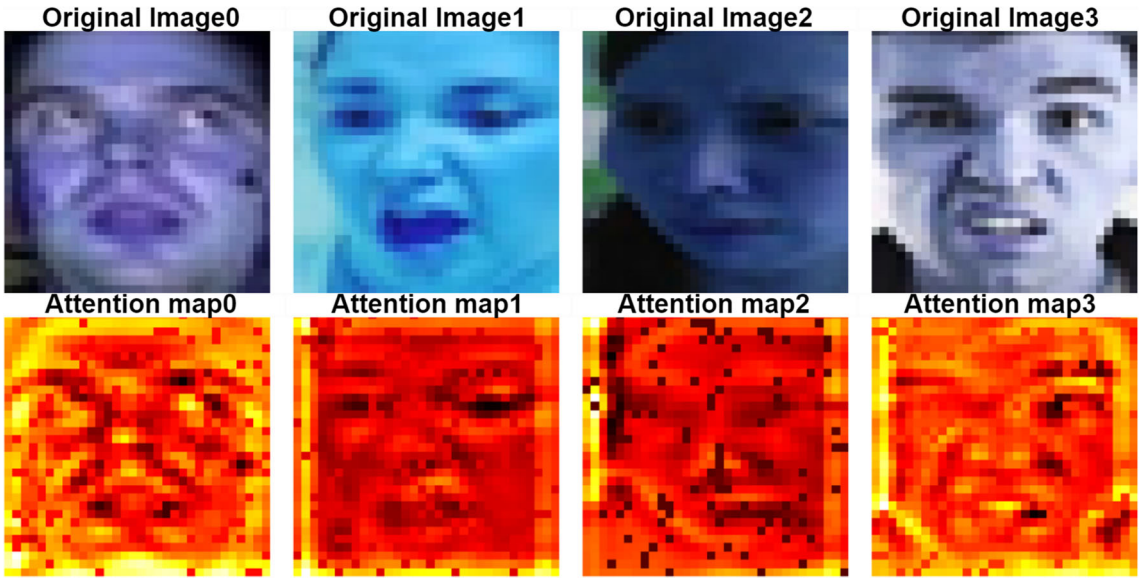

Fig. 4 Visualization of learned attention weights of CBAM attention on input images

and an MLP(2-layer) with a GELU activation function. A normalization layer is added before every MSA and MLP component, and these components are followed by the residual connection. The output of the Swin Transformer block is then passed to the patch merging layer in the network. By stacking two swin transformer blocks on top of each other, the model can learn increasingly complex representations of the input image.

In SW-MSA, the windows have been organized for image partitioning so that the partitions don't overlap with each other. This mechanism improves the computation complexity as shown in (3). Suppose the window has $W \times W$ patches, the complexity of window-based self-attention and the basic MSA module on a given image of $h \times w$ patches can be defined as:

$$\begin{aligned} \Omega(MSA) &= 4hwC^2 + 2(hw)^2C, \\ \Omega(W-MSA) &= 4hwC^2 + 2W^2hwC, \end{aligned} \tag{3}$$

A shifted Window partitioning approach is followed between successive swin transformer blocks to incorporate cross-window links and maintain the computation efficiency of non-overlapping windows at the same time. With this approach, the output of successive swin transformer blocks is defined as:

$$\begin{aligned} \hat{O} &= W-MSA(LN(O^{l-1})) + O^{l-1}, \\ O^l &= MLP(LN(\hat{O}^l)) + \hat{O}^l, \\ \hat{O}^{l+1} &= SW-MSA(LN(O^l)) + O^l, \\ O^{l+1} &= MLP(LN(\hat{O}^{l+1})) + \hat{O}^{l+1}, \end{aligned} \tag{4}$$

W-MSA denotes window-based self-attention and SW-MSA denotes shifted windows-based multi-head self-atten tion. In the above (4), $\hat{O}^l$ and O^l represent the output of SW-MSA and MLP modules for l block, respectively.

3.4 Compound emotion classification

The output of the swin transformer block is fed to the patch merging layer to merge two adjacent patches for downsampling of the feature map. This layer is followed by a global

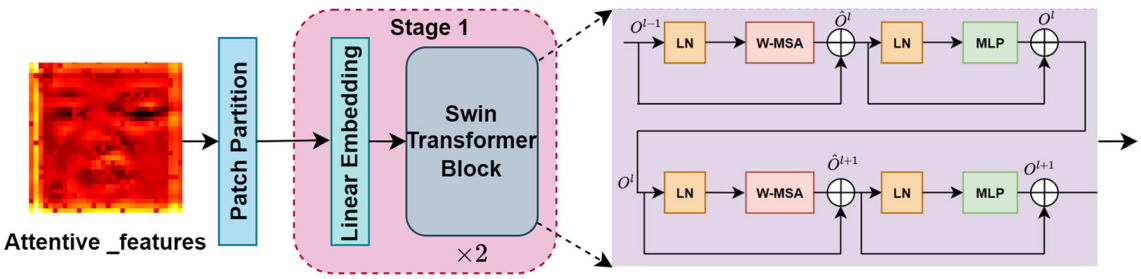

Fig. 5 Streamlined swin transformer architecture used in the proposed model

averaging layer to reduce the dimensionality of the output, making it computationally efficient while preserving relevant information for downstream tasks. The output of the global averaging layer serves as input to a dense layer. In a dense layer with softmax activation, the output is produced by applying the softmax function on outputs of the global average pooling layer s_j by applying the softmax function to obtain probabilities ($\mathbb{Y}$) for each class(i) as shown in (5). The categorical cross-entropy loss (CE) is computed using the predicted probability $\mathbb{Y}_i$ and true probability ditribution Y_i for the i^{th} class in (5).

$$\mathbb{Y}_i = \frac{e^{s_i}}{\sum_j^{\mathbb{C}} e^{s_j}}$$
$$CE = \sum_i^{\mathbb{C}} Y_i log(\mathbb{Y}_i) \tag{5}$$

The provided algorithm 1 outlines the processing steps for training a compound emotion recognition model, referred to as LSwin-CBAM, using a dataset (RAF-DB, EmotioNet). The algorithm starts by taking a dataset $\{X_i, Y_i\}$ n, where X_i represents facial images, and Y_i represents corresponding labels for compound emotions. The cutmix augmentation method is applied to the dataset, creating augmented samples $\{\hat{x}_i, \hat{y}_i\}$. The CBAM (Convolutional Block Attention Module) attention mechanism is applied to enhance the model's ability to focus on important regions within facial images. A 2D convolutional layer is used to produce a feature map M from the augmented images and further processed through channel and spatial attention operations producing M' and M'' output respectively. The feature map M'' is partitioned into patches of size P_s. The algorithm proceeds through the stage of swin transformer block which involves a linear embedding layer, iterative application of swin Transformer blocks $\times 2$ followed by a patch merging layer(generally applied, if the current stage is not the last one, but here single stage is used and patch merging layer is also applied exceptionally). Emphasizing efficiency without compromising accuracy, this model enables real-time processing, making it ideal for deployment in resource-constrained environments while maintaining a high level of precision in emotion detection.

Algorithm 1 Algorithm of the proposed model.

Input:

Dataset $\in \{X_i, Y_i\}_{i=1}^n$ where n is number of images in dataset
Model parameters θ
Initial learning rate l_r
Batch Size B
Dropout Dp
Learning rate decay factor d_r after every n epochs
Number of epochs $\mathbb{E}$
Patch size $\mathbb{P}_s$
Number of stages $\mathbb{N}_s$
Depth of Swin transformer block $\mathbb{D}$

Output:

Trained LSwin-CBAM model to recognize compound emotions from facial images

Input the dataset, where Dataset $\in \{X_i, Y_i\}_{i=1}^n$
Apply the cutmix augmentation method
for `i = 1 to n` **do**
    $\{\hat{x}_i, \hat{y}_i\} = cutmix(X_i, Y_i)$,
end for
Apply CBAM attention mechanism
    Apply a 2D convolutional layer to produce a feature map M
    Output of Channel attention: $M' = A_c(M) \odot M$,
    Output of Spatial attention: $M'' = A_s(M') \odot M'$,
Apply patch partitioning to partition the patches of size $\mathbb{P}_s$
Stages:
    Apply linear embedding layer
for `i = 1 to` $\mathbb{N}_s$ **do**
    for `j = 1 to` $\mathbb{D}$ **do**
        Apply swin transformer block
        if $\mathbb{N}_s = 1$ **or** $i < \mathbb{N}_s - 1$ **then**
            Apply patch merging layer
        end if
    end for
end for
Apply the global average pooling layer

4 Experimental results

The system requirements to evaluate the proposed model are 64-bit Windows 11, Intel Core i7 processor with 16GB RAM size, 8GB NVIDIA TITAN RTX graphics card. Tensorflow 2.8 has been used for the implementation of the proposed framework. The selection of hyperparameters is indeed a crucial aspect of our model development. The summary of hyperparameters of the model is shown in Table 1. All the hyperparameters used in the model are decided experimentally. These hyperparameters collectively define the configuration of a proposed model for facial emotion recognition, and these values have been meticulously selected through multiple experiments to determine the performance and behavior of the model during training. The learning rate is set to 0.001, this parameter is decided experimentally and controls the step size during the optimization process with learning rate decay of 0.0001. The dropout rate is 0.05 to prevent the model from overfitting by dropping several neurons. Several experiments were conducted using different dropout values, and the results, presented in Tables 2 and 3, indicate that the optimal value chosen is 0.05. The best results are highlighted with bold text. AdamW, is used for training LSwin-CBAM due to its improved weight decay handling

Table 1 Summary of hyperparameters used in LSwin-CBAM

Hyperparameter	Value
Batch Size	16
Learning rate	0.001
Learning rate decay factor	0.0001
Dropout	0.05
Number of Epochs	500
Patch Size	2×2
Window Size	2×2
Number of Stages	1
Depth of Swin transformer block	2

(weight decay = 0.0001). Improved weight decay handling in AdamW contributes to reduce the generalization gap, making the model generalize better to unseen facial expressions and diverse datasets. Along with that, AdamW has been observed to provide more stable training and faster convergence compared to standard Adam, which is crucial for effectively training complex models like transformers used in facial emotion recognition. Categorical Cross-Entropy (CCE) loss is used for Transformer models in multi-class classification due to its ability to compare predicted probability distributions with true labels, providing smooth gradients for optimization.

4.1 Datasets

4.1.1 Realworld Affective Face Database (RAF-DB)

The RAF-DB (Real-world Affective Faces Database) [19] is a face expression dataset. It contains 29672 facial photos labeled by 40 different taggers with seven basic ('Anger', 'Sadness', 'Happiness', 'Disgust', 'Fear', 'Surprise', and 'Neutral') and eleven compound expressions (0: 'Happily Surprised', 1: 'Happily Disgusted', 2: 'Sadly Fearful', 3: 'Sadly Angry', 4: 'Sadly Surprised', 5: 'Sadly Disgusted', 6: 'Fearfully Angry', 7: 'Fearfully Surprised', 8: 'Angrily Surprised', 9: 'Angrily Disgusted', 10: 'Disgustedly Surprised'). The participants' age, gender, and ethnicity, as well as lighting conditions, head postures, occlusions (e.g. spectacles, self-occlusion, or facial hair), and post-processing processes (e.g. special effects and various filters), are all represented in this database. The number of samples in each class is depicted in Fig. 6 which shows that the dataset is highly imbalanced.

4.1.2 EmotioNet

EmotioNet [7] is a large facial expression dataset that has nearly one million facial images and corresponding labels. It offers a wide range of facial expressions including basic and compound expressions. Images are downloaded from

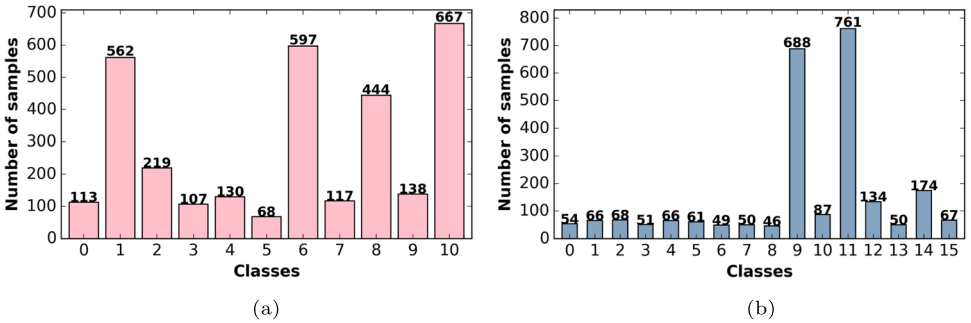

Fig. 6 Number of samples in a) RAF-DB dataset b) emotionet dataset

the internet by using different keys for 23 emotions based on action units (AUs). In our experiment, 2474 images are used which has 16 basic and compound emotion categories (0: 'Angrily disgusted', 1: 'Angrily surprised', 2:'Angry', 3: 'Appalled', 4: 'Awed', 5: 'Disgusted', 6: 'Fearful', 7: 'Fearfully angry', 8: 'Fearfully surprised', 9: 'Happily disgusted', 10: 'Happily surprised', 11: 'Happy', 12: 'Sad', 13: 'Sadly angry', 14: 'Sadly disgusted', 15: 'Surprised'). The EmotioNet dataset is highly imbalanced due to the presence of skewed class proportion as shown in Fig. 6

The proposed model is evaluated on two compound emotion datasets: RAF-DB and EmotioNet. Both datasets are imbalanced datasets as their class distribution is very unequal which significantly affects the performance of the model.

4.2 Class weights

Class imbalance is a common problem in image/video classification problems. It merely indicates that the frequency of a class is severely unbalanced, i.e., the frequency of one class is far more than that of the other classes. In other words, it introduces a bias towards the majority classes. To overcome this problem, class weights are adopted which assign weights to the classes by giving less weight to majority classes and high weights to minority classes which penalized the misclassification rate of the model. The general formula to calculate the class weight for each given class is shown in (6).

$$W_i = N_i/(C * N_i), \tag{6}$$

where W_i denotes weight for i^{th} class, N_i and C represents number of samples in i^{th} class and number of classes respectively.

4.3 Evaluation metrics

As RAF-DB and EmotioNet datasets are imbalanced, accuracy is not considered a good metric for evaluating the model. This can be understood by a simple example. Suppose a dataset has two classes: Real or Fake and Real class has 1000 samples (majority class) whereas the Fake class has only 10 samples (minority class). After training on the given dataset,

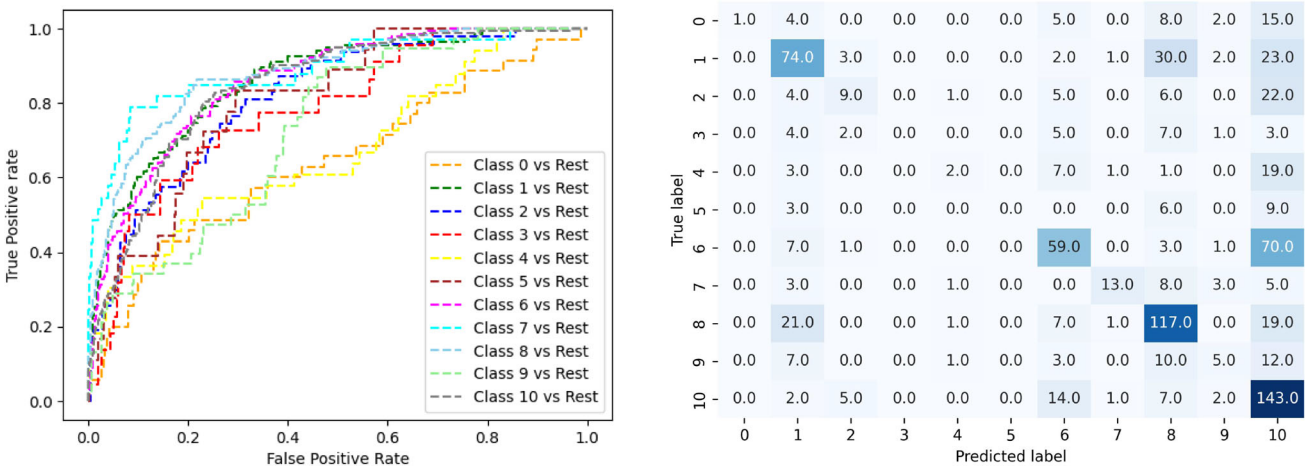

Fig. 7 Evaluated results on RAF-DB dataset a) ROC_Curve b) Confusion metric

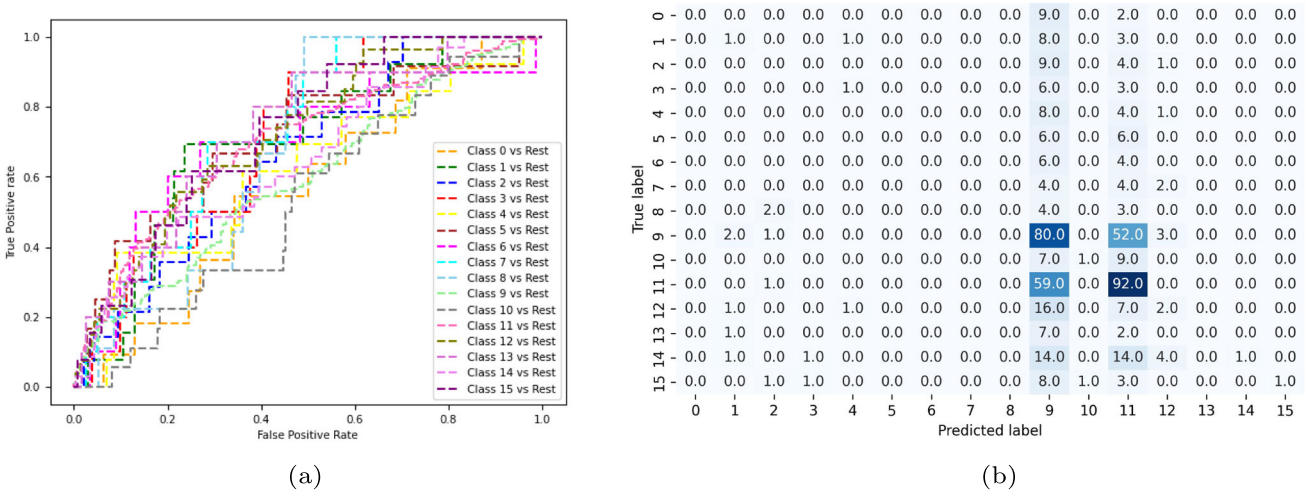

Fig. 9 Evaluated results on Emotionet dataset a) ROC_Curve b) Confusion metric

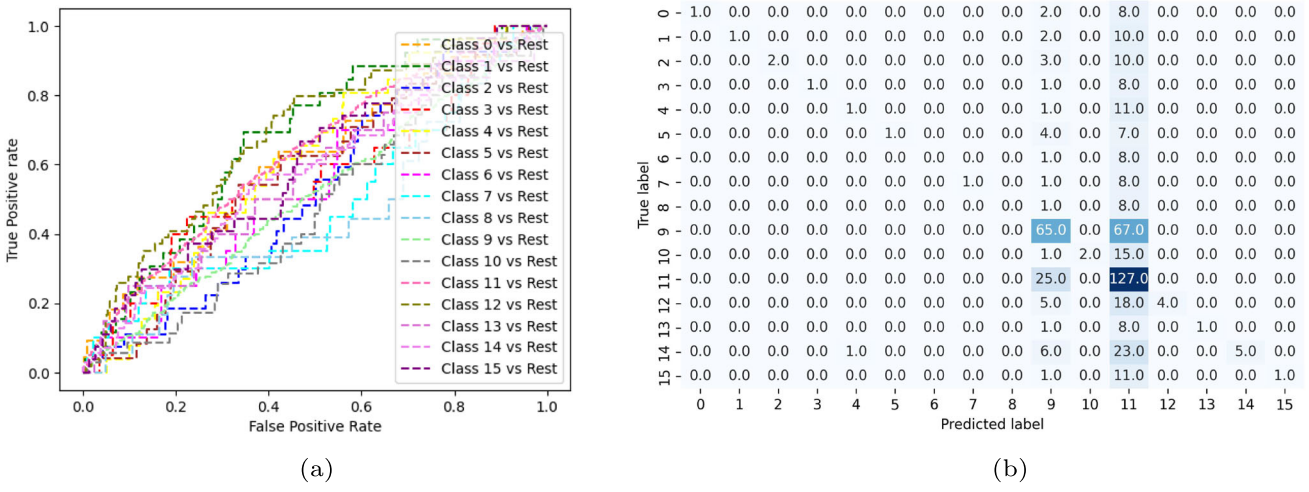

Fig. 10 Evaluated results on Emotionet dataset (with class weights) a) ROC_Curve b) Confusion metric

Table 4 Significance of adding each module to LSwin-CBAM while experimenting on RAF-DB dataset

Model	Acc	AUC	P	R	$F1_m$
Baseline Swin	45.25%	0.73	0.41	0.27	0.26
LSwin+Cutmix	47.22%	0.77	0.41	0.31	0.33
LSwin-CBAM	**51.81%**	**0.78**	**0.45**	**0.30**	**0.30**

the model gives 99% accuracy (predicting 1000 samples correctly including 999 real and 1 fake sample or Real: 99% accuracy and Fake: 1%) which is remarkable indeed. If we turn the spotlight on these results, it signifies that the model failed to predict the fake samples correctly which concludes that the proposed model is not a good predictor. So, it would be unfair to consider the accuracy as a performance metric for imbalanced datasets. Hence, other evaluation metrics are considered to justify the proposed model like precision (P), recall(R), f1 score (F1), ROC curve (Receiver operating characteristic curve), ROC AUC score (Area under the Receiver Operating Characteristics Curve). ROC curve and ROC AUC Score (AUC) have been considered as the optimistic metric to evaluate the performance of the classification model on imbalanced datasets because it is independent of class distribution and invariant to the threshold.

4.4 Experimental results on RAF-DB(Compound) dataset

The RAF-DB dataset contains 3240 images in the training subset and 840 images in the testing subset [19]. The proposed model is then trained with different configurations changing batch size, dropout, and learning rate whose results are shown in Table 2. The cosine learning rate decay is adopted to avoid the problem of local minima. Firstly, we experimented with the model by taking different batch sizes and dropout giving the best results with 16 and 0.05 in terms of accuracy(Acc), ROC_score, precision, recall, and f1-score (51.81%, 0.78, 0.45, 0.30, and 0.30 respectively). Through different experiments, it has been observed that increasing batchsize degrades the performance of the model. We also examined the influence of dropout on the model performance on different values of batchsize constant (16, 32, 64, 128) and found the optimal value of dropout which is 0.05. The value

Table 5 Significance of adding each module to LSwin-CBAM while experimenting on EmotioNet dataset

Model	Acc	AUC	P	R	$F1_m$
Swin	32.12%	0.55	0.13	0.10	0.11
LSwin+Cutmix	33.95%	0.57	0.10	0.07	0.6
LSwin-CBAM	**39.67%**	**0.59**	**0.21**	**0.09**	**0.09**

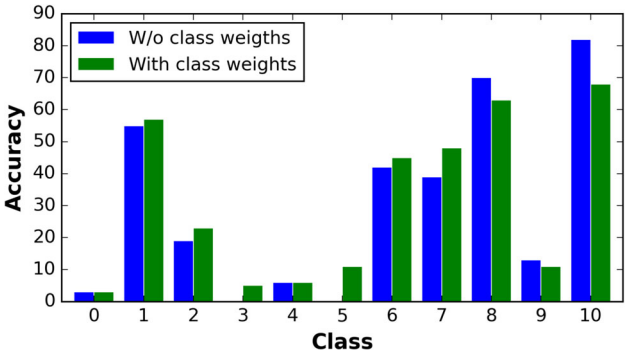

Fig. 11 Class-wise average accuracy obtained on RAF-DB without and with class weights

of dropout above 0.05 shows degraded results on the dataset as shown in Table 2.

The model gives 51.81% accuracy but due to an imbalanced dataset, it cannot classify minority classes (having a very less number of samples in the training and testing subset). To overcome this problem, class weights are introduced during the training process so that the model emphasizes the minority class to improve the classification rate of minority classes as well. The class weights are initialized according to the formula given in (6) but with multiple experiments using different weight sets, the optimized weight set is [0: 2.60, 1: 0.92, 2: 1.744, 3: 2.95, 4: 2.265, 5: 4.331, 6: 0.83, 7: 2.517, 8: 0.963, 9: 2.134, 10: 0.841]. The model with class weights classified the testing samples with an accuracy of 48% which is lowered but class weights are exploited to make the model learn all the classes (including the minority classes) and classify them as shown in Figs. 7 and 8. Figure 8a) shows that class weights improved the AUC of minority classes which is lower in Fig. 7a) due to imbalanced datasets. Figure 8b) shows how class weights improved the corrected classified samples of minority classes as well which are lesser or zero in the confusion metric shown in Fig. 7b).

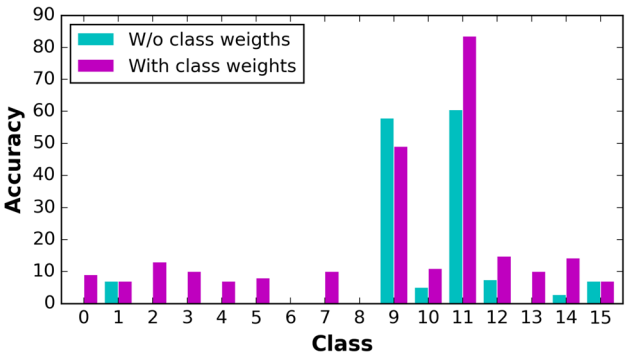

Fig. 12 Class-wise average accuracy obtained on Emotionet without and with class weights

4.5 Experimental results on EmotioNet dataset

In our experiment, a set of emotionet challenges having 2474 facial expression images have been used depicting basic and compound emotions [7]. The images are manually annotated but these are a very small number of images for the training of the model. The dataset is split in the ratio of 80:20 giving 1924 images to the training set and 481 to the testing set. With extensive experiments, the proposed model has achieved 39.67% accuracy. To the best of our knowledge, there is no manuscript available that has considered a small set of the EmotioNet dataset for training purposes. The results are obtained by varying different batch sizes and dropouts as shown in Table 3. Due to an imbalanced dataset, the minority classes are not well classified so class weights are incorporated and the performance of the model without and with class weights is depicted in Figs. 9 and 10. By comparing Figs. 9a) and 10a), it is clear that adding class weights has improved the AUC of minority classes. In the confusion metric shown in Fig. 9b), minority classes are not predicted well but adding class weights makes the model recognize the minority classes as well, shown in diagonal entries of confusion metric in Fig. 10.

The imbalance in the Emotionet dataset is what prevents it from accurately predicting minority classes. There are different methods available to handle imbalanced datasets. Class weights are used here to reduce the biases of the model towards the majority class by assigning higher weights to the minority class which affects the overall performance but improves the class-wise accuracy of the minority classes.

4.6 Ablation study

The ablation study is provided in this section to justify the reasonability of the proposed model. Quantitative evaluation is conducted to support the contribution of each module in the model. Initially, a swin transformer has experimented alone on RAF-DB and Emotionet datasets which classify the facial expression with 45.25% and 32.12% accuracy respectively. As the given datasets are imbalanced, adding the cutmix augmentation technique improved the performance by 3.02% (RAF-DB), 1.75% (EmotioNet) and hence classifies the basic and compound emotions with 47.22%(RAF-DB), and 33.95%(EmotioNet) accuracy. The CBAM attention mechanism emphasizes channel and spatial information, enhances the target regions, and extracts relevant and detailed information from the given images. Adding this module improved the classification performance improved by 4.59%(RAF-DB), 5.72%(EmotioNet) which leads to 51.81% and 39.67% accuracy for RAF-DB and EmotioNet datasets respectively. Tables 4 and 5 show the results of RAF-DB and EmotioNet datasets in terms of accuracy and ROC_Score (AUC), precision (P), recall(R), and f1-score ($F1_m$) obtained by adding each module to the model. Figures 11 and 12 shows the class-wise accuracy obtained without and with class weights on RAF-DB and EmotioNet datasets respectively. Results show that incorporating class weights has improved the class-wise accuracy of both datasets.

4.6.1 Parametric and architectural influence

The general architecture of the Swin transformer (ST) [9] has 4 stages where the ST block is preceded by a linear embedding layer in the first stage and a patch merging layer in the last three stages. This complex architecture leads to a large number of trainable parameters which increases training time without inducing much improvement in classification performance. So, this section shows the ablation study of parametric and architectural influence by adding the number of stages in the model. Tables 6 and 7 shows the significance of adding each stage to the model and results show the effectiveness of the lightweight LSWin-CBAM model for compound emotion recognition.

Table 7 Parametric and architectural influence of swin transformer stages on the performance of model on Emotionet dataset

Model	Stages	Param	Acc	AUC	P	R	$F1_m$
Swin4-CBAM	4	6M	35.56%	0.57	0.08	0.08	0.06

LSwin-CBAM	**51.81%**	≈ 0.582

4.7 Comparative analysis of the proposed model with state-of-the arts

Firstly, the model is trained with RAF-DB and EmotioNet datasets separately. The evaluated results are compared with the state-of-the-art methods as shown in Tables 8 and 9 for RAF-DB and EmotioNet datasets respectively. Table 8 shows that LSwin-CBAM outperforms state-of-the-art methods by 1.11% the best performing Multi-Scale Action Unit (AU)-based Network (MSAU-Net), 6.71% the DLP-CNN pre-trained on RAF-DB basic emotions and fine-tuned on RAF-DB compound emotions, 5.21% the Relation Convolutional Neural Network (ReCNN) to capture the associations between relevant regions and facial expressions, 4.21% the Amending Representation Module (ARM) (a variant of Resnet-18), 3.01% the finetuned FaceBehaviorNet which is pre-trained on millions of images taken from 10 datasets for multi-task learning of basic expressions and then finetuned on RAF-DB for compound emotion recognition, 4.81% the Pyramid with super-resolution (PSR) network for in-the-wild FER. The EmotioNet dataset has 2472 images with unequal distribution of the classes (imbalanced dataset) and there is limited literature leveraging this dataset. The Table 9 illustrates the comparison of the proposed model with state-of-the-art methods for EmotioNet dataset, indicating

Table 9 Comparative analysis of state-of-the-art methods and proposed method on EmotioNet Dataset

Model	Accuracy	Parameters_size(MB)
ResNet50 [44]	35.01%	≈ 22.53
ResNet50-LSR [37]	37.23%	≈ 22.53
ResNet50-PS-KD [38]	38.95%	≈ 22.53
ResNet50-ISLM [36]	38.15%	≈ 22.53
LSwin-CBAM	**39.67%**	≈ 0.582

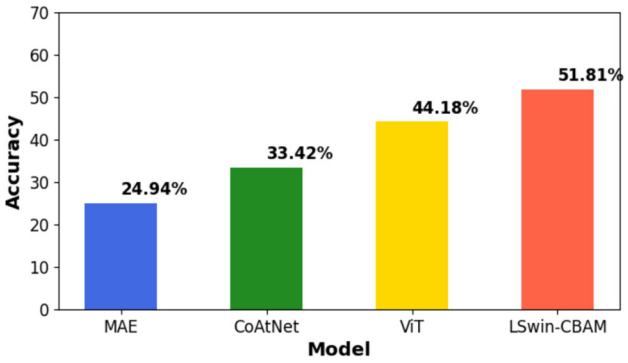

Fig. 13 Performance evaluation: LSwin-CBAM vs. Transformer Variants

its superior performance over existing models while utilizing a significantly lower number of parameters. Jiang et al. [36] used expression soft label mining (ESLM) to produce soft target labels automatically for the learning process with the ResNet50 classification model. ResNet50 was tested with LSR (Label smoothing regularization) [37] and PS-KD(Progressive self-knowledge distillation) [38], and ISLM(Iterated soft label mining [36] methods achieving classification accuracies of 37.23%, 38.95%, 38.15% respectively.In addition to the enhanced accuracy, the LSwin-CBAM model achieves a smaller parameter size of 0.581MB compared to other models (ResNet50-LSR [37], ResNet50-PS-KD [38], ResNet50-ISLM [36]) which utilize 22.53MB.

The comparison of LSwin-CBAM with transformer-based models like ViT [8], MAE [39], and COAtNet [40] highlights its superior performance in image classification of compound emotions as shown in Table 8 and Fig. 13. Its efficiency in utilizing limited training data makes it more suitable for scenarios with sparse data availability, as heavy models are prone to under-fitting. LSwin-CBAM's lightweight design also enables better scalability and adaptability to smaller datasets compared to transformer models like ViT and COAtNet, which struggle with imbalanced datasets due to their demand for extensive samples per class during training. Moreover, MAE suffers from poor reconstruction quality and instability during training, while CoAtNet and ViT struggle with insufficient representative samples for each class, resulting in suboptimal performance.

5 Conclusion and future work

This study proposed LSwin-CBAM model for compound emotion recognition that incorporates cutmix augmentation to augment the training data and CBAM attention mechanism to emphasize critical sections of the image. Experimental results on RAF-DB and EmotioNet datasets show the superiority of this model in terms of different evaluation metrics

(accuracy, auc, precision, recall, f1-score) over the state-of-the-art methods. The comparative results shown in Table 8 prove that LSwin-CBAM classified the compound emotion with good accuracy and with less computational complexity. The proposed model achieved 51.81% for RAF-DB and 39.67% for the EmotioNet dataset but fails to classify the minority classes as well. This problem occurs due to the imbalanced dataset which can be alleviated by incorporating class weights. Using class weights declined the overall accuracy but make it to classify minority classes for RAF-DB and EmotioNet datasets. The proposed model is very lightweight in terms of trainable parameters (0.15M) and still achieved impressive results which take it above the state-of-the-art methods.

This model improves the classification performance for compound emotions, but there is still scope for improvements that can be considered for future work. In future work, we would like to explore different feature extractors exclusively such as CoCa [45], OmniVec [46]. There are very less facial datasets available for compound emotions which limits the training of the network. As deep neural networks are data-hungry, the more the training data is provided, the more accurately it would classify the compound emotions. So, there is a need for balanced and large datasets for compound emotions which can improve the learning process and further improve the classification rate as well.

Acknowledgements The authors would like to acknowledge the Department of Information Technology (Cyber Forensic and Malware Analysis Lab), Delhi Technological University, New Delhi, India for providing me necessary resources to carry out the research.

Data Availability The datasets RAF-DB and EmotioNet used in this study are available to the public in original paper.

A Machine Learning and Augmented Reality based Framework for Multilingual Product Identification in Retail using Mobilenets and Vuforia

Geetanjali Bhola, Amogh Bansal, Divij Aggarwal, Gagan Kishor Upadhyay

Abstract*: *In the modern world, Machine Learning and Augmented Reality have taken the retail industry by storm. Machine Learning and Augmented Reality have provided a major boost to the industry of interactive retail by providing features such as real-time product detection and identification. The proposed research aims at overcoming several challenges in the present scenario which include the time consuming process of standing in long queues while purchasing the products at supermarkets, personalizing the shopping experience in order to maintain the privacy of the users, helping the customers to maintain their specified budgets, reducing the high labor costs and overcoming the language barriers while pertaining to selling products to groups with different linguistic backgrounds by combining the real-world interaction of Augmented Reality and Machine Learning-based product identification. This proposed research work aims at providing the customers with a futuristic shopping experience while maintaining their specified budgets. The Machine Learning-based object detection approach detected the products with around 96% accuracy and the Vuforia-based Augmented Reality approach detected objects with maximum accuracy.

Keywords*: *Augmented Reality, Vuforia, Machine Learning, MobileNets, Single Shot Multi-Box Detector.

I. INTRODUCTION

Augmented Reality and Machine Learning have created quite a buzz in the retail industry. Retail in today's economy can be combined with the functionalities of object detection and Augmented Reality to improve the customer experience.

Revised Manuscript Received on April 25, 2020.

Nowadays, customers tend to use high-end retail services but the retail industry presently faces a number of obstacles such as reducing the labor costs and eliminating the process of standing in long queues while purchasing various products.
One of the major challenges faced by the retail industry is the language barrier across different regions while maintaining budget constraints which makes shopping across borders quite a tedious task. This research work aims at providing retail services using the real-world interaction of Marker-less Augmented Reality and Machine Learning-based object detection. This provides users with a personalized multi-lingual shopping functionality so as to maintain the privacy of the users [1] with features such as accurate real-time product detection, display of nutritional contents, product characteristics and video advertisements while maintaining the specified budget constraints, presentation of purchase history using login credentials and SQL databases, all available in multiple languages across different regions. The ability to allow the customers to view the cart and instructions on how to use the product in their local language improves the overall shopping experience of the customer [2]. Object detection helps to locate certain classes in the image. Augmented Reality allows coupling and superimposition of computer-generated imagery with real-world entities [3].
AR also helps to improve the user interface (UI) of the applications, improve the speed of local target recognition, use of technology that provides highly robust target-tracking of low-light and partly covered targets while pertaining to language barriers [4]

II. CONCEPTUAL FRAMEWORK

A.Object detection using TensorFlow

The first step involved use of TensorFlow for Object Detection of products in case of the Machine Learning based approach. The TensorFlow Object Detection API is an open source framework which simplifies the detection of objects and makes construction, training and deployment of object detection models easy as it uses pretrained object detection models. It also acts as a medium for detecting objects and algorithmic implementation. TensorFlow is given the name because it takes multidimensional arrays, also known as tensors as input to the model. It can be used with small changes on the several diverse frameworks.

© Copyright: All rights reserved.

The framework is flexible in the sense that it is able to adjust to new conditions and hence, can be used for expressing several different algorithms.

B. Object detection using MobileNets and SSD

MobileNet [5] is based on depth wise convolution in the case of which each filter contains a single input. A light MobileNet based model must include at least five layers with feature size 14×14×512. There can be 2 types of MobileNets design models, thinner or shallower in which the thinner model is more efficient than the shallow model.

Before the SSD, several different algorithms for object detection like R-CNN, Fast- RCNN etc. were obtained by us. R-CNN [6] works by suggesting different spots present in an image that act as input to an object classifier at the time of training. Fast- RCNN [7] and Faster-RCNN [8] are the improved versions of R-CNN, they use some techniques so as to reduce the manipulation of proposed regions. The problem of inference speed for real life objects was overcome by the YOLO [9] system. YOLO was not able to identify smaller objects in the frame, which was its main limitation. The problem was solved by SSD [10], the mAP value approached 74 percent and detection speed was similar to that of YOLO [11].

SSD serves the purpose of real time detection of various objects. Faster R-CNN makes use of a region proposal network which creates boundary boxes so that the objects belonging to several different classes can be detected whereas in case of SSD, region proposal network is no longer needed as it helps to fasten the process and hence it is eliminated. To regain the accuracy, SSD makes minor technical advancements including the default boxes and multi-scale features, using which, SSD is capable of meeting the accuracy achieved by Faster R-CNN with the use of low-resolution object images. The working of SSD was divided in two parts i.e. extracting the feature maps and application of convolution filters. SSD makes the use of small convolution filters to compute both the class and location scores. After the above steps, in order to make predictions about the classes of the detected objects, feature maps are extracted and 3×3 convolution filters are applied on all cells individually. MobileNets and SSD provide the benefit of achieving lag-free accurate object detection on a system with nominal specifications.

C. Creation of SQLite Database in Machine Learning

The next step involved the creation of SQLite Database which serves as an open-source SQL database engine that doesn't require a separate server to operate. It is an in-process library that implements a self-contained, zero-configuration, serverless, transactional SQL database

Engine that has bindings to several programming languages such as Java, Python, C++, Basic [12]. In our case we have made use of Python so as to create a database in case of the Machine Learning based approach which serves the purpose of storing the login credentials as well as the purchase history pertaining to the previous visits of the users.

D. Vuforia based Image Recognition and superimposition of virtual information

In order to detect products in Augmented Reality, we make use of Vuforia which is an AR software development kit which was developed by Qualcomm and allows the creation of various Augmented Reality applications. It allows the recognition and tracking of planar images and 3-D objects in real-time. Virtual objects are placed through a camera viewfinder and then the position of objects is adjusted in the background of the objects and in front of the lens.

In the development process, Vuforia uses target images but any kind of image does not qualify as a target image. All the uploaded images, at first, are evaluated by the Vuforia web developer. Scoring of value target defines how well an image can be detected and tracked using Vuforia SDK. The score of an image acts as a target range of 0 to 5 which helps in assessment [13]. Greater number of stars allows to obtain stronger detection and tracking capabilities of an image target.

In order to determine the number of stars, various features serve as the attributes of the assessment criteria. Repetitive patterns should not be there in the image target and the image target should contain high local contrast, uniform distribution of features and high feature density, so as to obtain better quality of recognition of the image.

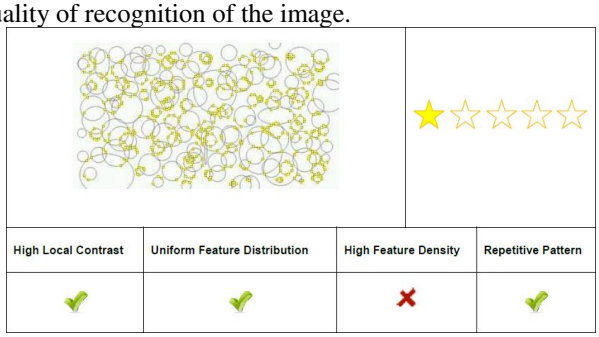

Fig. 1. IT with 1-star ball shape

For example, Fig. 1 which has been shown above, has a quality level in one star because the density of the features is poor. Hence, alteration of its line shape or texture is required, so as to increase (multiply) the number of features of this figure [14].

Fig. 2. IT with 4 stars square shape

Now, Fig. 2, which has been shown above, depicts the rise of quality in star level of the image target by increasing the number of features to improve feature density and similarly for different image targets the quality in star level can be improved by also increasing the local contrast, distributing the features uniformly and through avoidance of repetitive patterns.

This information was integrated in the research work by implementing Marker-Less Augmented Reality which helped in obtaining stronger detection and tracking capabilities of the image targets.

© Copyright: All rights reserved.

The ability of augmented reality technology to blend real scenes and virtual information was used for the superimposition of nutrient distribution and advertisement over a particular product along with information about the remaining budget and the shopping cart.

E. Database Creation using MAMP in AR

Creation of a database in the Augmented Reality approach was carried out using MAMP (Macintosh, Apache, MySQL, and PHP) which allows you to have access to a local PHP server and MySQL server and provides you with all the tools necessary to run WordPress on your machine, for testing and development purposes. The created database allowed storage of the login credentials of the different users in the Augmented Reality-based approach.

III. METHODOLOGY

The main aim of the research was to provide consumers with an interactive experience through real-time product identification in the retail sector.

The flow of the implementation of this idea has been shown in Fig. 3. At first, object detection was carried out with the help of TensorFlow, which because of its high GPU intensiveness and low efficiency resulted in low accuracy and fps, along with lag in product detection. So as to overcome these problems, product detection was therefore implemented using a joint version of Single Shot MultiBox Detector (SSD) structure and Mobile Net classifier [15].

On observation of improvement in detection accuracy and decrease in lag in the latter method, new features were added to enhance the overall user experience. Features such as advertisement, description of the products and interactive budget management for customers were added. Then, a database was created using Python so as to store the login credentials of various users and also provisions for different languages were provided in case of the Machine Learning-based approach. Multiple windows were being required for different features which posed to be a limitation of the Machine Learning-based approach,hence the focus was shifted towards incorporation of Augmented Reality in the research.

At first, the implementation of marker-based AR was done, which performed real-time superimposition of nutritional contents on their respective markers for various products.The marker-less technique was executed due to the additional cost of production of markers, and using marker-less technique, real-time superimposition was done without the use of predefined markers for various products.

Then in order to provide a better customer experience, new features such as display of advertisements, nutrition pie charts of different products as well as interactive budget management with shopping-mart guide for users. Finally, a database was created using MAMP so as to store the login credentials of the users and the option of choosing between various languages was provided.

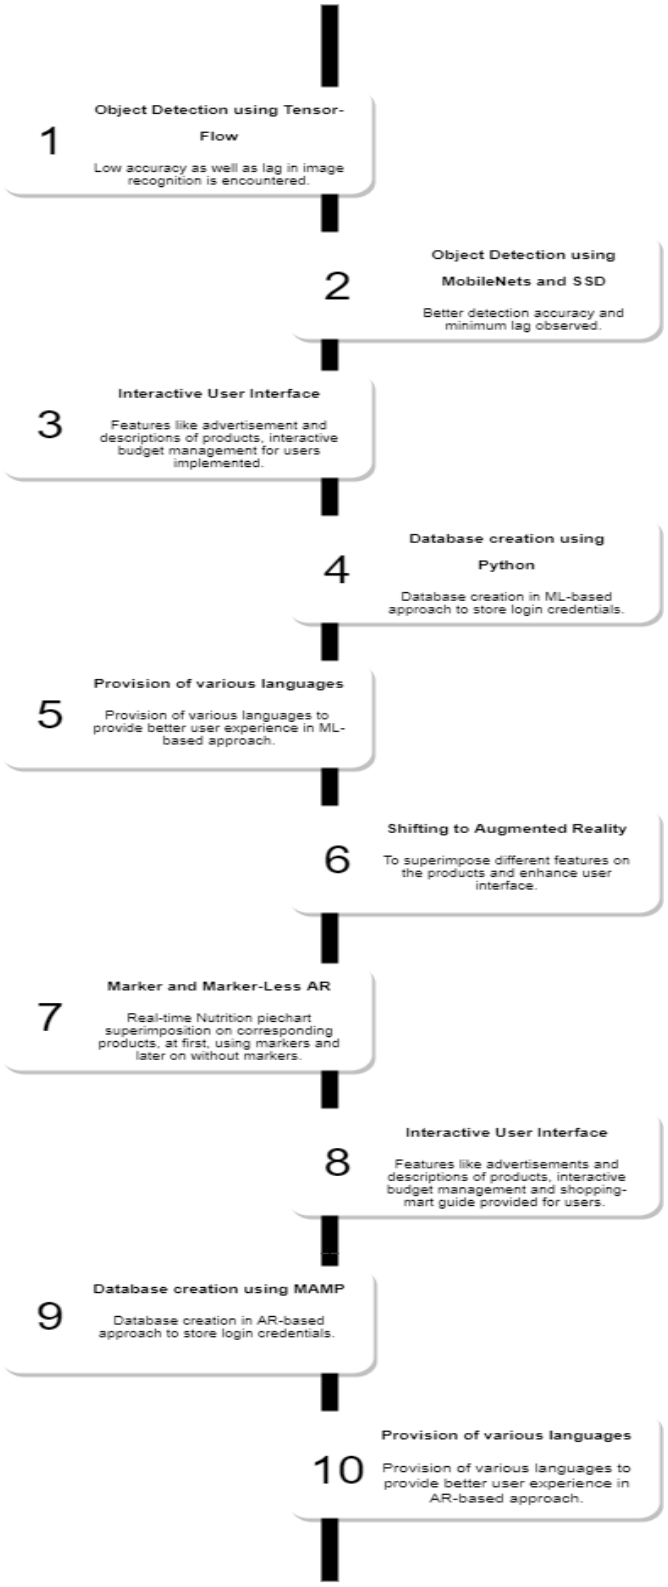

Fig. 3. Project Flow

A. Technology Stack

1. OpenCV

OpenCV is a large open-source library for Machine Learning, Computer Vision as well as Image Processing. It plays a great role in real-time operations. It performed the task of processing images and videos to detect objects and products.

© Copyright: All rights reserved.

OpenCV was the first piece of technology used to detect objects using Python in case of the Machine-Learning based approach.

2. AR Camera

In the case of Augmented Reality, AR Camera was needed to be imported in unity which is used to provide AR scenes. It takes the help of WebCamBehaviour class, VuforiaBehaviour class, DatabaseLoadBehaviour class to accomplish its functions. The WebCamBehaviour class, which also serves as the prime camera control class, informs about whether to switch on the main camera, which camera to use etc. The control entry of Vuforia is the VuforiaBehaviour class, which registers all the open interfaces of Vuforia. The DatabaseLoadBehaviour class is used to trigger identification library, which can perform the function of loading multiple databases that have been uploaded to Vuforia for processing and specifying which library to trigger [13].

B. Implementation

1. Coco Dataset for mobilenets and SSD based object detection

Common Objects in Context is a large-scale object detection, segmentation, and captioning dataset. COCO includes several features such as object segmentation, recognition in context, 330K images and 1.5 million object instances.

We have created a dataset similar to COCO dataset [16], for performing the Machine Learning based Product Identification, that has images of shopping objects like bottles and chairs. Nearly 300 images were taken of both the objects, amongst those images, 60% were utilized in the training phase and 40% in the testing phase. On the detection of multiple objects by the web camera, then a bounding box is drawn over every single detected object with its class as the heading of the bounding box.

2. Database Creation for image targets (Quality of Image targets)

The next step was the construction of the database of image targets for Augmented Reality based Object Detection using Vuforia SDK following which the license key of the created database was added to the research work. At first, the database consisted of the stickers which were used as image targets for products in marker-based object detection in AR. Since the initial rating of the stickers was low (as mentioned in Table 1), hence weaker detection and tracking ability of the image were experienced. Then so as to eliminate the concept of stickers and enhance the trackability of the image, Marker-Less product identification was implemented in AR. The database that was prepared for the marker-less execution consisted of images of actual products which were used as image targets for superimposition. The rating of both the image targets improved significantly (Refer Table 1) and reached 5 stars that ensured better trackability and detection of the images and hence enhanced the functioning of the model.

Table I- Target Score

No.	*Target Image (Marker-Based)*	*Star*	*No.*	*Target Image (Marker-Less)*	*Star*
1	Apple Sticker	2	1	Knorr Soup Image	5
2	Maggie Sticker	2	2	ACT II Popcorn Image	5
	Average (Marker-Based)	***2***		***Average (Marker-Less)***	***5***

3. Provision of Optional Languages

The option of choosing from various languages was then provided in both the Machine Learning and Augmented Reality based approaches in order to overcome the challenges of language barriers across different regions as per the requirement of the users.

4. Database Creation for purchase history and Login Credentials

Finally, databases were created for storing the purchase history as well as the login credentials of the users. In case of the Machine Learning-based approach the SQLite database [12] was created using Python and in case of the Augmented Reality-based approach a database was created using MAMP so as to store the login credentials and the purchase history of the users.

IV. RESULTS

We have tested the machine learning part of our research on an i5 processor laptop. In the machine learning based implementation of the research work, at first, the object detection is carried out using TensorFlow (Fig. 4), but due low accuracy as well as lag in image recognition, the focus was shifted towards object detection using MobileNets and SSD (Fig. 5). After that, the user is made to login (Fig. 6) which provides the user an option to view the user's purchase history (Fig. 7) and then the user can choose a language of his/her choice (Fig. 8). Then, the user enters the budget for shopping (Fig. 9) and after the budget is provided, the process of object detection starts. Once the object is detected successfully (Fig. 10), then the user is asked whether he/she is interested to view the description of the product (Fig. 11) or viewing the advertisement associated with the product. After the user makes the choice, the user has the option to either buy it or ignore it. If the user decides to buy the product, then the item is added to the cart. The user can access the cart anytime to know about the existing products in the cart and the total amount. However, when a user exceeds the budget entered by the user initially, a pop-up showing OVER-BUDGET notification appears and further purchasing of items can't be performed (Fig. 12). Hence, this whole system allows the user to automatically detect any product of interest and then take the decision of buying it or not after seeing the advertisement and nutritional contents of the product.

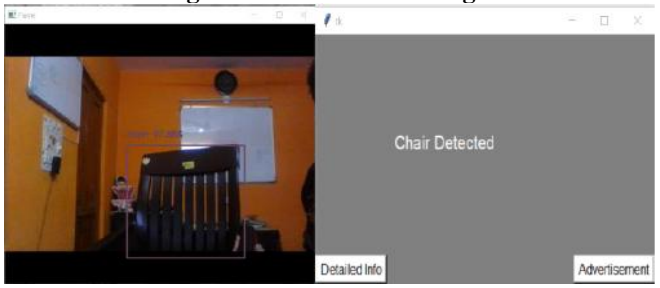
Fig. 8. User can choose language

Fig. 9. User enters the budget



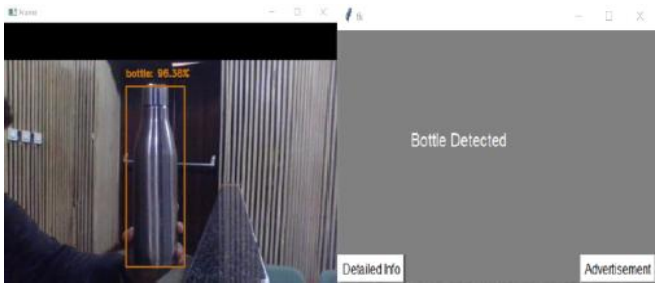


Fig. 10. Product detected

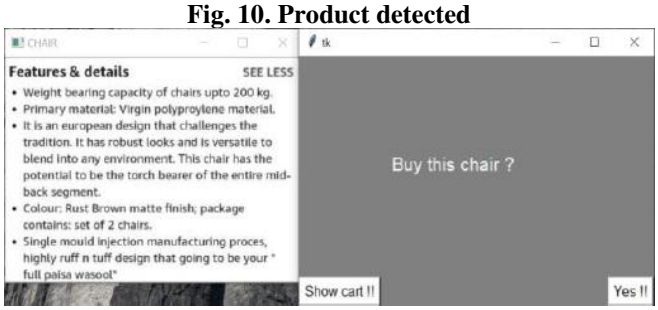

Fig. 11. User can view description

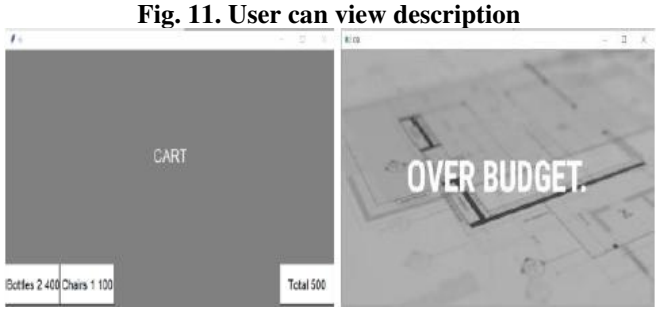

Fig. 12. Over Budget

The main limitation of this approach was that there were several pop-up windows through which the user had to go through to reach the final step, and hence, we then decided to perform the same implementation in Augmented Reality, where the user could interact with the features easily without switching between several windows.

In the marker-less AR implementation of the research work, initially the user is not registered (Fig. 13). Once the user completes the registration process (Fig. 14), his/her login credentials are visible in the database (Fig. 15). After that the user can sign into the login portal using his/her login credentials (Fig. 16). Once the user was logged in (Fig. 17), the product was scanned by the Vuforia SDK and the UI consisting of panels and shopping-mart guide was superimposed on the product (Fig. 18). After that, the user is made to enter the budget for shopping which is then displayed on the panel superimposed at the top of the product. The panel which is superimposed on the left side of the product shows the various choices for the users which include choosing the language preferred by the user, display of advertisement and nutrition value of the product along with add to cart and show cart options (Fig. 19). After viewing the advertisement and the nutrient value of the product, the user has the option to buy the product or not. If the user chooses to buy it, then the product is added to the cart and the budget is updated. The user has also been provided with an option to view the cart and the remaining budget (Fig. 20). Finally, the user can also view his/her purchase history till date (Fig. 21). Hence, this whole model provides an opportunity for users to select the products which are in their budget as well as are perfectly suited for their requirements.

The summarized test cases of the important functions of the AR (Marker-Less) implementation of the research work is shown in Table 2.

Table II- Test cases for important functions

No.	Precondition	Operation	Expected Results	Tested Results
1.	User not logged in	"Register button is clicked"	User is redirected to the registration portal	Pass

© Copyright: All rights reserved.

2.	Login Credentials of new users are added	"Register" button is clicked	Registration of new user complete, login credentials are added to database and the user is redirected to the login portal	Pass
3.	User Registered	Login Credentials of existing users are added	Login Credentials are displayed in text format on the panel	Pass
4.	Login Credentials of existing users are added	"Login" button is clicked	User is logged in	Pass
5.	User is logged in	"Scan Product" button is clicked	Product is scanned	Pass
6.	Product is scanned	Language of user's choice is entered	Changes displayed according to the language entered	Pass
7.	Product is scanned	Click on the shopping mart guide	"Hi! Welcome to mart" text is displayed and waving animation is performed by the guide	Pass
8.	Product is scanned	"Advertisement" button is clicked	Product advertisement with audio is shown in 3-D format	Pass
9.	"Advertisement" button is clicked	"Advertisement" button is clicked again	3-D advertisement is removed	Pass
10.	Product is scanned	"Nutrition" button is clicked	Product's nutritional pie chart with audio is shown in 3-D format	Pass
11.	"Nutrition" button is clicked	"Nutrition" button is clicked again	3-D display of product's nutritional pie chart is removed	Pass
12.	Budget is entered	Enter Budget for shopping	Budget is displayed in text format on the panel	Pass
13.	Budget is entered	"Add to Cart" button is clicked	Product is added to the cart and the updated budget (Current budget – price of the product scanned) is displayed	Pass
14.	Product is added to the cart	Wait for a few seconds	Shopping mart guide displays "Thank you for choosing (product name)" in text format on the panel	Pass
15.	Products are added to the cart	"Show Cart" button is clicked	Products in the cart are displayed in text format on the panel	Pass
16.	Budget becomes zero	"Add to Cart" button is clicked	"Over Budget" is displayed in text format on the panel	Pass
17.	Budget becomes zero	"Add to Cart" button is clicked	Shopping mart guide displays "Please check your budget" in text format on the panel	Pass
18.	Shopping mart guide is clicked	Shopping mart guide is clicked again	Text displayed by shopping mart guide is removed	Pass
19.	Product is scanned	"Purchase History" button is clicked	The entire purchase history of the customer including the customer's name, total amount spent till date, date and time of last purchase and total number of visits till date are displayed in text format on the panel	Pass
20.	At least 1 product is scanned	Scan another product	Features like budget and cart content are transferred to the newly scanned product's user interface (UI)	Pass

V.CONCLUSION AND FUTURE WORK

The research provides the retail functionality combined with the real-world interaction of Augmented Reality and Machine Learning-based product identification, thus providing a fresh experience to the customers. Supermarket shopping is provided in a stimulating and interesting manner to the customers.

Hence, the research work's design goals were achieved and therefore, research work's future vision includes increasing the scalability of the research work to include a larger database of users, provisions for more languages, a wide range of products in various industries such as sports, footwear, groceries and clothing Also, future work includes implementation of a recommender system for providing product suggestions to customers.

AUTHORS PROFILE

Ms. Geetanjali Bhola is an Assistant Professor in Information Technology Department of DTU. She has been taking subjects like database, computer graphics, programming etc. She has co-authored many research papers in the field of image processing. With a deterministic attitude she has helped and encouraged her students to take up challenging research problems which have later won awards at different platforms. Her current research includes augmented reality applications, image processing to name a few.

Amogh Bansal is pursuing B. Tech. in Information Technology from Delhi Technological University, Delhi, India. He has published a research paper titled 'Augmented Reality and Machine Learning based Product Identification in Retail using Vuforia and MobileNets' and presented at the International Conference on Inventive Computation Technologies (ICICT-2020) held at Coimbatore, India from 23-26th February, 2020. He is also the Corporate Head of the Society of Robotics of Delhi Technological University (SRDTU).

Divij Aggarwal is pursuing B. Tech. in Information Technology from Delhi Technological University, Delhi, India. He has published a research paper titled 'Augmented Reality and Machine Learning based Product Identification in Retail using Vuforia and MobileNets' and presented at the International Conference on Inventive Computation Technologies (ICICT-2020) held at Coimbatore, India from 23-26th February, 2020. He has successfully mentored a batch of 50+ students in Data Structures and Algorithms in Java.

Gagan Kishor Upadhyay is pursuing B. Tech. in Information Technology from Delhi Technological University, Delhi, India. He has published a research paper titled 'Augmented Reality and Machine Learning based Product Identification in Retail using Vuforia and MobileNets' and presented at the International Conference on Inventive Computation Technologies (ICICT-2020) held at Coimbatore, India from 23-26th February, 2020. He also has participated and won the I.S.G.W Appathon held in New Delhi, 2017.

ABSTRACT This study assesses the integration of renewable energy sources with grid-connected systems to power electric vehicle charging stations (EVCSs) in Riyadh, Kingdom of Saudi Arabia (KSA), emphasizing its significance for sustainable development. An environmentally friendly EVCS model and a novel metaheuristic optimization technique, the Giza Pyramids Construction Algorithm (GPCA) is employed, to determine the optimal sizing of system components. The objective is to ensure dependability, as determined by the lack of power supply probability (LPSP), while minimizing the levelized cost of energy (LCOE) and total net present cost (TNPC). We assess the efficacy of other algorithms in scaling system components by contrasting the performance of the GPCA with those of the Artificial Hummingbird Algorithm (AHA), Flower Pollination Algorithm (FPA), and Whale Optimization Algorithm (WOA). The study also examines the impact of climatic, financial, and technical factors on system costs, providing insights into the challenges, opportunities, and socio-economic factors influencing the deployment of EV infrastructure in KSA. Findings suggest that the optimal EVCS configuration is a solar photovoltaic/wind turbine (SPV/WT) grid-tied system, resulting in an LCOE of $0.0796/kWh, a TNPC of $102,042, and an annual CO_2 emission reduction of 18,840 kg. The system achieves a 67.9% renewable penetration rate with 30.8% annual grid electricity purchase and 32.4% sale. Sensitivity analysis on renewable parameters is also conducted, demand charges, grid purchase prices, discount rates, and inflation rates to assess their impact on the system's economic variables. By identifying current constraints and potential strategies, our study aims to inform policy-making and investment decisions for expanding electric vehicle charging infrastructure, with broader implications for developing nations.

INDEX TERMS Electrical vehicle charging stations; Renewable power resources; Kingdom of Saudi Arabia, Sustainable development; Giza Pyramids Construction Algorithm; Lack of power supply probability; CO_2 emission.

I. INTRODUCTION

The implementation of electric vehicles (EVs) signifies a fundamental change in the transportation sector through the provision of cost-effective alternatives and a significant mitigation of greenhouse gas emissions. The potential for these developments to improve public health and alleviate the impacts of climate change is considerable [1]. However, the substantial energy demand associated with charging EVs on a large scale presents considerable challenges [2]. The broad use of EVs is closely tied to the development of robust charging networks, crucial for increasing their appeal and user acceptance. Thus, the growing demand for EVs highlights the necessity to upgrade and expand existing charging infrastructures to facilitate a rapid societal transition towards electric mobility [3]. Given the heightened interest in EVs and the abundant generation of renewable energy in the EV sector,

content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411291

it is essential to conduct a comprehensive analysis of the technology, economics, and environmental aspects of EV charging stations utilizing hybrid intermittent generation systems [4]. The merging of Renewable Energy Sources (RESs) with EVs is crucial in attaining sustainable development goals (SDG), notably SDG7 (Ensuring access to affordable, reliable, sustainable, and modern energy for all) and SDG13 (Taking urgent action to combat climate change and its impacts) [5]. Furthermore, an optimal EV charging framework that leverages a combination of renewable sources, including solar photovoltaics (SPV), wind turbines (WT), battery energy storage (BES), grid connections, and various bio-energy options, is acknowledged for its technical, economic, and environmental advantages [6].

The accomplishment of sustainability objectives is enhanced by merging EVs with the power grid and different RESs using Vehicle-to-Grid (V2G) technology, forming a cooperative hybrid system. V2G's ability to provide electricity back to the grid offers an efficient tactic to alleviate the negative impacts of EV charging requirements [7]. EVs equipped with V2G not only tackle pressing environmental issues like air pollution but also reduce reliance on fossil fuels. Research conducted by [8] explores the economic operations of EV parking lots equipped with V2G-enabled charging facilities, RESs, and Energy Storage Systems (ESS), proposing an optimization model to maximize profits generated with the help of EV charging services and energy contributions to the grid while considering uncertainties, ESS wear, and variable EV parking behaviors. As EVs become more prevalent, they exert significant pressure on electrical grids, particularly when meeting the fluctuating demands of EV charging becomes challenging. The authors analyze the V2G system within Indonesia's JAMALI grid, investigating the effects of various feed-in tariff schemes [9]. Currently, V2G controls in microgrids suffer from inadequate coordination, leading to issues such as voltage instability and power supply disruptions when integrating EVs into residential or commercial microgrids [10]. To address these challenges, researchers in [11] evaluate microgrids incorporating wind and solar energy generation, battery operations, and Compressed Air Energy Storage (CAES), with a focus on V2G scheduling within the IEEE 33-bus network. V2G systems enable two-way electricity exchange between the EV battery and the grid, opening up new economic opportunities for owners of EVs and utility providers. In the context of smart grids, V2G technology is poised to provide additional grid services such as load balancing, peak shaving, and cost reductions for power generation enhancements [12].

The recent increase in electricity demand in KSA, propelled by economic expansion and population growth, has spurred initiatives advocating for renewable energy and changes in the energy composition. Incorporating EVs into the power system signifies a substantial step towards efficiency, potentially evening out the load pattern on the national grid [13]. However, the rapid growth of the EV market presents challenges, particularly in meeting demand on distribution networks. Studies have investigated the impact of EV deployment on electricity demand and distribution networks, proposing models to generate EV demand profiles based on factors such as driving patterns and charging characteristics [14]. RESs in KSA offer a promising opportunity to establish a renewable-powered grid capable of supporting EV charging while ensuring grid stability. Efforts to integrate renewable energy into the electric grid focus on minimizing CO_2 emissions and maximizing energy production from renewable sources [15]. Proposals for hybrid power systems at EV charging stations, incorporating SPV panels, WT, and fuel cells, aim to design a grid reliant on clean energy [16]. The transition toward smart grids and hybrid power systems marks a transformative phase in energy management systems (EMS), shifting toward decentralized systems integrating large-scale renewable resources [17]. KSA is well-positioned to advance smart energy and communication systems, striving to develop smart hybrid power systems that offer both security and flexibility for technological integration in the future [18].

The present circumstances are acknowledged by our research as a chance to conduct thorough evaluations regarding the dimensions, positioning, and integration of renewable energy sources into the power grid. This provides insightful information regarding the socioeconomic factors, obstacles, and prospects that influence the adoption of electric vehicles and charging stations in Saudi Arabia. The region's plentiful wind and solar resources can be efficiently utilized, and our research advocates for a techno-economic hybrid energy system. Such a system, employing a combination of RES, not only supports environmental sustainability objectives but also contributes to the country's economic and energy diversification strategies.

A. LITERATURE REVIEW

EVCSs are widespread across various locations, resulting in varying charging times for EVs. This variability is further amplified when integrating renewable energy resources into EVCSs. In three distinct regions of India, researchers examined the financial and technical viability of grid and renewable energy systems for environmentally sustainable EVCSs [19]. The study involved the optimization of system component sizing in order to minimize the levelized cost of electricity and total net present cost, while ensuring that the probability of power supply failure remained acceptable. This resulted from the implementation of an innovative optimization algorithm based on metaheuristics. This system aims to reduce dependence on strained grids [20]. With increasing concerns about climate change, EVs have emerged as a potent solution to pollution from fossil fuel transportation. To achieve a carbon-neutral transportation sector, EV batteries should be powered by RES. In [21], the authors devised an energy management strategy (EMS) with the objective of regulating the grid's peak and off-peak power requirements. The dimensions and placement of swift EVCS are critical

content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411291

determinants in the distribution network. An advanced bald eagle search algorithm is suggested by the authors with the following objectives: minimize energy loss in the distribution system, decrease transportation costs to EVCSs, and ascertain the most advantageous locations and capacities for EVCSs. Previous research, such as [22], focused on optimal sizing by integrating EVs into the distribution network. By segmenting the network into communities, strategically allocating photovoltaic systems (PVCS) within each community using the backward-forward sweep (BFS) method, and utilizing particle swarm optimization (PSO) to determine the optimal size and quantity of PVCS in order to minimize power loss and increase voltage, this methodology is implemented. This method's efficacy was validated using an IEEE 33-node test feeder. An additional investigation examines the optimization of charging station locations and capacities in Kota City, Rajasthan, India [23]. Other researchers have looked into the integration of capacitors with EV charging stations in distribution networks, examined how distributed generation affects the system's reliability [24]. In [25], the impact of distributed generation and EV charging stations on system reliability is examined. Site surveys, electric vehicle (EV) density, electricity demand analysis, load modeling, cost analysis, EV battery charging time, and power quality were integrated into the development of a mathematical model. Optimized distribution systems for integrating diverse RES, including SPV and WT units, with extant EVCSs in particular locations are the subject of this research [26]. Battery Energy Storage Systems (BESS) were deployed at the PV and WT units' sites. The performance of the distribution systems was improved through the utilization of these BES units, which utilized the Gorilla Troop Optimizer (GTO) algorithm to minimize power loss and total voltage deviation (TVD). This algorithm is applicable in optimization scenarios with a single objective or multiple objectives.

In the current environmental context, vehicle-to-grid (V2G) capable EVs present a viable answer to modern problems including air pollution and fossil fuel dependency. Using RESs such as solar systems and strategically planning EV charging and discharging schedules are two ways to address these problems [27]. EVs are gaining importance in the automotive industry due to their reduced CO2 emissions, simplified maintenance requirements, and decreased operating expenses. The increasing prevalence of electric vehicles (EVs) influences distribution network characteristics including power loss, voltage profiles, and harmonic distortion. In addition, the increased peak power demands that occur when EVs are being charged at charging stations present challenges for both EV users and EVCS investors. The integration of RESs at recharge stations is recommended in order to reduce the energy demand on the grid. In addition to maximizing the use of renewable energy and minimizing peak power consumption, energy management techniques (EMS) that regulate the charge and discharging of BES are crucial for achieving these objectives [28]. EV charging and discharging have a big impact on voltage profiles, operating costs, and the stability of electrical networks. When evaluating and integrating V2G and Grid-to-Vehicle technologies, it is recommended to employ a versatile multi-objective optimization approach that considers financial, environmental, and technological factors. Additionally, this approach considers the battery life cycle of electric vehicles (EVs), the charging and discharging schedules of EV users, and their driving patterns [29]. The increased adoption of electric vehicles (EVs) gives rise to sustainability concerns, such as the need to efficiently and sustainably procure electricity from renewable sources, manage grid demand, and construct additional charging stations. In this context, an optimized architecture for a wind-solar hybrid energy charging station is proposed, utilizing the HOMER software. This approach to measurement is adaptable on a global scale. The optimal configuration of this hybrid system utilizes 44.4% wind energy and 55.6% solar energy, producing 843,150 kWh of electricity annually at a cost of $0.064 per kWh [30].

The integration of renewables into EVCSs has demonstrated increased efficiency and grid balancing benefits. However, it's essential to consider the economic implications of connecting or disconnecting the grid from renewable sources. In [31], the authors conducted an exhaustive investigation into the technical and financial benefits of off-grid and grid-connected hybrid energy systems, including battery energy storage BES systems, solar, and wind power, for EV charging loads in the Qassim region of Saudi Arabia. Utilizing a novel optimization method, the Modified Salp Swarm Optimization method (MSSOA), they aimed to reduce energy costs and power outages. Through a comparison of MSSOA to traditional optimization techniques, the method's effectiveness was validated. The technical and financial feasibility of an electric vehicle (EV) charging initiative fueled by renewable energy sources was assessed in Nigeria across six distinct geographic and climatic regions using HOMER Pro® [32]. However, in [33], the authors point out that the widespread use of EVs for transportation raises new demands on utility grids for electricity, and they recommend using EVCSs in off-grid sites to relieve some of the strain on the current grid network. From a techno-economic standpoint, an innovative off-grid plan that combines RES to supply sustainable electricity to EVCSs is evaluated. In [34], an innovative approach is put forth to evaluate the techno-economic viability of retrofitting current petrol stations with EV Supply Equipment (EVSE), taking into account the incorporation of an onsite photovoltaic system for sustainability and the integration of a BES system with EV charging infrastructure to lower grid connection costs. According to [35], charging electric vehicles at home is favored by 90% of EV owners, which makes it a significant concern for grid administrators and car owners alike. The presentation of solutions spans a number of scenarios and includes developments in smart house design, incentives, software optimization for home energy management, and RES

content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411291

and storage. A real-time model for regulated EV load charging was presented by the authors in [36]. A demand-side management (DSM) strategy was implemented in this model by utilizing queuing analysis in conjunction with nonhomogeneous arrival rates and charging service periods. Reducing operational expenses while meeting the charging needs of electric vehicle (EV) users amidst unpredictability is the objective of Distributionally Robust Model Predictive Control (DRMPC) for energy management of a smart EVCS that incorporates PV and energy storage systems, V2G/Vehicle-to-Vehicle (V2V) technologies presented in [37].

The exploration of the energy efficiency relationship between RESs and EVs requires further investigation to bridge existing gaps and assess how EVs can enhance the sustainability of RESs. Addressing various challenges, including the need for rapid EV charging stations, numerous EV technologies have been employed. In [38], to enhance the efficiency of real-time management and strategic capacity allocation, the authors developed a framework for stochastic dynamic simulation modeling pertaining to a regional network of electric vehicle fast-charging stations. The framework is composed of two components: a multinomial logit station choice model and a multi-server queuing model. The latter is utilized to monitor supply and demand dynamics at each station, while the former incorporates charging costs, projected wait times, and detour distances. In [39], a model for a quick EVCS that is linked to the grid is provided, guaranteeing optimal power transmission with the least amount of harmonic current. The model has an integrated solar PV generation system to lessen grid effect, decentralized control for individual vehicle charging, and a converter connecting the grid to a DC bus. Increased EV use could provide power systems with a number of difficulties, including reliability problems. An extensive infrastructure for EV charging must be taken into account when analyzing the effects of EVs on power system reliability. The authors evaluated different charging infrastructures and customer preferences using the Loss of Load Expectation (LOLE) and Loss of Energy Expectation (LOEE) indices in order to comprehend the influence of EVs on power system reliability. When analyzing the effects of diverse charging infrastructure portfolios, two distinct scenarios are considered: a charging infrastructure share determined by consumer preferences and an equal percentage of all charging infrastructure [40]. SPV and BES combined with smart charging can lessen the detrimental effects of EVs on power distribution networks. Their study's objective, with regard to sizing, was to create an on-grid PV-BES system for Brazilian fast EVCS by utilizing modular solutions to boost PV power based on past load demand and utilizing Homer Grid software to analyze grid impact [41]. In [42], a unique planning approach is put out to coordinate the growth of RES with EV charging infrastructure in power networks. In order to comprehend the interactions between EVs and RES, this model takes into account individual EV charging behaviors, EV aggregation, system economic dispatch, and a Model Predictive Control (MPC) learning technique. Environmental concerns and the depletion of fossil fuels are driving a worldwide trend toward the incorporation of photovoltaics (PVs) and electric vehicles (EVs) into the electric power distribution system. Appropriate control design and schedule optimization are required to maintain system stability in light of the challenges presented by the concurrent integration of PVs and EVs into the power system, which include dynamic loading situations, unpredictable power penetration, and charge. An implementation of a solar-powered grid-tied charging station (SGTCS) is proposed, which optimizes electric vehicle (EV) charging while considering seasonal power generation fluctuations and EV charging connectivity through the use of a scheduling technique [43]. Based on day-ahead solar power generation forecasts, an algorithm for the best EV charge scheduling in solar-powered stations is proposed [44]. The objective of the algorithm is to reduce the total cost of charging. To optimize energy efficiency, reduce operating expenses, and gain effective control over load profiles, energy participants must implement coordinated power demand management at the residential or domestic level. In conclusion, a hierarchical coordination structure for managing residential loads is presented, which incorporates PV units, BESs, and EVs. On an actual power distribution network with real demand patterns and dynamics, this framework is evaluated. It facilitates bidirectional power transfer via Vehicle-to-Grid (V2G) operations, manages real-time profiles of residential loads, and coordinates operations via its controller [45].

Infrastructure for charging EVs must be dependable and easily accessible, as the market is predicted to continue growing at a rapid pace in the years to come. This infrastructure needs to support the growing number of EVs while also integrating RESs and enabling efficient data sharing between different stakeholders [46]. This case study-based article's primary goal is to present a comprehensive analysis of the most recent scientific research on various charging tactics. These tactics include renewable and grid-tied charging stations, conductive and inductive charging techniques, and the data required to charge various EV models.

B. KNOWLEDGE GAP

The prevailing studies in the literature predominantly focus on utilizing solar and wind energy to power EV loads, with a narrow scope concentrating exclusively on these renewable resources. The integration of SPV and WT systems is acknowledged as beneficial for the design of EVCS, considering the inherently variable nature of renewable resources. However, there is a notable paucity in research exploring EVCS and RES under diverse meteorological conditions. The literature reveals a limited number of studies that rigorously evaluate both the technical and economic feasibility of grid-tied, renewable energy-based EVCS.

This article has been accepted for publication in IEEE Access. This is the author's version which has not been fully edited and
content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411291

Furthermore, several studies neglect to consider key financial factors influencing EV charging systems, failing to conduct comprehensive sensitivity analyses of proposed system configurations.

The current research landscape lacks detailed exploration of Saudi Arabia's specific context in developing an EV charging infrastructure that integrates RESs and the electric grid. There's a crucial need for comprehensive analysis focusing on charging methodologies in major urban centers like Riyadh, accompanied by insights into implementation challenges, potential opportunities, socio-economic impacts, and strategic policy development for EVs and their charging infrastructures. This study aims to address these gaps, with a specific focus on Riyadh due to its abundant renewable energy resources, government-led e-mobility initiatives, readiness for swift policy adoption regarding EVs and EVCS, and the financial capacity of its inhabitants to adopt EVs. These factors are expected to drive the growth of a diverse EV charging infrastructure in Riyadh. Additionally, prevailing strategies utilizing metaheuristic algorithms often suffer from complex designs, an abundance of control parameters, and a tendency to converge on local optima. Many studies rely on intricate mathematical models requiring extensive data for effective operation, primarily developed through analytical methodologies. In contrast, metaheuristic approaches offer advantages such as reduced computational time, lower parameter control complexity, and the ability to generate satisfactory solutions. The proposed Giza Pyramid Construction Algorithm (GPCA) addresses these challenges by offering simplicity in implementation and effective convergence.

Furthermore, within the broader context of Riyadh, the growing trend for EVs underscores the need for a foundational framework for EV charging powered by solar and wind energy. Such a model could serve as a blueprint for other Saudi Arabian cities. Therefore, the establishment of a grid-tied EVCS infrastructure based on renewable resources in Riyadh is not only crucial but also symbolic of a broader national shift towards sustainable urban mobility.

C. CONTRIBUTION

On the basis of the findings of a prior literature review that investigated renewable resources data and EV charging patterns in depth, optimization strategies were implemented to develop the ideal model for the Saudi Arabian city of Riyadh. A concise overview of the primary contributions of this research endeavor is as follows:

- To optimize electric vehicle charging stations (EVCSs) powered by hybrid Renewable Energy (RE) in the Kingdom of Saudi Arabia (KSA), the study investigates the implementation of various algorithms. This includes an exhaustive comparison of various algorithms, which sheds light on how their implementation could enhance the design and functionality of EVCSs. With any luck, this analysis will contribute to the development of environmentally conscious, financially viable, and sustainable electric vehicle charging programs in Saudi Arabia, according to the research.
- The study performs a comprehensive technical and financial analysis of grid-connected EVCS and renewable energy systems that have been installed in Riyadh, Saudi Arabia. The utilization of the advanced Giza Pyramids Construction Algorithm (GPCA) is emphasized in order to maximize the Total Net Present Cost (TNPC) and the Levelized Cost of Electricity (LCOE). The study conducts a comparative analysis of the effectiveness of GPCA in relation to several other algorithms, such as the Artificial Hummingbird Algorithm (AHA), Whale Optimization Algorithm (WOA), and Flower Pollination Algorithm (FPA). This comparative analysis considers various system configurations as well as the optimal sizing of renewable energy components implemented into the grid and diesel generators (DG).
- The study conducts a sensitivity analysis in order to assess the influence of fluctuating environmental and economic variables on the TNPC and LCOE. Solar irradiance, wind speed, the discount rate, demand charges, and the inflation rate are some of these variables. Furthermore, the research investigates the effects of different levels of Lack of Power Supply Probability (LPSP) on these economic indicators, providing valuable insights into the feasibility and adaptability of EVCS in diverse circumstances.

II. METHODOLOGY

The methodology of our study focuses on a thorough analysis of a hybrid energy system that is specifically designed to charge EVs, as illustrated in Fig. 1. This system is meticulously designed with several components: SPV arrays and a WT for harnessing renewable energy; a BES unit for storing surplus power; a DG serving as a backup electricity source; an electric grid connection allowing bi-directional flow of energy in and out of the system; and a bi-directional converter facilitating energy conversion between alternating-current (AC) and direct-current (DC) forms. The SPV, BES, and EV charging load are linked to a DC link, while the DG, WT, and grid connection are attached to an AC bus. This configuration enables the system to store excess renewable energy in the BES or export it to the grid. During periods of insufficient power from the SPV and WT, the BES discharges its stored energy to meet the demand, with additional power sourced from the grid or the DG system if necessary. The bi-directional converter plays a crucial role in maintaining energy balance and flow within the system, ensuring that the output from the different components aligns with the requirements of the EV charging infrastructure. This hybrid system aims not only to optimize energy utilization by integrating renewable and conventional power sources but also to ensure a consistent and sustainable power supply for the effective operation of EV charging stations.

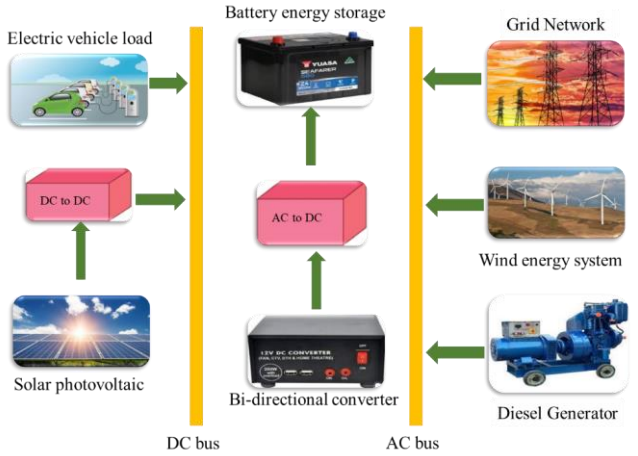

FIGURE 1. **Schematic layout of the proposed hybrid energy system**

FIGURE 2. **Location of the selected city (Riyadh) on the Map**

A. DESCRIPTION OF THE SELECTED SITE AND EV LOAD

Our research focuses on the KSA, the second-largest country in the Arab world, which is located in West Asia and occupies the majority of the Arabian Peninsula, or around 2,150,000 square kilometers (830,000 square miles). The Kingdom of Saudi Arabia is bordered to the north by Jordan, Iraq, and Kuwait; to the west by the Red Sea and Gulf of Aqaba; to the east by the Arabian Gulf, Qatar, and the United Arab Emirates; to the southeast by Oman; and to the south by Yemen. Strategically positioned in the region, KSA encompasses major cities such as Riyadh, the capital, with a population of 6.5 million; Jeddah, a significant sea-port on the Red Sea, with 4.0 million inhabitants; and the religious centers of Makkah (Mecca) and Madinah (Medina), with populations of 2.0 and 1.3 million inhabitants, respectively. Blessed with extensive RES due to its favorable climate, geographic location, and vast, unused landscapes, KSA holds significant potential for harnessing RESs, particularly for fulfilling the charging demands of EVs. The city of Riyadh has been chosen as the focal point for our study. Riyadh stands out for its abundant RESs, its pivotal role as a government hub for large-scale e-mobility development, its potential for rapid adoption of EV-related policies and regulations, and the financial capacity of its residents to afford EVs. This convergence of factors is expected to drive the proliferation of diverse EV charging infrastructure options in Riyadh. The study includes a map illustrating Riyadh's location (Fig. 2), underscoring its strategic importance as a focal point for analyzing the integration of EVCS and the potential for widespread EV adoption within the broader energy and transportation objectives of KSA.

Our research delineates a proposed energy system that has been specifically engineered to fulfill the needs of an EVCS situated in Riyadh, the capital city of the Kingdom of Saudi Arabia. Assuming the installation of this EVCS in Riyadh, the analysis takes into account the charging behaviors and demand patterns of electric vehicles utilizing this station. It is expected that the EVCS will provide service to around 30 to 40 EVs at various time intervals over the course of the day. Based on an analysis of user behavior, it has been determined that approximately one-third of the electric vehicle (EV) owners exhibit a preference for charging their vehicles at night, more precisely from 00:00 to 06:00. This preference is primarily influenced by traffic conditions experienced at the charging station during nighttime hours. Conversely, the remaining two-thirds of EVs are charged during daylight hours at various times. Understanding and managing this distribution of charging patterns are crucial for effectively balancing the load on the energy system. In terms of energy requirements, the EVCS is projected to necessitate approximately 172 kilowatt-hours (kWh) per day, with a maximum demand reaching around 17 kilowatts (kW). This demand profile is pivotal in designing the energy system to ensure it can adequately fulfill the requirements of the EVCS throughout the day and across different seasons. The daily load profile data for EVs at this specific charging station in Riyadh is elaborated in Fig. 3 of the study. The information presented in this data offers significant insights into the station's consumption patterns. These insights form the basis for optimizing the hybrid grid and renewable-powered energy system in order to cater to the station's particular demands. The optimization process holds significant importance in guaranteeing the sustainable and effective functioning of the EVCS, capitalizing on the capabilities of RESs while catering to the varied charging requirements of EV users in Riyadh. The provided data presents valuable insights into the station's energy usage patterns and serves as the foundation for enhancing the hybrid grid and renewable energy system specifically tailored to meet these requirements. It is critical to ensure the efficient and sustainable operation of the EVCS by maximizing the

potential of RESs and accommodating the diverse charging needs of EV users in Riyadh through this optimization process.

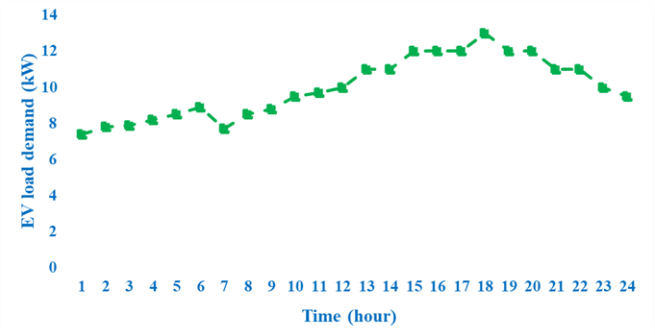

FIGURE 3. Daily EV load profile data of Riyadh city Location of the selected city (Riyadh) on the Map

B. DETAILS OF RESOURCES IN THE SELECTED SITE

Accurate assessment of Renewable Energy (RE) potential holds paramount importance for maximizing power output, particularly in countries like the KSA, which boasts vast land resources suitable for renewable energy installations. This potential plays a pivotal role in achieving KSA's developmental objectives, especially those outlined in its Vision 2030 plan. The efficacy of WT and SPV systems in KSA heavily relies on local wind speeds and solar irradiance. Data on solar irradiance, wind speed, and temperature for the selected site in KSA, obtained from NASA's POWER directory, are elaborated in Fig. 4 and Fig. 5. Fig. 4 illustrates the average monthly solar radiation and wind speed data. It indicates that the peak solar irradiance is recorded in June, while the nadir is observed in December, with an annual average value of 5.84 kilowatt-hours per square meter per day (kWh/m²/day). Regarding wind speed, the highest and lowest values occur in June and October, respectively, with an annual mean wind speed of 5.21 meters per second (m/s). Additionally, Fig. 5 presents details on the average monthly temperature at the study location, highlighting July and August as the months with the highest temperatures, and January and February as the coldest, culminating in an annual average temperature of 29.13°C. KSA's substantial solar potential, evidenced by its global ranking as the seventh among the top ten sites for clean electricity generation through direct sunlight and photovoltaic cells, underscores its capacity to generate significant clean power. These climatic factors – solar irradiance, wind speed, and temperature – are fundamental for strategic planning and implementation of renewable energy projects, particularly in supporting the energy requirements of EV charging stations in Riyadh. This comprehensive comprehension of local RESs is pivotal in developing efficient and sustainable energy solutions that align with KSA's broader environmental and developmental aspirations.

C. MODELING OF DIFFERENT COMPONENTS OF INTERCONNECTED ENERGY SYSTEM

The mathematical representation of the energy components within the proposed integrated energy system for recharging EVs is crucial for its layout and operation. The key components of this system, including the inverter, grid connection, DG, WT, SPV unit, and BES system, provided in Table 1, play essential roles in ensuring the overall performance and effectiveness of the hybrid energy system. In the proposed system, the inverter serves to convert the direct current (DC) generated by the SPV unit and stored in the BES into alternating current (AC), aligning it with the grid and DG. The grid connection serves as an additional power source and facilitates the export of excess renewable energy. The DG functions as a backup power source, supplementing the system during periods of insufficient renewable energy generation. The WT and SPV unit harness wind and solar energy, respectively, providing clean and renewable power to the system. A critical component of the system is the BES, particularly the battery, which plays a fundamental role in managing the variability in renewable energy generation. The BES ensures a more stable and reliable power supply for the EV charging requirements. By storing excess energy generated during peak renewable production periods, the BES can release this stored energy during periods of low renewable generation or high EV charging demand. The mathematical modeling of these components involves analyzing their performance characteristics, energy conversion efficiencies, storage capacities, and integration within the overall system. This analysis is essential for understanding the dynamics of

energy flow within the hybrid system and for optimizing the system's design to efficiently and sustainably meet the specific energy needs of EVCS. Additionally, the modeling includes considerations for the scalability and adaptability of the system to accommodate varying levels of EV charging demand and changes in renewable energy availability. This ensures that the integrated energy system remains flexible and capable of meeting evolving energy requirements over time.

TABLE 1. Specification of various hybrid system components [47]

Components	Characteristics	Values
Solar PV panel	Rated power	325 W
	Capital cost	1300 $/kW
	Cost of replacement	900 $/kW
	O and M cost	20 $/kW
	Life span	25 years
	Derating factor	80 %
	Module efficiency	16.94%
Wind turbine	Rated power	1 kW
	Capital cost	4450 $
	Cost of replacement	4450 $
	O and M cost	110 $
	Life span	20 years
Diesel generator	Minimum load ratio	50 %
	Operating time	15000 hours
	Capital cost	370 $/kW
	Cost of replacement	296 $/kW
	O and M cost	0.05 $
Battery	Battery material	Lead acid
	Nominal voltage	12 V
	Life span	12 years
	Capital cost	1100 $/kW
	Cost of replacement	1000 $/kW
	O and M cost	10 $/kW/year
Bi-directional converter	Rated power	60 kW
	Capital cost	800 $/kW
	Cost of replacement	750 $/kW
	O and M cost	8 $/kW/year
	Life span	15 years

1) MATHEMATICAL MODELING OF SOLAR PHOTOVOLTAIC ARRAY

The performance and productivity of a SPV system depend on several factors, such as the dimensions of the panels, the amount of sunlight received daily, the temperature of the solar cells, and the geographical location's coordinates. These elements collectively affect the SPV system's ability to convert solar energy into usable electrical power. To measure the power generated by an SPV system accurately, a mathematical equation can be utilized, as outlined in Eqn. (1) [47].

$$\mathrm{P_{SPV}(t)} = \eta_{\mathrm{SPV}} P_{SPV}^{max} \mathrm{n_{SPV}} \eta_{\mathrm{wire}} \frac{I(t)}{1000}\left(1 - \lambda_T\left(T_{amb} + \frac{(NOCT-20)}{800} I_{amb}(t) - 25\right)\right) \quad (1)$$

Where $\mathrm{n_{SPV}}$ denotes the number of SPV cells, P_{SPV}^{max} denotes the maximum power obtained from the SPV cells, η_{SPV} and η_{wire} are the efficiency and wiring efficiency of SPV cells, $\mathrm{P_{SPV}(t)}$ is the power output of the SPV cells, λ_T is the thermal coefficient of the SPV panels, T_{amb} stands for the ambient temperature, $I(t)$ represents the incident solar radiation and $I_{amb}(t)$ denotes the solar radiation at ambient temperature condition.

The total output power obtained from the SPV arrays can be mathematically expressed as:

$$P_{SPV}^{max}(t) = N_{SPV} \times \mathrm{P_{SPV}(t)} \quad (2)$$

2) MATHEMATICAL MODELING OF WIND TURBINE

A wind turbine's power output is determined by wind speed and hub height. These factors can be computed using the following equation [48]:

$$\frac{V_2}{V_1} = \left(\frac{H_2}{H_1}\right)^{\mu_{WT}} \quad (3)$$

Where V_1 denotes the wind speed at height H_1 and V_2 represents the wind speed at hub height H_2, μ_{WT} is the coefficient of friction and its value is taken to be 0.143 in this work.

WT power is not directly proportional to wind speed. The output power of each WT unit is determined by several elements, including the turbine's rated power, cut-in wind speed, cut-out wind speed, and rated wind speed.

$$\mathrm{P_{WT}} = \begin{cases} 0 & \mathrm{V(\tau) \le V_{cut-in} \text{ or } V(\tau) \ge V_{cut-off}} \\ \mathrm{P_{WT-rated}} \frac{\mathrm{V(\tau) - V_{cut-in}}}{\mathrm{V_{rated} - V_{cut-in}}} & \mathrm{V_{cut-in} < V(\tau) < V_{rated}} \\ \mathrm{P_{WT-rated}} & \mathrm{V_{rated} < V(\tau) < V_{cut-off}} \end{cases} \quad (4)$$

In the given context, V (τ) represents the wind speed at a specific height, while $\mathrm{V_{cut-in}}$ and $\mathrm{V_{cut-off}}$ represent the cut-in and cut-off speeds, respectively. $\mathrm{P_{WT-rated}}$ refers to the rated power of the WT, and $\mathrm{V_{rated}}$ represents the rated wind speed.

3) MATHEMATICAL MODELING OF RENEWABLE OUTPUT POWER

Efficiency parameters in a model represent the energy losses during the transformation process. When calculating the total renewable energy produced by WT and SPV units, the efficiencies of AC-to-DC and DC-to-DC converters are taken into account.

$$P_{RE}(t) = \eta_{dc\ to\ dc} \times \sum_{n=1}^{N_{SPV}} P_{SPV}(t) + \eta_{ac\ to\ dc} \times \sum_{n=1}^{N_{WT}} P_{WT}(t) \quad (5)$$

In this research work, the efficiency of DC to DC and AC to DC conversion is considered to be 95% [49].

As a result of solar radiation and wind speed unpredictability, the energy output of SPV and WT systems can be inconsistent. SPV units must be integrated with BES systems in order to regulate the power supply, especially when charging electric vehicles. BES systems contribute to enhanced energy supply reliability through the storage of

content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411291

surplus energy during periods of high generation and subsequent release in accordance with charging and discharging patterns.

4) MODELING OF DIESEL GENERATOR (DG)

Introducing DGs into the energy system can enhance its reliability and efficiency. DGs serve as backup sources of energy, particularly useful during peak demand or in cases of battery degradation. However, it's crucial to avoid running the DGs when they are unloaded or lightly loaded to ensure optimal efficiency and longevity.

When devising a hybrid energy system, it is crucial to consider the efficacy and hourly fuel consumption of the DG. These terms can be defined using the subsequent formula [50]:

$$u(t) = a * P_{DG}(t) + b * P_{rated-DG} \quad (6)$$

Here, $u(t)$ is the fuel consumption in liters per hour, $P(t)$ is the produced power in kW, $P_{rated-DG}$ is the rated power, and a and b are constant parameters in litre per kW that characterize the coefficients of fuel consumption and can be approximated to 0.246 and 0.08415, respectively.

The efficiency of DG can be computed by

$$\eta_{overall} = \eta_{brake\ thermal} * \eta_{DG} \quad (7)$$

Here, $\eta_{overall}$ is the overall efficiency of DG whereas $\eta_{brake\ thermal}$ stands for the DG's brake thermal efficiency.

5) MODELING OF BATTERY ENERGY STORAGE

This research examines the application of a BES in resolving demand-side power imbalances, thereby increasing the dependability and consistency of the electricity supply. Described below is the operation of the BES within the hybrid energy system.

When the power generated by the different components of the system surpasses the demand of the load, the surplus power is directed to the BES, where it initiates the charging procedure. The charging behavior of the BES at a specific moment (τ) is mathematically represented as follows: The BES receives the surplus power allocated to it when the power produced by the different components of the system surpasses the demand of the load. This causes the charging cycle to commence. The subsequent expression represents the charging behavior of the BES at a specific instant τ mathematically [51]:

$$SOC_{bat}(\tau+1) = SOC_{bat}(\tau)(1-\tilde{\lambda}) + \left[\left(P_{SPV}(\tau) + \frac{P_{WT}(\tau)}{\eta_{bdinv}}\right) - P_{EVCS}(\tau)\right] * \eta_{bat} \quad (8)$$

In situations where the RES fail to provide the EVs with the necessary power, the BES is triggered to supply the necessary power. The BES initiates discharge in accordance with the demand. Equation (9), which characterizes the discharge behavior of the BES at a specific moment τ, can be applied.

$$SOC_{bat}(\tau+1) = SOC_{bat}(\tau)(1-\tilde{\lambda}) - \frac{\left[P_{EVCS}(\tau) - \left(P_{SPV}(\tau) + \frac{P_{WT}(\tau)}{\eta_{bdinv}}\right)\right]}{\eta_{bat}} \quad (9)$$

In Eqn. (9). $SOC_{bat}(\tau+1)$represents the BES's state of charge (SOC) at a specific instant (τ+1), while $SOC_{bat}(\tau)$ represents the SOC of the BES at the same instant. The efficiency of the bi-directional inverter is denoted by η_{bdinv}, the output power of the SPV modules is denoted by $P_{SPV}(\tau)$, the output power of the WT unit is denoted by $P_{WT}(\tau)$, and the battery's efficiency is reflected in η_{bat}.

6) MODELING OF BI-DIRECTIONAL INVERTER

The bidirectional converter plays a crucial role in the efficient transfer of power in the system, allowing for the conversion of DC power from sources like batteries or renewable energy systems into AC power for consumption, and vice versa for excess AC power. When sizing an inverter, two power measurement parameters are considered: continuous power, which denotes the inverter's ability to handle a continuous load, and rated power, which represents the inverter's capacity to withstand short-term power surges. The effectiveness of a bidirectional inverter can be mathematically expressed as follows [52]:

$$\eta_{bdinv} = \frac{P_i}{P_i + P_{int} + fP_i^2} \quad (10)$$

Where, P_i, P_{int} and f can be given as follows:

$$P_i = \frac{P_{out}}{P_n} \quad (11)$$

$$P_{int} = 1 - 99\left(\frac{10}{\eta_{10}} - \frac{1}{\eta_{100}} - 9\right)^2 \quad (12)$$

$$f = \frac{1}{\eta_{100}} - P_{int} \quad (13)$$

Where, η_{10} and η_{100} represents the efficiency 10% and 100% of nominal power.

7) MODELING OF EV LOAD

The load requirement of EV can be formulated as follows:

$$PD_{EV}^{k} = PD_{EV,dch}^{k} \times \eta_{dch}^{EV} \quad \forall\, k = [k_a\ k_d] \quad (14)$$

The constraints related to EV charging and discharging for the time interval of arrival time (k_a) and departure time (k_d) are given by Eqn. (15) and (16) respectively

$$PD_{EV,ch}^{k} \le EV_{ch}^{k} \times bat_{cap}^{EV} \times \zeta \quad \forall\, k = [k_a\ k_d] \quad (15)$$

$$PD_{EV,dch}^{k} \le EV_{dch}^{k} \times bat_{cap}^{EV} \times (1-\zeta) \quad \forall\, k = [k_a\ k_d] \quad (16)$$

The maximum value of SOC of EV can be computed using Eqn. (17).

$$SOC_{EV}^{k} = SOC_{EV}^{k-1} + \left\{\eta_{ch}^{EV} EV_{ch}^{k} - EV_{dch}^{k} \times \frac{1}{\eta_{dch}^{EV}}\right\} \times \Delta k \quad \forall\, k = [k_a\ k_d] \quad (17)$$

η_{ch}^{EV} and η_{dch}^{EV} represents the charging and discharging efficiency of the EV battery. The depth of discharge of EV battery affects the charging and discharging efficiency.

The time required for charging the EV (T_{ch}^{EV}) is dependent on arrival time, EV battery type and SOC of each EV (SOC_{EV}) and can be calculated using Eqn. (18).

$$T_{ch}^{EV} = \frac{1 - SOC_{EV}}{P_{ch}^{m}} \times bat_{cap}^{EV} \quad (18)$$

This work is licensed under a Creative Commons Attribution 4.0 License. For more information, see https://creativecommons.org/licenses/by/4.0/

This article has been accepted for publication in IEEE Access. This is the author's version which has not been fully edited and
content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411291

The battery capacity of each EV can be represented by $\mathrm{bat}_{\mathrm{cap}}^{\mathrm{EV}}$ and power of m^{th} charging point is denoted by P_{ch}^{m}.

The daily total number of EVs has also been used to calculate the total EV demand. Consequently, the EV demand is computed using Eqn. (19) as follows:

$$\mathrm{PD}_{\mathrm{EV}}^{\mathrm{k}} = \sum_{m=1}^{N_{PEV}} P_{ch}^{m} \tag{19}$$

8) MODELING OF UTILITY GRID

When demand in the first phase outpaces the supply of power from various energy sources and the capacity of batteries for storage, the excess energy will be borrowed from the utility grid and can be stated as follows [53]:

$$\begin{aligned} P_P^{grid}(t) = P_D^{EV}(t) \\ - \Big[P_{SPV-out}^{total}(t) + P_{DG}(t) \\ + \Big[\Big(P_{SPV-out}^{total}(t) \\ + \big(SOC_{bat}(t) - SOC_{bat}^{min}(t) \big) \Big) \\ \times \eta_{bdinv} \Big] \Big] \end{aligned} \tag{20}$$

where $\llbracket SOC_{bat}^{min}(t)$ indicates the battery's minimal state of charge and $P_P^{grid}(t)$ is the amount of energy deficiency that must be borrowed from the grid in kWh.

The excess energy will be sold to the utility grid in the second phase, which may be described as follows, when demand is less than the amount of power generated from the various energy sources and the battery is fully charged:

$$\begin{aligned} P_S^{grid}(t) = \Big[P_{SPV-out}^{total}(t) + P_{DG}(t) \\ + \Big[\Big(P_{SPV-out}^{total}(t) \\ - \big(SOC_{bat}^{max}(t) - SOC_{bat}(t) \big) \Big) \\ \times \eta_{bdinv} \Big] \Big] - P_D^{EV}(t) \end{aligned} \tag{21}$$

where $SOC_{bat}^{max}(t)$ indicates the battery's maximum state of charge and $P_S^{grid}(t)$ is the additional energy to be sold to the grid in kWh.

III. OPTIMIZATION FRAMEWORK

The primary objective of this research is to enhance the SPV/WT/Grid system in order to reduce the TNPC and LCOE, while concurrently guaranteeing sufficient reliability as measured by the Loss of Power Supply Probability (LPSP). This segment provides an extensive elucidation of the formulation process employed to establish operational constraints and objective functions for the optimization procedure. It also outlines the energy management strategy for achieving the optimal configuration. Furthermore, a novel application of metaheuristic-based optimization techniques is introduced to optimize the SPV/WT/Grid system.

A. TECHNICAL AND ECONOMIC OBJECTIVES

The main aim of optimizing the hybrid energy system is to decrease both the LCOE and the TNPC. This cost reduction objective includes improving the reliability of power supply, which is a key concern for energy system designers. The proposed method identifies the optimal amounts of photovoltaic panels, wind turbine capacity, and battery storage. MATLAB is employed to simulate the objective function, TNPC, and LCOE, while considering the relevant constraints and limitations.

In order to ascertain the TNPC, the net present cost of replacement costs, operation and maintenance expenses, and capital expenditures are taken into account. It can be mathematically written as follows:

$$TNPC = NPC_{cap} + NPC_{O\ and\ M} + NPC_{rep} \tag{22}$$

$$NPC_{cap} = N_{SPV} \times C_{SPV}^{cap} + N_{WT} \times C_{WT}^{cap} + N_{BES} \times C_{BES}^{cap} + N_{bdinv} \times C_{bdinv}^{cap} \tag{23}$$

$$NPC_{O\ and\ M} = PWA \times \left(N_{SPV} \times C_{SPV}^{O\ and\ M} + N_{WT} \times C_{WT}^{O\ and\ M} + N_{BES} \times C_{BES}^{O\ and\ M} + N_{bdinv} \times C_{bdinv}^{O\ and\ M} \right) \tag{24}$$

$$PWA = \frac{(1+IR)^N - 1}{IR \times (1+IR)^N} \tag{25}$$

$$NPC_{rep} = \lambda \times \left(N_{SPV} \times C_{SPV}^{rep} + N_{WT} \times C_{WT}^{rep} + N_{BES} \times C_{BES}^{rep} + N_{bdinv} \times C_{bdinv}^{rep} \right) \tag{26}$$

$$\lambda = \sum_{N=1}^{z} \frac{1}{(1+IR)^{N \times L}} \tag{27}$$

Where, C_{SPV}^{cap} , C_{WT}^{cap} , $C_{BES}^{cap}$and C_{biinv}^{cap} denotes the cost of each SPV, WT, BES and inverter unit, $C_{SPV}^{O\ and\ M}$, $C_{WT}^{O\ and\ M}$ and $C_{BES}^{O\ and\ M}$ represents the operation and maintenance cost of each SPV, WT and BES unit, C_{SPV}^{rep}, C_{WT}^{rep}, C_{BES}^{rep} and C_{bdinv}^{rep} are the replacement cost of each SPV, WT, BES and inverter unit. PWA and λ are factors used to transform operational and replacement costs to a single present cost. IR represents the interest rate, N represents the project's lifespan, and L represents the number of component replacements over the project's tenure.

The LCOE serves as a valuable metric for assessing the economic viability of an interconnected energy system. It is computed by dividing the annualized cost of system components by the total energy production required to meet capacity needs, as illustrated in Eq. (28).

$$LCOE = \frac{TNPC \times PWA}{\sum_{\tau=1}^{T} P_{Gen}(\tau)} \tag{28}$$

LCOE is influenced by a multitude of factors, such as initial investment, solar irradiation, tenure, operation, and maintenance expenses, PWA, degradation of the utilized SPV units, and more.

B. OPERATIONAL CONSTRAINTS

1) RELIABILITY CONSTRAINT

In this research, the LPSP is considered a vital constraint that must be met during the design phase of the hybrid renewable energy system to ensure uninterrupted energy supply. LPSP is quantified on a scale from 0 to 1, where 0 signifies that the generated power fully meets the load demand, and 1 indicates that the load demand cannot be

This work is licensed under a Creative Commons Attribution 4.0 License. For more information, see https://creativecommons.org/licenses/by/4.0/

This article has been accepted for publication in IEEE Access. This is the author's version which has not been fully edited and
content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411291

fulfilled. Thus, LPSP serves as a metric for assessing the reliability of the hybrid system, as explained below:

$$\text{LPSP} = \frac{\sum_{\tau=1}^{T} LPS\ (t)}{\sum_{\tau=1}^{T} P_{load}(t).\Delta t} \quad (29)$$

$$PPS\ (t) = \frac{P_{load}(t)}{\eta_{\text{bdinv}}} - \left[P_{RES}.\Delta t + E_{BES}(t) - E_{BES}^{min}\right] \quad (30)$$

$$E_{BES}^{min} = (1 - DOD) \times E_{BES}^{max} \quad (31)$$

Hence, reliability plays a crucial role in ensuring a consistent and adequate supply, serving as an empirical indicator of optimized integrated systems. The storage system, in particular, significantly enhances reliability. During the optimal planning phase, the maximum LPSP reliability index is prioritized to establish an efficient hybrid electrical system.

$$\text{LPSP} \leq \text{LPSP}_{max} \quad (32)$$

It is assumed that the utmost value of LPSP is 1%.

2) DECISION VARIABLES RELATED CONSTRAINT

During the optimization process of an energy system, a balance is struck between the technical constraints related to reliability and the cost objectives. Decision variables must be defined to facilitate the implementation of the proposed optimization procedure. The constraints for the decision variables in the study, which define the upper and lower bounds of their quantities, are expressed by the equations below:

$$N_{SPV}^{min} \leq N_{SPV} \leq N_{SPV}^{max} \quad (33)$$

$$N_{WT}^{min} \leq N_{WT} \leq N_{WT}^{max} \quad (34)$$

$$E_{BES}^{min} \leq E_{BES} \leq E_{BES}^{max} \quad (35)$$

$$P_{biinv}^{min} \leq P_{biinv} \leq P_{biinv}^{max} \quad (36)$$

C. ENERGY MANAGEMENT APPROACH

The reliability of a power system is established when its capacity aligns with the demand requirement, as measured by the probability of power supply failure. The present study considers the electric vehicle (EV) power demand in the Riyadh region of Saudi Arabia. Energy requirements are met through the utilization of two main sources: SPV panels and WT. The following describes the discrepancy between the power produced by RES (SPV and WT) and the demand for EV loads:

$$\Delta P(t) = P_{SPV}(t) + P_{WT}(t) - P_{EV}^{load}(t) \quad (37)$$

When the power generated by RES is not sufficient for that of the demand, the shortfall is compensated by drawing power from the grid $P_{grid}^{borrow}(t)$. On the contrary, in the event that RES fail to meet the load demand, any remaining surplus power may be exported back to the grid denoted as $P_{grid}^{sold}(t)$. Nevertheless, purchasing and selling power to the grid are constrained, as indicated by the maximum purchase from the $P_{grid}^{borrow,max}(t)$ and the maximum sell to the $P_{grid}^{sold,max}(t)$.

- If $\Delta P(t) > 0$, the combined power output generated by the SPV panels and WT is adequate to charge the EVs, any surplus power $P_{grid}^{sold}(t)$ is determined to be sold to the grid. This surplus power available for sale to the grid is computed as follows:

$$(P_{grid}^{sold}(t)) = \left(P_{SPV}(t) + P_{WT}(t) - P_{EV}^{load}(t)\right) \quad (38)$$

- In a scenario where the output of a renewable energy source (RES) is sufficient to meet the power requirements of the electric vehicle (EV) load and exceeds the utmost selling capacity of the power grid, denoted as $\Delta P(t) > 0\ and\ \Delta P(t) > (P_{grid}^{sold,max}(t))$, the excess electrical energy is directed to the dump load. This surplus energy allocated to the dump load can be computed as follows:

$$P_{dump}(t) = P_{SPV}(t) + P_{WT}(t) - P_{EV}^{load}(t) - P_{grid}^{sold,max}(t)/\eta_{bdinv} \quad (39)$$

- If $\Delta P(t) > 0$, it indicates that the power generated by the SPV panels and WT is insufficient to meet the energy requirements of the EVs. Consequently, the required electrical energy is sourced from the grid network, as outlined below:

$$(P_{grid}^{borrow}(t)) = (P_{EV}^{load}(t) - P_{SPV}(t) - P_{WT}(t))/\eta_{bdinv} \quad (40)$$

- If $\Delta P(t) = 0$, it signifies that no power exchange occurs with the grid, and the power generated by the SPV panels and WT is adequate to satisfy the demand of the EV load.
- When the combined output from RES and grid power falls short of meeting the peak load demand, a power deficit occurs, which can be expressed as:

$$P_{def}(t) = P_{grid}^{borrow}(t) - P_{grid}^{borrow,max}(t) \quad (41)$$

To guarantee the dependable fulfillment of the EV load requirement, it is critical to reduce the power deficit $P_{def}(t)$ to zero while endeavoring to minimize the LPSP. Enforcing precise boundaries for LPSP is advantageous for resolving the optimization problem. One percent is the utmost LPSP limit for this investigation. Utilizing the flowchart depicted in Figure 6, the energy management strategy for grid-connected SPV and WT-based design of EV load can be clarified.

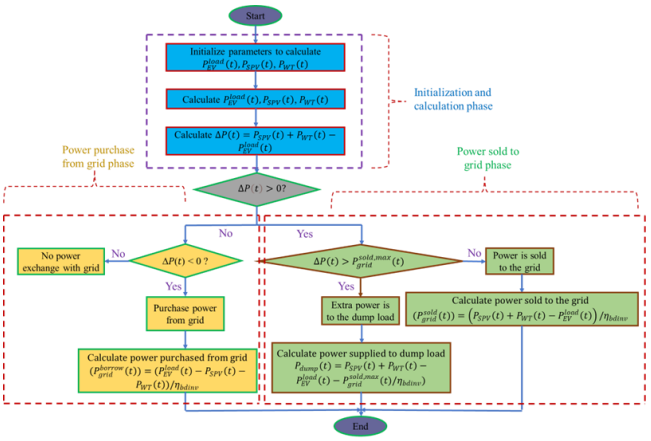

FIGURE 6. EMS for the optimal combination

C. OVERVIEW OF THE PROPOSED GIZA PYRAMID CONSTRUCTION ALGORITHM (GPCA)

In this study, the GPCA is employed to optimize the renewable energy system for fulfilling the EV demand in the Riyadh region of Saudi Arabia. The selection of this algorithm

This work is licensed under a Creative Commons Attribution 4.0 License. For more information, see https://creativecommons.org/licenses/by/4.0/

This article has been accepted for publication in IEEE Access. This is the author's version which has not been fully edited and
content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411291

is justified by its ease of implementation, efficient search capabilities, and the simplicity of its component algorithms.

1) OVERVIEW OF GPCA

The GPCA is a novel metaheuristic approach inspired by the ancient craftsmanship and architectural techniques used in the construction of the Giza Pyramids in Egypt [54]. This algorithm, based on population size, simulates the movements of laborers and the transportation of stone slabs up the slope under the supervision of a designated representative appointed by the Pharaoh. Demonstrated to handle multidimensional problems effectively, the GPCA is well-suited for optimizing both technical and economic objectives.

The core concept of the GPCA involves continuous pushing and movement of a stone block by workers to improve control. Unique positions and fitness values are assigned to a predetermined number of workers, determining their ideal locations. The movement and displacement of workers, akin to the shifting of stone blocks, generate new potential positions. Through a substitution probability, existing worker positions may be replaced with new ones. These positions are then sorted to identify the best solution. In the algorithm, the stone block's movement up the slope is governed by a random initial velocity u_0 ranging from 0 to 1. As the stone block advances, it encounters opposing kinetic friction force f_k, eventually coming to a stop after covering a certain distance d.

$$f_k = \mu_k mg\ cos\theta \tag{42}$$

where, m represents the mass of stone block, g is the acceleration due to gravity, $\mu_k$is the coefficient of friction, θ denotes the angle between slope and the horizontal surface.

Using the Newton second law of motion which can be represented as:

$$\vec{F} = m\vec{a} \tag{43}$$

Where, a denotes the acceleration.

Further, Eq. (43) can be expressed as follows:

$$ma = -mgsin\theta - f_k \tag{44}$$

The acceleration of stone block on the slope can be estimated using Eqn. (44) and Eqn. (45) as follows:

$$a = -g(sin\theta + \mu_k cos\theta) \tag{45}$$

The displacement covered by the stone block on the slope is represented by d and can be determined as follows:

$$d = \frac{{u_0}^2}{2g(sin\theta + \mu_k cos\theta)} \tag{46}$$

The position of worker to determine its position is calculated using Eqn. (47)

$$x = \frac{{u_0}^2}{2gsin\theta} \tag{47}$$

The updated position can be calculated using Eqn. (48)

$$\vec{P} = \left(\vec{P_l} + d\right) \times x\vec{\epsilon_l} \tag{48}$$

Where, $\vec{\epsilon_l}$ is an arbitrary vector which obeys levy distribution.

The probability of substituting workers can be given using Eqn. (49).

$$\rho_k = \begin{cases} \gamma_k & if\ rand[0,1] \le 0.5 \\ else\ \emptyset_k \end{cases} \tag{49}$$

Where $\emptyset$ and γ is the set of values of primary solutions and generated solutions respectively. The steps involved in the execution of GPCA is displayed in Fig. 7.

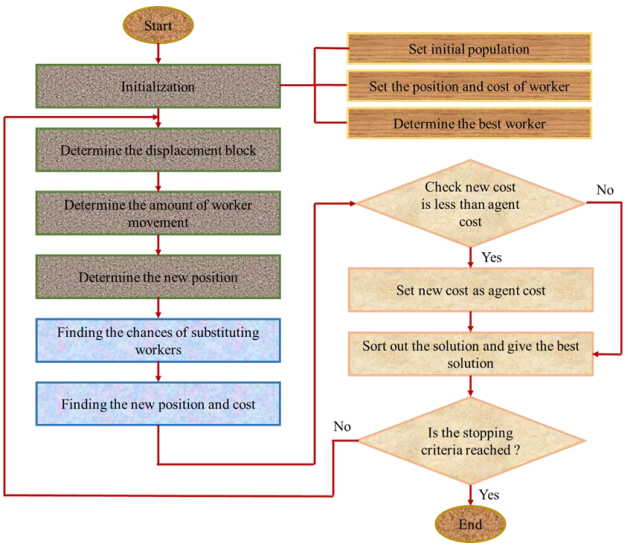

FIGURE 7. Flow chart of Giza Pyramids Construction Algorithm for the proposed combination

IV. RESULT AND DISCUSSIONS

This study endeavors to undertake a thorough technical and financial examination of renewable and grid-tied EVCS deployed in Riyadh, Saudi Arabia. It aims to capitalize on the plentiful RESs and the existing power network infrastructure in the area. Numerous optimization methodologies have been explored in previous literature to determine decision variables for fulfilling EV load demands while minimizing energy costs. In this research, the TNPC and LCOE of the proposed integrated EVCS framework are optimized utilizing the GPCA. The effectiveness and performance of GPCA are validated by comparing its outcomes with other optimization techniques such as the AHA, FPA, among others. Different system configurations, including combinations of energy resources and storage devices, are designed, investigated, and optimized to minimize electricity cost and TNPC. These configurations include SPV/WT/BES, SPV/DG/BES, WT/DG/BES, SPV/WT/Grid, and WT/DG/Grid. We examine the techno-economic variables for all feasible system configurations in Riyadh, Saudi Arabia. Overall, this research aims to provide insights into the optimal design and operation of EVCS integrated with renewable and grid-tied energy systems in Riyadh, KSA, considering various optimization approaches and system configurations.

In our study, we carefully considered the intermittent nature of RESs, which impacts their energy production and the bidirectional flow of electricity to and from the electric network. We simulated the energy system under various climatic seasons to account for these fluctuations. The design of the EVCS system model and the implementation of optimization techniques were conducted using the MATLAB environment. We analyzed several performance indices,

content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411291

including the LCOE, TNPC, system component capacities and productions, and grid sales and purchases for all possible system configurations. Additionally, we conducted sensitivity evaluations to assess the impact of varying solar irradiation, demand charge, wind speed, grid purchase price, discount, and inflation rates on TNPC and LCOE. Moreover, we investigated the impact of varying LPSP levels on both TNPC and LCOE. The convergence curve for the proposed GPCA and three other algorithms is illustrated in Fig. 8. We found that the computational time required by the GPCA technique was lower, with a small number of iterations needed to converge towards the optimal solution compared to the other approaches. Moreover, our analysis revealed that the GPCA technique consistently provided superior results for all levels of LPSP considered. Additionally, the operating cost of GPCA was the lowest compared to other techniques, as shown in Fig. 9, with a value of $2,845.42. Therefore, we propose the GPCA technique for further investigation and optimization of the energy-integrated EV charging station. The basic parameters used for tuning GPCA are displayed in Table 2, providing insights into the optimization process and parameter settings for future studies.

A. TECHNO-ENVIRON-ECONOMIC EVALUATION OF DIFFERENT SYSTEM CONFIGURATIONS FOR EVCS

1) PERFORMANCE ANALYSIS OF EVCS SYSTEM CONFIGURATIONS

In this subsection, we delve into the various system configurations for EVCS using performance indicator parameters. The electricity generated by RE systems exhibits significant fluctuations, leading to the incorporation of backup supply systems such as DGs, BES, and grid connectivity options to enhance reliability. Thus, the analysis considers possible system configurations designed for EV charging: SPV/WT/BES, SPV/DG/BES, WT/DG/BES, SPV/WT/Grid, and WT/DG/Grid. Table 3 presents the optimized results for all feasible system configurations aimed at meeting EV charging requirements in the specified area, achieved using the GPCA. A thorough examination of the table reveals that the SC#4 configuration (SPV/WT/Grid) exhibits the lowest TNPC of $102,042 and LCOE of $0.0796/kWh, making it the most desirable and cost-effective option compared to other configurations. The simulation outcomes suggest that the optimal setup, comprising SPV, WT, and grid integration (SPV/WT/Grid), effectively meets the demands of EV charging. As RESs exhibit intermittent energy production, the grid network acts as a backup to address any shortfall in energy supply, thereby augmenting reliability. The SPV and WT systems collectively contribute to 69.2% of the annual electricity production, with the remaining energy sourced from the electric power network. Moreover, the optimal configuration involves purchasing approximately 29,810 kWh of energy annually from the grid while exporting around 30,124 kWh/year of electricity to the grid through sales. This highlights the competitive renewable penetration of 67.9% achieved by SC#4, emphasizing its efficacy in leveraging RES for EV charging infrastructure.

Furthermore, the analysis delves into the detailed examination of system configurations for EVCS using performance indicator parameters. The electricity generated by renewable energy systems exhibits significant fluctuations. Hence, various backup supply systems such as DGs, BES, and grid connectivity options are often employed to enhance the reliability of such systems. In this analysis, the potential system configurations designed for EV charging are SPV/WT/BES, SPV/DG/BES, WT/DG/BES, SPV/WT/Grid, and WT/DG/Grid. Table 3 showcases the optimized results for all feasible system configurations to meet the EVs' charging requirements in the considered area. These results, obtained using the GPCA, highlight that the SC#4 (SPV/WT/Grid) configuration demonstrates the lowest TNPC of $102,042 and LCOE of $0.0796/kWh, making it the most desirable and cost-effective option compared to other feasible configurations. Additionally, the optimal configuration encompasses more energy sources compared to SC#1, SC#2, and SC#3 models, signifying its reliability in electrification. While SC#1 (SPV/WT/BES) boasts a 100% renewable fraction, indicating its preference from an environmental standpoint, it records the

This work is licensed under a Creative Commons Attribution 4.0 License. For more information, see https://creativecommons.org/licenses/by/4.0/

This article has been accepted for publication in IEEE Access. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411291

highest TNPC ($985,235.92) and LCOE ($1.02/kWh), making it financially unviable for EV charging. Conversely, configurations interconnected with the grid, like SC#4, sell more electricity to the grid than they purchase, unlike SC#5 (WT/DG/Grid), which primarily imports its charge demand from the grid. This suggests that the optimal system can generate additional revenues for the EVCS operator. Furthermore, SC#2 integrates SPV, DG, and a storage battery, with solar PV contributing to the majority of energy production and achieving a renewable penetration of 41.5%. However, its high LCOE of $0.509/kWh and TNPC of $424,028.4 render it economically unfeasible for EVCS. Substituting SPV with WT in SC#2 results in SC#3, with reduced LCOE and TNPC of $0.4231/kWh and $362,877, respectively. SC#3 exhibits the highest environmental impact due to DG usage, alongside the least renewable penetration. Comparatively, the optimized system (SC#4) showcases the lowest emissions profile after SC#1, which has no carbon footprint. It significantly reduces emissions for all pollutant emission parameters compared to SC#2, SC#3, and SC#5 systems. SC#3 records the highest total emissions rate due to high fuel consumption of the DG, while SC#2 and SC#5 emit considerable quantities of carbon dioxide emissions.

TABLE 3. Optimized comparative results of system configurations for EVCS

Configurations for EVCS model	SPV/WT/BES	SPV/DG/BES	WT/DG/BES	SPV/WT/Grid	WT/DG/Grid

2) COST-WISE BREAKUP OF DIFFERENT EVCS SYSTEMS

A detailed breakdown of the costs associated with different components for the system configurations designed to meet the EVs' charging requirements in the selected location is provided in Fig. 10. In the case of SC#1, the majority of expenses are attributed to the BES and the WT. Notably, the capital cost of the BES ($266,200) exceeds double that of the WT ($106,800), resulting in higher replacement costs for these components compared to the SPV system and converter. The expenditure on purchasing the WT is 6.25% higher than that of the SPV system. Analyzing the cost breakdown of the components for the SPV/WT/BES system in detail, the capital cost ($481,824.2) and the replacement cost ($339,623) stand out as the most significant cost parameters. These costs are notably higher compared to other cost variables. The substantial capital cost can be attributed to the significant expenditure on the BES and WT, with the BES alone

This work is licensed under a Creative Commons Attribution 4.0 License. For more information, see https://creativecommons.org/licenses/by/4.0/

This article has been accepted for publication in IEEE Access. This is the author's version which has not been fully edited and
content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411291

contributing more than half of the total capital cost, while the converter has the smallest share ($8,306) of this cost. Specifically, the BES accounts for approximately 55.2% of the system's gross capital cost, while the WT has approximately 22.2%. Overall, the high capital cost observed in the SPV/WT/BES system is primarily due to the substantial expenditure on the BES and WT, highlighting their importance in the system.

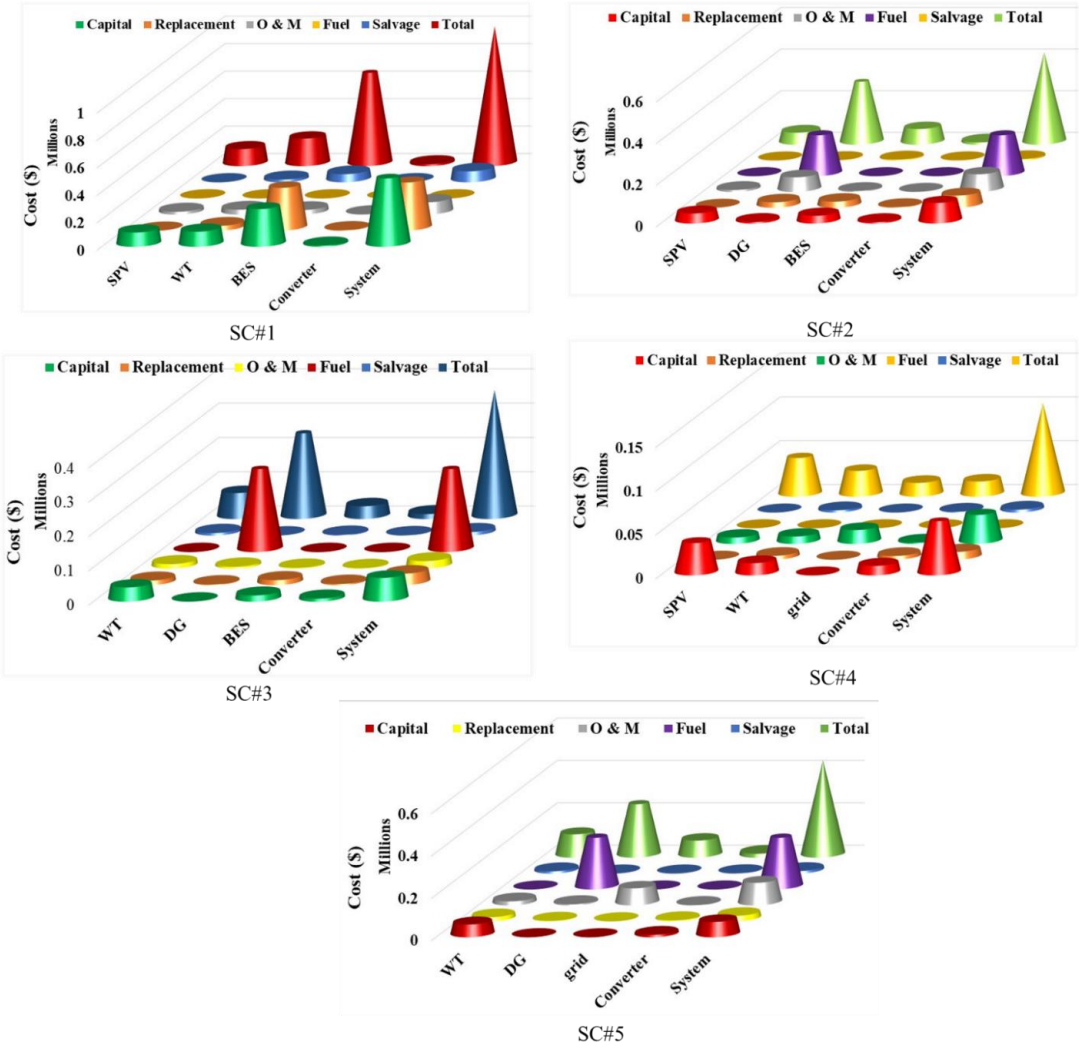

FIGURE10. Cost-wise breakup of various components for the different possible system configurations

In contrast, the elevated system replacement cost primarily stemmed from the substantial expense incurred when replacing the battery storage device. Specifically, the replacement cost of the BES comprises approximately 89% of the system replacement cost, followed by the WT, which accounts for about 10%. The operational and maintenance (O&M) costs of the WT system and BES were slightly higher, totaling $86,477.14, with the converter contributing the least at $1,073. Unlike the WT and BES, the SPV system incurs zero replacement and salvage costs due to its lifespan, which aligns with the project's duration. It's noteworthy that the SPV/WT/BES system reported the highest TNPC of $985,235.92 among all feasible configurations for the EVCS due to the higher capital and replacement costs. These costs accounted for approximately 48.9% and 34.47% of the TNPC, respectively. In the case of SC#2, the cost breakdown reveals that fuel and capital costs account for approximately 44.1% and 22.2% of the TNPC, respectively. The high fuel cost is attributed to expenses associated with DG fuel resources and operating conditions. Additionally, the high capital cost is due to substantial expenditures on SPV and BES devices. The DG's maintenance and operating conditions significantly contribute to high O&M costs, approximately 19.2% of the TNPC for the configuration. Similarly, the replacement cost accounts for approximately 13.2% of the TNPC, largely contributed by the BES and DG, with no replacement costs incurred by the SPV. Consequently, the TNPC of SC#2 is $424,028.4, lower than that of SC#1 and SC#5.

The total system capital cost (TSCC) for the SC#3 configuration is reported at $66,645. Within this cost

This work is licensed under a Creative Commons Attribution 4.0 License. For more information, see https://creativecommons.org/licenses/by/4.0/

This article has been accepted for publication in IEEE Access. This is the author's version which has not been fully edited and
content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411291

breakdown, the WT capital cost comprises approximately 60.1% of the TSCC, followed by the BES at about 26.4%. Conversely, the DG represents the least expensive component, accounting for only 0.56% of the TSCC. Regarding the overall replacement cost of $32,311, the BES constitutes around 43.7%, the WT about 39.5%, and the converter approximately 10.6% of this cost. The DG contributed the lowest cost at $1,978, while the storage device accounted for the highest share of the total replacement cost due to its shorter operational lifespan compared to the system's overall duration. Maintenance and operating conditions of the WT resulted in approximately 60.4% of the overall O&M cost. The total fuel (64.2%) and capital (18.4%) costs together constitute about 82.5% of the TNPC. This is primarily due to the significant expenditure on the WT and the storage device, as well as the expenses associated with the fuel resources for the DG.

For the SC#4 optimal configuration, the capital cost represents the highest share of the TNPC, with SPV and WT constituting approximately 59.7% and 22.7% of the overall capital cost, respectively. In terms of operating and maintenance (O&M) costs, the grid network dominates, accounting for approximately 47.8% of the total O&M cost, while the converter contributes the least share at around 4.25%. Due to the absence of DG in this system configuration, no expenditure is recorded on fuel resources, resulting in a zero-fuel cost. Additionally, the zero-replacement cost reported by the SPV and the distribution grid components leads to a low system replacement cost of $8,390. As a result, the optimal system configuration reports the lowest TNPC of $102,042 compared to other feasible configurations. In the case of SC#5, the total fuel cost constitutes more than half (53%) of the TNPC, primarily due to expenses associated with fuel resources. This is followed by the overall O&M cost, which accounts for about 23%. The high total O&M cost is attributed to the operational condition and maintenance of the grid and the WT, with the grid alone representing approximately 75% of the overall O&M cost. Regarding the total capital and replacement costs for SC#5, in both instances, the WT makes the largest contribution, comprising 83.6% of the capital cost and 74.4% of the replacement cost. Conversely, the DG constitutes a negligible 8% of the total replacement cost and a mere 0.54% of the overall capital cost. Overall, the capital and replacement costs represent about 15.7% and 5.63% of the TNPC for this configuration, respectively.

The operating costs of various EVCS configurations are illustrated in Fig. 11. Analysis of the results indicates that the optimal configuration, SC#4, has the lowest operating cost of $2,845.42, significantly lower than that of SC#1 ($26,980.48), SC#2 ($24,661.73), and SC#3 ($21,399.8) configurations. Additionally, the operating cost of SC#5 ($8,367.71) is almost three times higher than that of the optimal system. Furthermore, replacing the WT in the SC#1 configuration with a DG to form the SC#2 system reduces the operating cost by approximately $2,319. Similarly, eliminating the SPV component in the SC#2 configuration and replacing it with a WT to create the SC#3 configuration further decreases the operating cost by around $3,262.

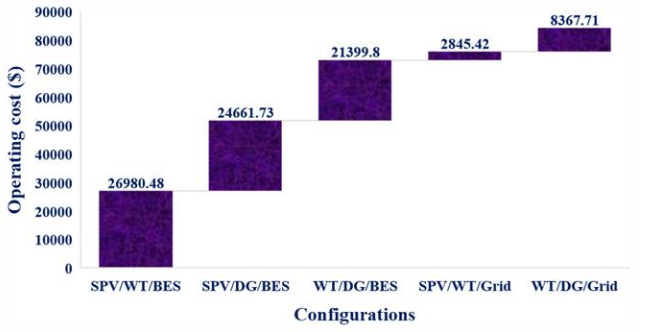

FIGURE 11. Operating cost of different EVCS system configurations

B. HOURLY SIMULATION RESULTS UNDER DIFFERENT CLIMATE SEASONS

The 24-hour profile of various energy components' power production, including grid purchase, for four different climatic seasons, is presented in Fig. 12. The seasons were categorized into four distinct cases: Case #1 represents the winter season, Case #2 the spring season, Case #3 the summer season, and Case #4 the autumn season. Upon closer examination of the figs, it is observed that there is generally lower power output from the SPV and WT systems from 12:00 AM to 6:00 AM for all seasons, except for the wind power output, which peaks during the summer season. The hourly simulation outcomes for the different climatic seasons are further explained below:

Case#1: During the winter hours, there is a decrease in output power from the WT with minimal solar output between 12:00 AM and 7:00 AM, which is not sufficient to meet the EV charging load. Consequently, additional energy is sourced from the grid to supplement the wind output and meet the EV charging demand adequately. During this period, the system experiences the highest energy purchase from the grid, resulting in zero revenue for the EVCS operator as no energy is sold back to the grid. Subsequently, after 7:00 AM, the output of solar and wind increases sufficiently, becoming the primary contributors to the charge requirement, with surplus energy sold back to the grid whenever generation exceeds EV load demand. Solar and wind outputs, along with energy sold to the grid, peak during the daytime (indicated by green, red, and yellow dashed lines in Fig. 12(a)). Consequently, the system purchases minimal electricity from the grid during this period (purple line in Fig. 12(a)). This trend continues until 6:00 PM, after which the system significantly increases its electricity purchases from the grid due to reduced power generation from SPV and WT systems.

Case#2: During the spring season, the system experiences minimal wind and solar power production in the early and late hours of the day, leading to a notable import of electricity from the grid to meet the EV load demand (illustrated by the light green dashed line in Fig. 12(b)). Similar to the winter season, the majority of solar and wind energy production occurs

This work is licensed under a Creative Commons Attribution 4.0 License. For more information, see https://creativecommons.org/licenses/by/4.0/

This article has been accepted for publication in IEEE Access. This is the author's version which has not been fully edited and
content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411291

during the middle of the day. During this period, solar and wind output adequately meets the EV charging demand, with surplus energy being injected into the grid. An examination of Fig. 12(b) reveals a significant surplus of exported energy, generating additional revenue for the charging system operator after satisfying the EV load. During this time, minimal electricity is withdrawn from the grid. The wind power output and grid sales are illustrated in Fig. 15(b) by the blue and green dashed lines, respectively.

Case#3: In the summer season, the optimal configuration exhibits a different pattern of solar and wind power production compared to the winter and spring seasons. As shown in Fig. 12(c), the WT reaches its maximum power output at the start of the day (indicated by the red dashed line), while the solar PV generates most of its power during the daytime (illustrated by the blue dashed line). Compared to previous seasons, there is minimal electricity drawn from the grid network during the summer period. However, to fulfill the load requirement, there are two distinct periods of heightened electricity import from the grid: between 5:00 PM and 11:00 PM, and between 3:00 AM and 7:00 AM. From the provided image, it's evident that the system generates excess energy after meeting the load demand during the day and early morning, attributed to the substantial renewable resource output. This surplus energy is subsequently sold to the electric network, capitalizing on advantageous incentives, thereby generating additional revenue for the charging system operator.

Case#4: The red dashed line depicted in Fig. 12(d) illustrates the WT commencement of energy production after 6:00 AM, maintaining relatively consistent power generation throughout the day. Similar to scenario #3, the bulk of the electricity drawn from the electric grid to supplement renewable energy output and fulfill the EV load occurs during the early and late hours of the day. Concurrently, the solar PV system predominantly generates power during daylight hours. As indicated by the purple dashed line in Fig. 12(d), during periods of surplus energy generation, the excess energy is sold to the power network operator once the system has met the EV charging requirement. This surplus energy sale contributes to additional income for the EVCS operator.

The comprehensive power analysis conducted for the optimal configuration of Riyadh's EV charging stations underscores the critical role of solar and wind energy sources in meeting the city's EV load demands. These RES effectively fulfilled the EV charging requirements to a satisfactory extent during periods of high solar and wind production. Nonetheless, a small amount of electricity was drawn from the grid to compensate for times when solar and wind energy production were minimal or absent. One notable aspect is the surplus electricity generated by the renewable components whenever their output exceeded the EV load demand. This surplus energy was effectively sold to the electric network at favorable incentives, providing an additional source of revenue for the EV charging station owners. This demonstrates the potential for renewable energy systems not only to meet local demand but also to contribute to the wider electric grid, fostering sustainability and economic viability in the energy sector.

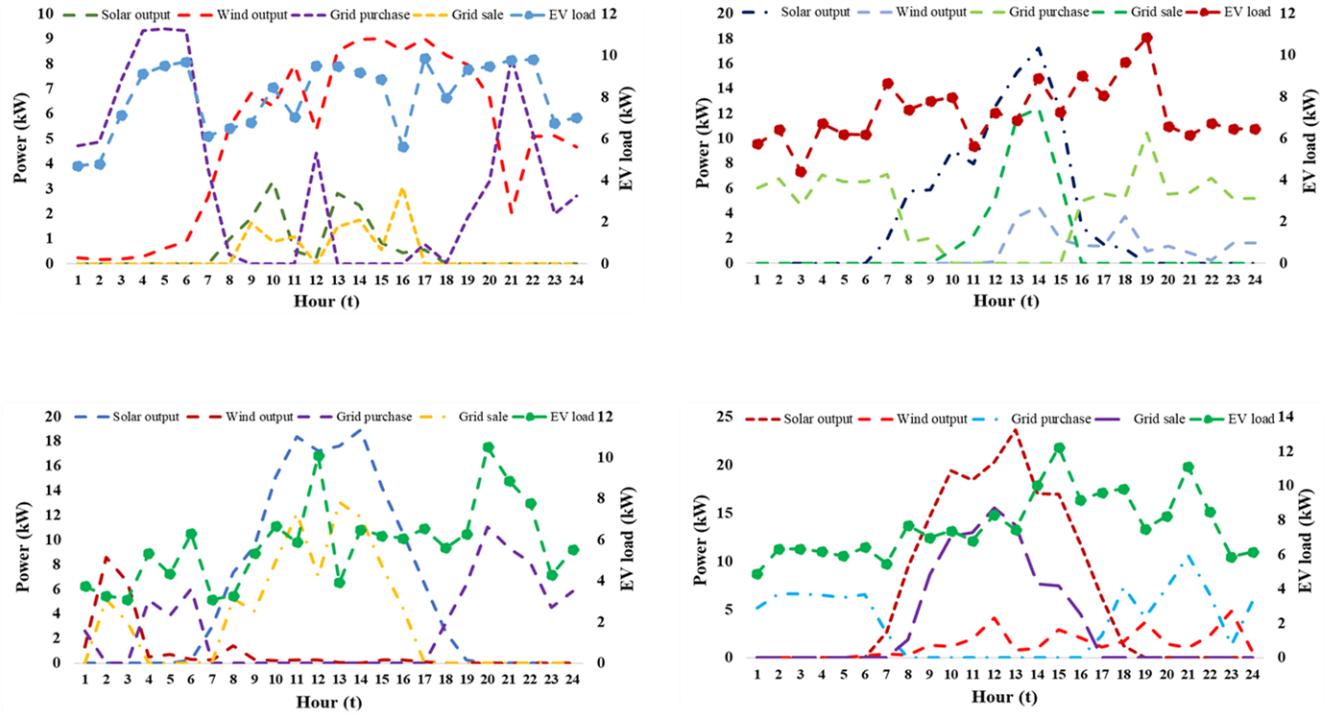

FIGURE 12. **Power assessment for SPV/WT/Grid configuration for EVCS during the (a) Winter (b) Spring (c) Summer and (d) Autumn season**

content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411291

C. MONTHLY GRID POWER PURCHASE AND SALE

The monthly exchange of electricity with the distribution grid, as depicted in Fig. 13, showcases the system's ability to consistently generate surplus power throughout the year, particularly from March to October. This surplus energy was effectively sold to the electric network, generating additional revenue for the system operator. July witnessed the highest grid sales at 3041 kWh, while December recorded the lowest at 1937 kWh. Conversely, January and December saw the highest imports of electricity from the grid due to insufficient energy from renewable resources. However, in months like June and July, minimal power was imported from the grid as the SPV and WT systems provided ample electricity. In summary, these findings emphasize the technological and economic advantages of adopting a grid-tied renewable energy system. They highlight its capacity to utilize surplus energy production for financial benefits and ensure a dependable power supply, even in instances of low renewable energy generation.

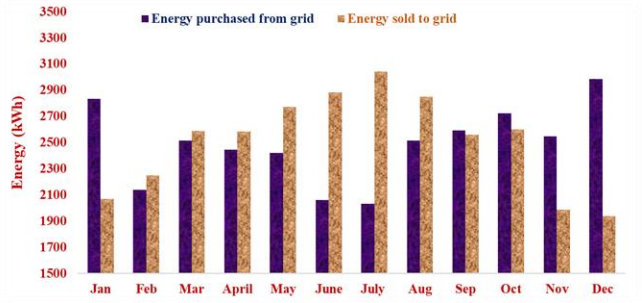

FIGURE 13. Monthly energy purchase and sale with the electric power network

D. IMPACT OF THE VARIATION IN LPSP ON TNPC AND LCOE

The comparative analysis presented in Table 5 highlights the impact of varying levels of LPSP on the TNPC and LCOE of EVCSs optimized using GPCA, WOA, AHA, and FPA techniques. Across all LPSP levels, the GPCA technique consistently yielded the lowest TNPC and LCOE compared to the other optimization methods. Specifically, at a 5% LPSP index, the GPCA approach achieved the lowest TNPC ($89,767.71) and LCOE ($0.053/kWh) among all techniques. The TNPC and LCOE of the GPCA-optimized results ranged between $89,767.71 to $95,692.75 and $0.053/kWh to $0.079/kWh, respectively, for varying LPSP levels. Notably, increasing the LPSP index percentage led to reductions in both TNPC and LCOE for the GPCA technique. Similar trends were observed with other optimization techniques, albeit with some variations. For instance, the LCOE of AHA and FPA increased by 16.4% and 22.2%, respectively, when the LPSP levels rose from 3% to 5%. In contrast, the GPCA system exhibited a reduction in LCOE by 15.2%, 8.95%, and 13.1% as the LPSP index increased from 0% to 1%, 1% to 3%, and 3% to 5%, respectively. Moreover, the TNPC value determined by the GPCA decreased by 2.21%, 1.08%, and 3.02% with increasing LPSP index levels from 0% to 1%, 1% to 3%, and 3% to 5%, respectively. These findings underscore the superior performance and robustness of the GPCA technique in optimizing EVCS configurations across varying levels of LPSP.

The comparison of optimized results at different LPSP levels highlights the superior performance of the GPCA technique across various scenarios. At a zero LPSP index, the SPV/WT/Grid configuration optimized by GPCA achieved a TNPC of $95,692.75, representing reductions of 7.6%, 17.2%, and 23.9% compared to the TNPC obtained using WOA, AHA, and FPA techniques, respectively. Similarly, the LCOE of $0.079/kWh for the GPCA-optimized system is notably lower, being 3.66%, 48.36%, and 60.1% less than that determined by WOA, AHA, and FPA techniques, respectively. Moving to a 1% LPSP, the GPCA-optimized system exhibited a further reduction in both TNPC and LCOE. The TNPC of $93,578.21 is 6.96%, 15.37%, and 23.1% lower than that of WOA, AHA, and FPA, while the LCOE of $0.067/kWh is 10.67%, 27.17%, and 39.1% less than the results obtained using WOA, AHA, and FPA approaches. At a 3% LPSP, the GPCA-optimized system continued to demonstrate its effectiveness, achieving a TNPC of $92,564.59 and an LCOE of $0.061/kWh. These values represent reductions of 6.27%, 13.29%, and 20.1% for TNPC, and 11.6%, 22.78%, and 38.38% for LCOE compared to the results obtained using WOA, AHA, and FPA techniques, respectively. Finally, at a 5% LPSP index, the GPCA-optimized system presented the lowest LCOE and TNPC values of $0.053/kWh and $89,767.71, respectively. These results highlight significant improvements over the outcomes obtained using WOA, AHA, and FPA techniques, with reductions ranging from 5.68% to 22.1% for TNPC and 12.48% to 56.2% for LCOE. Overall, these findings underscore the effectiveness and efficiency of the GPCA technique in optimizing EVCS configurations across varying levels of LPSP, outperforming other optimization methods in terms of both TNPC and LCOE.

E. IMPACT OF AVERAGE SOLAR RADIATION AND WIND SPEED

The study investigated the impact of varying solar irradiation and wind speed on the TNPC and LCOE of the system, recognizing the intermittent nature of RESs and its influence on energy production and associated costs. The findings, depicted in Fig. 14, highlight notable changes in TNPC and LCOE values across different levels of solar irradiation and wind speed. In the scenario of average solar irradiation (6.41 kWh/m2/day), both TNPC and LCOE exhibit reductions of approximately 17.86% and 13.3%, respectively, compared to the base case values (TNPC=$102,042 and LCOE=$0.0796/kWh). Further increasing solar irradiation to 6.91 kWh/m2/day results in additional reductions in TNPC and LCOE, with the LCOE decreasing by about 10% and the

content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411291

TABLE 5. Optimal results using GPCA, WOA, AHA, and FPA for different LPSP levels

LPSP	System Cost	Techniques GPCA	WOA	AHA	FPA
0 %	TNPC ($)	95692.75	103576.12	115583.56	125761.78
	LCOE ($/kWh)	0.079	0.082	0.153	0.198
1 %	TNPC ($)	93578.21	100583.56	110578.11	121765.43
	LCOE ($/kWh)	0.067	0.075	0.092	0.11
3 %	TNPC ($)	92564.59	98762.57	106754.12	115842.57
	LCOE ($/kWh)	0.061	0.069	0.079	0.099
5 %	TNPC ($)	89767.71	95178.21	102573.11	109548.59
	LCOE ($/kWh)	0.053	0.068	0.092	0.121

TNPC dropping by approximately 11% compared to the values observed at 6.41 kWh/m2/day. However, when the average solar radiation decreases to 4.91 and 5.41 kWh/m2/day, TNPC and LCOE values experience increases. Specifically, TNPC rises by approximately 12% and 2.1%, while LCOE increases by 21.86% and 8%, respectively, compared to the base case values. These findings underscore the sensitivity of TNPC and LCOE to variations in solar irradiation, emphasizing the importance of accurately assessing and accounting for such fluctuations in RESs when designing and optimizing energy systems, particularly those integrated with EV charging stations.

In the second scenario, depicted in Fig. 14(b), the graph illustrates the TNPC and LCOE as functions of varied wind speed. Similar to the first condition involving average solar irradiation, the TNPC and LCOE exhibit linear reductions as the average wind speed increases from 3.75 to 5.75 m/s. Specifically, there is a reduction of approximately 34.7% in TNPC and 36.56% in LCOE over this range of wind speeds. When the average wind speed is 5.25 meters per second, the TNPC and LCOE decrease by approximately 17.8 percent and 17.1 percent, in comparison to the values in the base case scenario (TNPC=$102,042 and LCOE=$0.0796/kWh). These reductions in TNPC and LCOE across varying wind speeds can be attributed to decreased fuel consumption and reduced costs associated with the electric grid network. The results emphasize the substantial influence of wind speed on the expenses of energy systems (TNPC and LCOE), thereby underscoring the criticality of incorporating and optimizing wind resources during the planning, construction, and operation phases.

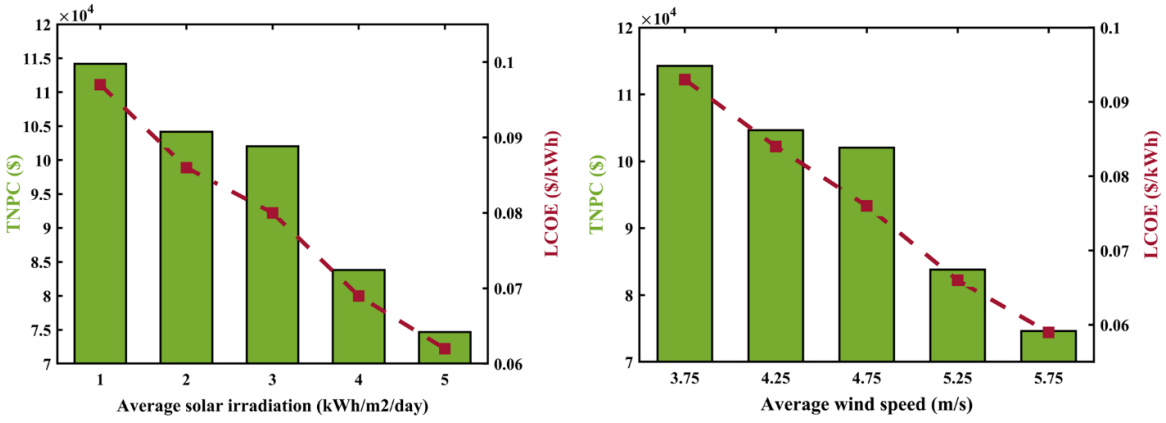

FIGURE 14. Effects of varying average (a) solar irradiation and (b) wind speed on TNPC and LCOE Monthly energy purchase and sale with the electric power network

F. IMPACT OF DISCOUNT AND INFLATION RATES

In this section, the impacts of varying discount rates from 9.09% to 13.09% and inflation rates from 6.5% to 10.5% on TNPC and LCOE are demonstrated in Fig. 15. It's crucial to assess the impact of varying these variables on the system cost, especially considering the uncertainty in the country's economy. The sensitivity analysis results depicted in Fig. 15(a) indicate that increasing the discount rate from 9.09% to 13.09% results in a decrease in TNPC and an increase in LCOE values. Conversely, the TNPC increases while the LCOE reduces as the inflation rate level rises, as depicted in Fig. 15(b). Specifically, the LCOE rises from $0.054/kWh for a 9.09% discount rate to $0.092/kWh as the discount rate increases to 13.09%. In contrast, the TNPC falls to $74,615.68 from $116,754.2 as the discount rate increases from 9.09% to 13.09%. This indicates a 70.3% increase in LCOE and a

36.1% decrease in TNPC due to the increment in the discount rate from 9.09% to 13.09%. Conversely, the TNPC increases from $74,654.45 at a 6.5% inflation rate to $115,754.2 when the inflation rate rises to 10.5%, while the LCOE drops from $0.095/kWh to $0.061/kWh for the same variation scenario. Notably, a rise in the inflation rate by approximately 12% from the baseline value (8.5%) is found to increase the TNPC by about 2.2% and reduce the LCOE by around 15.2%. These results underscore the sensitivity of TNPC and LCOE to variations in discount and inflation rates, highlighting the importance of considering economic factors in the planning and analysis of energy systems.

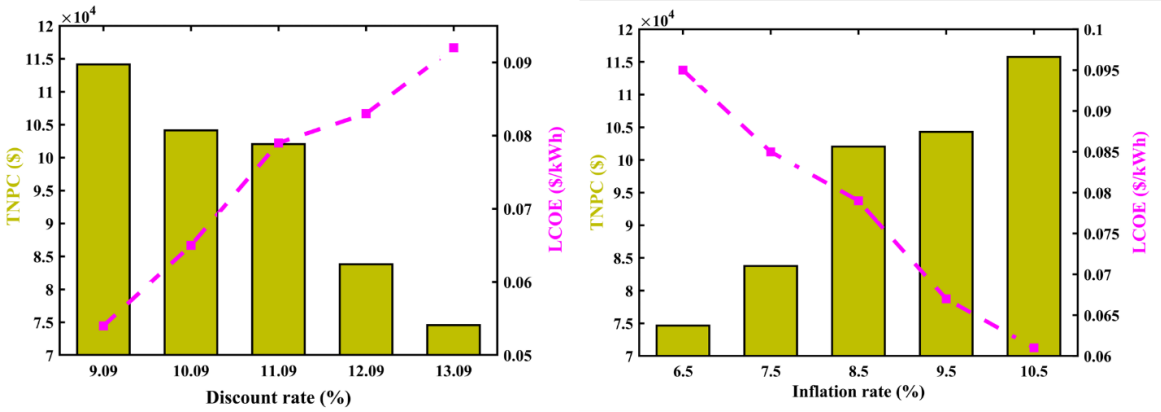

FIGURE 15. Impacts of varying (a) Discount rate and (b) Inflation rate on TNPC and LCOE

G. EFFECTS OF GRID PURCHASE PRICE AND DEMAND CHARGES

In this section, we delve into the impact of the electricity purchase price from national grid facilities and demand charges on both TNPC and LCOE. It has been demonstrated that TNPC and LCOE rise with increasing electric network purchase price and demand charges. As depicted in Fig. 16, an escalation in the cost of energy imported from the electric power network to meet the load requirement leads to an increase in both the LCOE and TNPC. For example, as the grid purchase price rises from $0.04 to $0.2 per kWh, the LCOE elevates from $0.054/kWh to $0.098/kWh, while the TNPC increases from $76,575.68 to $117,154.2. Similarly, an increase in the purchase price of about 33.3% from the base-case value ($0.12/kWh) causes the LCOE and TNPC to rise by approximately 10% and 5%, respectively. Conversely, reducing the baseline purchase price by 66.67% will reduce the optimal TNPC and LCOE by 25% and 31.6%, respectively. Additionally, the LCOE rises from $0.052/kWh when the demand charge is $0.7 per kW to $0.094/kWh as the demand charge increases to $2.7 per kW, while the TNPC increases from $74,575.68 to $114,154.2 for the same varying condition. The TNPC increases by 11.87%, and the LCOE rises by approximately 19% when the base-case demand charge increases by about 58.8%. These results emphasize the sensitivity of TNPC and LCOE to variations in the price of electricity purchase from the grid and demand charges, highlighting the importance of considering these factors in the economic analysis of energy systems.

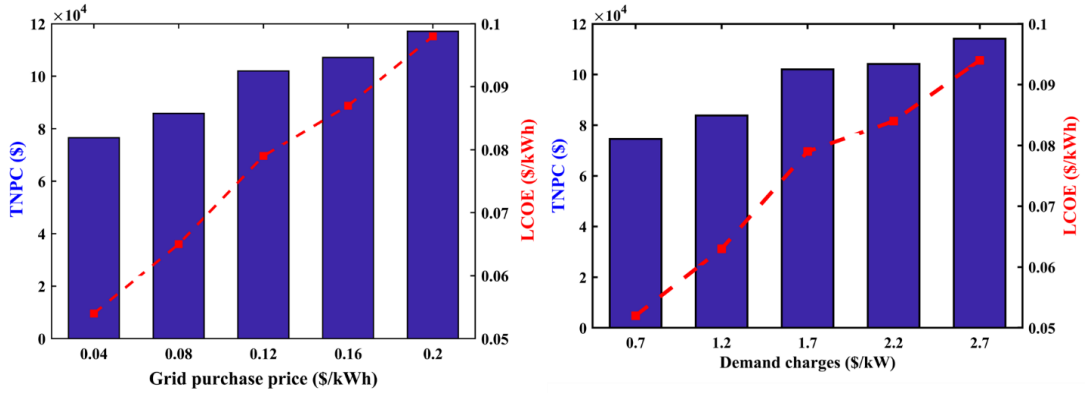

FIGURE 16. Effects of varying (a) grid purchase price and (b) demand charges on TNPC and LCOE.

V. CONCLUSION

Integrating renewable energy systems with the electrical vehicle charging station (EVCS) in Riyadh, Saudi Arabia, is a technologically and economically viable endeavor, as thoroughly examined in this study. Riyadh was selected due to its substantial supply of renewable energy sources, its crucial

contribution to the advancement of e-mobility, and its capacity to swiftly implement policies pertaining to electric vehicles. The objective of this research was to minimize the TNPC and LCOE while ensuring LPSP dependability through optimal component measurement using the GPCA. In contrast to alternative algorithms including the WOA, FPA, and AHA, this approach was utilized. The optimal system model, comprising solar PV, a WT, and the electric power network (SPV/WT/Grid), significantly reduced TNPC to $102,042 and LCOE to $0.0796/kWh. This configuration, labeled SC#4, achieved a remarkable 67.9% renewable penetration and effectively balanced grid energy purchases and sales. Conversely, the environmentally superior SC#1 (SPV/WT/BES) configuration with a 100% renewable fraction was economically unfeasible due to its high TNPC and LCOE. Configurations integrated with the grid, particularly SC#4, demonstrated more favorable energy transaction balances compared to others like SC#5 (WT/DG/Grid). The study also explored the impact of varying LPSP levels and diverse climatic, financial, and technical parameters on system costs, providing insights into the challenges, opportunities, and socio-economic aspects of EV implementation in KSA. The GPCA emerged as the most effective optimization technique, offering the lowest TNPC and LCOE values. Enhancements in wind speed or solar irradiance, along with reductions in demand charges or grid purchase prices, yielded significant financial advantages. Overall, the study provides valuable insights for policymakers and stakeholders involved in sustainable EV infrastructure development in Riyadh and beyond.

Despite the thoroughness of our study, we acknowledge certain limitations stemming from the scarcity of available data on EVs and charging infrastructure in KSA, as well as the early stage of EV adoption in the country. These limitations have led to certain assumptions in our analysis, which may affect the accuracy of our findings. To address these limitations, future research efforts should focus on collecting more comprehensive and accurate data on EV usage patterns, charging behavior, infrastructure requirements, and renewable energy potential in KSA. This would enable more precise modeling and optimization of EV charging systems, leading to more reliable results and actionable insights for policymakers and stakeholders. Despite these challenges, our study aims to contribute valuable insights to the development of policies that support the widespread adoption of EVs in Riyadh and across KSA. By aligning with the nation's Vision 2030 objectives of environmental sustainability and technological advancement, our findings can inform the strategic planning and implementation of EV charging infrastructure in the country. Furthermore, by identifying current challenges and proposing potential strategies, our study offers a framework for the optimal design and deployment of EV charging infrastructure. This framework can serve as a blueprint for policymakers and stakeholders in KSA and other developing countries seeking to expand their EV charging networks and accelerate the transition to sustainable transportation systems.

ACKNOWLEDGMENT

The authors extend their appreciation to the Deputyship for Research & Innovation, Ministry of Education in Saudi Arabia for funding this research work through the project number 223202.

FAYEZ ALANAZI is an assistant professor in the department of Civil Engineering at Jouf University. Dr Alanazi specializes in Traffic and Transportation Engineering, with focus on enhancing urban mobility and improving transportation systems. Dr Alanazi obtained his PhD in Civil Engineering from the University of Akron in Ohio, USA, in 2021. His Doctoral research focused on developing innovative solutions for traffic management and transportation planning. Prior to his PhD, he completed his Master of Science in Civil Engineering at the University of Dayton, also in Ohio, in 2016. With strong educational background in Civil Engineering, Dr. Alanazi earned his Bachelor od Science degree in Civil Engineering from Jouf University in Saudi Arabia in 2013. Dr Alanazi is dedicated to imparting knowledge and particle skills to his students, fostering their understanding of transportation infrastructure, traffic control, and urban planning. Dr. Alanazi research interest include traffic flow modeling, intelligent transportation systems, sustainable transportation planning, and traffic safety. He published his research findings in reputable journals and he presented his work at national and international conferences.

Mohd Bilal received the B.Tech. degree in electrical engineering and the M.Tech. degree in instrumentation and control engineering from Aligarh Muslim University, Aligarh, India, in 2014 and 2016, respectively. He completed his Ph.D. degree in power system from Delhi Technological University, New Delhi, India in 2022. Currently, he is working as a postdoctoral research fellow in Department of Electrical Engineering Technology, University of Johannesburg, South Africa. He has published/presented several technical papers and conference proceedings in international journal of repute. His research interests include electric vehicles, renewable energy integration, artificial intelligence and optimization techniques.

AMMAR ARMGHAN (Senior Member, IEEE) received the bachelor's degree from COMSATS University, in 2006, the M.S. degree in electronics and communication engineering from the University of Nottingham, in 2010, and the Ph.D. degree from the Wuhan National Laboratory of Optoelectronic, Huazhong University of Science and Technology, Wuhan, China. He is currently an Associate Professor of electrical engineering with Jouf University. He has published more than 100 high-impact factor articles in the last three years. His research interests include machine learning, renewable energy, complementary metamaterial-based microwave and terahertz devices, biosensors, optics, and photonics. He is a Reviewer of several reputed journals.

MD REYAZ HUSSAN received his B.Tech. degree in 2014 and M.Tech degree in 2016 in Electrical Engineering and Instrumentation and Control, respectively from the Aligarh Muslim University, Aligarh, India. He is currently a Research Scholar in the Department of Electrical Engineering, Aligarh Muslim University. He is also currently a visiting Research Assistant with the department of Electrical Engineering, Qatar University, Doha, Qatar. His research interests include multilevel inverters and their control, photovoltaic systems, and multilevel inverter for solar PV applications.

ABSTRACT

This work presents a compact dual-band two-port multiple input multiple output (MIMO) antenna with high performance that is specifically used for 5G applications. The proposed design comprises closely spaced, mirror-symmetrical X-shaped structures positioned at an edge spacing of 0.02 λ_0 between antenna elements. Subsequently, a metasurface is located at a distance of 0.27 λ_0 above the radiator to improve the performance of the MIMO antenna. The proposed antenna resonates at 3.27 GHz within a frequency range of (3.03–3.44) GHz in the primary band, achieving a peak realized gain of 7.57 dBi. In the secondary band, the resonance occurs at 4.78 GHz with a range of (4.01–5.87) GHz below −10 dB reflection coefficient and produces a peak realized gain of 5.60 dBi. After positioning the metasurface on top of the reference antenna, the peak realized gain improves by 116.28 % in the primary band and 69.69 % in the secondary band respectively. Whereas the isolation is increased to −30.01 dB from –22.26 dB in the primary band, similarly for the secondary band the isolation is amended to −21.00 dB from −18.20 dB. Moreover, circular polarization is realized at working frequencies after placing the metasurface on the reference antenna. Simulation and measurement results prove that the S-parameters exceed more than −20 dB in both frequency bands. Additionally, MIMO performance metrics, including envelope correlation coefficient (ECC), channel capacity loss (CCL), total active reflection coefficient (TARC), mean effective gain (MEG), and diversity gain (DG) are simulated and measured. The designed antenna proves suitable for the new radio (NR) 5G of n48 (3.55–3.70 GHz) in the primary band and the n79 (4.4–5.0 GHz) in the secondary band respectively.

1. Introduction

In modern wireless communication systems, multiple input multiple output (MIMO) technology is widely adopted to improve service quality, minimize latency, and satisfy for increasing demand for higher data rates [1,2]. The primary goal when designing a MIMO antenna is to minimize the correlation coefficient among received signals by various transmitting sections. It is crucial to achieve substantial isolation when the antenna elements are close to each other,this leads to prevent degradation in antenna performance, particularly concerning radiation patterns and interference [3]. To address these challenges, the literature discusses various methods for improving MIMO antenna isolation such as self-decoupling techniques [4,5], closely paired techniques [6,7], metamaterial based electromagnetic bandgap (EBG) structures [8], MTM absorber loading [9], metasurface reflector [10], and superstrate [11,12]. In [5,10,12,13] MIMO antennas face issues such as increased size and low gain with lesser antenna isolation. The performance metrics consider how the nearby positioning of antennas impacts the overall system performance. Also, when designing MIMO antennas, it's crucial to assess the envelope correlation coefficient (ECC) for both correlated and uncorrelated channel estimations for close proximity of antenna elements can lead to increased mutual coupling, which can degrade the performance by causing interference between the elements. The presence of nearby elements can affect the impedance matching of each antenna, potentially making it more difficult to achieve the desired impedance and leading to increased reflection and reduced power transfer. In this design, we have implemented a metasurface on top of the radiator to address these effects. Although the use of metasurface

cannot entirely eliminate the constraints, it does provide a measure of protection in gain and isolation improvement in our design, mitigating these challenges to some extent. [14,15]. The reference [16] introduces a four-port MIMO antenna that exhibits good isolation. The primary purpose of the antenna is to provide coverage for the n48 band of Frequency Range-1 (FR-1) using Time Division Duplex (TDD) mode and used large dimensions. An additional decoupling structure is not required for port-to-port isolation in a simple MIMO antenna system, which leads to increased efficiency but a higher total antenna size [17].A connected ground MIMO antenna for 5G sub-6 GHz with four ports is built using a dielectric resonator. Dual bands were obtained by using the aperture feeding approach to excite the antenna [18].As a result, a simple X-shaped patch with two port arrangements using a metasurface proves that the designed antenna offers good isolation and enhanced gain even when the elements are close to each other Furthermore, the antenna design optimization ensures stable operation at the desired frequency. The proposed antenna projects superior isolation for closely spaced elements and the creation of a metasurface-based two-port antenna by determining the best design considerations using less space, and easy for fabrication.

The following are the primary contributions of this work:

In this work, a MIMO antenna is designed to operate at dual-band 5G frequencies and the two elements in this design are arranged in a mirror-symmetrical closely spaced configuration, featuring an edge-to-edge spacing of 1.7 mm. Moreover, the metasurface is created using an array of 2x3 unit cells, each comprising concentric circular rings. This metasurface is positioned atop with an air gap of 0.27 λ_0 produces that

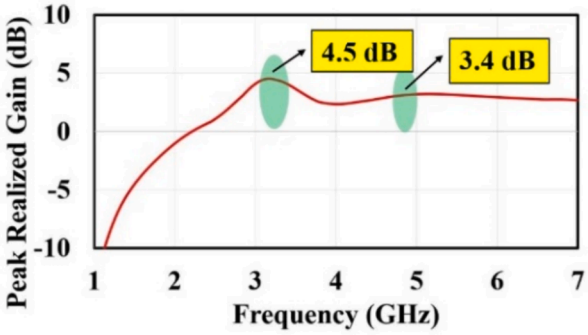

Fig. 3. Response of peak realized gain for single-element.

the polarization is converted, linear to circular polarization (CP) in both operating bands. After stacking the metasurface the peak realized gain is enhanced in the working bands. Furthermore, after optimizing the closely spaced design structure, the isolation improves to −30.01 dB from –22.26 dB in the primary band and to −21.00 dB from −18.20 dB in the secondary band. The configuration is further analyzed to examine its diversity performance in terms of MIMO configuration.

2. MIMO antenna geometry and design

2.1. Design of Single-Element antenna

Fig. 1 shows the arrangement of a single-port X-shaped structure resonating in dual-band and characterized by two distinct operating frequencies. Fig. 2 shows the response of the reflection coefficient resonating at 3.43 GHz ranging from (3.23–3.85 GHz) as the primary band and the secondary band resonates at 4.89 GHz ranging from (4.19–5.46 GHz). The peak realized gain for both resonances are 4.5 dBi and 3.4 dBi, which are shown in Fig. 3. Fig. 4. shows the responses of S-Parameters by varying the parameters C_{SG} and C_{10} and studying the effect of the proposed antenna for single-port configuration. The structure is designed and simulated using Ansys HFSS. The substrate used for simulation is Rogers 5880 with a dielectric constant of 2.2 and a loss tangent of 0.0009. The length and dimensions of the substrate are 23 x 23 mm^2 with a thickness of 1.6 mm. Table 1 shows the dimensions of a single-element antenna.

2.2. Evolution process and analysis

Fig. 5 presents the developmental stages of the proposed antenna and it is categorized into four distinct phases. The main objective is to design an antenna suitable for 5G applications. In stage 1 (ant-1), a basic rectangular patch is positioned diagonally from the feed, resonating at 5.99 GHz. Then, in ant-2 a slot is introduced within the inner part of the diagonally placed patch, resulting in a response at 5.34 GHz. To meet the specific application requirements we introduce slots to optimize the performance of a designed antenna.Ant-3 incorporates the addition of a stub from the opposite direction to the radiator, yielding a response at 5.14 GHz. In the final stage, an extra stub is introduced, transforming the structure into an X-shaped resonator operating in the dual-band for 5G applications.

2.3. Analysis of self-isolation with two-port MIMO

The design process of a two-port configuration includes the placement of a second element, which mirrors the same symmetrical structure of the first element and is positioned adjacent to it with a center-to-center distance (C_{DC}) of 13 mm between the antenna elements shown in Fig. 6. The gap between these two elements plays a pivotal role in assessing mutual coupling. In general, less mutual coupling occurs

between antenna elements when there is more space between them and it requires larger physical dimensions, but in this design, the elements are closely coupled with an edge spacing of 1.7 mm between antenna elements. This arrangement optimizes the design. Additionally, a ground strip (C_{DS}) is incorporated to regenerate the resonance observed in the basic antenna without using any decoupling circuit, and in the same way, the isolation is preserved without affecting the configuration. The analysis contrasts a two-port structure with and without the inclusion of a ground strip. As shown in Fig. 8, when the antenna is not using any ground strip, then the response of the reflection coefficient is shifted to the non-working band, and the peak realized gain of an antenna is reduced. The response presented in Fig. 7 reflects a two-port MIMO design with a common ground that effectively ensures minimum isolation of –22.26 dB in the primary band and −18.2 dB in the secondary band with a peak realized gain of 3.5 dBi and 3.3 dBi shown in Fig. 8(b). The separation between two antenna elements is $0.02\lambda_0$ at 3.2 GHz. Table 2 shows the parametric dimensions of the two-port antenna.

The S-Parameters and peak realized gain is studied by experimenting the edge-to-edge gap, (C_{DE}) with values of 5 mm, 3 mm,2.5 mm, 2

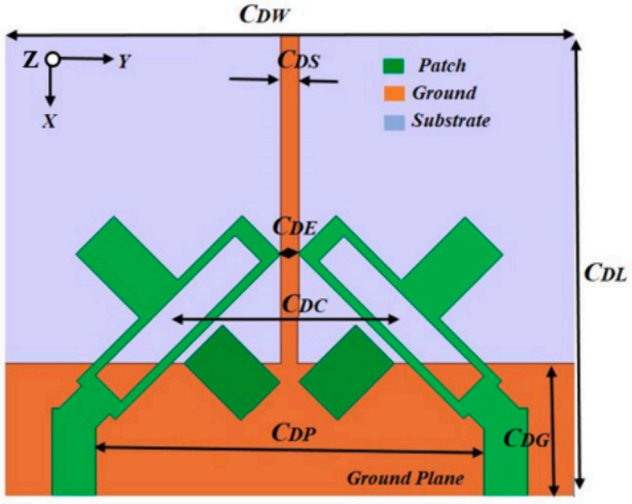

Fig. 6. Two-element MIMO Antenna.

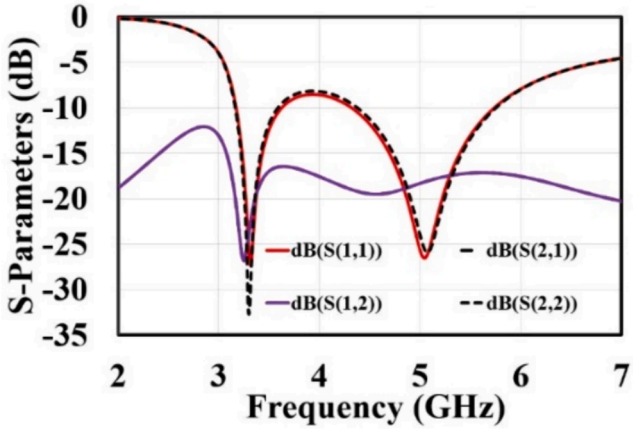

Fig. 7. Response of S-Parameter in two-port MIMO.

mm,1.7 mm and 1 mm and the results are presented in Figs. 9 and 10. Similarly, the parameter of C_{DG} is adjusted and optimized based on the response shown in Fig. 9(a).When C_{DE} increases, the substrate size concurrently enlarges. It can be seen that in the primary band, the reflection coefficient and transmission coefficient experience an increase while in the secondary band, it undergoes a decrease, as illustrated in Fig. 10. Based on this parametric analysis, we optimized the

performance of the antenna structure for our specific application. Finally, a center-to-center distance (C_{DE}) of 1.7 mm between the antenna elements was selected for superior results compared to other parameters.

3. Developing and analyzing a decoupling circuit for optimal performance

3.1. Design of metasurface

In order to enhance the performance of the MIMO antenna, a metasurface-superstrate layer is incorporated into the design. This addition aims to mitigate mutual coupling in both the lower and upper bands of the closely coupled antenna. The metasurface array eventually helped to improve the antenna gain while achieving polarization conversion at operating frequencies. The design procedure of the single-

element unit cell is shown in Fig. 11 (a). Similarly, an array of 2x3 unit cells is positioned on the identical substrate (layer-2) utilized in the reference antenna shown in Fig. 11 (b). The unit cell simulation analysis is carried out by employing periodic boundaries and floquet ports are shown in Fig 12 (a). Fig 12(b) illustrates the phase variance between the incident and reflected waves of the proposed antenna. The graph demonstrates that the antenna's reflection phase remains consistent within the operational bandwidth, ranging between + or – 90 degrees. Table 3 shows the dimensions of the proposed metasurface structure.

3.2. MIMO system integrated with metasurface

The primary motivation for our work is to enhance isolation between closely spaced antenna elements in a MIMO system. We have achieved this by positioning the antenna elements in mirror-symmetrical structures opposite each other. Based on our extensive literature review, we selected a metasurface as a decoupling circuit. This choice was driven by its effectiveness in reducing mutual coupling and enhancing the peak realized gain of closely coupled elements. References [3] and [15] review the various mutual coupling reduction techniques for MIMO antennas, which provided a foundational understanding of our design. We compared our proposed design with references [4 to 13], which focus on different approaches to improve isolation and performance in MIMO systems. The comparative analysis with existing works highlights the effectiveness of our approach.

3.2.1. Design stages and their Descriptions

The following Table 4 summarizes the key stages of our antenna design and the improvements achieved at each stage.

The proposed metasurface array reduces the coupling effect of the closely coupled antenna elements by generating reflected waves. The superstrate is placed on top of the MIMO antenna with an air gap of 25 mm ($0.26\lambda_0$) represented in the two-layer of Fig. 13. The metasurface helps in improving the peak realized gain from 3.50 dB to 7.57 dB in the

Stage	Description	Improvements
Stage 1	Initial Antenna Design	The basic single-port antenna design is extended to two-port antenna elements is positioned in mirror symmetry. No decoupling technique applied.
Stage 2	Implementation of Metasurface	A metasurface has been introduced as a decoupling circuit and is positioned 25 mm above the radiator.
Stage 3	Optimization of Metasurface Parameters	Fine-tuning the metasurface dimensions and substrate height to achieve optimal isolation and gain.
Stage 4	Comparative Analysis with Previous designs (References. [4] to [13])	Evaluation of the proposed design against previous works, demonstrating superior isolation and peak realized gain.

primary band and in the secondary band the gain increases from 3.30 dB to 5.60 dB are shown in Fig. 14(a). The isolation experiences a notable enhancement in the primary band, escalating from –22.26 to −30.01 dB at 3.2 GHz. Conversely, in the secondary band, the isolation rises from −18.20 dB to −21.00 dB at 4.78 GHz as shown in Fig. 14(b). After stacking the metasurface with different heights (H_2), the peak realized gain and isolation are observed through simulation as shown in Fig. 15. Finally layer 2 is fixed with an air gap of 25 mm from the radiator, and also a circular polarization is realized in the operating band assuming metasurface acts as a polarization converter [19,20] Table 4.

3.3. Polarization conversion metasurface

The main purpose of the metasurface's unit cell elements is to alter the properties of electromagnetic waves. In this work, the metasurface improves the gain and isolation of the planned antenna and permits polarization conversion. The reference antenna proposes linear polarization when it is not equipped with a metasurface. After integrating the metasurface on the reference antenna with a free space height of 25 mm, circular polarization is acquired at 3.2 GHz and 4.2 GHz, as seen in Fig. 16(a), By varying the height (H2) of the metasurface, an analysis is carried out to assure that the suggested antenna functions in a circularly polarized mode. The circular polarization projection is used to determine the height of the metasurface (layer-2) through the iterations depicted in Fig. 16(b). Finally, the maximal realized gain and isolation are enhanced by stacking the metasurface above the radiator, as mentioned in section 3.2.

3.4. Surface current distribution

The movement of electrical current across the surface of an antenna structure is referred to as surface current distribution. Determining the antenna's polarization is largely dependent on this dispersal. An antenna will produce both electric and magnetic fields when subjected to an electromagnetic wave. Meanwhile, for phases (0^0,90^0 and 180^0) of the suggested antenna, the surface current distribution is shown at 3.2 GHz. On the antenna's surface, these fields induce current flow. The surface current flow for antennas 1 and 2 is in a clockwise direction (LHCP), as seen in Fig. 17. The geometry and electrical characteristics of the antenna control how these currents are distributed.

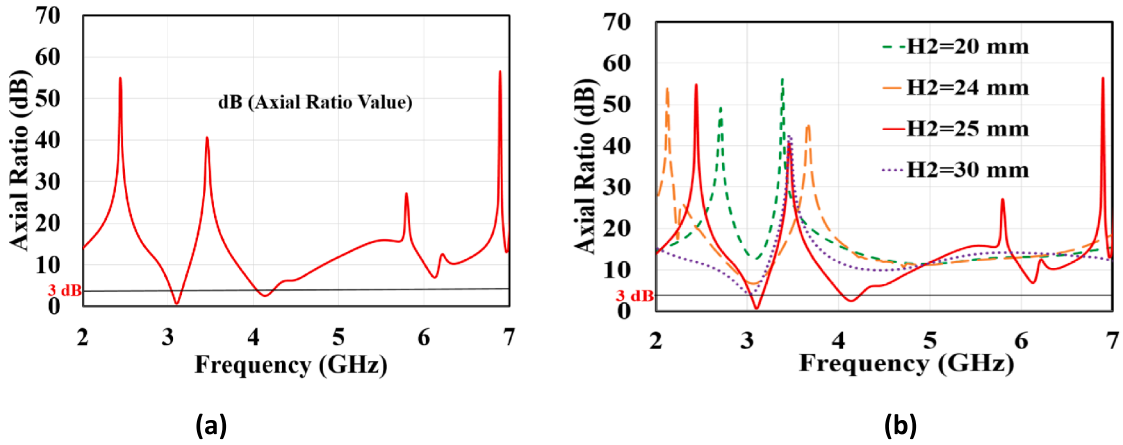

Fig. 16. Axial ratio analysis: (a) Axial ratio vs frequency. (b) Response of axial ratio with different values of H_2.

4. Results and discussion

4.1. Performance comparison table for single-element, two element and proposed structure with metasurface

For the 5G New Radio spectrum, the 3rd Generation Partnership Project (3GPP) has developed Frequency Division Duplex (FDD) frequency bands, notably in the FR1 range [1]. In this setup, our proposed design effectively fulfills the operational requirements of NR bands n48 and n79 respectively. In Table 5, we present a performance comparison between single-port and two-port design structures. Initially, the configuration was developed for a single element, later it extended to a

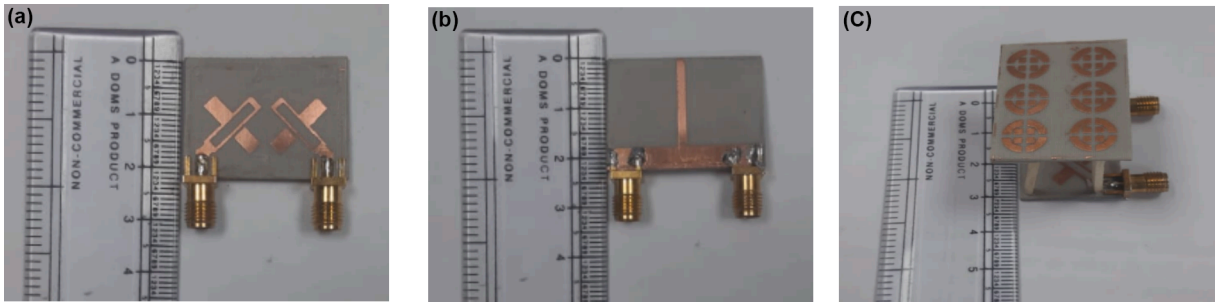

Fig. 18. Proposed MIMO Antenna after Fabrication Process (**a**) Top view (**b**) Back view (**c**) Top-view with metasurface.

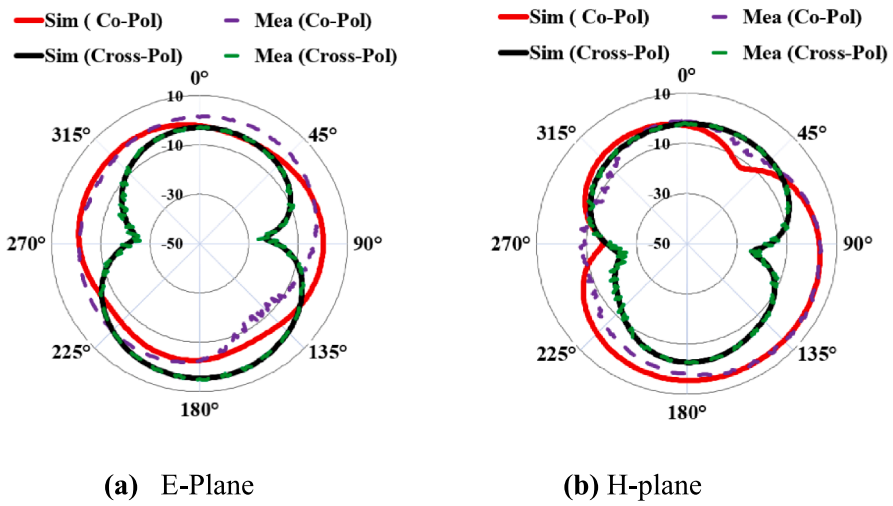

Fig. 20. Co & Cross-Polarisations at 3.27 GHz.

1x2 MIMO configuration operating in dual-band mode. The key observation from the proposed design is it includes a narrow impedance bandwidth in the primary band compared to a wider bandwidth in the secondary band. Particularly, the maximum peak realized gain increases by integrating the metasurface-superstrate into the design. The isolation between closely coupled elements appears as a critical factor. Through optimization of design parameters and the inclusion of metasurface, isolation is enhanced, ensuring the proposed design can be operated satisfactorily for the 5G spectrum.

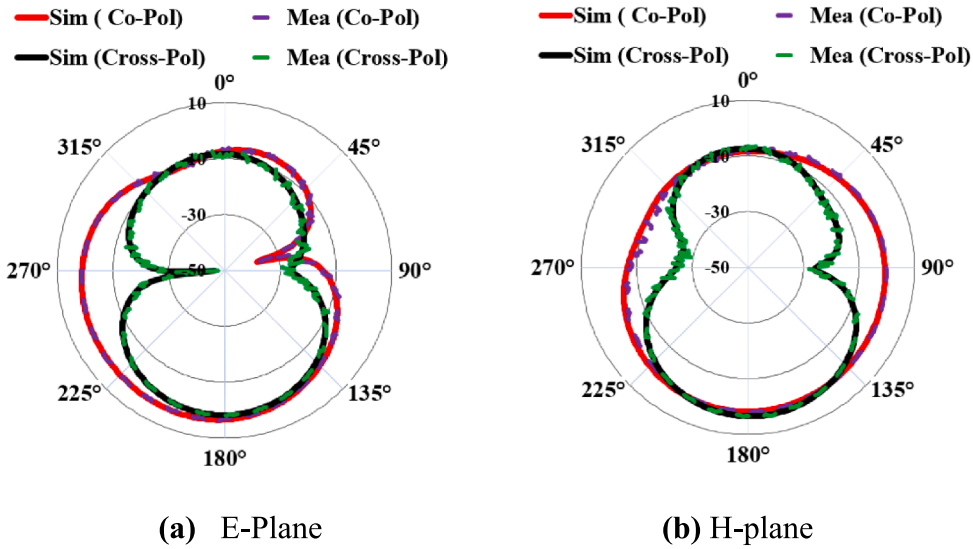

Fig. 21. Co & Cross-Polarisations at 4.78 GHz.

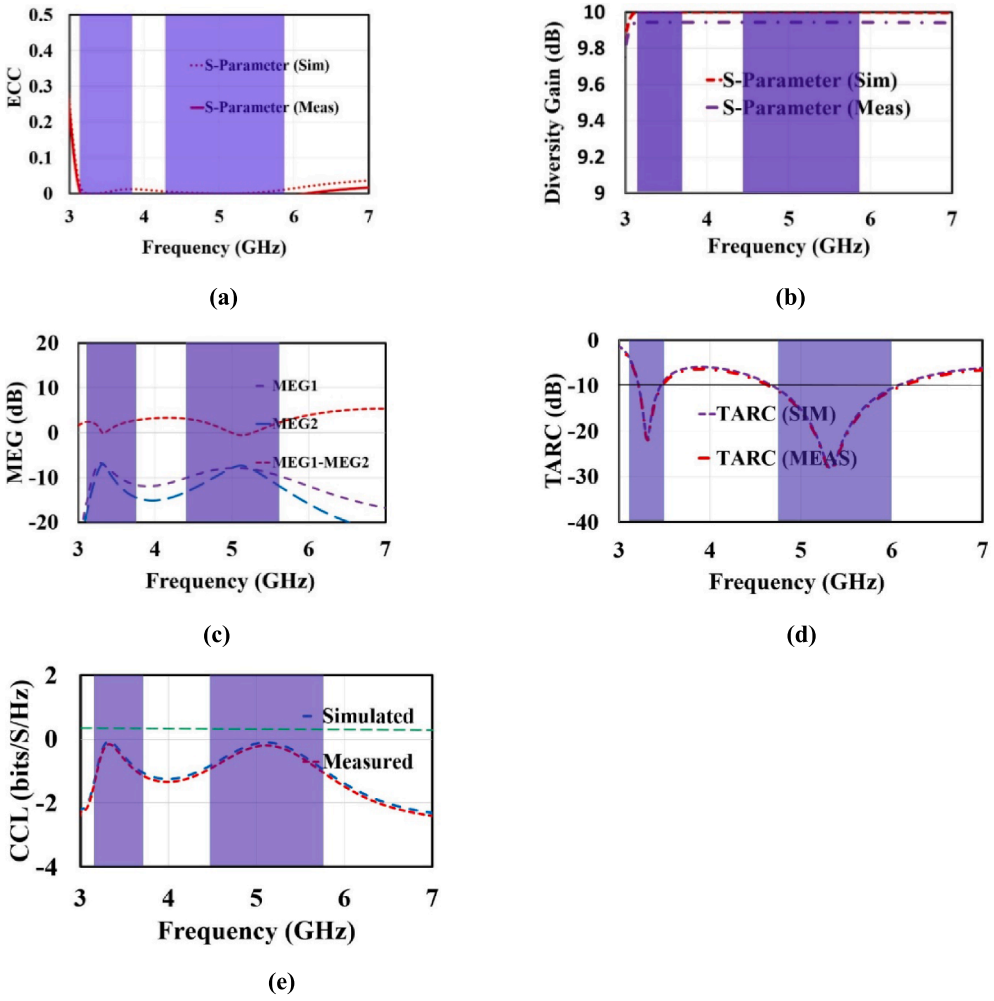

Fig. 22. Response of simulation and measurement results of MIMO Parameters: (a) ECC (b) Diversity Gain (C) TARC (d) MEG (e) CCL.

4.2. S-parameters and peak realized gain

Fig. 18. Shows the fabricated images of the proposed configuration. In Fig. 19, the responses of simulated and measured results of original antenna parameters are illustrated. The measured S_{11} exhibits a bandwidth of 600 MHz and a maximum isolation of −30.01 dB in the primary band. Where in the secondary band, the measured bandwidth is approximately 1.75 GHz, with an isolation of −21.00 dB are shown in Fig. 19(a). Moreover, the measurement of the peak realized gain of port-1 is determined by connecting port-2 to a 50 Ω matched load, revealing an approximate value of 7.57 dBi in the primary band and 5.60 dBi in the secondary band, due to the fabrication losses, an estimation of 1 dB of peak realized gain is reduced in the secondary band reflected in Fig. 19 (b).

4.3. Radiation pattern

The distribution of radiated power as a function of direction in space is represented graphically by an antenna's radiation pattern. It offers vital details regarding the energy radiation of an antenna and is necessary to comprehend the functionality and appropriateness of the antenna.

The anechoic chamber gathers the antenna's far-field data. The proposed antenna is used as a receiver (R_X), while a conventional gain horn antenna serves as the transmitter (T_X). To obtain measurements from various orientations, the antenna under test is rotated. Figs. 20 and 21 show the simulated and measured results of the radiation patterns for the proposed closely coupled metasurface-based two-port MIMO antenna for both operating frequencies, it is observed that the co-polarization of the E-plane pattern is omnidirectional and the cross-polarization is bi-directional whereas in the H-plane the cross-polarisation is observed as omni-directional and co-polarisation is in bi-directional resembling like figure of eight representation.

4.4. MIMO parameters

The measured and simulation values of the reflection coefficient and transmission coefficient isolation metrics for the designed antenna consistently adhere to and remain below the standard values for MIMO parameters [21]. The envelope correlation coefficient (ECC) of the proposed design is displayed in Fig. 22(a). The measured and simulated ECC values in the working bands are less than 0.01. Similarly, Fig. 22(b) shows the diversity gain (DG), which is calculated using the expression, $DG = 10\times\sqrt{(1 - ECC^2)}$. The calculated diversity gain (DG) values show acceptable MIMO antenna performance since they are within the typical value range. Fig. 22(c) displays the mean effective gain (MEG) responses. The following expression is used to calculate MEG. $MEG_i = 0.5(1\text{-}\sum_{j=1}^{k}(P_{ij}))$ where k is no. of antennas which satisfies the condition less than 3 dB [22]. The total active reflection coefficient (TARC) response are shown in Fig. 22(d) and it is calculated using the expression $\gamma_a^t = \sqrt{\frac{(S_{11}+S_{12}e^{j\theta})^2+(S_{21}+S_{22}e^{j\theta})^2}{2}}$, and the response is maintained below 0 dB. The calculation of channel capacity loss (CCL) is determined by utilizing the

provided expression. $CCL = -log_2 Det(K^R)$ where $K^R = \begin{bmatrix} \varnothing_{11} & \varnothing_{12} \\ \varnothing_{21} & \varnothing_{22} \end{bmatrix}$ the elements of the correlation matrix are calculated by $\varnothing_{ii} = (1 - \left|\sum_{n=1}^{2}(S^*_{ij}.S_{nj})\right|)$ and $\varnothing_{ij} = -\left|\sum_{n=1}^{2}(S^*_{ij}.S_{nj})\right|$ where i and j are 1 or 2 according to the port number [20]. It is evident that Fig. 22(e) indicates that the channel capacity loss (CCL) values consistently remain within the acceptable limit, as the allowed threshold for CCL is set at < 0.4 bits/s/Hz Table 6.

5. Conclusion

This work introduces a closely coupled two-port MIMO using polarization conversion metasurface is designed for NR band of n48 and n79 operating in 5G applications. Initially, a single antenna element is transformed into a two-port MIMO. To enhance the performance of the proposed MIMO system, a metasurface with identical dielectric properties to the radiator is integrated and placed on top of the radiator. With these the isolation and peak realized gain was improved. The proposed metasurface based two-port MIMO antenna produces a circular polarization on operating bands. Operating in circular polarization mode the surface current distribution is projected and analyzed for two elements in the design. The diversity performance metrics of the proposed antenna are ECC, MEG, CCL,TARC and DG as evaluated and compared with measured results for proposed configuration. Thus, it can be concluded that the proposed MIMO antenna is well-suited for next-generation 5G technology.

***Abstract*—This paper reports a novel enhancement mode GaN HEMT designed to mitigate gate leakage current. The device combines a p-GaN layer with HfO_2 layer beneath the metal. The p-GaN layer acts as a barrier, diminishing tunneling, while HfO_2 exhibits fewer trap sites compared to SiN, resulting into reduced gate leakage current. Moreover, the proposed device achieves improved gate leakage current, maximum drain current and threshold voltage compared to the devices in the already reported literature.**

***Index Terms*—p-GaN, HfO_2 and Gate leakage**

Introduction

GaN HEMTs have revolutionized semiconductor devices, finding applications in power electronics [1] [2], wireless communications, and radar systems. However, gate leakage current in GaN HEMTs is a major concern for power electronics applications, causing increased power dissipation and reduced switching efficiency, limiting the performance and reliability of these devices. Overcoming these challenges is essential for advancing the effectiveness of GaN HEMTs in power electronics.

In the past decade, various studies were reported to improve the gate leakage current of the device. In some published reports [3]–[5], the gate leakage current was improved by: (i) including Al_2O_3/AlN composite gate insulator in p-GaN MISHEMT, (ii) employing Si-rich and stoichiometric SiN_x first passivation in buffer free GaN MISHEMT, and (iii) using vertically-ordered h-BN in AlGaN/GaN MISHEMT on Si substrate. Nevertheless, the above-mentioned techniques are not optimal for GaN MISHEMT. The first method exhibited higher capacitance than the conventional p-GaN MISHEMT leading to lower switching speed of the device. Further, the barrier leakage current is increased by using the second method. Moreover, in the third technique, a series capacitance is introduced due to which the threshold voltage is shifted to more negative. Hence, further improvements are required to ensure that performance remains uncompromised.

Due to these shortcomings, we have introduced and thoroughly examined a novel enhancement mode GaN HEMT featuring a MIS [6] and p-GaN structure, referred to as MG-HEMT. The design employs p-GaN layer (forming a schottky contact with the gate of the device) in parallel with HfO_2 layer below the metal gate in the device. By integrating MIS and p-GaN structures side by side within the gate area, we harness the combined advantages such as enhancing gate control, reducing gate leakage, and increasing current capacity. By applying passivation only at the drain side, the capacitance is selectively reduced, minimizing the impact on the overall capacitance and potentially enhancing the device speed and performance. Further, the dielectric layer exhibits a higher bandgap than p-GaN, creating a wider potential barrier for tunneling electrons. This significantly reduces tunneling current through the gate dielectric itself.

Device structure, Calibration and Simulation setup

Figures 1(a) and 1(b) illustrate the schematic representations of the conventional p-GaN HEMT and the proposed MG-HEMT, respectively. In the MG-HEMT configuration, a p-GaN layer is integrated in parallel with an HfO_2 layer, positioned beneath the metal gate within the device structure. Table I shows the parameters of the proposed MG-HEMT structure. For the AlGaN barrier layer, the aluminum content is set at 0.2, and the p-GaN layer has a doping density of $3\times10^{17}/cm^3$ in both the devices.

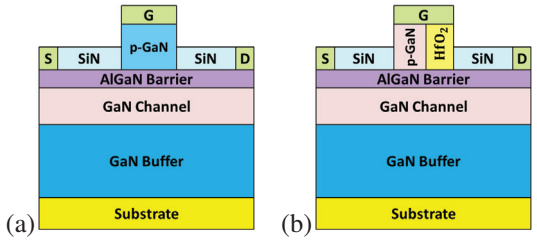

Fig. 1: The schematic diagram of (a) the conventional device and (b) the proposed MG-HEMT.

Calibration of a p-GaN HEMT included parameters like a 2 μm $Al_{0.25}Ga_{0.75}N$ buffer layer, an 85 nm GaN channel layer, a 15 nm $Al_{0.26}Ga_{0.74}N$ barrier layer and a 110 nm thick p-GaN layer [7]. Figure 2 compares experimental and simulated transfer characteristics, showing excellent agreement, validating the precision of our simulation models. Simulation models included the SRH model, GaN polarization model, high-field and low-field mobility models, Fermi–Dirac model,

TABLE I: The structural parameters of the proposed MG-HEMT

S.No.	Parameter	Value
1	p-GaN layer in parallel with the HfO_2 layer thickness ($T_{Parallel}$)	110 nm
2	AlGaN barrier layer thickness ($T_{AlGaNbarrier}$)	15 nm
3	GaN channel layer thickness ($T_{GaNchannel}$)	85 nm
4	GaN buffer layer thickness ($T_{GaNbuffer}$)	2 μm
5	SiN passivation layer thickness ($T_{SiNpassivation}$)	300 nm

and Toyabe model. Additionally, drift-diffusion transport based on Boltzmann theory accounted for carrier transport in the channel, ensures comprehensive simulation coverage [7].

Results and Discussion

This section investigates the DC and AC characteristics of the device. Figure 3(a) compares the electric field characteristics in the MG-HEMT for varying dielectric constants in the insulator layer. To enhance performance, we have incorporated a high-k dielectric material, known for its superior charge storage capacity compared to low-k materials. This choice reduces the electric field within the device, as high-k materials inherently offer higher capacitance per unit area. Figure 3(b) shows the corresponding leakage current, where the lower electric field decreases the probability of electron tunneling within the device. HfO_2, with its high dielectric constant, exhibits the lowest electric field and gate leakage current, making it the optimized dielectric material for our device.

To optimize device performance, minimizing gate leakage current was crucial for enhancing reliability. We conducted simulations by varying the length of the HfO_2 dielectric material (L_{dt}) to investigate its impact on the device's electrical characteristics. Systematically adjusting L_{dt} from 2.5 μm to 2.8 μm in 0.1 μm increments while keeping other parameters constant revealed that the minimum gate leakage current occurred at 2.7 μm (L_{dt}). This length represents the optimal value for reducing gate leakage and improving device reliability, as depicted in Figure 4(a). Temperature-dependent gate current versus gate voltage (I_g-V_g) curves were analyzed, ranging from 200 K to 400 K, showing that gate leakage current increased with temperature due to rising carrier

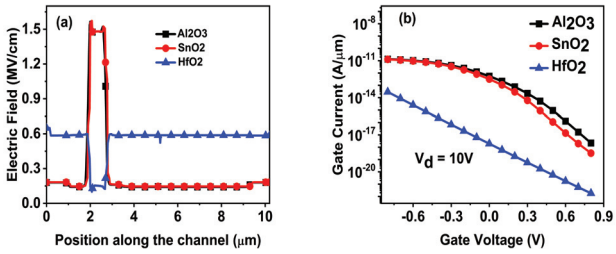

Fig. 3: The comparison of the proposed device with respect to dielectric constant of insulating layer (a) the electric field and (b) the gate leakage current.

concentration and thermal energy, promoting carrier tunneling within the device (shown in Figure 4(b)).

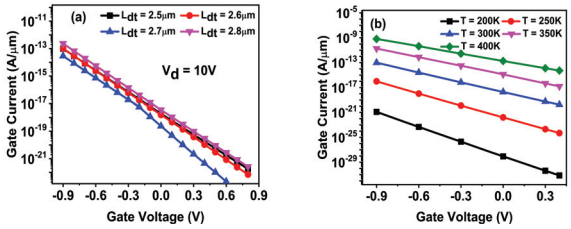

Fig. 4: (a) The gate leakage current for different values of length of the HfO_2 dielectric layer (L_{dt}), and (b) The temperature-dependent I_g-V_g curves of the proposed device from 200K to 400K.

Moreover, we conducted a comparative analysis of the DC and AC characteristics between the conventional p-GaN HEMT and our optimized proposed device. Figure 5(a) displays electric field distributions, showing successful suppression of the electric field in the proposed device's channel due to the HfO_2 dielectric layer [8]. Consequently, our device exhibits lower gate leakage current in Figure 5(b) compared to the conventional device.

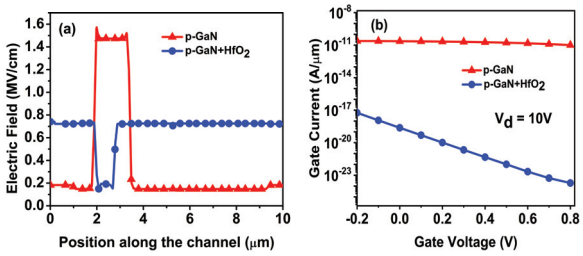

Fig. 5: (a) The electric field and (b) the gate leakage current comparison of the proposed and conventional device.

Figure 6(a) shows the C-V characteristics of our proposed MG-HEMT, highlighting its superior performance over the conventional p-GaN HEMT with reduced parasitic capacitance and lower power consumption. In Figure 6(b), the transconductance comparison reveals that our proposed device outperforms

TABLE II: Comparison of performance parameters of the proposed device with the reported literature

Reference	Gate leakage current (A/μm)	Maximum drain current (A/μm)	Threshold Voltage (V)
[3]	10^{-15}	0.35	2.5
[4]	10^{-18}	0.8	-15
[5]	10^{-17}	0.7	-5
Conventional p-GaN HEMT	10^{-12}	0.6	0.49
This work	10^{-21}	1	5

the conventional p-GaN HEMT, indicating enhanced current drive capability.

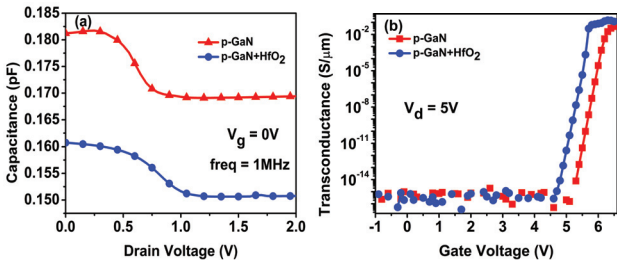

Fig. 6: (a) Gate capacitance and (b) transconductance comparison of the proposed and conventional device.

Figures 7(a) and 7(b) depict the characteristics of I_d - V_d and I_d - V_g, respectively. In Figure 7(a), the proposed MG-HEMT presents a substantially higher maximum drain current, $I_{ds,max}$, reaching 1 A/μm, exceeding the 0.6 A/μm achieved by the conventional p-GaN HEMT. Moreover, the fixed charges can be introduced at the interface or within the HfO_2 layer itself, thereby impacting threshold voltage of the device, as shown in Figure 7(b). Table II depicts the comparison of the proposed MG-HEMT and the already reported devices with respect to their performance parameters.

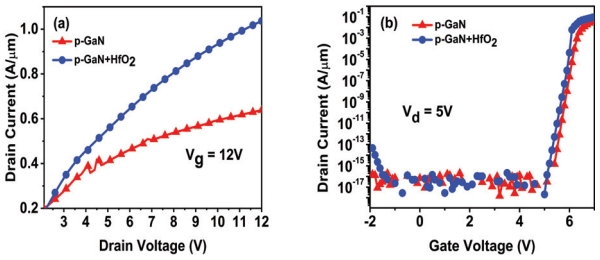

Fig. 7: (a)I_d-V_d and (b)I_d-V_g characteristics comparison of the conventional and proposed device.

CONCLUSION

This paper successfully reports a novel enhancement mode GaN HEMT featuring a MIS and p-GaN structure, referred to as MG-HEMT. The simulation results present a significant decrease of 14% in gate leakage current compared to the already reported device due to low electric field within the proposed device. Also, the proposed device demonstrates 20% and 50% increase in maximum drain current and threshold voltage, respectively, in comparison with the already reported device. These findings indicate that the proposed device shows great potential for power converter application within the field of high-power electronics.

Abstract

In the restructured power system, where uncertainties are common, managing congestion becomes a crucial aspect of power system operation and control. Congestion management aims to alleviate the power system transmission line congestion while meeting the system constraints at minimal cost. This research introduces a generation rescheduling method for congestion management in the electricity market, leveraging an innovative nutcracker optimizer algorithm. The nutcracker optimizer algorithm, inspired by nutcrackers' food accumulation mechanisms, is a recently developed nature-inspired algorithm. The efficacy of this proposed approach is assessed across modified IEEE 30-bus, and IEEE 118-bus test systems, considering the system parameters. The effectiveness of the proposed congestion management with the nutcracker optimizer algorithm is analyzed by comparing its results with those generated by other recent optimization techniques. Results demonstrated that the nutcracker optimizer algorithm surpasses other comparative methods, requiring fewer fitness function evaluations, avoiding local optima, and displaying encouraging convergence traits. Implementing this approach can assist the system

Introduction

The ability of transmission lines to carry electrical power is limited by various factors, including voltage, heat, and stability. When any of these limits is reached, the power system is considered congested. Congestion can have significant implications on the power dispatch, potentially impacting the overall performance of the system. Managing power system congestion is a critical task undertaken by independent system operators (ISOs) and grid operators (Bouhouras et al., 2024). They play a crucial role in coordinating and overseeing the functioning of the power market, ensuring efficient power flow, and maintaining system stability. With the increasing demand for electricity, aging infrastructure, and limitations on new transmission line construction, congestion has become a prevalent issue in power systems worldwide (Alavijeh et al., 2024).

Several factors contribute to congestion. These include an upsurge in power demand beyond the infrastructure's capacity, unexpected generation outages, limitations on building new transmission lines due to environmental or logistical constraints, unscheduled power flow, transmission line tripping, or equipment failures. The resulting congestion can lead to reduced reliability, increased energy costs, and potential disruptions in power supply to consumers (Dehnavi et al., 2024). To address congestion effectively, various congestion management (CM) strategies are employed. These strategies aim to alleviate constraints, optimize power flow, and maintain system stability. Some common approaches include reactive power support, generation rescheduling, demand response programs, transmission line reconfiguration, and dispatching of power resources (Ansari et al., 2020; Shaikh et al., 2020; Zhou et al., 2023). These methods help balance the power system and mitigate congestion-related issues, ensuring reliable and uninterrupted electricity supply to consumers.

Literature survey

In recent years, advancements in technology, such as smart grid technologies, advanced metering infrastructure, and real-time monitoring systems, have provided enhanced capabilities for CM. These tools enable grid operators to gather precise data, monitor system conditions, and implement timely control actions to alleviate congestion and optimize power flow. Zaidan and Toos proposed an emergency CM method for power systems using a static synchronous series compensator (SSSC). The authors focused on alleviating congestion during emergency situations and introduced the SSSC as a device to enhance the power transfer capability of transmission lines (Majeed Rashid Zaidan, 2022). The research focuses on optimizing transmission line parameters using an enhanced moth flame optimization technique, demonstrating its superiority over other methods through simulations on various test cases. Results indicate that the proposed method achieves rapid convergence to optimal values for capacitance and inductance, showcasing its effectiveness and competence in managing transmission and distribution networks (Shaikh et al., 2022c). Wang et al. introduced the concept of virtual storage plants (VSPs) for frequency regulation and CM in power systems. They proposed a framework where distributed energy resources are aggregated into VSPs to provide

ancillary services for frequency regulation and CM. The study evaluates the performance of the VSP and its potential for improving the stability and efficiency of power systems (Wang et al., 2022). Managing the transmission line flows with the influence of optimization algorithm for transmission line parameter optimization can be found in (Shaikh et al., 2021a, 2022a, 2022b, 2023). Mahajan et al. provided a review of CM in deregulated power systems. The review associated with the CM summarized the existing literature on CM techniques, including market-based approaches, generation rescheduling, load shedding, and demand response programs. The review also provided insights into the challenges and opportunities in managing congestion in deregulated power systems (Mahajan et al., 2022). Hobbie et al. investigated the effect of model parametrization of the transmission channels during the congested environment of the power system. The authors compare different existing models used for CM in electricity networks and analyze the influence of model parameters on CM (Hobbie et al., 2022). Zakaryaseraji and Ghasemi-Marzbali evaluated CM in power systems considering demand response programs and distributed generation (DG). They incorporated demand response and DG as flexible resources for managing congestion (Zakaryaseraji and Ghasemi-Marzbali, 2022). Shaikh et al. conducted their research to select the optimal transmission-line parameters that would assist efficient power flows (Shaikh et al., 2021b). Roustaei et al. formulated a voltage security-constrained CM methodology for improving the controlling of transmission systems. They addressed the challenges of voltage security and CM and proposed an approach that optimizes generation rescheduling to alleviate congestion while considering voltage security constraints (Roustaei et al., 2022). In another research, Mishra et al. provided a review of the utilization of AI-based methods in alleviating the congestion of transmission channels considering the electricity market constraints. The review mainly highlighted the application of artificial intelligence techniques, such as neural networks, fuzzy logic, and evolutionary algorithms, for CM in restructured power systems (Mishra et al., 2022). Paul formulated an enhanced framework of a grey wolf optimization algorithm that controls the congestion considering the impact of renewable sources. The CM focused on optimizing the operation of transmission lines to alleviate congestion and incorporates the impact of solar photovoltaic systems in the optimization process (Paul, 2022a). Dehnavi et al. proposed a novel CM method through power system partitioning. In the CM approach, they considered the power system into multiple partitions and applied a decentralized control strategy to manage congestion (Dehnavi et al., 2022). Sarwar et al. developed an effective transmission CM approach for contemporary power system operations using optimal DG capacity and hybrid swarm optimization. The authors focused on determining the optimal capacity of DG units at specific locations in the power system to mitigate congestion (Sarwar et al., 2022).

In the CM, generator rescheduling (GR) plays a crucial role by optimizing the generation dispatch to alleviate congestion. It allows for the efficient utilization of existing transmission infrastructure, reducing the need for costly grid expansion. By strategically adjusting generator schedules, congestion can be alleviated, ensuring reliable and secure power system operation. GR also enables the integration of renewable energy sources and promotes the economic dispatch of generation resources, leading to enhanced system efficiency and cost-effectiveness. Subramaniyan and Gomathi presented a soft computing-based analysis of CM in transmission systems with the application of generator rescheduling. The CM approach explored the application of soft computing techniques, such as fuzzy logic and genetic algorithms, for managing congestion (Subramaniyan and Gomathi, 2023). Agrawal et al. proposed a cascaded deep neural network-based approach for customer participation in CM, considering renewable energy sources and GR in deregulated power markets. Their research focused on optimizing the participation of customers with distributed energy resources to alleviate congestion (Agrawal et al., 2022). Chakravarthi et al. investigated real-time CM using generation redispatch. They designed controllers for efficient

generation rescheduling to mitigate congestion in power systems (Chakravarthi et al., 2022). Srivastava and Yadav proposed a rescheduling-based CM approach using a hybrid algorithm that combines lion and moth search models. The authors optimized generator schedules to alleviate congestion and enhance the operational efficiency of power systems (Srivastava and Yadav, 2021). Ogunwole and Krishnamurthy developed a transmission CM approach using generator sensitivity factors and particle swarm optimization. The authors focus on optimizing active and reactive power rescheduling to alleviate congestion and enhance system performance (Ogunwole and Krishnamurthy, 2022). Prajapati et al. proposed a GR-based CM approach considering the demand response characteristic for power systems and uncertainty of the renewable resources (Thiruvel et al., 2023) and presented a modern power system operations approach for effective transmission CM using optimal distributed generation (DG) capacity and GR. The authors determined the optimal capacity of DG units and real power deliveries by the generators to alleviate congestion (Thiruvel et al., 2023). Balaraman and Kamaraj managed congestion for a deregulated electricity market with the application of GR methodology. They implemented particle swarm optimization (PSO) to alleviate overloads and minimize deviations from the initial market settlement. The PSO application for CM addressed system constraints security constraints, using a penalty-based approach (Kamaraj, 2011). Saravanan and Anbalagan proposed an intelligent hybrid technique for optimal GR in deregulated power markets. They combined genetic algorithms (GA) and PSO to optimize generator schedules and alleviate congestion (Saravanan and Anbalagan, 2022). Sharma and Walde proposed a novel optimization technique based on swarm intelligence for CM in transmission lines. They applied a hybrid algorithm combining PSO and GSA to optimize power flow and alleviate congestion (Sharma and Walde, 2022). Haq et al. proposed a game-theoretic approach using plug-in electric vehicles (PEVs) and GR for real-time CM. Their work investigated the participation of PEVs and GR in alleviating congestion by adjusting their charging and discharging patterns (Haq et al., 2022). Verma and Mukherjee implemented real power GR rescheduling using a novel ant lion optimizer for CM. The CM approach aimed at optimizing generator schedules to alleviate congestion and enhance power system performance (Verma and Mukherjee, 2016b). Paul et al. reduced rescheduling costs and efficiently alleviated line overloads with minimal deviations in active power generation. The developed CM strategy involved prioritizing generators based on their sensitivity values. The GSA is then employed to minimize rescheduling costs while simultaneously reducing total active power output and system losses (Paul et al., 2019).

The emergence of competitive energy markets has driven the advancement of optimization algorithms that effectively tackle mathematical problems related to power system challenges, resulting in precise and improved outcomes. The classical optimization methods have been widely used and effective in certain scenarios but have some limitations that make metaheuristic optimization methods more preferable in many cases. Classical optimization methods have limitations such as getting entombed in local optima, sensitivity to initial conditions, lack of flexibility, high computational cost, and difficulty in handling uncertainties and noisy environments. In contrast, metaheuristic algorithms overcome these limitations by exploring the entire solution space, being less sensitive to initial conditions, offering flexibility in problem domains, providing computational efficiency, and accommodating uncertainties and noisy environments through robust and adaptive mechanisms. The metaheuristic algorithms strike a balance between exploration (diversification) and exploitation (intensification) of the search space. They avoid getting stuck in local optima by exploring different regions while also exploiting promising areas. This ability to balance exploration and exploitation enhances their capability to find better solutions. Various approaches such as grey wolf optimization (Paul, 2022b), Fennec Fox optimization (Verma and Mukherjee, 2016a), flower pollination algorithm (FPA; Gupta et al., 2023), cuckoo search algorithm (CSA; Wangunyu et al., 2022), and an enhanced version of crow search algorithm (CSA) (Paul et al., 2022) have been implemented to oversee the efficient operation of power

systems. The selection and adjustment of control parameters associated with these meta-heuristic techniques greatly influence the achieved solution. This has motivated the development of an efficient CM strategy with the application of the evolutionary algorithm that will deliver optimal outcomes for the optimization problem.

The novelty can be stated as the minimization of the congestion cost/rescheduling cost always creates a scope for implementation of new efficient optimization approaches that would deliver appreciable outcomes w.r.t previously adopted approaches. The integral novelty of this paper lies in the mathematical model formulation of the congestion cost minimization with the incorporation of the new nutcracker optimization algorithm (NOA).

In this research work, NOA which is a new metaheuristic optimization technique has been considered for the CM problem. The NOA has been designed by Basset et al. in the year 2023 (Abdel-Basset et al., 2023). The framework of NOA is inspired by the intelligent behaviors of nutcrackers to search for and store food. It draws inspiration from the hunting behavior of antlions. According to Abdel-Basset et al. (2023), the NOA has been validated on standard mathematical functions (CEC-2014, CEC-2017, and CEC-2020) and classical engineering problems. The findings presented by Abdel-Basset et al. (2023) demonstrated the advantages of the NOA in terms of improved exploration capabilities.

Motivation

The primary motivation behind this endeavor is to devise a proficient approach for CM aimed at enhancing the efficiency of power system operations. The competitive dynamics and trading behavior within the electricity market have heightened the vulnerability of the power network to congestion, prompting researchers in the field to investigate various CM strategies for their applicability and effectiveness. Given the extensive scale of the power network, any implemented CM strategy must possess qualities of robustness, effectiveness, and cost-efficiency, and must not disrupt the network's existing topology. Thus, in light of these considerations, the implementation of the generators rescheduling (GR) approach emerges as a fitting solution for CM. Furthermore, in power system operations, it's imperative to mitigate congestion at minimal cost, necessitating the utilization of efficient optimization techniques that yield optimal cost solutions. While many optimization techniques exhibit commendable performance, they often become ensnared in local optima, unable to navigate the search space effectively to identify the optimal solution. Consequently, there's a strong impetus to enhance the performance of optimization techniques by refining their operational stages. This drive has spurred advancements in the efficiency of exploration and exploitation stages within the NOA.

Research contribution

- Development of a CM model to minimize the congestion cost based on the optimal rescheduling of the generators' real power.
- Implementation of NOA to achieve the optimal power rescheduling patterns for generators for congestion cost minimization.
- Application of the CM strategies on power stream standard test system; IEEE 30-bus and IEEE 118-bus to validate the efficiency of the proposed CM model.
- Establish comparative performance analysis based on the congestion cost, bus voltage profile, and system losses achieved with NOA with the recent optimization techniques.

Problem formulation

The primary goal of CM is to reduce the expenses caused by congestion while adhering to the limitations of the network. This study addresses the CM problem by adjusting the actual power output of generators, either increasing or decreasing it. However, modifying the real power output incurs costs that are decided based on the price offers provided by the generating companies. This can be represented as.

$$\min CC = \sum_{n=1}^{N_g} (C_{inc} \cdot \Delta P_g + C_{dec} \cdot \Delta P_g) \, \$ / \mathrm{h} \tag{1}$$

The equation involves various variables: CC represents the aggregated cost of adjusting real power in \$/h, C_{inc} and C_{dec} denotes the incremental and decremental price bids, respectively, ΔP_g is the adjusted power by the generators. The constraints considered for this optimization problem are as follows:

Inequality constraints

These constraints are expressed through the following equations:

$$P_{Gn}^{\min} \le P_{Gn} \le P_{Gn}^{\max}; \quad \forall n \in N_g \tag{2}$$

$$Q_{Gn}^{\min} \le Q_{Gn} \le Q_{Gn}^{\max}; \quad \forall n \in N_g \tag{3}$$

$$(P_{Gn} - P_{Gn}^{\min}) = \Delta P_{Gn}^{\min} \le \Delta P_{Gn} \le \Delta P_{Gn}^{\max} = (P_{Gn}^{\max} - P_{Gn}); \quad \forall n \in N_g \tag{4}$$

$$V_n^{\min} \le V_n \le V_n^{\max} \tag{5}$$

$$P_{ij} \le P_{ij}^{\max} \tag{6}$$

Equality constraints

$$P_{Gn} - P_{Dn} = \sum_j |V_j||V_k||Y_{kj}| \cos(\delta_k - \delta_j - \theta_{kj}); \quad j = 1, 2, 3, \ldots, N_b \tag{7}$$

$$Q_{Gn} - Q_{Dn} = \sum_j |V_j||V_k||Y_{kj}| \sin(\delta_k - \delta_j - \theta_{kj}); \quad j = 1, 2, 3, \ldots, N_b \tag{8}$$

$$P_{Gn} = P_{Gn}^{C} + \Delta P_{Gn}^{+} - \Delta P_{Gn}^{-}; \quad k = 1, 2, 3, \ldots, N_g \tag{9}$$

$$P_{Dj} = P_{Dj}^{C}; \quad j = 1, 2, 3, \ldots, N_d \tag{10}$$

Here, in equations (7) and (8), P_{Gk} and Q_{Gk} represent the active and reactive powers generated at the kth bus, respectively. Similarly, P_{Dk} and Q_{Dk} denote the active and reactive powers at the kth bus,

respectively. In equations (7) and (8), V_j and V_k indicate the voltages at buses, while δ_k and δ_j are the bus voltage angles. The parameter θ_{kj} represents the admittance angle. The count of the generators, buses and loads are given by N_b, N_g, and N_d, respectively. P_{Gk}^{C} is the generated power and P_{Dj}^{C} is the consumed by the load. It should be noted that equations (7) and (8) outline the balances of active and reactive power at individual nodes, whereas equations (9) and (10) portray the resulting power in relation to the market clearing price.

Nutcracker optimizer algorithm

This section presents a bio-inspired optimization algorithm (NOA) that draws inspiration from the intelligent behaviors of nutcrackers. The NOA has been designed by Basset et al. in the year 2023 (Abdel-Basset et al., 2023). The nutcracker's behavior can be segregated and portrayed into two sections. The first part involves collecting and storing pine seeds as food. The second part involves searching for and retrieving the stored seeds.

Foraging stage: Exploration phase I

In the starting position, each nutcracker examines the cone holding seeds; if good seeds are found, they are taken to the storage area for burial. If no good seeds are found, the nutcracker seeks another cone among pine/trees. The mathematical representation of this behavior representing the position update can be stated as

$$\overrightarrow{Z}_i^{t+1} = \begin{cases} Z_{i,j}^{t}; & \text{if } \tau_1 < \tau_2 \\ Z_{m,j}^{t} + \psi(Z_{A,j}^{t} - Z_{B,j}^{t}) + \xi(r^2 U_j - L_j); & \text{if } t \le T_{\max}/2.0 \\ Z_{C,j}^{t} + \xi(Z_{A,j}^{t} - Z_{B,j}^{t}) + \xi(r^2 U_j - L_j); & \text{otherwise} \end{cases} \tag{11}$$

$\overrightarrow{Z}^{t+1}$ denotes the current position of the ith nutcracker, and $Z_{i,j}^{t}$ represents its jth position. Vectors U_j and L_j define the upper and lower bounds of the jth dimension in the optimization problem, respectively. ψ is a randomly generated number using the levy flight. $\overrightarrow{Z}_{best,j}^{t}$ signifies the jth dimension of the best solution. τ_1, τ_2, and r ranges [0, 1]. $Z_{m,j}^{t}$ is the mean of all solutions. In equation (12), ξ is generated based on the normal distribution (τ_4), levy-flight τ_5, and τ_3 [0, 1].

Top of form

$$\xi = \begin{cases} \tau_3 \text{ if } r_1 < r_1 \\ \tau_4 \text{ if } r_2 < r_3 \\ \tau_5 \text{ if } r_1 < r_3 \end{cases} \tag{12}$$

In this scenario, r_1, r_2, and r_3 are arbitrary real numbers between 0 and 1. Equation (11) has been created to study top-notch food options. The initial part of equation (11) shows how likely it is for nutcrackers to find good seeds on their first try, suggesting they won't change the original dimension in the solution Z_i^t. Equation's (11) second stage helps nutcrackers explore the search space globally, boosting NOA's search power. In the third stage, nutcrackers explore positions near a randomly chosen solution while keeping the chance to move globally with a δ probability. A and B offer data on new food spots, while τ_1 and τ_2 regulate NOA's exploration. The algorithm switches between local and global searches using diverse τ_1 and τ_2 values. μ guides nutcrackers with directions and step sizes for exploring new positions.

Storage stage: Exploitation phase 1

Initially, nutcrackers traverse with the gathered foodstuff in the prior exploration phase, called phase 1, to interim stowing in the storage area. This phase is termed "exploitation phase 1" as it involves both exploiting and storing pine seed crops. This behavior can be mathematically represented as:

$$\overrightarrow{Z}_i^{t+1(new)} = \begin{cases} \overrightarrow{Z}_i^t + \xi \cdot (\overrightarrow{Z}_{best}^t - \overrightarrow{Z}_i^t) \cdot |\gamma| + r_1 \cdot (\overrightarrow{Z}_A^t - \overrightarrow{Z}_B^t) & \text{if } \tau_1 < \tau_2 \\ \overrightarrow{Z}_{best}^t + \xi \cdot (\overrightarrow{Z}_A^t - \overrightarrow{Z}_B^t) & \text{if } \tau_1 < \tau_3 \\ \overrightarrow{Z}_{best}^t \cdot l & \text{otherwise} \end{cases} \tag{13}$$

In the current iteration, the position of a new item in the storage area of the nutcrackers is represented by a vector $\overrightarrow{Z}_i^{t+1(new)}$. $\overrightarrow{Z}_{best}^t$ represents the jth dimension of the best solution obtained so far. The value of γ is determined by a Lévy flight, while τ_3 is a random number between 0 and 1. The factor l gradually decreases from 1 to 0, aiding in broadening NOA's exploitation behavior, this diversity in approach speeds up convergence and avoids getting stuck in local minimums that may occur when exploring in just one direction.

Throughout the optimization process, a consistent equilibrium between exploration and exploitation operators is upheld by applying the following formula to regulate the interaction between the foraging stage and the cache:

$$\overrightarrow{Z}_i^{t+1} = \begin{cases} \text{Equation (11), if } \varphi > P_{a1} \\ \text{Equation (13), otherwise} \end{cases} \tag{14}$$

In this stage, a random number ϕ is generated between zero and one, and the probability value P_{a1} gradually decreases from one to zero. The generated solutions are directed towards a specific region to cover as many solutions as possible.

Cache-search and recovery strategy

- Cache-search stage: Exploration phase 2: Nutcrackers employ spatial memory tactics to uncover their caches, where multiple objects might signify a single cache. Each cache corresponds to just two markers or objects, known as reference points (RPs). Within the NOA, two RPs are established for each population's cache/nutcracker using the following matrix:

$$RPs = \begin{bmatrix} RP_{1,1}^t & RP_{1,2}^t \\ \vdots & \vdots \\ RP_{i,1}^t & RP_{i,2}^t \\ \vdots & \vdots \\ RP_{n,1}^t & RP_{n,2}^t \\ \vdots & \vdots \end{bmatrix} \tag{15}$$

In this equation, $RP_{i,1}^t$ and $RP_{i,1}^t$ stand for the RPs linked to the ith nutcracker's cache position $\overrightarrow{Z}_i^t$ at generation t.

Nutcrackers find caches accurately, but about 20% of attempts fail initially. If they cannot locate the food with the first RP, they try the second RP. Failing that, they turn to the third reference. Two equations boost nutcrackers' exploration for caches. The first *RP* updates the position to uncover nearby caches. Its formula is

$$\overrightarrow{RP}_{i,k}^{t} = \overrightarrow{Z}_{i}^{t} + \alpha \cdot \cos(\theta) \cdot ((\overrightarrow{Z}_{A}^{t} - \overrightarrow{Z}_{B}^{t})), k = 1 \tag{16}$$

The second RP adjusts the existing solution to assist nutcrackers explore diverse areas. Its calculation follows a specific formula:

$$\overrightarrow{RP}_{i,k}^{t} = \overrightarrow{Z}_{i}^{t} + \alpha \cdot \cos(\theta) \cdot ((\overrightarrow{U} - \overrightarrow{L}) \cdot \tau_3 + \overrightarrow{L}) \cdot \overrightarrow{U}_2; k = 2 \tag{17}$$

$$\overrightarrow{U} = \begin{cases} 1; \overrightarrow{r_2} < P_{rp} \\ 0; \text{ otherwise} \end{cases} \tag{18}$$

Equations (16) and (17) create two RPs for each nutcracker, aiding in cache recovery. Close RPs make retrieval easier; initially, nutcrackers lack experience but learn over time. In the equations, α trains nutcrackers, preventing RPs from converging too soon. θ, randomly picked from 0 to π. When $\theta = \pi/2$, $\overrightarrow{RP}_{i,k}^{t}$ matches $\overrightarrow{Z}_{i}^{t}$ which portrays their overlap. To handle this, equations (16) and (17) can be combined and represented as

$$\overrightarrow{RP}_{i,1}^{t} = \begin{cases} \overrightarrow{Z}_{i}^{t} + \alpha \cdot \cos(\theta) \cdot ((\overrightarrow{Z}_{A}^{t} - \overrightarrow{Z}_{B}^{t})) + \alpha \cdot RP; & \text{if } \theta = \pi / 2 \\ \overrightarrow{Z}_{i}^{t} + \alpha \cdot \cos(\theta) \cdot ((\overrightarrow{Z}_{A}^{t} - \overrightarrow{Z}_{B}^{t})); & \text{otherwise} \end{cases} \tag{19}$$

$$\overrightarrow{RP}_{i,2}^{t} = \begin{cases} \overrightarrow{Z}_{i}^{t} + (\alpha \cdot \cos(\theta) \cdot ((\overrightarrow{U} - \overrightarrow{L}) \cdot \tau_3 + \overrightarrow{L}) + \alpha \cdot RP) \cdot \overrightarrow{U}_2; & \text{if } \theta = \pi / 2 \\ \overrightarrow{Z}_{i}^{t} + \alpha \cdot \cos(\theta) \cdot ((\overrightarrow{U} - \overrightarrow{L}) \cdot \tau_3 + \overrightarrow{L}) \cdot \overrightarrow{U}_2; & \text{otherwise} \end{cases} \tag{20}$$

$\overrightarrow{RP}_{i,1}^{t}$ refers to the element in the *i*th row and first column of the matrix in equation (15), while $\overrightarrow{RP}_{i,2}^{t}$ is in the *i*th row and second column of the same matrix. Each row corresponds to a cache/nutcracker, each column to an *RP*. *RP* means a random position. To avoid *RPs* converging too soon, the third term in equations (19) and (20) ($\theta = \pi/2$) is added. α ensures regular convergence in NOA, improving RP selection in later generations. Calculate α with this equation:

$$\alpha = \begin{cases} \left(1 - \frac{t}{T_{\max}}\right)^{2 \cdot \frac{t}{T_{\max}}}; & \text{if } r_1 > r_2 \\ \left(\frac{t}{T_{\max}}\right)^{\frac{2}{t}}; & \text{otherwise} \end{cases} \tag{21}$$

In this case, t is the current generation, and $T_{\max}$ is the maximum number of generations. The first stage in equation (21) decreases with each round, speeding up convergence. Meanwhile, the second stage rises gradually to avoid trapping the algorithm in local lows caused by the first stage.

During optimization, nutcrackers gain expertise in *RP* selection. They adjust their storage based on these RPs. In NOA, all nutcrackers explore promising regions using an exploration mechanism. Progressively, the algorithm avoids local lows by dynamically exploring and exploiting areas

around caches with suitable *RPs*. The nutcracker's updated position follows this equation:

$$\overrightarrow{Z}_i^{t+1} = \begin{cases} \overrightarrow{Z}_i^t; & \text{if } f(\overrightarrow{Z}_i^t) \text{lt} (\overrightarrow{RP}_{i,1}^t) \\ \overrightarrow{RP}_{i,1}^t; & \text{otherwise} \end{cases} \tag{22}$$

The equation demonstrates the new cache $\overrightarrow{Z}_i^{t+1}$ of the *i*th nutcracker in iteration $(t+1)$, where $\overrightarrow{Z}_i^t$ represents the current cache, and $\overrightarrow{RP}_{i,1}^t$ is the initial link associated with the current cache in iteration *t*. Equation (22) steers NOA toward exploring and exploiting areas near $\overrightarrow{RP}_{i,1}^t$.

- *Recovery stage: Exploitation phase 2:* The main scenario: a nutcracker recalls the cache with the first RP. Figure 8 shows two options: food present or absent. Mathematically, it's expressed as follows:

$$\overrightarrow{Z}_{i,j}^{t+1} = \begin{cases} \overrightarrow{Z}_{i,j}^t; & \text{if } \tau_3 < \tau_4 \\ \overrightarrow{Z}_{i,j}^t + r_1 \cdot (\overrightarrow{Z}_{best,j}^t - \overrightarrow{Z}_{i,j}^t) + r_2 (\overrightarrow{RP}_{i,j}^t - \overrightarrow{Z}_{i,j}^t); & \text{otherwise} \end{cases} \tag{23}$$

Let $\overrightarrow{Z}_{i,j}^{t+1}$ be the updated cache, $\overrightarrow{Z}_{i,j}^t$ is the current dimension, and $\overrightarrow{Z}_{best,j}^t$ shows the best cache found so far in iteration *t*. $\overrightarrow{RP}_{i,j}^t$ is the random parameter of the *i*th nutcracker's current cache in iteration *t*. r_1, r_2, τ_3, and τ_4 ranges between [0, 1].

Equation's (23) first condition assumes food is present, passing certain dimensions to the consecutive generation. The second condition in equation (23) assumes no food, signaling an unpromising solution; an escape mechanism avoids local lows. Food loss in the cache could be due to theft or natural elements. The first part of equation (23) helps the nutcracker exploit promising areas locally. The second part allows exploration globally in the search space.

If the nutcracker cannot find food with the first *RP*, it tries the second one. Nutcrackers store multiple *RPs* in early storage, but sometimes the first *RP* fails. Some rely on changing landmarks when autumn becomes winter. Equation (24) updates nutcracker memory with the second *RP*.

$$\overrightarrow{Z}_i^{t+1} = \begin{cases} \overrightarrow{Z}_i^t; & \text{if } f(\overrightarrow{Z}_i^t) \text{lt} (\overrightarrow{RP}_{i,2}^t) \\ \overrightarrow{RP}_{i,2}^t; & \text{otherwise} \end{cases} \tag{24}$$

In this setting, $\overrightarrow{Z}_i^t$ is the current cache, and $\overrightarrow{RP}_{i,2}^t$ is the second *RP* linked to the *i*th nutcracker. Equation (24) enables NOA to observe new locations within the vicinity of the second *RP* and perform exploitation within the most prominent areas. In NOA, finding the cache with the second *RP* updates equation (13) based on this information.

$$\overrightarrow{Z}_{i,j}^{t+1} = \begin{cases} \overrightarrow{Z}_{i,j}^t; & \text{if } \tau_5 < \tau_6 \\ \overrightarrow{Z}_{i,j}^t + r_1 \cdot (\overrightarrow{Z}_{best,j}^t - \overrightarrow{Z}_{i,j}^t) + r_2 (\overrightarrow{RP}_{i,2}^t - \overrightarrow{Z}_{Cj}^t); & \text{otherwise} \end{cases} \tag{25}$$

In the given equation, r_1, r_2, τ_5, and τ_6 are random numbers from 0 to 1. Equation's (25) first part intensifies local search in optimal areas. The second part explores new spaces for a better global

search.

$$\overrightarrow{Z}_i^{t+1} = \begin{cases} \text{Equation (13), if } \tau_7 < \tau_8 \\ \text{Equation (15), otherwise} \end{cases} \tag{26}$$

In this equation, τ_7 and τ_8 are random numbers from 0 to 1. First case: nutcracker recalls the store; second: cannot remember. Equation balances exploration between the two RPs:

$$\overrightarrow{Z}_i^{t+1} = \begin{cases} \text{Equation (12)}, & \text{if } f(\text{equation (12)}) < f(\text{equation (14)}) \\ \text{Equation (14)}, & \text{otherwise} \end{cases} \tag{27}$$

To sustain a steadiness between exploration and exploitation, the transition between the cache-search phase and the recovery phase is executed through the utilization of the subsequent formula.

$$\overrightarrow{Z}_i^{t+1} = \begin{cases} \text{Equation (16), if } \phi < P_{a2} \\ \text{Equation (17), otherwise} \end{cases} \tag{28}$$

In this equation, φ ranges from 0 to 1, and P_{a2} is set at 0.2 based on several trial runs, and the best result is obtained from stand benchmark functions.

Performance analysis of NOA

The NOA's performance has been evaluated across 23 standard benchmark functions, including seven unimodal and 13 multimodal functions. The details of these functions can be found by Dolatabadi et al. (2020). Comparisons with GTO, AHA, and the original NOA are conducted. In this study, search agents and maximum iterations are set at 40 and 500, respectively, with findings gathered from 30 separate runs. Results show that NOA exhibits significant performance during both the exploration and exploitation stages. Table 1 provides the average (Avg), standard deviation (SD), median (Med), and worst (worst of the best-so-far solution) values obtained for GTO, AHA, and NOA the original MRFO in the final repetition. The test results with 23 benchmark functions are given in Table 1. Convergence profiles of the 23 benchmark functions using NOA, AHA, and GTO are depicted in Figure 1, while Figure 2 illustrates the flowchart for NOA in addressing the proposed CM problem.

Computational complexity of NOA

The evaluation of algorithm complexity in dimensions 20, 40, and 50 is conducted according to the guidelines outlined by Liang et al. (2013) and the results are illustrated in Table 2. The runtime is determined through the assessment of the CEC 2014 benchmark function FCEC18. The determination of T_0 is accomplished resulting in a computed execution time of $T_0 = 0.7539$ s. T_1 signifies the duration required for executing 2.00×10^5 evaluations of the benchmark function FCEC18 individually across dimensions of 20, 40, and 50. Meanwhile, T_2 denotes the time taken for executing an algorithm encompassing 2.00×10^5 evaluations of FCEC18 in 20, 40, and 50 dimensions.

Results

The proposed NOA is tested on three different power systems: the modified IEEE 30-bus (Sharma et al., 2018) and IEEE 118-bus test systems (Dash and Mohanty, 2015). The necessary data for these systems is obtained from Paul (2022b) and Paul et al. (2022). In addition to applying the

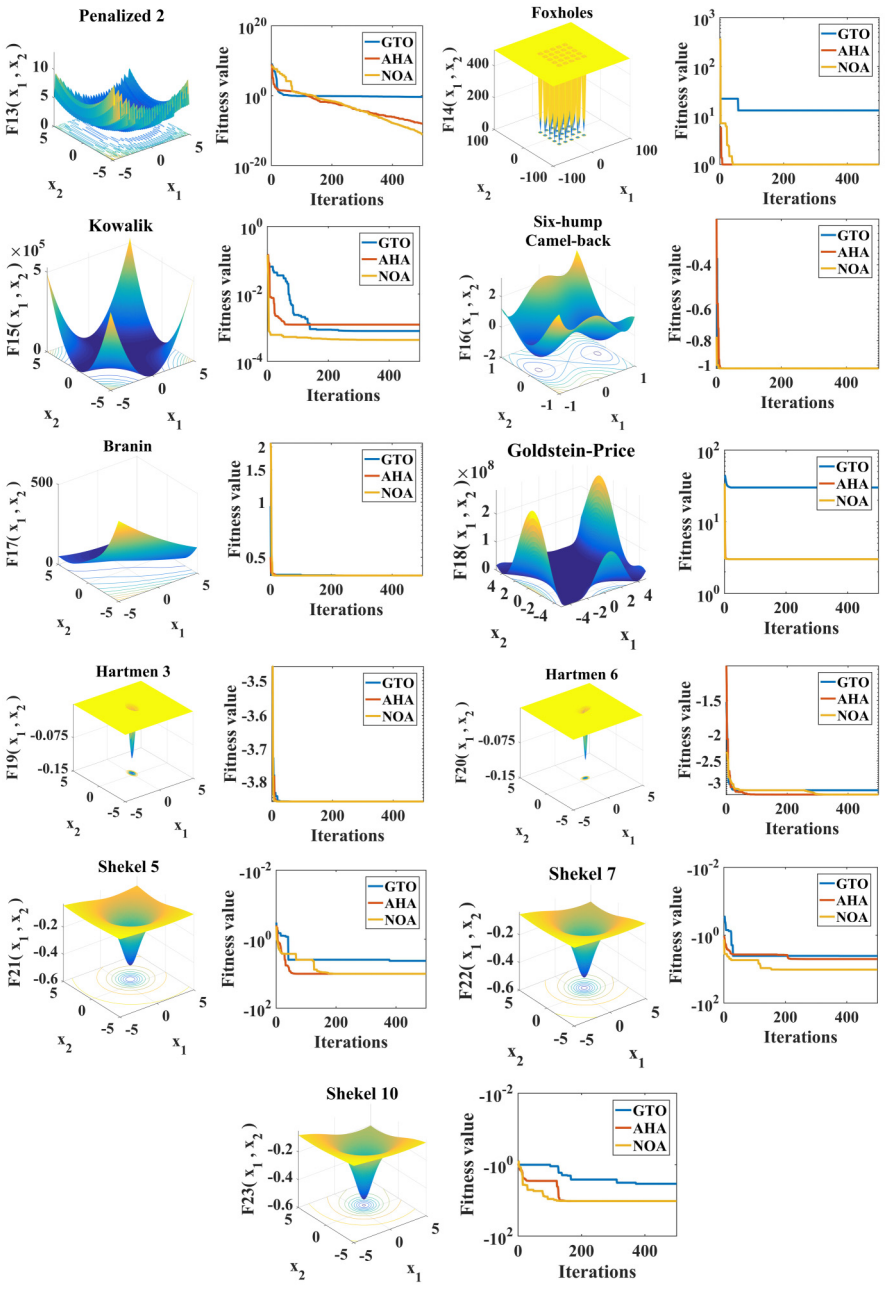

Figure 1. Continued.

NOA to solve the CM problem, the same problem has also been solved with other recent well-known optimization techniques such as gorilla troops optimization (GTO), and artificial hummingbird algorithm (AHA). These techniques are applied in the same environment, enabling a fair comparison among different optimization methods for solving the CM problem.

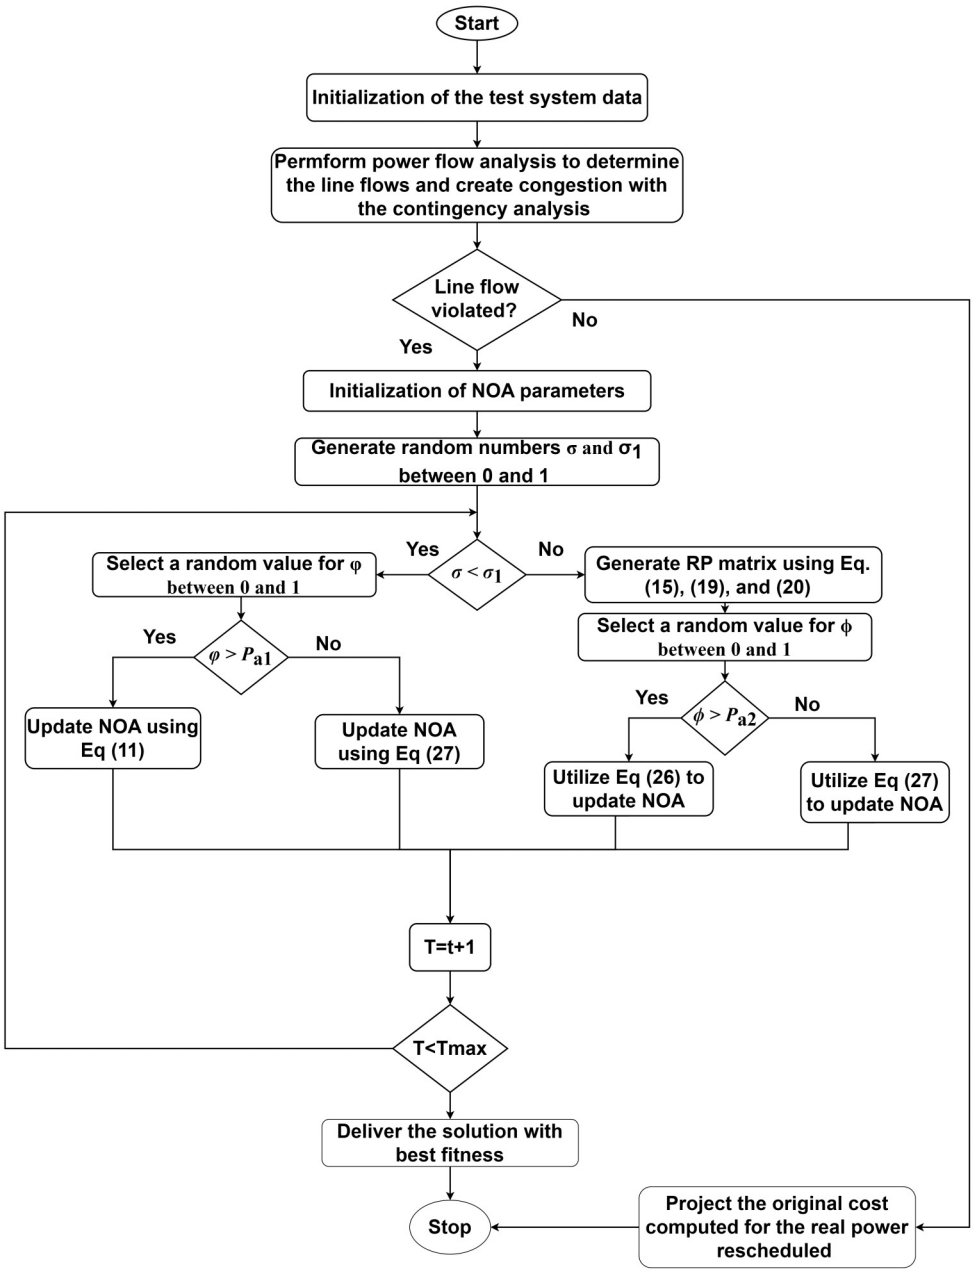

Figure 2. Flowchart for CM with NOA.
NOA: nutcracker optimizer algorithm; CM: congestion management

The software used in this study is MATLAB 2016a and implemented on a system with an Intel Core i7 processor running at a clock speed of 2.4 GHz and equipped with 8 GB of RAM. Table 3 provides specific information about the simulated cases conducted on the test systems. In this

Table 2. Computational complexity time (NOA) in seconds.

Dimension (D)	T_0	T_1	T_2	$(T_2-T_1)/T_0$
20	0.7539	7.8295	38.1602	34.3647

Table 3. Test cases considered for the congestion management (CM) problem.

Cases	Test system	Contingency scenario considered
1	IEEE 30-bus system (Sharma et al., 2018)	Tripping of lines 1 and 2
2	IEEE 118-bus system (Dash and Mohanty, 2015)	Tripping of lines 8–5 and load increment to 57% at buses 11–20

Table 4. Line power flow details for the congested line.

	Congested lines	Power flow (MW)	Power flow limit (MW)	Excess power flow (MW)	% overload
Outage of lines 1 and 2	1–3	147.46	130	17.46	13.43
	6–8	136.29	130	6.29	4.84

research, line overloads have been created considering two cases, firstly, by decreasing the power flow capacity of the capacity of the lines, and secondly, by simulating line outage(s) for contingency purposes.

To find the optimal parameter values, multiple trial runs have been conducted for solving the CM problem on all three test systems under study. The best results obtained from these trials are presented. Through these trial runs, the population size of 40 has been considered to be sufficient for the CM problem in this particular study.

IEEE 30-bus system

The modified IEEE 30-bus test system has been considered for the evaluation of the CM problem. It consists of 41 transmission channels with six generator buses and 24 load buses. The configuration of this system is depicted in Figure 2. The test case that has been considered for the IEEE 30-bus system is listed in Table 3. The details of the congested power flow scenario are given in Table 4.

In this case, the congestion has been created by an outage of line 1, between buses 1 and 2 (Figure 3). This leads to congestion in line 2 (connecting buses 1 and 3) and line 4 (connecting buses 6 and 8) and is represented in Table 4. To ensure secure functioning, counteractive measures are necessary to relieve these overloaded lines. The NOA has been employed to minimize the congestion cost, with the optimal generator output. The congestion costs obtained using the NOA are presented in Table 5. These values are then compared with results from literature, such as PSO (Kamaraj, 2011), RSM (Kamaraj, 2011), SA (Kamaraj, 2011), FPA (Verma and Mukherjee, 2016b), CBA (Verma and Mukherjee, 2016b), ALO (Verma and Mukherjee, 2016b), TLBO (Verma et al., 2018) as well as recent algorithms like GTO, AHA. The optimal total congestion cost obtained through the NOA-based approach is determined to be 476.84 $/h.

Table 5. Comparative outcomes for IEEE 30 bus system with NOA.

[a]NR: not reported.

Representation of the comparative congestion costs is depicted in Figure 4. Figure 5 illustrates the real power rescheduling for different generators achieved by the comparative algorithms. The convergence profiles of GTO, AHA, and NOA, are presented in Figure 6. The iterative values for 30 runs with 500 iterations and the box plot are given in Figures 7 and 8.

Additionally, the total system loss is reduced to 12.047 MW after CM, compared to the initial value of 16.023 MW during congestion. The bus voltages after CM using the NOA approach are shown in Figure 9, where it is evident that all bus voltages remain within acceptable limits.

Statistical test for NOA on IEEE 30-bus system. To assess the effectiveness and resilience of the proposed NOA, an extensive examination has been conducted on the obtained results. This involved

running all three optimization algorithms 30 times across various population sizes (number of search agents). According to Derrac et al. (2011), the authors recommended employing several non-parametric statistical tests within the realm of computational intelligence. Table 6 shows the cases with the best fitness function values. Notably, the NOA yielded the best result when utilizing 40 search agents. Table 7 presents the minimum, maximum, mean, and standard deviations of fitness function values obtained with GTO, AHA, and NOA when using 40 search agents.

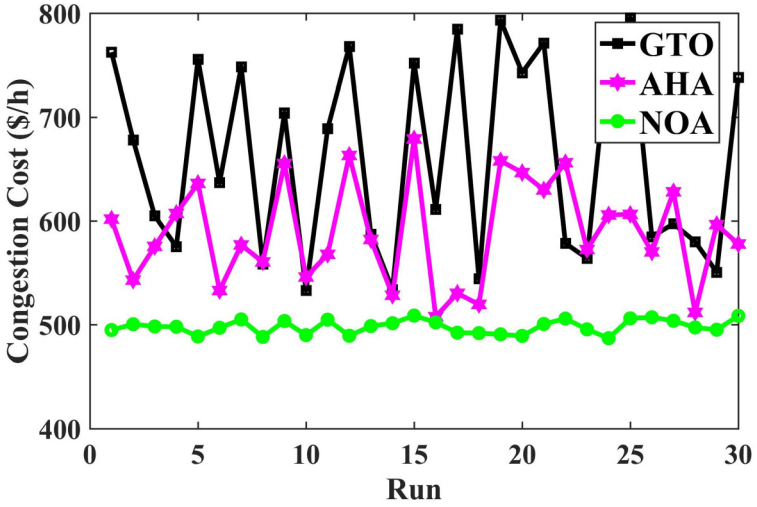

Figure 7. Fitness function values for 30 runs with 500 iterations (IEEE 30 bus).

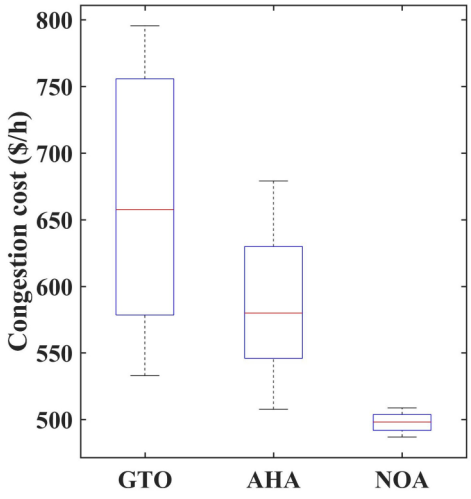

Figure 8. Box plot for 30 trail runs (IEEE 30 bus).

Furthermore, statistical analyses including Friedman, and Quade tests have been conducted to validate the optimization algorithms. Let H_0 denote the hypothesis stating no difference among the three methods, while H_1 represents the alternative hypothesis suggesting differences (Sheskin, 2003). A significance level of $\alpha = 0.05$ has been chosen. Table 8 presents the recorded *p*-values from Wilcoxon's paired sign rank test. The symbols +/−/∼ indicate whether the proposed NOA outperforms, underperforms, or is approximately equal to the compared algorithm, respectively. A *p*-value < 0.05 for all test cases refutes the null hypothesis, affirming the validity of Wilcoxon's signed-rank test for the proposed algorithm (Sheskin, 2003).

Analysis of variance relies on the principle of total variance. This approach involves breaking down the observed variance in a specific variable into segments attributed to various sources of variation. The critical F-value is determined with the chosen significance level ($\alpha = 0.05$). If the

calculated F-ratio exceeds the critical *F*-limit, the null hypothesis is rejected. Additionally, Table 9 indicates that the computed *F*-value falls below the tabulated *F*-value at a 5% significance level, where the degrees of freedom are specified as 4 and 25.

To conduct the Friedman and Quade tests, initially, an average error table is highlighted in Table 10. Subsequently, Friedman ranks and the *F*-statistic (also known as the χ^2 value) are computed and presented in Table 11. The method with the lowest rank is deemed superior, clearly indicating the efficacy of NOA. The computed χ^2 value of 16 from Table 11 exceeds

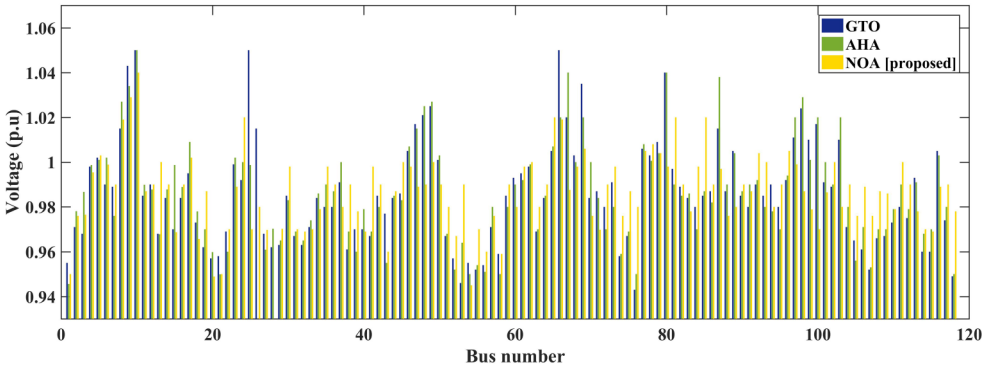

Figure 15. Comparative bus voltage with nutcracker optimizer algorithm (NOA) and other optimization techniques.

Table 16. Fitness function values delivered by GTO, AHA, and NOA for 40 search agents (118 bus).

Algorithms	Min	Max	Avg	SD
GTO	1528.07	2100.48	1602.05	14.9342
AHA	1438.90	1845.78	1549.49	12.3857
NOA	1389.56	1420.56	1436.66	3.8469

NOA: nutcracker optimizer algorithm; GTO: gorilla troops optimization; AHA: artificial hummingbird algorithm.

Table 17. *P*-values for the optimization algorithm (118 bus).

Algorithm	*p*-value	+/−/~
GTO versus NOA	1.6723×10^{-6}	+
AHA versus NOA	1.7318×10^{-6}	+

NOA: nutcracker optimizer algorithm; GTO: gorilla troops optimization; AHA: artificial hummingbird algorithm.

Table 18. Analysis of variance for the optimization algorithms (118 bus)

Source of variation	Sum of square	Degrees of freedom	Mean square	*F*-ratio	5% *F*-limit
Between techniques	3.6319×10^{7}	5–1 = 4	8.1479×10^{6}	15.5348	F (4, 25) = 3.4186
Within techniques	1.2187×10^{7}	30–5 = 25	4.5547×10^{5}		

Similar trends are evident in the Quade test results presented in Table 12, where NOA achieved the lowest rank. The calculated Q-statistic value of 15 surpasses the critical value referenced by Sheskin (2003), and the resulting p-value of 1.9209×10^{-6}, being < 0.05, supports the rejection of the null hypothesis H_0. This reinforces the effectiveness of NOA.

IEEE 118-bus system

This test framework consists of 54 buses as generator buses, 186 transmission lines, and 64 load buses. The network topology for this test system can be found in Figure 10.

In this test system, contingency is established with the tripping of lines 8–5 and increasing the load demand by 1.57 times. Congested lines detail have been represented in Table 13. The NOA has been employed to settle the CM problem and obtain the solution. The detail of the solutions achieved with the NOA has been highlighted in Table 14. It can be seen that the line flows have been reduced below the maximum limits with the NOA and other competitive

optimization algorithms. The congestion cost and the real power rescheduled by the NOA, and other recent algorithms are summarized in Table 14. It is observed that the application of NOA and generator rescheduling have relieved the overloaded lines achieving a congestion cost of 1389.56 $/h, which is comparatively lower than the cost achieved with other techniques.

The congestion cost is represented in Figure 11. Convergence of the fitness function based on the NOA for this case is depicted in Figure 12. System loss before CM was 247.968 MW, whereas post CM it has been reduced to 168.539 MW. Furthermore, tests have shown that NOA consistently provides the best optimal solution even for large systems. The iterative values for 30 runs with 500 iterations and the box plot are given in Figures 13 and 14. The bus voltages obtained post-CM are represented in Figure 15, demonstrating that the voltages are within normal specified limits.

Statistical test for NOA on IEEE 118-bus system. The fitness obtained with GTO, AHA, and NOA is highlighted in Table 15. Notably, the NOA yielded the best result when utilizing 40 search agents. Table 16 presents the minimum, maximum, mean, and standard deviations of fitness function values. Various statistical analyses, including Wilcoxon's signed-rank test, Friedman, and Quade tests, were undertaken to assess the algorithms. H_0 represents the hypothesis asserting no distinctions among the three methods, while H_1 suggests otherwise (Verma and Mukherjee, 2016a). A significance level of $\alpha = 0.05$ was selected for the analyses. The *p*-values obtained from Wilcoxon's paired sign rank test are presented in Table 17. The symbols +/−/∼ indicate whether the proposed NOA performs better, worse, or comparably to the compared algorithm, respectively. A *p*-value < 0.05 across all test cases negates the null hypothesis, confirming the credibility of Wilcoxon's signed-rank test for the proposed algorithm (Verma and Mukherjee, 2016a).

Additionally, as depicted in Table 18, the computed *F*-value for both systems falls below the tabulated *F*-value at a 5% significance level, with degrees of freedom specified as 4 and 25. In conducting the Friedman and Quade tests, an average error table is established in resembling Table 19. Subsequently, Friedman ranks, and the *F*-statistic (also referred to as the χ^2 value) are computed and presented in Table 20. The method achieving the lowest rank is deemed superior, thereby highlighting the effectiveness of NOA. The calculated χ^2 value of 16 from Table 20 surpasses the critical value, and the resulting *p*-value of 0.0030, falling below 0.05, leads to the rejection of the null hypothesis, indicating significant disparities among the employed methods. Similar patterns are observable in the Quade test outcomes showcased in Table 21, where NOA secures the lowest rank. The calculated *Q*-statistic value of 15 exceeds the referenced critical value by Verma and Mukherjee (2016a), and the resulting *p*-value of 1.9209×10^{-6}, being below 0.05, supports the rejection of null hypothesis H_0, thus reinforcing the efficacy of NOA.

Conclusions

This research introduces a novel approach for power system CM within the power market, utilizing a generation rescheduling method. The contribution can be stated as the formulation of a novel CM model to minimize congestion costs through optimal rescheduling of generators' real power, utilizing NOA for determining optimal power rescheduling patterns. This model's efficacy is validated on power system standard test systems, IEEE 30 bus, and IEEE 118 bus. Comparative performance analysis is conducted, assessing congestion cost reduction, bus voltage profile improvement, and system losses, demonstrating the superiority of the proposed CM model with NOA over contemporary optimization techniques. The method employs a unique NOA and accounts for contingencies like line outages and sudden load variations. It aims to alleviate congestion in overloaded lines

by adjusting the power generation schedules while minimizing the congestion cost. The NOA technique has been successfully applied to IEEE 30- and IEEE 118-bus systems for CM purposes. Comparisons are made between the outcomes generated by the proposed NOA and various established algorithms documented in recent literature. Results indicate that the power rescheduled with NOA incurs lower congestion costs as compared to other similar techniques. Furthermore, applying CM reduces the overall system loss.

Consequently, the NOA offers a fresh and efficient approach to resolving power system CM challenges within a deregulated framework. Considering future approaches, the suggested approach for power system congestion management, employing NOA, has the potential for expansion towards optimizing power system operations, encompassing power dispatch and load scheduling strategies. It can also be utilized to examine the optimal positioning and control of power delivery from renewable energy systems and distributed generation, offering a comprehensive analysis of the proposed methodology.

Further, researchers dealing with large-scale power system issues might find the NOA a valuable optimization tool based on its demonstrated effectiveness. Research on power system transmission line congestion management using optimization techniques encounters several challenges. These include the complexity of power networks, data availability and accuracy issues, long computational times, the need for adaptable algorithms, and the integration of renewable energy sources. Overcoming these limitations is essential for enhancing the effectiveness and practicality of optimization approaches in real-world applications. Further, the researchers dealing with large-scale power system issues might find the NOA a valuable optimization tool based on its demonstrated effectiveness.

Abstract
The process of accurately predicting software defects is highly crucial during the early period of software development before testing activities begin. A variety of computational methods have been constructed to achieve this based on static code metrics. However, one of the major issues in predictive modelling is the presence of redundant and irrelevant features in available datasets, which can lead to inaccuracies in the prediction model. Swarm optimization methods have shown excellent performance in Feature Selection (FS) issue mitigation and reduced the execution time of the prediction model. This study proposes a novel model for predicting software defects. This model utilizes a variant of Grey Wolf Optimiser as a wrapper-based feature selection method, paired with Synthetic Minority Oversampling Technique to balance the dataset, with the objective of maximizing the prediction efficiency of the learning model. The performance of the proposed model is assessed on 27 open-source datasets. The result findings show that the feature selection method improves prediction performance. Furthermore, the two-phase Grey Wolf Optimization-based feature selection with Random Forest classifier demonstrates superior efficacy on datasets compared to another benchmark model in handling the problem of FS. The results are also validated using statistical techniques.

Keywords Software defect prediction · Feature selection · Grey wolf optimisation · Synthetic minority oversampling technique (SMOTE) · Machine learning

1 Introduction

Software quality is a significant aspect of software engineering that needs to be considered when developing software products. The extent to which software conforms to customer needs and expectations is the software quality [1]. High-quality software products are more likely to meet user needs and expectations, resulting in greater user satisfaction. High-quality software is effective and efficient, with minimal defects. This can result in smoother business processes and better use of resources. Quality software development can reduce overall testing and maintenance efforts, resulting in lower costs. Reducing the number of faults through quality development practises might ultimately save money because correcting defects can be expensive. High-quality software can give organizations a competitive advantage in the marketplace. Customers are more likely to choose a software product that meets their needs and performs well. Standardizing software quality practices can improve overall software quality and promote consistency across organizations [2].

Additionally, by predicting software defects, software engineers can improve their overall development processes, as they can use the data generated by Software Defect Prediction (SDP) to identify parts of the code that are prone to defects and make changes to reduce the risk of future defects data [3]. SDP is the process of identifying those software components that are most likely to have defects based on current software metrics or features for prospective software releases [4]. Software characteristics may indicate software properties like complexity and the number of operators, and the connections between the features and the class may change. Some of these traits

might be more relevant to the class than others, while some of them might be redundant or not necessary. With Feature Selection (FS), the high-dimensional feature set can yield high correlation features. FS may select only those elements that are essential to the class. Including FS in SDP could thereby boost its performance [5]. The problems of multicollinearity and the "curse of dimensionality" are avoided by only using a few features. The total count of features present in the given dataset can be decreased with the use of FS and reduction techniques.

The overall performance of ML classifiers will suffer from high data dimensionality and the presence of redundant, noisy, and irrelevant data. These features may be selected to decrease dimensionality and improve ML algorithm performance. Additionally, FS helps researchers and programmers comprehend the data on its own and focuses on the most significant and relevant features. The performance of SDP systems can be improved by FS algorithms, according to several research publications in the literature.

Dealing with huge datasets can be challenging for the classification process due to their high dimensionality. Because of this, utilizing the most useful features possible while also optimizing classification accuracy, FS pre-processing is a must for lowering the dimensionality of datasets. The FS for classification issues based on wrapper techniques is addressed in this study using a novel Grey Wolf Optimizer (GWO) procedure, including two phases of mutation [6].

The most useful features from the actual dataset can be chosen using a variety of FS techniques. Wrapper, filter, and embedded FS techniques fall within this category. Wrapper methods evaluate the chosen subset of characteristics using a classification procedure.

The filter approach assesses the chosen features according to the different aspects of the dataset. The filter methods are more rapid than the wrapper approach because the wrapper approach serves no purpose in assessing the classifier accuracy. As opposed to the filter technique, the improved set of features which correspond with the classifier may be obtained through the wrapper technique. Low computational cost is a benefit of hybrid approaches; however, they are often machine learning-specific. The two objectives that FS must accomplish are reducing the size of the feature pool and greater accuracy in classification.

Finding an ideal subset of features is crucial in FS [7]. By analyzing the whole collection of features, the exhaustive search can create all potential subsets. Due to the fact that there are 2M subsets of features for a dataset with M features, this method is unfeasible for big datasets and has an extraordinarily high computational cost. In the last two decades, metaheuristics approaches have proven to be productive and effective in resolving complex and large-scale issues in applications based on Machine Learning (ML) and data mining [8]. Metaheuristics drawn from nature comprise the majority of nature-inspired algorithms. Two contrasting factors are frequently used when employing these algorithms: intensification (using the most effective solutions found) and diversity (investigation of the search area). Swarm algorithms have recently been proposed and demonstrated to perform admirably for FS problems. Most of the metaheuristic algorithms suffer from local optimum, lack of diversity of the search, and imbalance between the explorative or the exploitive capabilities of the algorithm [6].

Given the challenges that can hinder effective feature selection, we were motivated to develop a method that leverages the Grey Wolf Optimizer algorithm GWO. This approach addresses the issues associated with feature selection and aims to find more efficient solutions. The Grey Wolf Optimizer algorithm has demonstrated notable success across various applications, making it a strong candidate for this purpose.

To address the issues of local optima and limited diversity, the proposed algorithm incorporates a two-phase mutation operation (2M-GWO) to enhance its performance. This mutation operation is designed to improve the algorithm's exploitation capabilities, resulting in more effective and diverse solutions.

The following are the key contributions of our work:

- We propose a novel prediction model based on the 2M-GWO algorithm and five ML classifiers for SDP, which will select the most promising features and enhance the predictive capability of the prediction model. To the best of our knowledge, this model has never been employed for SDP.
- The performance of the proposed SDP model is assessed using 27 publicly available datasets to ensure the generalizability of the results. The investigation aimed to determine the impact of the improvements in 2M-GWO on optimization performance and robustness.
- A number of comparisons are made on the Receiver Operating Characteristic Area Under Curve (ROC_AUC) value using statistical concepts such as mean value and Friedman test. These methods offer a robust assessment of algorithm performance across different scenarios, providing insight into average ROC_AUC results and identifying significant variations among the compared algorithms.
- The proposed model based on the 2M-GWO algorithm is evaluated against five other metaheuristics techniques (Harris Hawks Optimization (HHO), Salp Swarm Optimization (SSO), Whale Optimization (WO), Jaya Optimization (JO), and Sine Cosine Optimization

(SCO)), and experimental results demonstrated its superiority over competing algorithms.

The organization of the research paper is as outlined: The review of the past literature is covered in Sect. 2, which discusses the various methodologies that have been used for SDP using evolutionary FS methods. In Sect. 3, the proposed SDP model based on 2M-GWO for FS is described. Section 4 covers the simulated results of the proposed model, along with qualitative and comparative analysis using statistical tools. Finally, Sect. 5 contains the conclusion and suggestions for future work.

2 Related work

The effectiveness of SDP models was examined in recent studies to determine how evolutionary FS techniques affected their performance. Table 1 presents a detailed description of existing literature related to the use of metaheuristic techniques in SDP.

3 Proposed methodology

To solve the SDP issue, we developed a wrapper strategy based on an enhanced version of the GWO algorithm. Figure 1 explores the mechanism of the suggested algorithm. A tenfold cross-validation (10-CV) procedure is performed at each iteration. Initially, the algorithm applies GWO on the SDP dataset. Using the 10-CV method, the chosen dataset is subdivided at each iteration. The SMOTE mechanism is used to resolve the unbalanced problem of the dataset on which the model should be trained. This procedure will generate a training dataset using oversampling. Five distinct classifiers (i.e., SVM, RF, GB, AB, and KNN) are used to construct an SDP model, which is then assessed using K-Fold = 10. The suggested method terminates whenever the best solution in terms of the objective function is attained, or the value of iterations reaches its maximum value. The model is shown in the following points.

3.1 Dataset

Defects are faults or errors that have been made in the past when developing software systems. These inaccuracies are used to forecast the likelihood of a fault or the total number of defects. Statistics on software defects can clearly show which software modules or components are particularly susceptible to faults. These undesirable defects can occur at many software systems levels and in a variety of granularities. Software metrics and developer information make up the majority of the data in software defect databases. Software attributes may be divided into process, product, and requirements attributes.

For this study's defect datasets, data from four different sources were collected (NASA, PROMISE, RELINK, and AEEEM). This study made use of the NASA dataset as it was created by Shepperd, et al. The NASA datasets include metrics generated from static code parts that take into account the size and complexity of the code [9]. Projects from the PROMISE repository are based on features that are gathered at the class level for object-oriented software and information about defects found in software components. This dataset was developed using the JAVA programming language and was retrieved from the Apache software [10]. The open-source RELINK dataset comprises three open-source projects (Apache HTTP, Safe, and Zxing) and has a total of twenty-six attributes [11].

AEEEM datasets differ from other data [12] as they include software attributes from source code measurements. The change metrics, entropy, and churn of source code metrics form the foundation of source code metrics. These datasets are obviously dependent on various software features. The datasets details are mentioned in Table 1.

3.2 Feature selection using 2M-GWO

3.2.1 Grey wolf algorithm (GWO)

Grey wolves (GWs) are superb predators with exceptional hunting abilities. This is due to the fact that they live in a disciplined and orderly pack. The GWO algorithm was recently presented to imitate the hunting, seeking, and surrounding behaviour of GWs [13]. There are four main varieties of GWs with varying levels of dominance and leadership in the wolf population (Table 2). The first, second, and third-best solutions in the GWO method are denoted by the letters α β and δ, correspondingly. The rest of the possible solutions are referred to as ω.

The hunting mechanism in GWO involves three main steps: encircling the prey, hunting (attacking), and searching for prey. These steps are mathematically modelled as follows:

Encircling Prey The wolves encircle the prey during the hunt. This behaviour is modelled using the position vectors of the prey and the wolves. The position of each wolf is updated according to the position of the prey using the following equations:

$$D_v = |C_v.X_v p - X_v(t)| \quad (1)$$

$$X_v(t+1) = X_v p(t) - A_v \cdot D_v \quad (2)$$

$$A_v = 2a_v \cdot random_{v1} - a_v \tag{3}$$

$$C_v = 2 \cdot random_{v2} \tag{4}$$

$$a = 2 - t\left(\frac{2}{iterations}\right) \tag{5}$$

Here, $X_v(t)$ represents the position vector of a wolf at iteration t, $X_v p(t)$ represents the position of the prey. C_v and A_v are coefficient vectors. The parameter *iterations* determine the maximum number of iterations. The $random_{v1}$ and $random_{v2}$ are random vectors, whereas a_v decreases linearly from 2 to 0 over the course of iterations.

Attacking the Prey The alpha (best solution), beta, and delta wolves have better knowledge about the potential location of the prey. Therefore, the positions of the other wolves (omegas) are updated based on the positions of the alpha, beta, and delta wolves:

$$X_v(t+1) = \frac{X_{v1} + X_{v2} + X_{v3}}{3} \tag{6}$$

Here X_{v1}, X_{v2} and X_{v3} are the positions of the alpha, beta, and delta wolves, respectively, updated using similar equations to the encircling mechanism but cantered around each of these three wolves.

Searching for Prey To simulate the search for prey, the wolves diverge from each other and explore the search space. This is modelled by allowing the random vectors $random_{v1}$ and $random_{v2}$ to take values that can potentially increase the distance between the position of a wolf and the position of the prey.

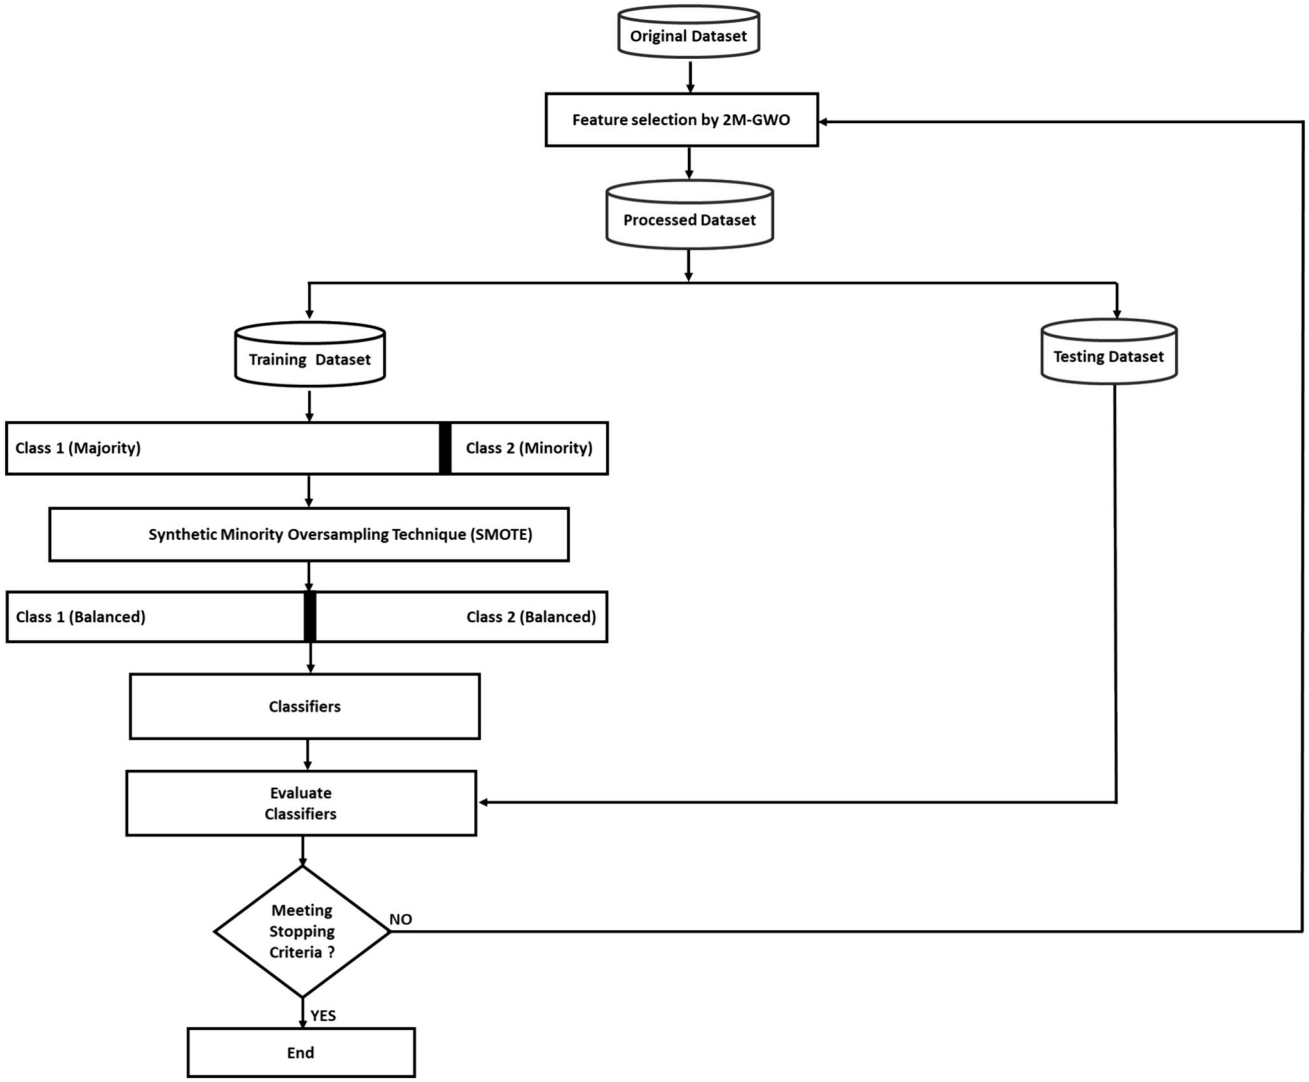

Fig. 1 Proposed methodology

Although the standard GWO is known for its effectiveness in various optimization tasks, but it faces challenges such as premature convergence and getting trapped in local optima when dealing with complex feature selection problems.

To address these challenges, the authors propose a two-phase mutation mechanism integrated into the GWO. This enhancement aims to improve the exploitation capabilities of the algorithm, making it more effective in navigating the search space of feature selection problems.

3.2.2 Two-phase mutation grey wolf optimisation (2M-GWO)

The Two-Phase Mutation Grey Wolf Optimizer (TMGWO) is an enhanced version of the standard GWO, specifically adapted for feature selection problems in classification tasks. This enhancement integrates a two-phase mutation mechanism to improve the exploitation capabilities of the algorithm, making it more effective in navigating the complex search space of feature selection problems. The benefits of using two mutation phases are as follows.

First Mutation Phase This phase aims to reduce the number of selected features while maintaining high classification accuracy. It selectively mutates certain features of the best solution (alpha wolf), turning some of the selected features off (from 1 to 0).

Second Mutation Phase This phase attempts to add potentially informative features that could increase classification accuracy. It operates by turning some unselected features on (from 0 to 1) based on their potential to improve the solution.

This 2M-GWO algorithm includes four steps: Initialization (step 1), evaluation (step 2), transformation

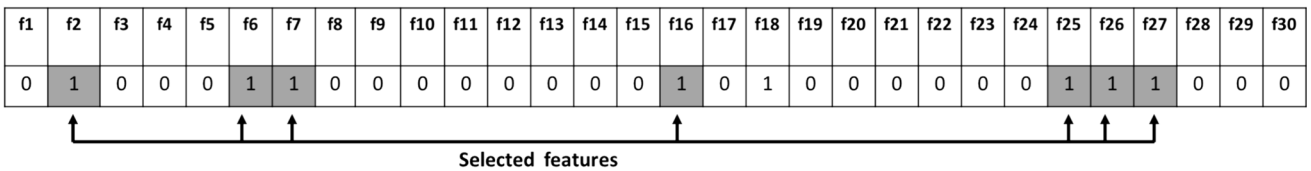

Fig. 2 Solution representation of 2M-GWO

function (step 3), and two-phase mutation (step 4) make up the core components of 2M-GWO.

Initialization The first step is to initialize a colony of "n" GWs or search agents (SA) generated randomly. Each SA represents a potential solution and has a size of "d" equal to the number of attributes in the actual dataset [14]. For classifying classes, the FS is used to identify the subset of features that produce the most accurate results. This is achieved by setting some features to "1" (selected) and others to "0" (not selected), as shown in Fig. 2. At the start; each solution is represented by binary values of either "0" or "1".

Evaluation The FS has multiple objectives since it must achieve two goals: reduce the count of features that must be selected and increase the classifier's accuracy. To achieve this balance, the fitness function is designed to evaluate the solutions and meet both objectives simultaneously in Eq. (7), where $\gamma_R(D)$ represents the rate of classification error of R, the condition attribute set in respect to decision D, which is computed via the ML classifier KNN.

$$fitness = \alpha\gamma_R(D) + \beta\frac{|s|}{|d|} \tag{7}$$

The span of the chosen attribute subset's cardinality is represented by the symbol |s|. Each sample of the actual dataset that contains features is represented by a cardinality of |d|. α and β are the two constraints of weight, which are equivalent to the value of the classification_accuracy and

Algorithm 1 The proposed 2M-GWO

Inputs: n, Number of grey wolves in the population.
iterations, maximum number of iterations.

1. Initialize a population of n grey wolves Xi, $i = 1$ to n
2. Initialize parameters a, A, and C
3. Calculate the fitness of each grey wolf
4. Assign the best three grey wolves to $X\alpha$, $X\beta$, and $X\delta$ respectively
5. Set $t = 0$

6. while $t <$ *iterations* do
   for each grey wolf Xi do
      Update the position of Xi using Eq. (6)
   end for
   Update parameters a, A, and C
   Convert the position of grey wolves to binary using Eq. (8) and Eq. (9)
   Calculate the fitness of all grey wolves
   Update the best three grey wolves $X\alpha$, $X\beta$, and $X\delta$
   Apply two-phase mutation to $X\alpha$ and update its fitness
   Increment t by 1
end while

return the best grey wolf $X\alpha$

Output: The best grey wolf $X\alpha$

the length of the subset of the chosen feature, $\alpha \in [0,1]$ and $\alpha + \beta = 1$. The evaluation function will overlook results that could have the equivalent accuracy but use fewer attributes, which is a key component in reducing the dimensionality problem if it solely considers classification accuracy.

Transformation function

The GW's positions produced by the typical GWO are continuous in nature. Since it conflicts with the binary structure of the FS, it cannot be as it is applied to our case. Since the issue with FS arises from picking (1) or ignoring (0) the advantageous attributes that improve the capability of the classifier. The task of changing the continuous value of the search space to binary values is performed by the transformation function (TF). The TF used in this study is an S-shaped sigmoidal function [15].

Conversion of binary values to continuous values is done by using the following Eqs. (8) and (9) of the sigmoidal transformation function:

$$x_i = \frac{1}{1 + e^{-x_i}} \tag{8}$$

$$x_{binary} = \begin{cases} 0 \; if \; rand < x_i \\ 1 \; if \; rand \geq x_i \end{cases} \tag{9}$$

where x_i depicts the continuous value of the feature, the value of i varies from 1 to d, x_{binary} can have a value of 0 (not selected) or 1 (selected) on comparing the x_i with a random value *rand.*

Two-phase mutation

A mutation operator is utilized to enhance the performance of the proposed algorithm. In the initial phase of mutation, the primary objective is to reduce the number of selected attributes while preserving high classification accuracy [13]. The subsequent phase focuses on improving classification efficacy by introducing more nuanced attributes. To mitigate delays that may arise from the mutation operator, step 4 can be executed with a mutation probability (Mp). This approach optimizes the mutation process, allowing for controlled adjustments without compromising efficiency.

Algorithm 1 provides the detailed pseudocode for the proposed mutation process. Additionally, the complete pseudocode for the 2M-GWO algorithm, incorporating both mutation and other key components, is outlined in Algorithm 2.

In Algorithm 2, $X\alpha$, $X\beta$, and $X\delta$ represent the positions of the best three grey wolves (alpha, beta, delta), which

Algorithm 2 Two-Phase Mutation

Input: Xα: the best grey wolf from each iteration

1. Calculate the fitness of Xα and store it as *fitness*
2. Initialize *one_positions* to store the indices of selected features in $X\alpha$
3. Set $Xmutated1 = X\alpha$

// First Mutation Phase
4. for each index *i* in *one_positions* do
   Generate a random number r
   if $r < Mp$ then
      Set *Xmutated*1 [*i*] = 0
      Calculate the fitness of *Xmutated*1 and store it as *fitness_mutated*
      if *fitness_mutated* < *fitness* then
         Set *fitness* = *fitness_mutated*
         Set $X\alpha$ = *Xmutated*1
      end if
   end if
end for

// Second Mutation Phase
5. Initialize *zero_positions* to store the indices of unselected features in $X\alpha$
6. Set $Xmutated2 = X\alpha$

7. for each index *j* in *zero_positions* do
   Generate a random number *r*
   if $r < Mp$ then
      Set *Xmutated*2 [*j*] = 1
      Calculate the fitness of *Xmutated*2 and store it as *fitness_mutated*
      if *fitness_mutated* < *fitness* then
         Set *fitness* = *fitness_mutated*
         Set $X\alpha$ = *Xmutated*2
      end if
   end if
end for
return $X\alpha$

Output: The improved $X\alpha$

guide the search process. *Xi* denotes the position of the i^{th} grey wolf. *Fitness* is the variable which shows the fitness value of *Xα*. *one_positions* is avector storing the positions of selected features in Xα, and *zero_positions* store the positions of unselected features in Xα.

Computational complexity of the 2M-GWO technique The overall computational complexity of the algorithm primarily pivots on the number of iterations t, the number of Grey Wolves n, the dimensionality d of each wolf, and the complexity f of the fitness evaluation function. The computational complexity expression, $O(t \times n \times (d + f))$, suggests that the algorithm scales linearly with the number of iterations and the number of wolves but also depends linearly on the sum of the dimensionality and the complexity of the fitness function. This indicates that while the algorithm can handle moderate sizes efficiently, large values or complex fitness functions could significantly increase computational demands.

3.3 Classifiers

The literature has a number of learning classifiers. As a result, we restrict our research to using only five distinct classifiers:

3.3.1 Support vector machine (SVM)

It aims to find the best hyperplane in a high-dimensional space that can successfully separate different classes. The hyperplane is defined by a set of parameters that are optimized during training to maximize the margin between the hyperplane and the closest data points from each class. One of the main advantages of SVM is its ability to handle high-dimensional data and small sa_{mp}le sizes [16].

3.3.2 Random forest (RF)

This is an example of an ensemble learning method used for classification, which involves creating multiple Decision Trees at training time and then combining the outputs of these trees to make a final decision. RF uses a bagging technique to train each DT on a random subset of the data used for training, which reduces overfitting and improves the generalizability of a model [17].

3.3.3 Gradient boosting (GB)

This is an ML technique that is commonly used for classifying software into defective and non-defective modules. It involves accumulating weak decision trees to a model on a recurring basis, with each new tree fitting the residual errors of the preceding tree. The model then makes a final decision by merging the outputs of all of the trees in the model. Gradient boosting can be used with a variety of loss functions, allowing it to handle a range of classification problems [18].

3.3.4 AdaBoost (AB)

The AB is also known as adaptive boosting, which trains a sequence of weak classifiers on the same dataset. Each subsequent classifier is trained to give more weight to the samples that were misclassified by the previous classifiers. Finally, the algorithm combines the predictions of all the weak classifiers to make a final prediction [10].

3.3.5 K-nearest neighbour (KNN)

The KNN works on the distance-based phenomenon. It is a non-parametric algorithm and is not dependent on the distribution of the given dataset. The KNN algorithm works by first training on a labelled dataset, and then using the learned information to classify new, unlabelled data points based on their resemblance to the training examples. The KNN algorithm determines the similarity between data points by calculating the distance among them, often using Euclidean distance [19].

3.4 Evaluation method

To assess the model's performance and facilitate result comparison, we employ ROC_AUC. It is a graphical tool that assesses a binary classifier's effectiveness by varying the discrimination threshold value. Ranging from 0 to 1, a score of 1 indicates a flawless classifier, while 0.5 signifies performance no better than random chance. The ROC_AUC curve illustrates the True Positive Rate (TPR) against the False Positive Rate (FPR) across different threshold values [20]. The True Positive Rate (TPR) is computed by dividing the number of correctly identified positive instances by the total number of positive instances, whereas the False Positive Rate (FPR) is determined by dividing the number of incorrectly identified positive instances by the total number of negative instances [21].

A high ROC_AUC value indicates that the classifier is able to distinguish between positive and negative cases well, while a low ROC_AUC value indicates poor performance. ROC_AUC is a popular evaluation metric other than accuracy in machine learning because it is insensitive to imbalances in class distribution and is well-suited for imbalanced datasets. Additionally, the ROC_AUC can be used to compare the performance of different classifiers.

3.5 Parameter setting

To address the stochastic character, each algorithm is performed 20 times independently using a random seed. The maximum number of iterations for all subsequent tests is set at 100. There are 5 SA in the entire population. Additionally, 10-CV is used in this case. In order to choose the optimal values for $\propto$ and β and based on certain values collected from past studies, several tests are carried out on various datasets. As a consequence, $\propto$ and β are set to corresponding values of 0.01 and 0.99. To enable a fair comparison of the algorithms, the parameter specifications of the techniques are collected from the existing studies. The parameters of some of the optimization techniques are mentioned in Table 3. For all other techniques, the default value is taken.

3.6 Statistical test

In software defect prediction, the Friedman test is often employed to evaluate and compare the effectiveness of various defect prediction models or techniques. This is crucial because software defect prediction models are designed to predict the likelihood of defects in software modules, and choosing the most effective model can significantly impact the quality and reliability of software.

Table 3 Parameter settings for optimization techniques

Technique	Parameter	Value
2M-GWO	Mutation probability, Mp	0.5
SCO	Constant value, a	2
WO	Spiral coefficient, b	1

The Friedman test serves as a non-parametric statistical method utilized for identifying variations among treatments across numerous test iterations. In the context of software defect prediction [22], it is particularly useful because it allows researchers to compare the performance of different prediction models or methods over multiple datasets without assuming a normal distribution of the data.

4 Result analysis

This subsection provides the findings in response to the Research Questions (RQ) as follows:

RQ 1 What is the effect of FS techniques on the SDP models? Does 2M-GWO significantly improve the performance of SDP models as compared to GWO and WFS Models?

Tables 4, 5, 6, 7, 8 and 9 explores the experimental results of the original GWO, modified 2M-GWO and WFS model for 27 datasets using five classifiers, namely SVM, RF, GB, AB and KNN. The experimental data include the feature size and ROC_AUC value for each dataset. We employed SMOTE to balance the classes in the given dataset. The ROC_AUC value for 27 open-source datasets is obtained by taking the average value of 20 runs for each project.

The data presented in Table 4 clearly demonstrates that the 2M-GWO algorithm outperforms the other two algorithms, showing promising results in terms of ROC_AUC values across a majority of projects. Analysis of average ROC_AUC values indicates that the modified 2M-GWO algorithm surpasses the original GWO and WFS methods, with a maximum average value of 0.785. Furthermore, the proposed algorithm, in conjunction with SVM, significantly improved average ROC_AUC values by over 6% across all datasets, demonstrating strong overall performance.

Table 5 illustrates the results of the RF classifier utilized to evaluate the original GWO, the modified 2M-GWO, and the complete dataset. It is evident that the 2M-GWO algorithm outperforms the other two methods, as it demonstrates the highest ROC_AUC values across a larger number of projects. The enhanced 2M-GWO surpasses the original GWO and WFS techniques in terms of average ROC_AUC values, with a maximum average value of 0.8. The average ROC_AUC value for all datasets saw an increase of approximately 2% when utilizing the proposed algorithm.

The ROC_AUC value calculated by Gradient Boosting (GB) for the full dataset and processed datasets, in which features were selected GWO and 2M-GWO, is presented in Table 6. The results indicate that the 2M-GWO-based model demonstrates superior performance compared to the GWO and WFS cases, with an average improvement of 2.3% in the ROC_AUC value. In approximately 40% of datasets, the 2M-GWO-based model outperformed the others, while in approximately 19% of datasets, its performance was comparable to either the GWO-based model or the full dataset.

Table 7 presents the computed ROC_AUC value by AB for the entire datasets and the processed datasets, where the

features were selected by GWO and 2M-GWO. It is observed that the 2M-GWO-based model outperforms the GWO and WFS case in terms of overall performance, with an average ROC_AUC value improvement of 4.6%. Specifically, for approximately 33% of the datasets, the 2M-GWO-based model performs better, while for around 11% of the datasets, it performs similarly to either of the two approaches.

According to the data presented in Table 8, the 2M-GWO-KNN demonstrates superior classification performance compared to the other model in over 50% of the datasets, as indicated by the ROC_AUC value. The average ROC_AUC value for the overall performance of 2M-GWO shows an increase of approximately 4% when compared to the other two models.

Based on the analysis presented in Table 9 and Fig. 3, on taking an average value, the 2M-GWO algorithm achieved an approximate 80% reduction in feature sets across various datasets. The NASA dataset showed the most significant reduction at around 86%, followed by the AEEEM and RELINK datasets, which saw an 80% reduction each. In contrast, the PROMISE dataset had the smallest reduction in features at 75%.

Table 10 presents the comparative performance of different feature selection techniques based on their mean rank achieved by Friedman's test, determined through the ROC_AUC metric. The mean rank serves as a measure of each technique's efficacy in enhancing the prediction accuracy of a software defect prediction model. A lower mean rank indicates better performance. The p-value associated with these rankings is 0.022, suggesting that the differences in performance among these techniques are statistically significant at the 95% confidence interval. 2M-GWO stands out as the most effective technique, achieving the highest performance with a mean rank of 1.00, denoted as rank I. GWO is ranked second with a mean rank of 2.40,

labelled as rank II. This shows that the standard Grey Wolf Optimiser, while effective, is outperformed by its two-phase variant in the context of feature selection for defect prediction. WFS is closely ranked third with a mean rank of 2.60, marked as rank III.

Summary: RQ1 reveals that it is apparent that the 2M-GWO method is an effective approach for reducing feature size while maintaining model performance for SDP for all five datasets. The 2M-GWO technique emerges as the most effective approach, achieving the highest level of performance with a mean rank of 1.00. Additionally, the 2M-GWO algorithm facilitated an average reduction of approximately 80% in feature sets across multiple datasets

RQ 2 Which is the best-performing ML technique for predicting software defects?

Table 11 displays the mean ranks obtained by the Friedman's test on the basis of ROC_AUC for the ML techniques used in the study. 2M-GWO-RF achieved the best mean rank of 2.19, indicating its superior performance in terms of prediction accuracy and efficiency. 2M-GWO-KNN attained a mean rank of 2.94, placing it second in terms of performance. While it is not as effective as 2M-GWO-RF, it still demonstrates good performance and is viable with a mean rank of 3.15; SVM, along with 2MGWO, is ranked third in terms of performance. AB and GB are the ensemble classifiers with a mean rank of 3.35 and 3.37, ranking fourth and last among the classifiers evaluated. The p-value of 0.034 indicates that the differences in the mean ranks of these techniques are statistically significant. Overall, the combination of 2M-GWO and

Random Forest (2M-GWO-RF) appears to offer the best performance among the tested classification techniques.

Summary: From RQ 2, it is evident that the combination of 2M-GWO and Random Forest (2M-GWO-RF) is the best-performing machine-learning technique for predicting software defects, as indicated by its superior mean rank of 2.19

RQ 3 Which software metrics are frequently selected using the proposed algorithm?

The analysis of feature selection across various datasets using the 2M-GWO FS technique is detailed in Figs. 4, 5, 6 and 7. These figures graphically represent the selection frequency of specific software metrics (features) crucial for predicting software defects. The x-axis of each figure indicates different software metrics derived from the

Table 10 Mean Rank obtained on the basis of ROC_AUC for feature selection technique

Techniques	Mean rank (p value = 0.022)
2M-GWO	1.00 (I)
GWO	2.40 (II)
WFS	2.60 (III)

Table 11 Mean Rank obtained on the basis of ROC_AUC for ML techniques

Classification Techniques	Mean rank (p value = .034)
2M-GWO-RF	2.19 (I)
2M-GWO-KNN	2.94 (II)
2M-GWO-SVM	3.15 (III)
2M-GWO-AB	3.35 (IV)
2M-GWO-GB	3.37 (V)

datasets, while the y-axis quantifies how frequently each metric was selected across multiple iterations.

For the RELINK dataset (Fig. 4), metrics such as CountLineCodeDecl, CountLineBlank, and CountLineCode show high selection frequencies of 26, 21, and 20 times, respectively, out of 60 total runs distributed across three projects (each executed 20 times). In the case of the PROMISE dataset (Fig. 5), the object-oriented metrics rfc, ce, and npm were selected 131 and 102 times each out of 280 iterations. Regarding the AEEEM dataset (Fig. 6), which includes 61 process metrics across five projects, metrics such as CVSEntropy, numberOfNontrivialBugsFoundUntil, and Ck OO numberOfMethodsInherited were most frequently selected, with counts of 49, 45, and 41 respectively, out of 100 runs. For the NASA project (Fig. 7), which focuses on Halstead's and size metrics, the metrics LOC CODE AND COMMENT, LOC BLANK, and LOC EXECUTABLE were identified as the most frequently occurring, with each being selected 28, 25, and 25 times respectively in twenty runs across five projects.

Summary: Analysis from RQ3 reveals key patterns in metric selection across different datasets. For the RELINK dataset, metrics such as CountLineCodeDecl, CountLineBlank, and CountLineCode were consistently chosen. In the PROMISE dataset, the most frequently selected metrics were object-oriented measures, including rfc, ce, and npm. In the AEEEM dataset, encompassing 61 process metrics across five projects, CVSEntropy, numberOfNontrivialBugsFoundUntil, and Ck OO numberOfMethodsInherited were the metrics most often chosen. In the NASA project, which focuses on Halstead's size metrics, LOC CODE AND COMMENT, LOC BLANK, and LOC EXECUTABLE were the most prominent metrics. The frequent selection of these metrics underscores their importance in the defect prediction process, suggesting that they provide valuable insights into software quality and should be considered in data collection for future projects

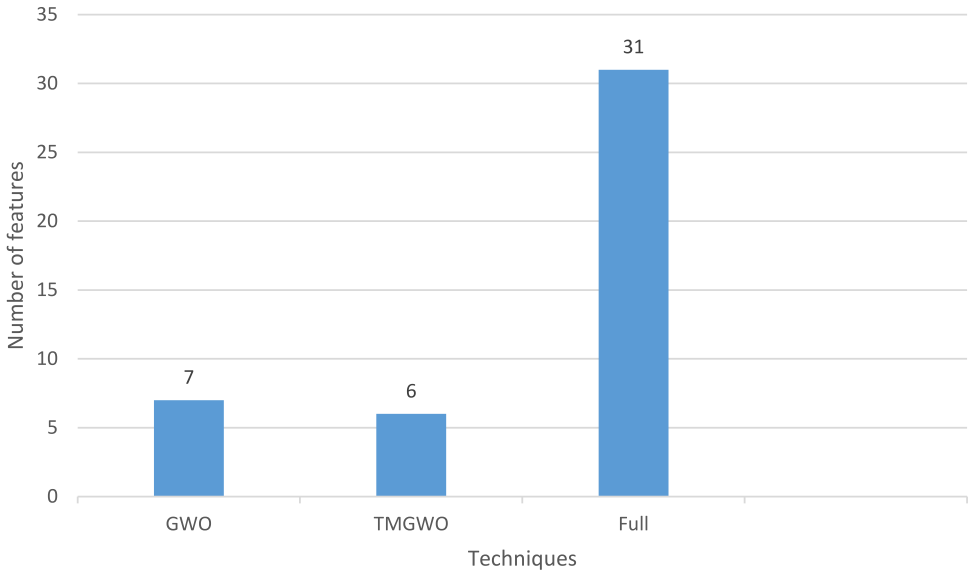

Fig. 3 Comparison of feature selection techniques on the basis of the number of features selected

RQ 4 What is the predictive performance of the proposed model as compared to other benchmark FS models for SDP?

In order to conduct a comprehensive comparative analysis, two types of analysis are made.

In first type, the proposed algorithm is evaluated against five closely related meta-heuristic algorithms: Harris Hawks Optimization (HHO) [23], Salp Swarm Optimization (SSO) [24], Whale Optimization (WO) [25], Jaya Optimization (JO) [26], and Sine Cosine Optimization (SCO) [27]. These comparisons, summarized in Table 12, were carried out under consistent experimental conditions to ensure fairness and accuracy in the results. Each algorithm was implemented and executed within the same computational environment, adhering to identical parameter settings. This approach facilitated direct comparisons and minimized variations that could arise from differing configurations. The ROC_AUC measure was used as the primary basis for evaluating performance across all algorithms, as it provides a comprehensive measure of an algorithm's ability to distinguish between classes or optimize solutions effectively. By examining the AUC scores, we analyzed the fact that the proposed technique outperforms the other techniques in approximately 55.5% of the total datasets. SSO obtained a promising outcome in approximately 18.5% of the datasets. HHO and WO resulted in the best ROC_AUC value for two datasets, whereas SCO and JO outperformed for only one dataset each. This showcases the effectiveness of the proposed method in selecting the most pertinent features, which notably boost the performance of the SDP model.

In the second type, the performance outcomes of established approaches are sourced from existing literature and subjected to a thorough comparison. In the RKEE-based model, Riaz et al. [28] proposed two-stage data preprocessing which incorporates FS and a new rough set Easy Ensemble scheme, which shows an average value of 0.771, whereas the existing model proposed by Tumar et al. [29] was based on improved binary Moth Flame Optimization with Adaptive synthetic sampling (ADASYN) to predict software defects. BMFO is employed as a wrapper FS, while ADASYN enhances the input dataset, addresses the imbalanced dataset and shows a ROC_AUC value of 0.7552. When compared with the existing methods based on evolutionary FS techniques, the proposed model based on 2M-GWO and Random Forest classifier obtained a ROC_AUC of 0.800, which is better than the existing methods.

Summary: Research Question 4 demonstrates that the proposed model, integrating 2M-GWO with Random Forest, surpasses the performance of five related metaheuristic techniques in more than 55% of the datasets. Furthermore, it exhibits competitive results when evaluated against current state-of-the-art approaches

5 Threats to validity

This section explores the potential threats to the validity of the study and outlines its limitations.

5.1 Internal validity

To ensure internal validity, we have used a modified version of the GWO algorithm, which incorporates a two-phase mutation operation to improve the algorithm's exploitation capability. We have used a sigmoid function to transform the continuous search space to a binary one, matching the binary nature of feature selection. We have also employed a two-phase mutation to reduce the number of selected features while preserving high classification accuracy.

5.2 External validity

The external validity pertains to the degree to which the findings of an empirical study can be generalized and applied beyond the specific conditions of the study. In this research, the proposed algorithm's performance was assessed across 27 datasets. This wide range of datasets ensures the generalizability of the results to various types of datasets and classification problems.

5.3 Construct validity

Construct validity ensures that both independent and dependent variables accurately represent the intended concepts. This paper does not encounter any threats to construct validity, as the predictors utilized in the study are commonly employed in predictive modelling within the domain of software engineering.

5.4 Conclusion validity

This concerns the degree to which the conclusions drawn in the study are robust. Statistical analyses were conducted to validate the efficacy of the proposed algorithm and its superiority. This encompassed comparative assessments between the proposed algorithm and other metaheuristic algorithms, with the results subjected to statistical scrutiny employing the Friedman Test and Wilcoxon Signed Rank Test.

The study is limited to the use of public/open-source datasets, which can lead to constraints in terms of the generalizability of the SDP model's findings to a broader range of software applications, particularly those in the industrial sector. Open-source projects typically exhibit notable differences from proprietary or industrial projects in terms of development methodologies, team compositions, and code standards. These differences can impact the effectiveness of our proposed work when applied to industrial/proprietary software projects. In future, we aim to use the proposed SDP model for proprietary datasets from several industries to evaluate its predictive performance and improve the model for wider applicability.

6 Conclusion and future work

In this study, we proposed a prediction model based on 2M-GWO for SDP, which incorporates FS to enhance the quality of the ML techniques, i.e., SVM, AB, GB, NB and KNN, are used for the classification of the binary class dataset. We systematically designed the experiments based on 27 datasets from AEEEM, PROMISE, RELINK and NASA datasets. The key findings of the study are as follows:

- The proposed two-phase Grey Wolf Optimizer-based feature selection method, paired with the Random Forest classifier (2M-GWO-RF), effectively enhances software defect prediction (SDP). By reducing feature size, the 2M-GWO method improves model performance across multiple datasets and supports the accurate identification and removal of redundant and irrelevant features.
- The 2M-GWO-RF model achieves superior results, ranking highest in terms of ROC_AUC with a mean rank of 2.19, demonstrating exceptional prediction accuracy and efficiency (RQ2).
- Statistical analysis using Friedman's test confirms the significance of the mean rank differences ($p = 0.034$), validating 2M-GWO-RF as the top classification technique.
- The proposed model's robustness is evident through its focus on key metrics across various datasets, including CountLineCodeDecl, rfc, ce, npm, CVSEntropy, and LOC CODE AND COMMENT, among others, indicating its potential for future data collection and analysis.
- The 2M-GWO-RF model outperforms five related metaheuristic techniques in over 55% of the datasets, showcasing its superior choice in comparison to state-of-the-art approaches.

The study concludes that the two-phase Grey Wolf Optimizer with Random Forest classifier (2M-GWO-RF) significantly enhances software defect prediction by

offering superior feature selection and high prediction capability.

A Single Bitline Highly Stable, Low Power With High Speed Half-Select Disturb Free 11T SRAM Cell

LOKESH SONI, Delhi Technological University, Delhi, India
NEETA PANDEY, Delhi Technological University, Delhi, India

A half-select disturb-free 11T (HF11T) static random access memory (SRAM) cell with low power, better stability and high speed is presented in this paper. The proposed SRAM cell works well with bit-interleaving design, which enhances soft-error immunity. A comparison of the proposed HF11T cell with other cutting-edge designs such as single-ended HS free 11T (SEHF11T), a shared-pass-gate 11T (SPG11T), data-dependent stack PMOS switching 10T (DSPS10T), a single-ended half-selected robust 12T (HSR12T), and 11T SRAM cells has been made. It exhibits 4.85×/9.19× less read delay (T_{RA}) and write delay (T_{WA}), respectively as compared to other considered SRAM cells. It achieves 1.07×/1.02× better read and write stability, respectively than the considered SRAM cells. It shows maximum reduction of 1.68×/4.58×/94.72×/9×/145× leakage power, read power, write power consumption, read power delay product (PDP) and write PDP respectively, than the considered SRAM cells. In addition, the proposed HF11T cell achieves 10.14× higher I_{on}/I_{off} ratio than the other compared cells. These improvements come with a trade-off, resulting in 1.13× more T_{RA} compared to SPG11T. The simulation is performed with Cadence Virtuoso 45nm CMOS technology at supply voltage (V_{DD}) of 0.6 V.

Additional Key Words and Phrases: Single-bitline SRAM, half-select disturb-free, read and write delay, read static noise margin (RSNM), hold static noise margin (HSNM) and write ability, power consumption, I_{on}/I_{off} ratio

1 Introduction

Power dissipation has emerged as a crucial design constraint due to the rise in demand for low power devices pertaining to wireless sensor networks, biomedical devices, and other battery-operated portable devices. The power dissipation in Systems-on-Chip (SoCs) is primarily influenced by Static Random Access Memory (SRAM) since it occupies a significant portion of the chip. Moreover, the proportion of SRAM is expected to increase even more in the future [1]. Therefore, designing of low power SRAM cell is important. To extend the battery life in SRAM cells and reduce power dissipation, the most efficient approach is to decrease the supply voltage (V_{DD}). This downscaling of V_{DD} proves to be the most effective method. The reason behind this is that, standby power decreases exponentially and dynamic power decreases quadratically as the V_{DD} is reduced [2]. However, process variation significantly limits the performance of the SRAM cell at lower supply voltages. Therefore, it is challenging to maintain the device strength ratio in conventional 6T SRAM cell leading to read/write stability issue at low V_{DD} [3]. Various SRAM cells have been proposed to address the read stability issue [4-9]. These cells provide significant improvements in read static noise margin (RSNM) by employing the separate read/write path, but they have poor write margin and more power consumption [4-7,9] due to the presence of dual bitline. Additionally, a number of write-assist methods have been discussed in the literature to boost the SRAM cell's

write ability [10-12]. Wordline (WL) boosting [10], [11], and negative bitline (NBL) [12] are popularly used write assist methods for enhancing the write ability. On the other hand, soft errors become more prominent with the technology scaling, that affect the stability of a cell [13]. To overcome this a bit-interleaving architecture is commonly used. However, this method is applicable to the cells that are fully half-select (HS) free in nature. In order to address HS issue, different approaches have been suggested, by employing the two distinct wordlines (WLs) [14-20]. Though, the use of serially coupled transistors in the write path, the designs from [14-20] have poor write ability. As a result, various write-assist strategies, like WL boosting or negative BL, are necessary for effective write operation, but these techniques having a large area overhead and more dynamic power consumption. The cells in [14-17] consumes more power due to the presence of two bitlines (BLs) for read and write operations. Although, the single BL cells present in [18-20] shows low dynamic power consumption but they have poor write and read ability and more leakage power consumption. The read ability and leakage power are more since two access transistors are connected to BL [18] that may lead to more BL capacitance, whereas one of the two series connected transistor in [19-20] are getting off that will cause charge sharing. Other single BL SRAM cells using shared-pass-gate [21] and power cut-off with floating avoidance [22] to remove HS issue are presented in literature. However, [21,22] shows the more write delay and power consumption due to the presence of more number of transistors in their write path and large BL capacitance, respectively.

In this paper, a single bitline half-select disturb-free 11T (HF11T) SRAM cell is proposed. This cell shows high read and write stability, less write delay, lower power consumption and better I_{on}/I_{off} ratio. The key characteristics of the suggested cell are outlined below:

(1) The RSNM is improved by using a read decoupled structure.
(2) The write delay (T_{WA}) and stability is improved by employing a power cut-off transistor with virtual ground (VGND) along with dedicated write path for '1' and '0'.
(3) By utilising a single bitline (BL) structure, it's dynamic power consumption is reduced.
(4) Leakage current and power are reduced with the help of stacked transistor, leading to better I_{on}/I_{off} ratio.
(5) It is free from Half-select-issue. As a result, bit-interleaving architecture can be used to improve resilience against soft errors.

This paper is organized as follows: Section II, describes the structure and operation of the proposed HF11T SRAM cell. In Section III, simulation results and analysis for the proposed and considered single BL SRAM cells are presented. Finally, conclusion are drawn in Section IV.

2 Proposed HF11T SRAM cell Design

Fig. 1(a), depicts the proposed HF11T SRAM cell. It is made up with a cross-coupled structure of a right inverter (P2, N2), and a left inverter with stacked transistors (P3, P1, N1) with VGND. The P3 is used as a power cut-off transistor at the time of write operation. The P5 and N4 are used for controlling the write access transistors N3 and P4 through the row and column control signals WL, CWL and WLA, respectively. The read access path consist of N5 and N6 transistors controlled by read wordline (RWL) signal. The VGND signal is used to control the write operation, whereas Q and QB are the storage nodes of a SRAM cell. The operating condition for hold, read, and write modes are enlisted in Table 1 and timing diagram is depicted in Fig. 1(b).

2.1 Hold Operation

Fig. 2(a) shows the schematic for the hold mode. The signals WL, WLA, RWL and VGND are maintained at '0', whereas CWL and BL are at '1', respectively. As a result, N3, P4, N4, and N5 are turned off, which makes the storage node Q isolated from the BL. Therefore, the cell successfully retains the data.

Just Accepted

Table 1. HF11T SRAM Cell Control Signals

Signal	Hold	Read	Write '1'	Write '0'
WL	0	0	0	1
WLA	0	0	1	0
CWL	1	1	0	1
RWL	0	1	0	0
VGND	0	0	1	0
BL	1	Precharged	1	0

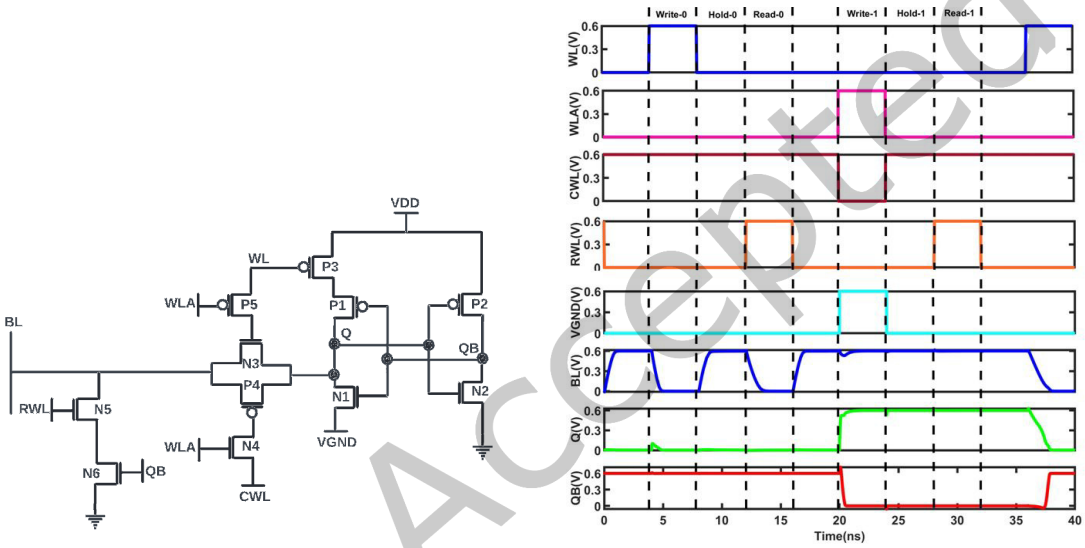

Fig. 1. Proposed HF11T SRAM cell (a) Schematic and (b) operation timing diagram.

Just Accepted

2.2 Read Operation

The read operation is elucidated in Fig. 2(b). BL is precharged to V_{DD} prior to starting a read operation. At the time of read operation WL, WLA and VGND are kept at '0'; CWL and RWL are kept at '1'. This makes N3, N4 and N5 are turned off and on, respectively. If the data stored in cell is '0' then QB is at '1' which activates N6. It allows discharging of BL through N5-N6 which is interpreted as '0' stored in the cell. On the other hand no discharging of BL indicates that stored value in cell is '1'.

2.3 Write Operation

The HF11T SRAM cell write '1' operation is shown in Fig. 2(c). Initially '0' and '1' are stored at Q and QB respectively. For write '1' operation WL, CWL and RWL are kept at '0', while WLA and VGND are connected to '1', and write driver makes BL to '1'. As P3 is on it connects the left inverter to the power supply (V_{DD}). The write access transistor P4 (PMOS) and N3 (NMOS) are turned on and off, respectively. As PMOS passes strong '1', the

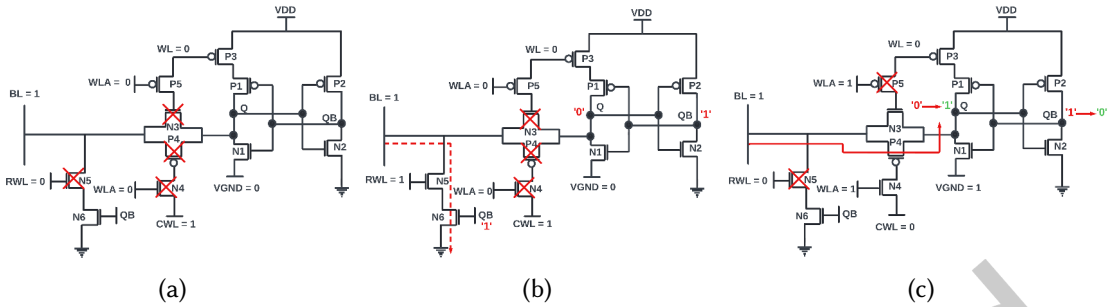

Fig. 2. (a) Hold, (b) Read, and (c) Write '1' operations of proposed HF11T cell

data at storage node Q get easily flipped from '0' to '1'. Also, P3 and VGND support write '1' operation, therefore the write ability of the proposed cell is improved.

Similarly, assume that '1' is stored at Q, so while performing a write '0' operation, BL is set to '0' by the write driver. The control signals WLA, RWL and VGND are disabled, whereas WL and CWL are enabled. The left inverter is disconnected from the V_{DD} as P3 is turned off. N3 and P4 are switched on and off respectively, which forming a write path. Since NMOS act as strong for '0', Q is easily pulled low by BL via N3. As it reaches the threshold voltage of P2, QB is pulled up, which represent a successful write '0' operation. Furthermore, the write '0' operation is supported by P3 and VGND. Therefore, the above discussion shows that write operation of the proposed cell is improved with the help of power cut-off transistor, VGND, and strong write access transistor depending on write '1' & '0' operation.

2.4 Write-Half-Select Free Operation

A disturbance created by any unselected cells in selected rows or columns during a writing process is known as a half-select (HS) disturb [22]. In order to address the multi-bit errors HS free SRAM cell is required to implement BI architecture. The proposed HF11T completely removes HS issue as shown in Fig. 3. There are four bit-cells, each of which represents one of four possible conditions namely Selected cell, Row half-selected cell (RHS), Column half-selected cell (CHS) and Unselected cell during write operation. The unselected and selected cells are working in normal hold and write modes as explained in Section II-A and II-C, respectively. As P5, N3 and P4 are deactivated for the CHS cell, the storage nodes are separated from BL, so that the latch consistently holds the data just as it would in a hold operation. For RHS cell, WL, CWL and BL are at '0', whereas WLA and VGND are at '1'. Assuming that, if the cell stores '1', then Q will remain at '1'. Since the strong pull-up path prevents it from being discharged. As a result, QB keeps at '0', allowing for secure latching of the stored data. In case of '0' stored in a cell, due to an existing discharging path from Q to ground via P4, Q state is unaffected and remains at '0'. As a result, the data stored in RHS cell is unaffected like hold state. In conclusion, the proposed SRAM cell is free from write-half-select disturb issue.

3 Simulation Results And Analysis

The performance of the proposed HF11T SRAM cell in terms of read, hold and write stability, read and write delay, read and write power, leakage power, and I_{on}/I_{off} ratio is evaluated using a 45 nm CMOS technology in Cadence Virtuoso. The V_{DDmin} of all the compared single BL SRAM cells namely SEHF11T [18], SPG11T [21], DSPS10T [19], HSR12T [20], 11T [22] and proposed HF11T SRAM cells is examined and the maximum of V_{DDmin} (0.6V) is chosen for further exploration. For fair comparison the minimum width of each transistor i.e. 120 nm, is taken

Just Accepted

into account when simulating and comparing all the considered cells. The performance metrics of the proposed and compared bit cells are analyzed by conducting 5000 Monte Carlo (MC) simulations, used to determine the effect of process variations. The outcomes are discussed separately in the following subsections.

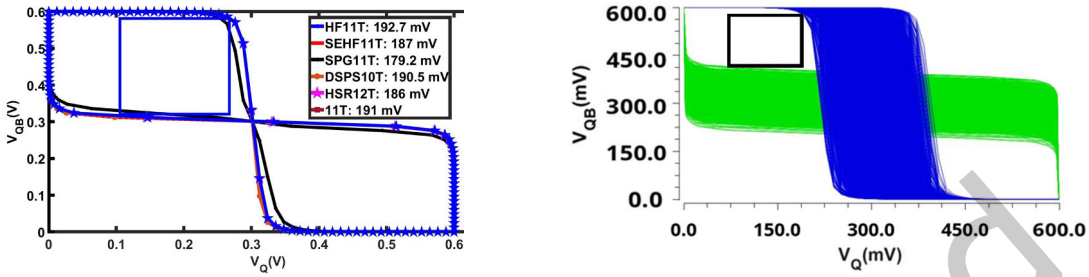
3.1 Read/Hold Static Noise Margin (RSNM/HSNM)

The RSNM and HSNM are used to determine the read and hold stability of a SRAM cell's, respectively. During read and hold operations, RSNM and HSNM are defined as the maximum dc noise voltage at each storage node that can be tolerated without affecting the status of stored data. They are calculated using the largest square that can fit inside the butterfly curve [23,24]. The read decoupled structure is employed in the proposed and compared SRAM cells, which having independent read path, as a result, their RSNM and HSNM are equivalent.

The RSNM/HSNM curve for all the compared SRAM cells are shown in Fig. 4(a). It can be seen from Fig. that the RSNM/HSNM of the proposed HF11T is 192.7 mV which is about 1.07× more than the other considered cell's. The proposed cell features stacked PMOS in the pull-up path, combined with the left-side structure, resulting in increased resistance toward the storage node. This configuration helps control noise, leading to a higher RSNM. The SEHF11T, DSPS10T, HSR12T, and 11T shows comparable RSNM to the proposed cell. The SEHF11T, and DSPS10T are having same kind of pull up structure and HSR12T, and 11T shows the similar pull up network with feedback cutting with stacked PMOS. This increases the equivalent resistance, contributing to the control of noise at the storage nodes during a read/hold operation. However, SPG11T doesn't have the stacked PMOS in

Just Accepted

the pull up path leading to smaller RSNM than the other cells. The MC simulation for 5000 samples of HF11T is illustrated in Fig. 4(b). It indicates a worst-case RSNM/HSNM of about 110 mV.



(a) (b)

Fig. 4. RSNM (a) Butterfly curve for compared SRAM cells, (b) of HF11T using MC 5000 runs at V_{DD} = 0.6 V.

3.2 Write ability

The N-Curve [25,26], which is depicted in Fig. 5(a), is used to evaluate the write capability of the SRAM cell's. The write stability of bitcells can be measured using two different metrics: write-trip voltage (WTV) and write-trip current (WTI). The WTV, which is defined by the difference between points C and B (Fig. 5(a)), is the smallest voltage drop necessary to modify the internal nodes of the bitcell. The negative current peak between points C and B in Fig. 5(a), used to determine the WTI, which represents the minimum current required to write the bitcell. Fig. 5(b) depicts the N-Curve corresponding to each SRAM cell. It can be seen that the WTV of the proposed HF11T cell is 1.02× better than the considered cells. The power cut-off transistor with VGND and a dedicated write path for '0' and '1' improves the write capability of HF11T. Fig. 5(c) demonstrates that the worst-case WTV for the proposed cell is 370 mV, as determined by MC simulation with 5000 samples at V_{DD} of 0.6 V.

3.3 Read Delay

Read delay/access time (T_{RA}) is used to measure the time required to complete a read operation. For single ended bit cells, it is determined as the time needed to discharge precharged BL by 50 mV when WL is activated [25,27,31]. The T_{RA} of various SRAM cells at varying supply voltages are displayed in Fig. 6(a). As shown HF11T has 1.48×/4.85×/1.92×/1.64× lower read delay than SEHF11T/ DSPS10T/ HSR12T/ 11T SRAM cells, respectively at V_{DD} of 0.6 V, due to reduced bitline capacitance. However, it has slightly more read delay than SPG11T, because of bit large BL capacitance. The DSPS10T and HSR12T shows maximum delay due to voltage division occurs at the intermediate node between two series connected access transistors and decoupled read path. In the 11T cell, the node QX gets charged before the activation of the WL signal. Upon WL activation, QX is rapidly discharged, causing a swift drop on RBL. Consequently, a smaller delay is observed compared to previous cells. The SEHF11T shows more read delay due to large capacitance offered by two parallelly connected access transistors with single BL. Fig. 6(b) illustrates the T_{RA} at V_{DD} of 0.6 V with MC 5000 runs. The proposed cell exhibits a lower mean (μ) and minimum standard deviation (σ) value of up to 4.85× and 10.53×, respectively than other considered cells.

3.4 Write Delay

Write delay/access time (T_{WA}) shows the speed at which it executes the write operation. The amount of time an internal node needs to increase up to 90% of the supply voltage while the wordline is enabled is referred to as the write '1' access time (T_{WA}'1'). Similarly, write '0' access time (T_{WA}'0') is defined as the time when the storage

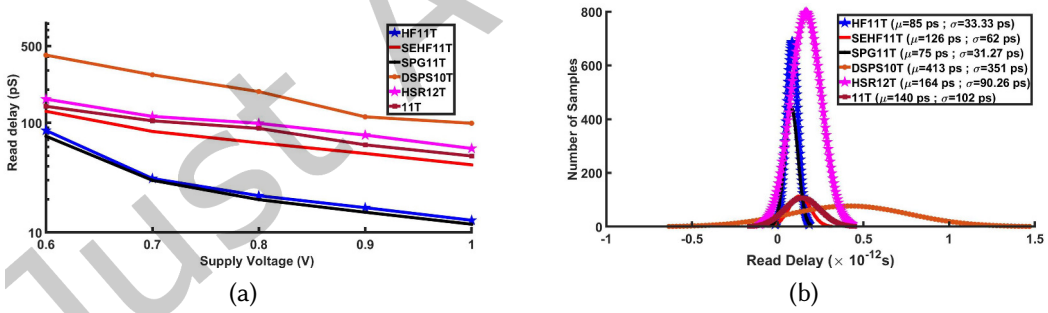

Fig. 6. Read delay (a) versus varying supply voltages, (b) with MC simulation of 5000 samples.

node voltage drops upto 10% of the supply voltage during wordline activation [25,28]. Fig. 7(a) shows the T_{WA} of considered SRAM cells at various supply voltages. Because of the power cut-off transistor with VGND and dedicated write path for '1' and '0', HF11T has 8.81×/1.12×/9.19×/8.18×/1.35× lower write delay than SEHF11T/ SPG11T/ DSPS10T/ HSR12T/ 11T SRAM cells, respectively at V_{DD} of 0.6 V. MC simulation with 5000 samples at V_{DD} of 0.6 V is shown in Fig. 7(b). The proposed cell indicates a lower mean (μ) and minimum standard deviation (σ) of up to 9.19× and 16.36×, respectively than other considered cells.

Just Accepted

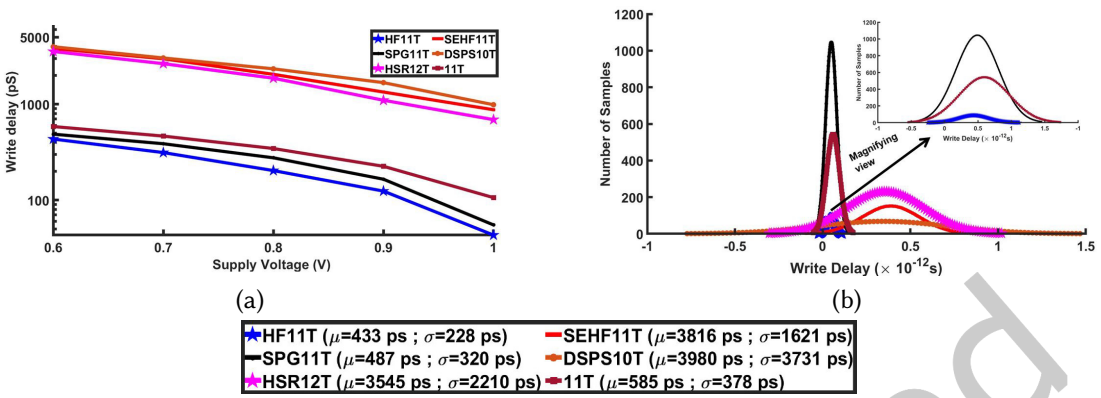

Fig. 7. Write delay (a) versus varying supply voltages, (b) with MC simulation of 5000 samples.

3.5 Read/Write Power Consumption

Read power is calculated as the average power during read operations. In similar way, write power is determine as the average power during write operations including write '1' and '0' [21]. Variation in read and write power with supply voltage is shown in Fig. 8(a) & (b), respectively. From Fig., HF11T has 1.59×/2.75×/1.77×/4.58×/3.84× and 16.35×/94.72×/13.55×/3.48×/60.81× lesser read and write power consumption than SEHF11T/ SPG11T/ DSPS10T/ HSR12T/ 11T SRAM cells, respectively at V_{DD} of 0.6 V. The proposed cell shows lower read and write power consumption due to less BL capacitance. The SEHF11T consumes more read and write power this occurs because of two transistors are linked to the bitline resulting in an overall increase in the bitline capacitance. The HSR12T, 11T, and SPG11T consumes maximum read power owing to the substantial read current flow and due to the introduction of P2, which gives rise to a larger BL capacitance, respectively; whereas DSPS10T shows less read power than these cells due to minimal flow of read current in the read path. Also, the SPG11T and 11T exhibits the highest write power among the mentioned cells, primarily attributed to the presence of the write assist transistor and scheme; whereas DSPS10T and HSR12T shows less write power consumption due to larger delay as delay and power are inversely related to each other. MC simulations of read and write power with 5000 samples at V_{DD} of 0.6 V is shown in Fig. 9(a) & (b), respectively. In comparison to considered cells, the proposed cell indicates the lower mean (μ) and minimum standard deviations (σ) for read and write power of up to 4.58× and 8.10× and 94.72× and 97.48× respectively.

Fig. 10(a) & (b) illustrates the read and write power-delay product (PDP) at various supply voltages, respectively. HSR12T has largest read PDP due to its more read power, whereas SEHF11T has more write PDP because of large write delay. However, HF11T has minimum read power and least write delay/power as a result, it shows lower read and write PDP as compared to other considered cells.

3.6 Leakage Power Consumption

Leakage power is another crucial parameter for SRAM design. Because majority of the SRAM cells in an SRAM array remain in standby mode when not activated [21,32]. Leakage power consumption of various SRAM cells with supply voltage variation is shown in Fig. 11(a). The outcomes demonstrate that HF11T has 1.63×/1.09×/1.65×/1.68×/1.66× lower power consumption than SEHF11T/ SPG11T/ DSPS10T/ HSR12T/ 11T SRAM cells, respectively, due to the presence of stacking transistors a smaller number of leakage path and negligible current flowing through their off transistors; whereas SPG11T has the lowest leakage power consumption among

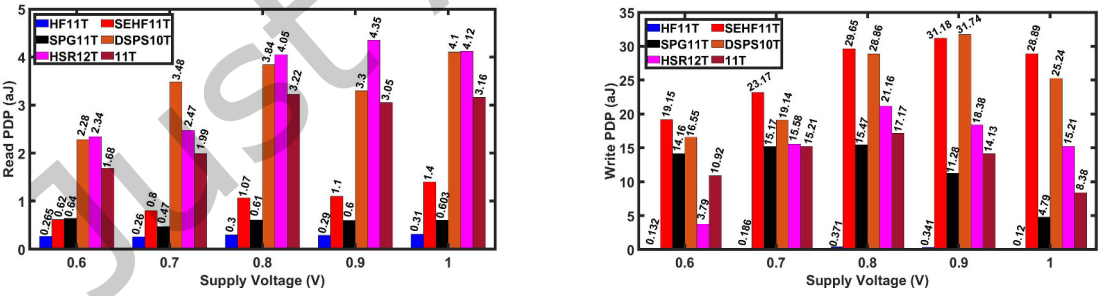

Fig. 10. Supply voltage variation on (a) Read PDP, and (b) Write PDP.

the compared cells due to low leakage through their off transistors. However, SEHF11T, DSPS10T, HSR12T, and 11T shows slightly more leakage power due to more leakage current flowing through their off transistors and more leakage path is present. Fig. 11(b) illustrate the MC simulation of leakage power consumption with 5000

Just Accepted

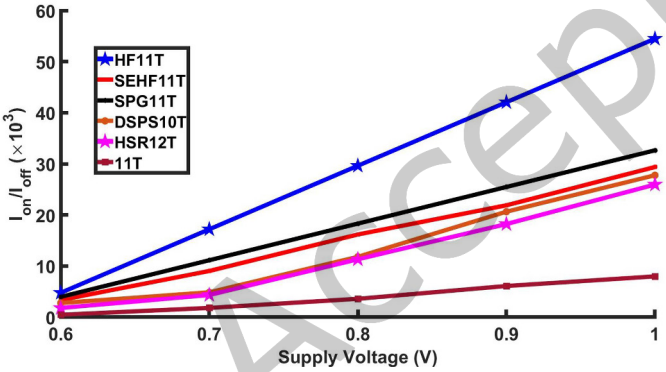

Fig. 12. I_{on}/I_{off} ratio variation with supply voltage.

samples at V_{DD} of 0.6 V. Compared to considered cells, the proposed cell indicates a lower mean (μ) and minimum standard deviation (σ) in leakage power consumption of up to 1.68× and 2.58×, respectively.

3.7 I_{on}/I_{off} ratio

The relationship between read current (I_{on}) and leakage current (I_{off}) is referred to as the I_{on}/I_{off} ratio. The designer can make a large SRAM array if the I_{on}/I_{off} ratio is higher. As a result, a large current ratio ensures that a designer can add more bit cells per column [25,29]. The I_{on}/I_{off} ratio with supply voltage variation is indicated in Fig. 12. The result shows that, HF11T has 1.42×/1.20×/1.72×/2.65×/10.14× more I_{on}/I_{off} ratio than SEHF11T/ SPG11T/ DSPS10T/ HSR12T/ 11T SRAM cells, respectively at V_{DD} of 0.6 V. The I_{on}/I_{off} ratio of the proposed cell is larger due to more I_{on} and less I_{off}, which is the direct consequence of stacking effect. The SEHF11T, DSPS10T, HSR12T and 11T shows least I_{on}/I_{off} ratio as two access transistors are connected in series, with one being off. This configuration introduces a potential for charge sharing between the two, leading to increased leakage current in the read path, whereas SPG11T shows slightly less I_{on}/I_{off} ratio due to the introduction of P2 in their read path causing the leakage.

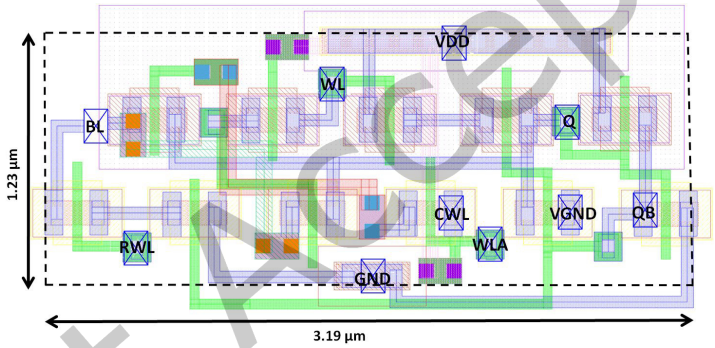

Fig. 13. Layout of HF11T.

Just Accepted

3.8 Cell Area

High density cache memory is created by grouping the bit cells, which requires layout area observation for each cell. Additionally, as cache memory occupy a significant amount of chip area, every memory designer aim to reduce the cell area while maintaining performance. The layouts were created using 45nm technology rules. The layouts of proposed and considered cells are drawn by keeping same widths and lengths of transistors. The area of all considered cells are placed in Table 2. The HF11T layout is shown in Fig. 13. The HF11T occupies 1.1×/1.07×/1.28×/1.22× lesser area than SEHF11T/ SPG11T/ HSR12T/ 11T SRAM cells, respectively. As SEHF11T and HSR12T, 11T has PMOS transistors positioned vertically on both sides and in feedback cutting path, respectively leading to more area requirement. The SPG11T has vertically connected PMOS on one side and contains more complex connections between the transistors leading to more area consumption. However, HF11T shows 1.1× more area consumption than DSPS10T. As HF11T has slightly more number of transistors than DSPS10T.

3.9 Figure of Merit (FOM)

In order to evaluate the proposed cell relative performance effectiveness with other compared SRAM cells under consideration, the SRAM figure of merit (FOM) presented in [30] has been used. The read delay (T_{RA}) and write delay (T_{WA}) are taken into account by this FOM, which is given in Eq. (1), as the speed metrics. For the hold, read, and write operations, respectively, the HSNM, RSNM, and WTV are taken into account as the cell's stability metrics.

$$FOM = \frac{RSNM \times HSNM}{WTV \times (T_{RA} \times T_{WA}) \times (Readpower \times Writepower \times Leakagepower) \times Cellarea} \quad (1)$$

The HF11T indicates $6.5\times10^2\times/5.4\times10^2\times/1.6\times10^3\times/5.8\times10^2\times/1\times10^3\times$ higher FOM than SEHF11T/ SPG11T/ DSPS10T/ HSR12T/ 11T SRAM cells, respectively. The difference in the FOM value of the proposed and SEHF11T [18], SPG11T [21], HSR12T [20] cells is nearly about 100 times. The large difference in the FOM values of the proposed and other compared cells [19,22] may be attributed to the fact that write delay and power of the proposed cell is approximately 100 times less than the compared cells respectively. A larger value of this FOM signifies improved cell performance.

To summarise the results, it can be seen from Table 2 that the HF11T performs better than any other SRAM cells compared in this paper.

4 Conclusion

A novel HF11T SRAM cell is proposed in this paper. This cell has power cut-off transistor with VGND along with dedicated write path for '1' and '0'. The proposed cell solves read disturb and write-half-select disturb problems. The HF11T results in low leakage power, low read and write power consumption, better read and write delays, better I_{on}/I_{off} ratio, and improved RSNM, HSNM and write ability. It achieves up to 1.68×/4.58×/94.72× reduction in leakage power, read power and write power consumption, respectively than other compared SRAM cells, as it contains stacking transistor, single BL for read/write and low BL capacitance. The write delay and stability of the proposed cell is up to 9.19×/1.02× better than other considered cells, as a result of power cut-off transistor with VGND and dedicated write path for '1' and '0'. Although, read delay is least among the compared SRAM cells but it shows slightly more delay than SPG11T. The I_{on}/I_{off} ratio of HF11T is 10.14× larger than the considered cells, as it has high on current (I_{on}) and low leakage current (I_{off}). RSNM of HF11T is 1.07× more than other compared cell due to the use of read decoupled structure. The results of various SRAM cells in 45 nm CMOS technology are complied in Table 2 at supply voltage of 0.6 V. From Table 2, it is evident that the proposed HF11T SRAM cell has superior performance compared to other single BL SRAM cells. As a result, the HF11T is an appropriate alternative for submicrometer technologies that require low power, high speed, and better stability.

ORIGINAL PAPER

Adaptive control strategy for isolated renewable energy-based generation system with intermittency

Sombir Kundu[1] · Ashutosh K. Giri[2] · Madhusudan Singh[3] · Sunil Kadiyan[4]

Abstract
This paper implements a three-phase four-wire renewable generation system using wind and solar energy sources that feed standalone consumer loads. A solar photovoltaic (SPV) array, a bidirectional converter (BDC), and a battery storage system (BSS) are being integrated into a self-excited induction generator-based wind energy conversion system. A Modified Proportionate Affine Projection Algorithm (MPAPA) is designed to compute the amplitude of the fundamental load current component with reduced oscillations and keep the power equilibrium between the energy sources and load. An MPAPA-based control of voltage source inverter (VSI) provides numerous functions like harmonics abatement, compensation of neutral current, active and reactive power, load leveling, and voltage stabilization at the common point of intersection (CPI). A BDC controls the charging/draining of BSS by buck–boost modes operation and MPPT of the SPV during intermittent conditions. Moreover, the BSS is connected at the DC link of the VSI to absorb extra power and provide power support during intermittency. Moreover, a comparison is performed between the proposed MPAPA control and existing LMS and leaky momentum control approaches. The MPAPA control settles in less than one cycle (18 ms), becoming within the 2% specified limit. The dynamic simulation and test results of the isolated generation system are assessed under intermittency in non-conventional energy sources and unbalanced load. The total harmonic distortion of the CPI current is less than 5%, which meets the boundary of IEEE-519 standard.

Keywords Adaptive control approach · Battery storage system · Isolated power generation · Power quality

Abbreviations

3P4W, SEIG	Three-phase four-wire, self-excited induction generator
SPV, IC	Solar photovoltaic, incremental conductance,
BSS, VSC	Battery storage system, voltage source converter
WECS, CPI	Wind energy conversion system, common point of inter-section
MPAPA, THD	Modified Proportionate Affine Projection Algorithm, total harmonic distortion
BDC	Bidirectional converter
PLL, FLL	Phase-locked loop, frequency-locked loop
PQ, MLMS	Power quality, modified least mean square

1 Introduction

Electricity usage has been rapidly growing owing to continuous increases in the global population. Global electricity demand is expanding twice as fast as primary energy demand, increasing electricity's proportion of total energy utilization from 19% in 2018 to 24% by 2040. Presently global

Published online: 13 June 2024

electricity demand is mainly met through fossil fuels-based generation. However, continuous depletion coupled with environmental problems due to the emission of greenhouse gases has attracted the interest of researchers toward the use of renewable energy sources. Because of this growing environmental concern, world is focusing on renewable energy-based electricity generation such as hydro, solar and wind energies among others. All these account for approximately 40% of the total installed energy capacity. With sustained cost reduction and advancement in technique, solar energy-based generation has increased significantly [1–4]. Hydropower plants even if they contribute less to the global energy supply have quite a large potential worldwide, and the development of hydropower for sustainable energy supply continued in the recent part but deployment rates accelerated for wind and SPV systems [5, 6]. However, out of all renewable resources wind energy stands out because of its high proficiency and low contamination. In recent years, continued technological advances in wind turbine technology have enhanced the strength of the WECS [7, 8]. Small-scale wind energy systems have been gaining popularity for off-grid or remote applications. Different electrical machines are taken into consideration for electromechanical conversion in small wind turbines, depending on the particular requirements and conditions of the application [9, 10].

The induction machine, and more specifically the three-phase squirrel induction machine, is still commonly employed for this peculiar operation. Indeed, the construction is sturdy, requires minimal servicing and is reasonably priced. As a result, substantial research has been conducted on SEIGs in remote and isolated places [11, 12]. Kundu et al. [13] and Sharma et al. [14] have identified significant problems with isolated renewable-based resources, such as variability and intermittency. As a result, although discussing the power quality (PQ) standard, it causes technical issues such as active power-sharing, unbalanced load adjustment, and reactive power compensation. Maintaining microgrid stability in islanded mode is a huge task. Voltage/frequency oscillations in the microgrid are minimized by using a BSS at the DC link to maintain the necessary power equilibrium. To adjust the characteristics of an isolated system under a variety of operating circumstances, an adaptive control strategy is utilized [15, 16]. Adaptive and a novel approach [17]-based control for WECS is described to work under intermittent conditions [18, 19]. A control approach for SPV panels to draw maximum power is discussed [20, 21]. To harness maximal power using INC and P&O MPPT techniques are described [22, 23] and an MLMS control is discussed to generate gating pulses for VSC [24, 25]. A hybrid microgrid system is developed and discusses the various challenges in microgrid systems [26]. Various PLL-based control schemes are available for PV-based generation. The development of generators in recent years has made wind energy an even better choice for a grid-connected or islanded DG system [27]. Controllers are required in wind turbines and solar photovoltaic systems to ensure low expenses of maintenance and effective operation [28]. The BSS is interfaced at the DC link to absorb the excess electricity [29], and the stored power in BSS is utilized during high load demand [30]. Saeed Golestan has given a review of different types of PLL (phase-locked loop) controllers with their pros and cons [31]. The control strategy for wind turbines and solar PV systems needs a PLL controller based on an all-pass filter (APF) to mitigate PQ issues in a standalone generation. PLL cannot produce unit vectors by itself, and the inclusion of a moving average filter is utilized in the loop which leads to a sluggish response. As a result of the improved PQ in the DG system, PLL based on APF is recommended [32]. The APF allows all types of frequencies to pass through without making any changes in their magnitude. It is only responsible for changing its phase change. In single-phase systems, the phase shift is required to generate a fictitious orthogonal signal, while in three-phase systems the phase shift is required to cancel the unbalances of grid voltage [33]. The controls are employed to limit the PQ issues of a wind–SPV–battery-based microgrid under transient load conditions [34]. Further, the control algorithms are employed to provide synchronization and smooth control of the standalone system for remote applications [35]. In the present work, an adaptive MPAPA control approach [36, 37] is designed to manage the voltage profile and frequency in a wind–solar PV–BSS-based hybrid system for all operating conditions. This controller yields rapid response and is acceptable for applications of rapid dynamics like wind and solar energy-based power generation.

The authors' originality and substantial contribution are listed as:

(1) An improved filtering strategy based on adaptive MPAPA is performed to estimate the amplitude of fundamental component to preserve sinusoidal and stabilized source currents even under the irregular conditions of solar radiations, wind speed, and polluted load.
(2) The proposed MPAPA control with VSI yields a fast response in the regulation of frequency and voltage, compensation of neutral load current and reactive power, harmonics eradication, balancing of load and reduces the PQ issues of the standalone system.
(3) Under different dynamic circumstances, the BSS response is examined, and the total harmonic distortion (THD) of CPI current is examined based on simulation and hardware analysis which are well below the IEEE-519 permissible level.
4) Moreover, a comparison is made between the proposed adaptive MPAPA control and the existing control techniques. The settling time of the proposed adaptive

MPAPA control is found to be shorter than one cycle (18 ms) within the 2% specified limit.

2 System description

The major components of the 3P4W standalone DG system are a 3-phase SEIG, wind turbine, solar PV array, IGBT-based VSI, and BSS. The capacitor bank is being utilized to provide the desired reactive power at no load for the SEIG. The capacitor bank serves dual functions: First, it reduces the high noise generated by the controllers, and second, it provides reactive power support to the proposed generator. All other device ratings are selected with proper design considerations. The wind turbine acts as a prime mover for the proposed SEIG, which in turn helps the generator's rotor to turn faster than synchronous speed, thus acting as an induction generator [13]. The generated energy is supplied to the three-phase nonlinear load. Here, we have also used an IC-based MPPT technique to extract maximal power from an SPV. Further, a BSS is interfaced at a DC link with a BDC controller to consume the excess electricity and supply power during intermittency and increase in consumer [14].

3 Control strategy

Figure 1 represents the control mechanism of the 3P4W standalone renewable-based isolated system (Fig. 2). An adaptive MPAPA control is designed to estimate the fundamental component of the polluted and unbalanced load current under the uncertain condition of NCES's. Further, the proposed control produces the triggering pulses for the VSI as depicted in Fig. 3.

3.1 Maximum power extraction and control scheme of bidirectional controller

The DC-link voltage oscillations are caused due to real power imbalances. Active power imbalances/disruptions can occur for a variety of reasons, including (1) deviation in solar power generation, (2) changes in wind speed power generation, and (3) unbalanced and increased in consumer loads. The BDC controller adjusts the DC-link voltage and controls the BSS charging and draining modes in intermittent wind speed and solar radiations. The proposed BDC controller is constructed using two PI controllers (inner and outer) for BSS management. The outer controller is in charge of managing the DC-link voltage and tracking the PV array's maximum power. The inner side controller loop is employed to trace the reference current of the BSS. The outer PI controller employed to control the DC-link voltage is denoted as

$$i_{\mathrm{b}}(q) = i_{\mathrm{b}}(q-1) + k_{\mathrm{bp}}\{v_{\mathrm{dce}}(q) - v_{\mathrm{dce}}(q-1)\} + k_{\mathrm{bi}}(q) \tag{1}$$

$$\text{where,}\quad v_{\mathrm{dce}}(q) = v_{\mathrm{mpp}}(q-1) - v_{\mathrm{dc}}(q) \tag{2}$$

where v_{mpp} is the evaluated reference voltage at the DC link from an IC-MPPT algorithm. The actual DC-link voltage is denoted by V_{dc}. The duty cycle (α) of the BDC is described as the outcome of the inner PI controller.

$$\alpha(q) = \alpha(q-1) + k_{\mathrm{sp}}\{i_{\mathrm{be}}(q) - i_{\mathrm{be}}\,(q-1)\} + k_{\mathrm{si}} i_{\mathrm{be}}(q) \tag{3}$$

where (i_{be}) is the difference between the reference battery current (i_{b}^{*}) and the observed battery current (i_{b}) [16].

$$i_{\mathrm{be}}(q) = i_{\mathrm{b}}^{*}(q) - i_{\mathrm{b}}(q) \tag{4}$$

3.2 Control strategy for VSI

Primarily, the structure of the MPAPA is established, which serves as the foundation for our subsequent derivations. Let (μ_{opt}) denote the plant's unknown impulse response vector and ($\xi^{(i)}$) the adaptive filter's input signal vector as displayed in Fig. 2 [37].

$$\mu_{\mathrm{opt}}^{(i)} = \left[\mu_0^{(i)}, \mu_1^{(i)}, \ldots\ldots \mu_{M-1}^{(i)}\right]^T \tag{5}$$

$$\xi^{(i)} = [\xi^{(i)},\ \xi^{(i-1)}, \ldots \xi^{(i-k+1)}] \tag{6}$$

where (M) signifies the adaptive filter length and (i) indicates the current sample. The recorded signal ($X^{(i)}$) with added impulsive noise ($N^{(i)}$) can be computed from Fig. 2 as (7)

$$X^{(i)} = \mu_{\mathrm{opt}}(\xi^{(i-1)})^T + N^{(i)} \tag{7}$$

The output of the undetermined system is subjected to the calculated posterior, and the adaptive filter is

$$\mu_{\mathrm{opt}} = X^{(i)} - (\xi^{(i)})^T \xi^{(i)} \tag{8}$$

After each iteration, $\xi^{(i)}$ is computed using $\mu_{\mathrm{opt}}^{(i)}$. It is possible to calculate the novel MPAPA update weight coefficient as

$$\mu^{(i)} = \mu^{(i-1)} + \rho\xi^{(i)} X^{(i)}\left[(\xi^{(i)})^T \xi^{(i)} X^{(i)} + \delta I\right]^{-1} \eta^{(i)} \tag{9}$$

The gain-controlling matrix is denoted by $X^{(i)}$=diag[$x_0^{(i)}$, $x_1^{(i)}$, $\ldots..x_{M-1}^{(i)}$], where I is an (M × M) identity matrix

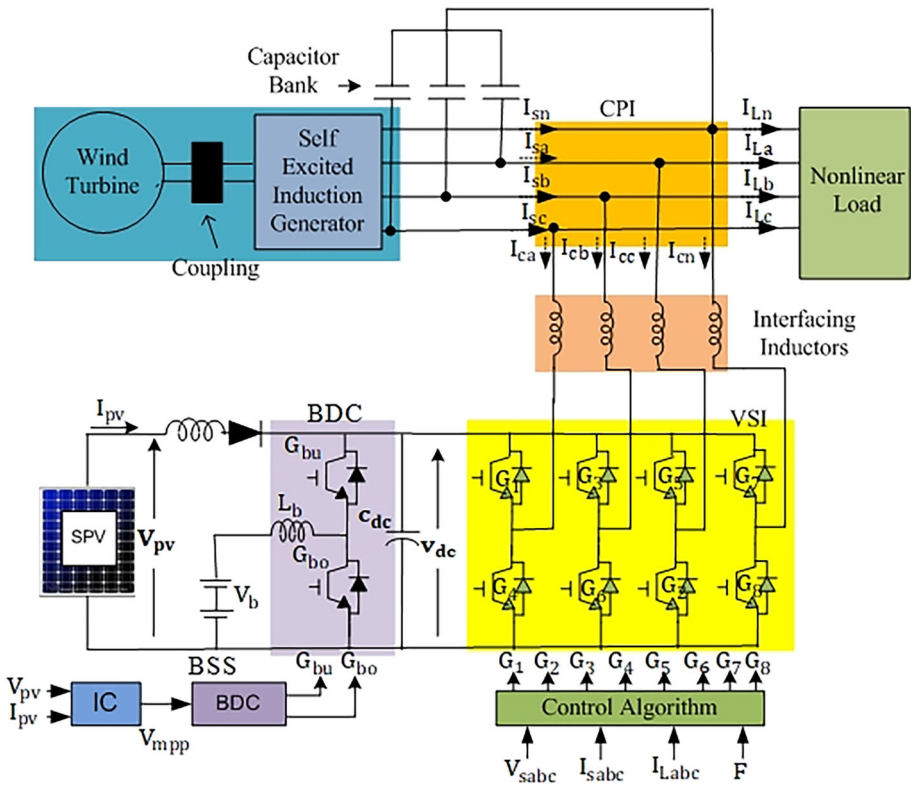

Fig. 1 Control topology of 3P4W standalone system

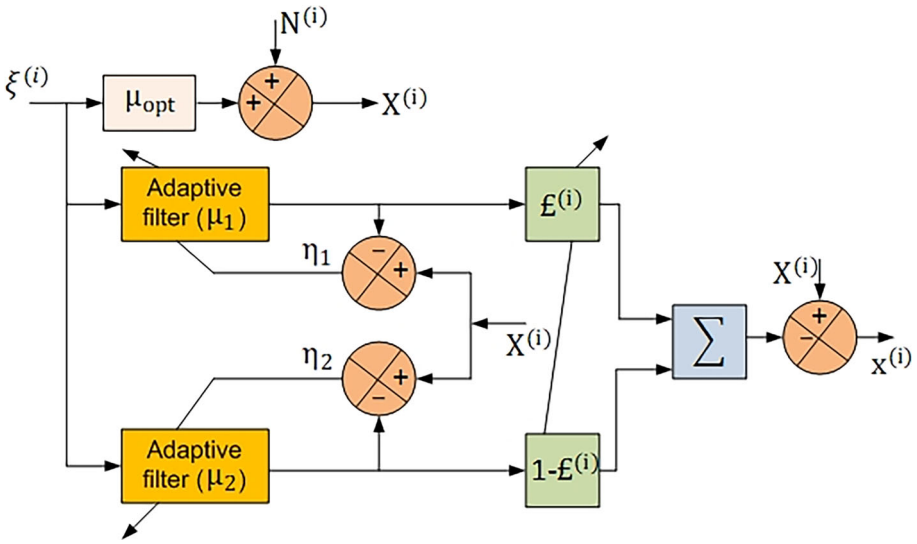

Fig. 2 Schematic diagram of MPAPA control

and (ρ) is the iteration's step size. (10), which represents the individual gain unit ($x_k^{(i-1)}$, $k \in [0, \ldots, M-1)$.

$$x_k^{(i-1)} = \frac{M d_k^{(i-1)}}{\sum_{k=0}^{M-1} d_k^{(i-1)}} \tag{10}$$

In this case, $d_k^{(i-1)} = \max\{\mathrm{p} \max\{\mathrm{q} \left|\mu_{\mathrm{opt}}^{(i)}\right|\}, \left|\mu_k^{(i-1)}\right|\}$. The initialization technique has to employ the parameter p when the procedure begins with all weight coefficients set to zero. This concludes the weight coefficients from stopping during updates. Similarly, although having a considerably lower value than the maximum coefficient, the parameter (q) is a relatively positive quantity that eliminates ($\mu_{M-1}^{(i)}$) from stalling.

Throughout the iteration process, the largest step size (ρ_1) and the smallest step size (ρ_2) get recorded and meet the requirement $0 \leq \rho_2 \leq \rho_1$.

Taking into consideration these two distinct step sizes, given in (11) & (12), the value of the weight coefficient $\mu^{(i-1)}$

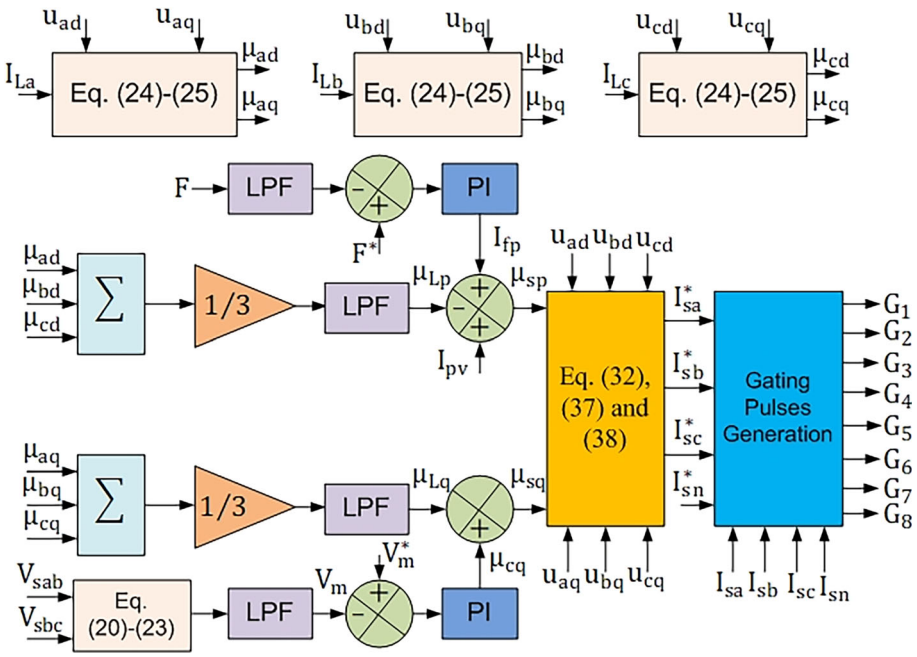

Fig. 3 Control strategy of the 3P4W standalone system

is adjusted as $\mu_1^{(i)}$ and $\mu_2^{(i)}$.

$$\mu^{(i)} = \mu^{(i-1)} + \rho_1 \xi^{(i)} X^{(i)} [(\xi^{(i)})^T \xi^{(i)} X^{(i)} + \delta I]^{-1} \eta^{(i)} \quad (11)$$

$$\mu^{(i)} = \mu^{(i-1)} + \rho_2 \xi^{(i)} X^{(i)} [(\xi^{(i)})^T \xi^{(i)} X^{(i)} + \delta I]^{-1} \eta^{(i)} \quad (12)$$

With the restriction $0 \leq £^{(i)} \leq 1$, the two new weight vectors, $\mu_1^{(i)}$ and $\mu_2^{(i)}$, are arranged by a variable mixing factor $£^{(i)}$ to update the weight vector as (13).

$$\mu^{(i)} = £\mu_1^{(i)} + (1 - £^{(i)}) £ \mu_2^{(i)} \quad (13)$$

Substituting (11) & (12) into (13), the weight vector coefficient's newly determined equation is (14).

$$\lambda^{(i)} = £^{(i)} \lambda_1 + (1 - £^{(i)}) \lambda_2 \quad (14)$$

The total number of steps size, denoted as $\lambda^{(i)}$, ranges from λ_1 to λ_2. A sigmoid activation function's output concerning a variable $\beta^{(i)}$ is the definition of the variable mixing factor ρ, which may be obtained as (15).

$$\rho^{(i)} = \text{sgn}\left[\beta^{(i)}\right] = \frac{1}{1 + e^{-\beta^{(i)}}} \quad (15)$$

In this case, ρ is determined at each iteration by minimizing the system output error L_1-norm.

$$Y^{(i)} = X^{(i)} - (\xi^{(i)})^T \mu^{(i-1)} \quad (16)$$

$\beta^{(i)}$ has been updated using the gradient descent method to optimize the L_1-norm of the system error $Y^{(i)} = X^{(i)} - (\xi^{(i)})^T \mu^{(i-1)}$, ensuring the algorithm's robustness in the existence of non-Gaussian impulsive interference. Equation (17) can be obtained by integrating Eqs. (14) and (15) to obtain the updated $\mu^{(i)}$.

$$\mu^{(i)} = \mu^{(i-1)} + \frac{\lambda \xi^{(i)} X^{(i)} \eta^{(i)}}{\left[(\xi^{(i)})^T \xi^{(i)} X^i + \delta I\right]} \quad (17)$$

The step size of the adaptation $(\beta^{(i)})$ is represented by (ρ_β) in this case, and D_1 is a positive value that keeps the simulation from halting when $£^{(i)}$ becomes 0 or 1. The objective of the MPAPA approach is to determine, from the input signal $\xi^{(i)}$ and the preferred output signal $x(i)$, the genuine system impulse response $\mu^{(i)}$. Since the sigmoid activation function's output (18) defines the variable mixing factor, it is limited to falling inside the open interval (0, 1).

$$\beta^{(i)} = \beta^{(i-1)} - \rho_\beta \frac{\partial |\eta^{(i)}|}{\partial |\beta^{(i-1)}|} \quad (18)$$

The revised $\rho^{(i)}$ can now be expressed as

$$\rho^{(i)} = \begin{Bmatrix} 1, & \text{if} > -\ln \frac{D+1}{D-1} \\ 0, & \text{if} < -\ln \frac{D+1}{D-1} \\ \frac{D}{1+e^{\rho(i)}} - \frac{D}{2} + 0.5, & \text{otherwise} \end{Bmatrix} \quad (19)$$

where $\rho^{(i)} = \text{sgn}[\beta^{(i)}]$. It is possible to modify (19) by adding a modest positive integer to keep the simulation from halting when $\rho^{(i)}$ is equal to 1 or 0.

3.3 Estimating amplitude of supply voltage and unit template generation for reference current

V_m Is the voltage amplitude of the terminal voltage, which is expressed as

$$V_m = \left(\frac{2}{3}\right)^{1/2}\left(v_{sa}^2 + v_{sb}^2 + v_{sc}^2\right)^{1/2} \tag{20}$$

Here, phase voltages are estimated as

$$\begin{aligned} v_{sa} &= \frac{1}{3}\left(2v_{sab} + v_{sbc}\right), \quad v_{sb} \\ &= \frac{1}{3}\left(-v_{sab} + v_{sbc}\right), \quad v_{sc} = \frac{1}{3}\left(-v_{sab} + 2v_{sbc}\right) \end{aligned} \tag{21}$$

Thus, by using Eqs. (20, 21), the unit templates (in-phase and quadrature) are evaluated as [9]

$$u_{ad} = v_{sa}/V_m, \quad u_{bd} = v_{sb}/V_m, \quad u_{cd} = v_{sc}/V_m \tag{22}$$

$$\begin{aligned} u_{aq} &= -\frac{u_{ad}}{\sqrt{3}} + \frac{u_{cd}}{\sqrt{3}}, \quad u_{bq} = -\frac{3u_{cd}}{2\sqrt{3}} - \frac{u_{cd}}{2\sqrt{3}} + \frac{u_{bd}}{2\sqrt{3}}, \\ u_{cq} &= -\frac{3u_{ad}}{2\sqrt{3}} + \frac{u_{bd}}{2\sqrt{3}} - \frac{u_{cd}}{2\sqrt{3}} \end{aligned} \tag{23}$$

The new weight in (17) is converted to weighted values corresponding to the active power components (24), and the reactive components are formed as (25).

$$\mu_{px}^{(i)} = \mu_{px}^{(i-1)} + \frac{\left[£^{(i)}\rho_1 + (1 - £^{(i)})\rho_2\right]}{\left[\left(\xi_{px}^{(i)}\right)X^{(i)}{\xi_{px}}^{(i)} + \delta I\right]^{-1}}\eta_x^{(i)} \tag{24}$$

$$\mu_{qx}^{(i)} = \mu_{qx}^{(i-1)} + \frac{\left[£^{(i)}\rho_1 + (1 - £^{(i)})\rho_2\right]}{\left[\left(\xi_{qx}^{(i)}\right)X^{(i)}{\xi_{qx}}^{(i)} + \delta I\right]^{-1}}\eta_x^{(i)} \tag{25}$$

From Eq. (26) comes the average per phase fundamental active weight component (μ_{lp}). Equation (27) can also be used to compute the reactive weight component (μ_{lq}).

$$\mu_{lp} = \frac{1}{3}\sum_{x\epsilon\{a,b,c\}} \mu_{px} \tag{26}$$

$$\mu_{lq} = \frac{1}{3}\sum_{x\epsilon\{a,b,c\}} \mu_{pq} \tag{27}$$

Further, the frequency error is computed by subtracting the reference frequency (50 Hz) from the system frequency as below

$$F_e(q) = F^*(q) - F(q) \tag{28}$$

The system frequency is computed using a phase-locked loop (PLL). The frequency-side PI controller output (i_{fp}) is computed as

$$i_{fp}(q) = i_{fp}(q-1) + k_{pf}\{F_e(q) - F_e(q-1)\} + k_{if}F_e(q) \tag{29}$$

Therefore, to evaluate the total fundamental active current (μ_{sp}), the fundamental average load current output (μ_{Lp}) is subtracted from the addition of the output of the frequency PI controller (i_{fp}) and solar PV current (I_{pv}), and the equation is written as

$$\mu_{sd} = i_{fp} + I_{\text{pv}} - \mu_{Lp} \tag{30}$$

$$\text{where,} \quad \mu_{Lp} = \frac{\mu_{ad} + \mu_{bd} + \mu_{cd}}{3} \tag{31}$$

The active component of the reference current is calculated as (32).

$$i_{xd}^* = \mu_{sd}u_{ad}, \quad x \in \{a, b, c\} \tag{32}$$

The load current component, i.e., fundamental average active component per phase, is estimated using all three-phase active components in Eq. (31). After computing the extracted current (I_{Labc}) and active components (i_{xd}^*), the sample and hold logic is employed. As a result, one can find the active load current component (μ_{ad}) for phase 'a', and the (μ_{bd}) and (μ_{cd}) are the active load current components for phases '*b*' and '*c*'. The reactive component (μ_{cq}) is formed by the voltage PI controller. This is expressed mathematically as

$$\mu_{cq}(q) = \mu_{cq}(q-1) + k_{pq}\{v_e(q) - v_e(q-1)\} + k_{iq}\{v_e(q)\} \tag{33}$$

$$\text{where,} \quad V_{\text{merr}}(q) = V_m^*(q) - V_m(q) \tag{34}$$

The amplitude of terminal voltage (V_m) and its reference value at CPI is taken as (V_m^*). So, the total fundamental reactive component is evaluated as

$$\mu_{sq} = \mu_{cq} - \mu_{Lq} \tag{35}$$

$$\mu_{Lq} = \frac{\mu_{aq} + \mu_{bq} + \mu_{cq}}{3} \tag{36}$$

The reactive component of the reference current is determined as (37).

$$i_{xq}^* = \mu_{sq}u_{aq}, \quad x \in \{a, b, c\} \tag{37}$$

Therefore, the source reference currents are calculated as [36, 37] (38).

$$i_{sx}^{*} = i_{xd}^{*} + i_{xq}^{*} \quad x \in \{a, b, c\} \tag{38}$$

The gating pulses of the VSI are formed by the hysteresis current controller (HCC) [25]. However, the HCC approach is faster despite various limitations such as greater switching frequencies and changeable switching frequencies. The hysteresis band ($\delta = 0.01$) is chosen for the proposed controller's proper operation. The error is calculated by subtracting the detected grid currents (I_{sa}, I_{sb}, and I_{sc}) from the grid reference currents (I_{sa}^{*}, I_{sb}^{*}, and I_{sc}^{*}).

4 Results and discussion

The result of the proposed 3P4W standalone system is analyzed under intermittency in solar radiations, wind speed, and consumer load. During variations in load demand and changes in solar PV insolation, the reliability of the proposed MPAPA approach is confirmed through simulation and test results. The simulation results of CPI voltage (V_{sabc}), CPI current (I_{sabc}), load current (I_{Labc}), compensator current (I_{cabc}), DC-link voltage (V_{dc}), frequency (F), neutral load current (I_{Ln}), PV current (I_{pv}), duty cycle (α), and PV power (P) are taken under various operating circumstances.

4.1 Dynamic response of wind and SPV system during unbalanced load

Figure 4 indicates the dynamic response of the suggested wind and SPV system during constant wind speed/solar radiations feeding an unbalanced load. The solar radiations and wind speed are fixed at 900 w/m^2 and 15 m/s, respectively. The load of phase 'b' is detached at t = 2.7 s to t = 2.9 s. During the removal of a load of phase 'b', the load current is decreased and the controller manages the CPI voltage, CPI current, frequency, and DC-link voltage of the proposed DG system. The total generation of the standalone system is increased from 5.2 to 5.8 kW during the elimination of the load of phase 'b'. Further, the compensator current and neutral load current are increased during load detached. The MPAPA control with VSI provides multi-functions like voltage/frequency control, neutral current compensation, harmonics eradication, power support and enhances the overall PQ of the isolated system.

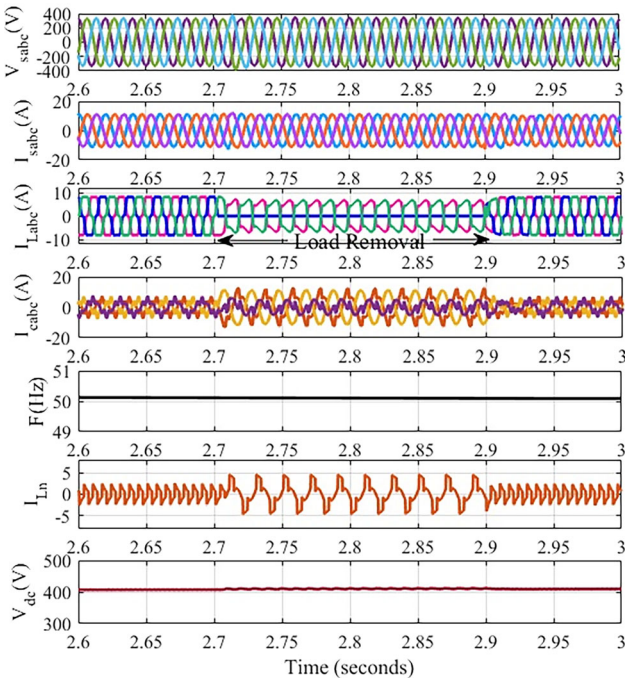

Fig. 4 Dynamic response of wind and SPV system during unbalanced load

4.2 Dynamic response under intermittency

The dynamic performance of the standalone wind and SPV system during wind variation feeding balanced nonlinear load is observed and displayed in Fig. 5a and b. Figure 5a represents the wind speed is altered from 15 to 12 m/s at t = 2.8 s and the solar radiation is shifted 500–900 w/m^2 at t = 2.7 s. Due to inflation in solar radiations, the PV current and the PV power of the proposed isolated system are increased from 5.9 to 11.77A and 1.8–2.8 kW, respectively, and the duty cycle is decreased. Further, the total power generation is reduced from 5.8 to 4.4 kW due to a decrease in wind speed from 15 to 12 m/s. Figure 5b depicts that during the variation in solar radiations at t = 2.7 s, the CPI voltage shows a slight deflection of 0.01 s, and then, the controller manages the CPI voltage. The (I_{sabc}) and (I_{Labc}) are increased during the intermittency of wind speed and solar radiation. Further, the VSI continuously provides power support during the change in wind/solar radiations with the help of a DC-link connected BSS. Moreover, the controller manages the (F) and (V_{dc}) of the renewable energy-based system.

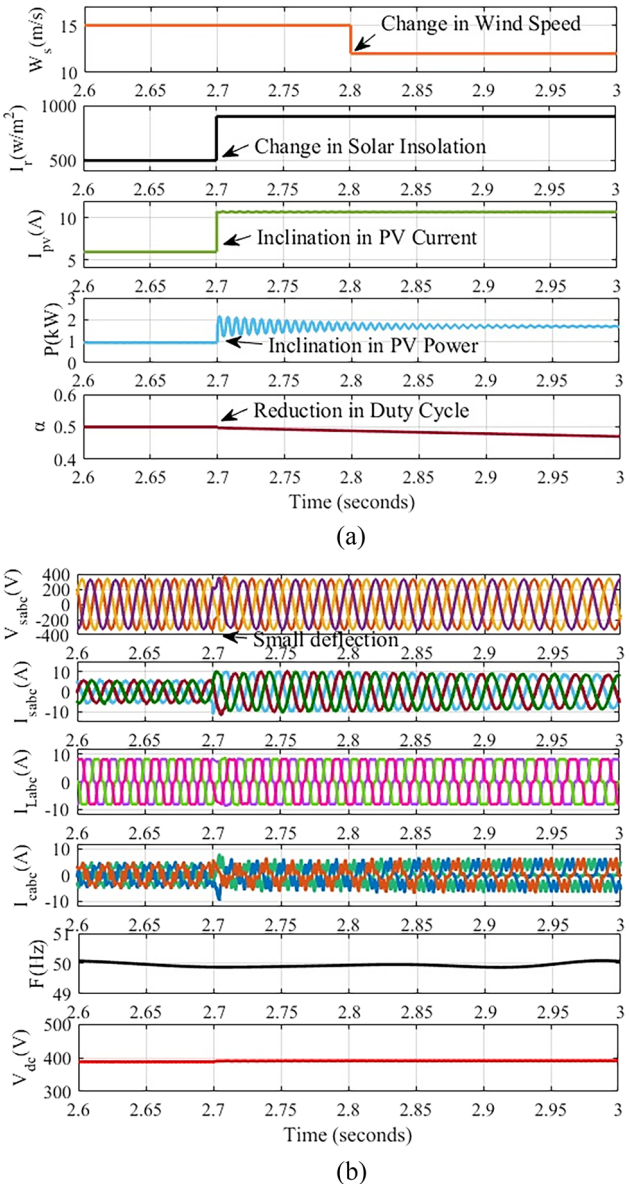

Fig. 5 **a** and **b** Dynamic response of renewable energy-based system under intermittency

4.3 Harmonic profiles of standalone system

Figure 6a, b illustrates the harmonic profiles of CPI current and load current of the proposed renewable-based isolated system. Figure 6a, b illustrates the THDs of (I_{sb}) and (I_{Lb}) of phase 'b' are 4.16% and 25.19%, respectively. The harmonic analysis of the 3P4W standalone system is analyzed under uncertain load conditions. The THDs of the standalone system are found in limit and follow the IEEE-514 standard.

5 Test result

The experimental configuration used to assess the performance of the MPAPA control approach under dynamic load is displayed in Fig. 7. An oscilloscope, dSPACE-1104 control board, voltage and current sensors, host computer, and DC power supply, power analyzer, nonlinear load make up the setup. Specifically, integration between the dSPACE-1104 control desk and the MATLAB/Simulink environment, where the proposed control is modeled, is made possible by the host computer. The MPAPA-based models are automatically generated code and then assembled and uploaded onto the dSPACE control board, allowing the dSPACE control desk to track the MPAPA estimations in real time. Lastly, the dSPACE digital-to-analog converter transmits the estimates to the oscilloscope.

5.1 Response Isolated system at unbalanced load

Figure 8a–f represents the steady-state and dynamic response of the proposed isolated system under various loading circumstances. The said figures show different signals of isolated system such as in-phase unit template (u_{ad}), CPI voltage (V_{sa}), CPI current (I_{sa}), load current (I_{La}), and DC-link voltage (V_{dc}). Figure 8a, b depicts the steady-state and dynamic response of u_{ad}, V_{sa}, I_{La}, and I_{sa} under nonlinear load conditions. Figure 8c shows the dynamic response of V_{sa}, I_{La}, $\mathrm{I_{sa}}$, and I_{sc} under load insertion of different phases at different times. During the insertion of load at different times as depicted in Fig. 8c, the I_{La}, I_{sa}, and I_{sc} are increased. Figure 8d, e shows the response under load insertion and load removal conditions. Figure 8d shows during the reduction in load, the I_{La} and I_{sa} are increased, and on another side in Fig. 8e shows the signals under insertion of load, the I_{La} and I_{sa} are reduced. Figure 8f reveals the performance of V_{dc}, V_{sa}, I_{sa}, and I_{La} during dynamics in load. The V_{dc}, I_{sa}, and I_{La} are decreased during the load reduction duration. The dynamic results illustrate the proposed MPAPA control approach is able to maintain the aforementioned parameters under unbalanced and highly nonlinear load conditions. Further, the CPI current of the proposed system remains sinusoidal during the exclusion or insertion of load.

5.2 BSS Response during intermittency

The transient response of BSS under various operating conditions is depicted in Fig. 9. The BSS response is analyzed: (i) uniform solar radiations/wind speed feeding balanced nonlinear load, (ii) solar radiations/constant wind speed under uncertain conditions of nonlinear load, (iii) change in wind speed and uniform solar radiations feeding balanced load, (iv) change in solar radiations and constant wind speed feeding

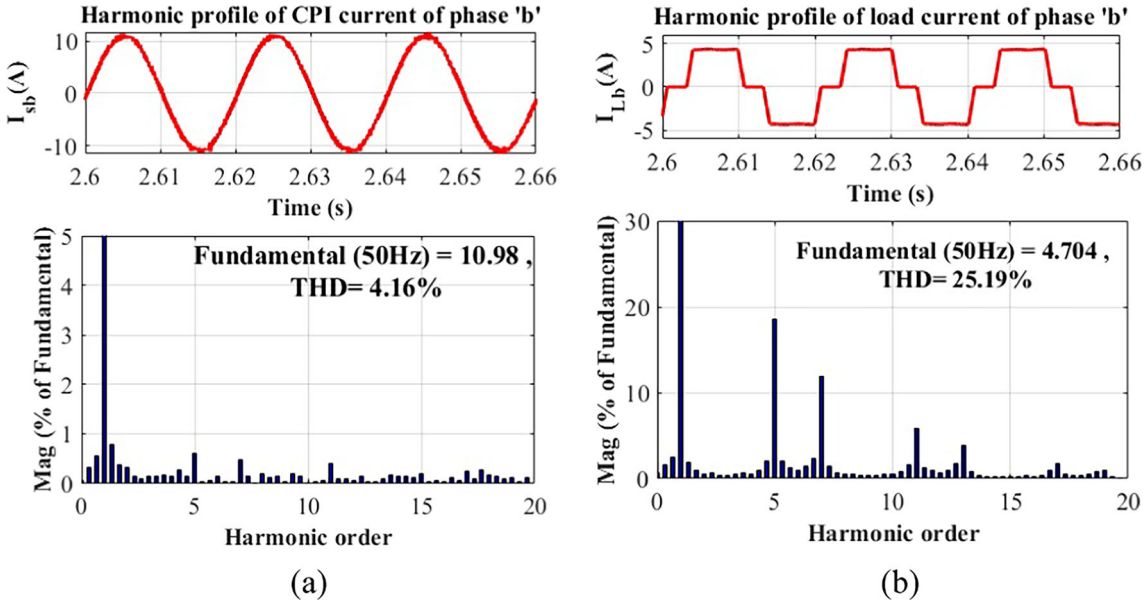

Fig. 6 **a** & **b** Harmonic profiles of the isolated system

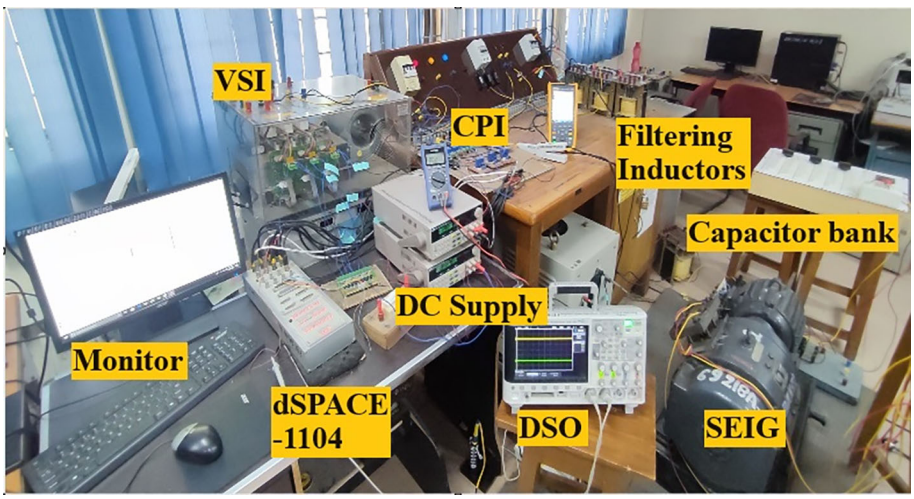

Fig. 7 Experimental prototype of isolated system

balanced load. During the elimination of a load of phase 'b', the excess power is transferred to the BSS. The BSS is shifted to the charging mode, and the BSS current is improved due to the removal of load. During the abrupt change in wind speed from 15 to 12 m/s, the BSS charging current is diminished. Also, during the decrement in solar radiations 900–500 w/m^2 at $t = 2.8$ s, the BSS is switched to draining mode and delivers power to CPI through VSI. The designed controller successfully balances all standalone system parameters under all operating situations.

Further, Table 1 depicts the comparison performance of proposed adaptive MPAPA, leaky momentum, and LMS-based existing control approaches. The parameters of the proposed standalone system are analyzed under different operating conditions and found that the proposed MPAPA control gives better performance, fast convergence, least oscillations with better stability, and minimum change in DC-link voltage.

5.3 Harmonic profiles of isolated system

Figure 10a, b represents the experimental results of harmonics under a polluted load. The THDs of CPI current and load current are 4.40% and 25.32%, respectively. The harmonic analysis of the 3P4W standalone system is analyzed under uncertain and highly nonlinear load conditions. On the observation of simulation and hardware results, the harmonic profile of the standalone system is found almost similar. The THDs of the standalone system are found in the limit and meet the IEEE-514 standard.

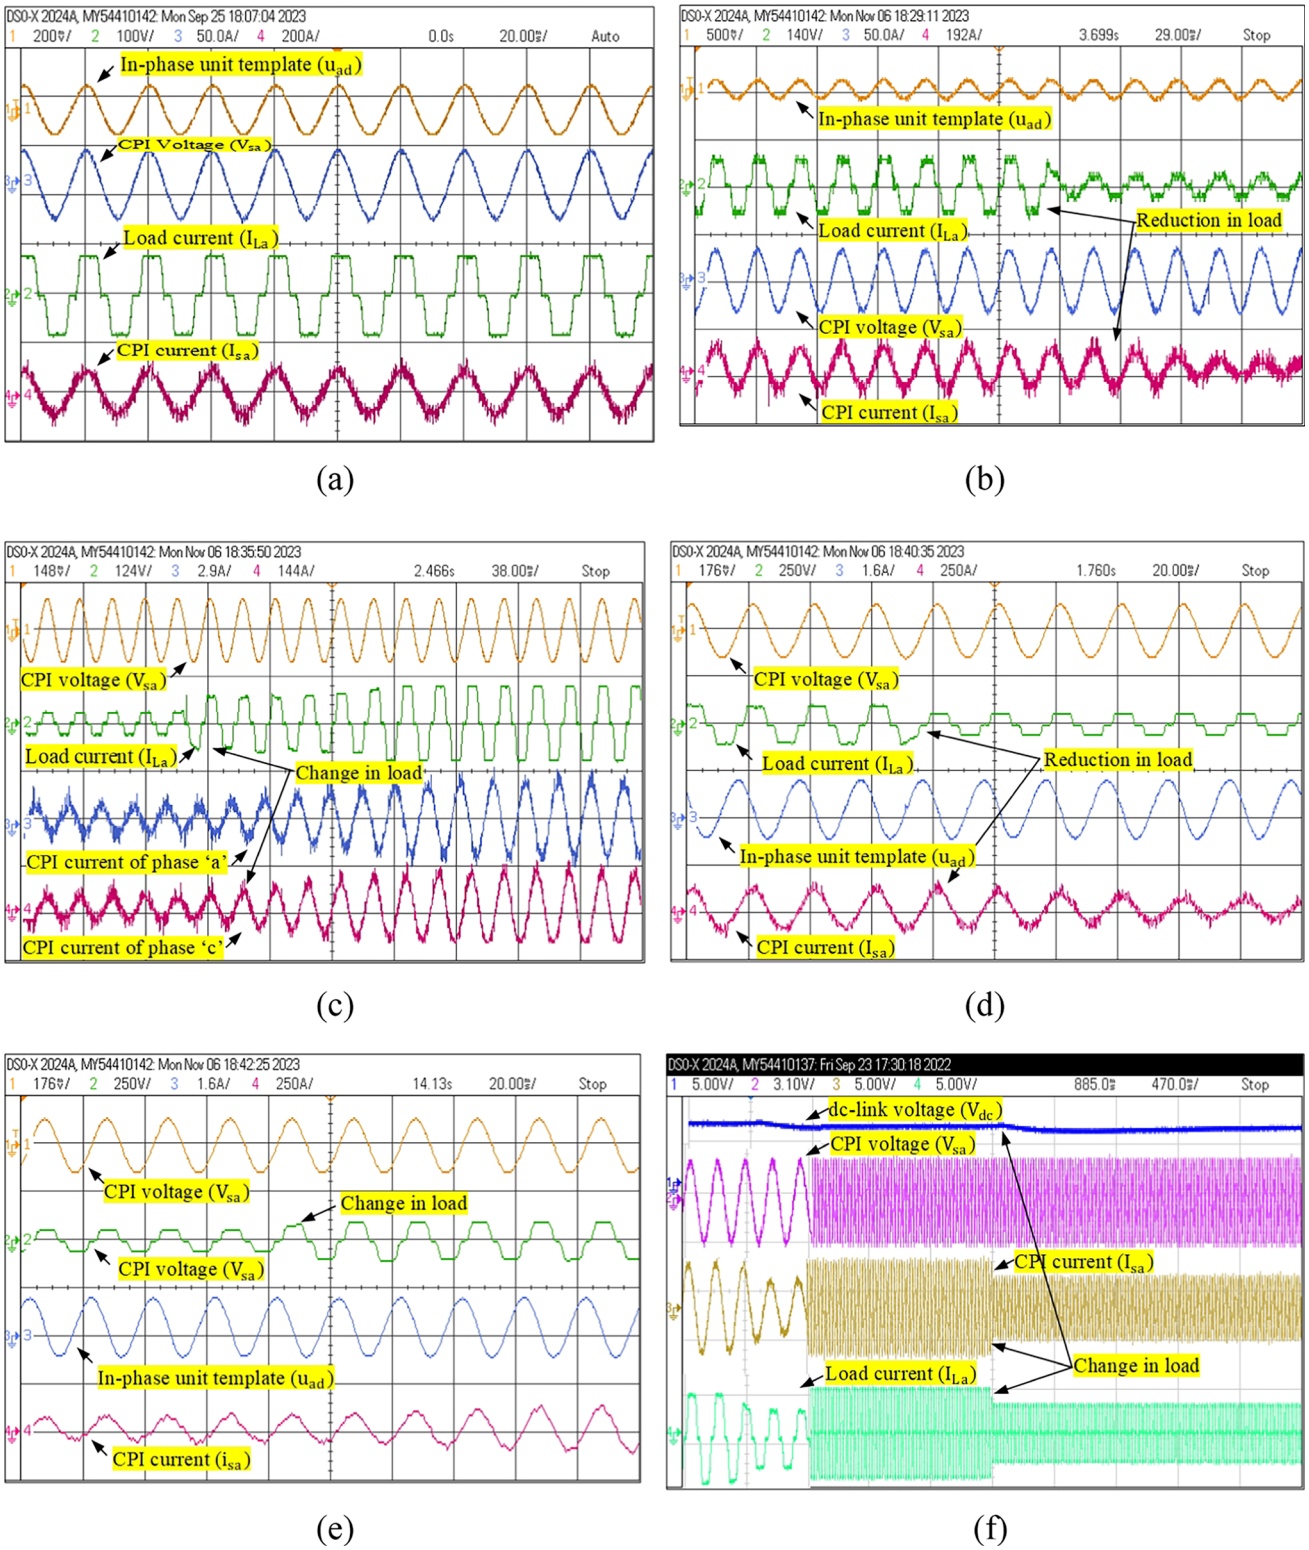

Fig. 8 Response of proposed isolated system at unbalanced load **a**, **b** u_{ad}, V_{sa}, I_{La} and I_{sa}, **c** V_{sa}, I_{La}, I_{sa}, and I_{sc} **d–e** V_{sa}, I_{La}, u_{ad}, and I_{sa} and **f** V_{dc}, V_{sa}, I_{sa}, and I_{La}

6 Conclusion

An in-loop filter-based adaptive MPAPA control algorithm is implemented to enhance resilience in wind and SPV-based standalone generation system with intermittency and testing consumer loads. A BSS of adequate capacity is being used to ensure power balance in this isolated system. The proposed MPAPA control successfully computed the reference source currents under intermittent conditions of wind speed, SPV radiations, and unbalanced loading. The simulation results indicated PQ enhancement with the stabilization of the frequency and voltage profile of the renewable-based standalone system. Moreover, the MPAPA control approach with VSI effectively provides power support, neutral current and reactive power compensation, and load leveling under all operating conditions. The simulation and hardware results confirmed that the CPI voltage and current THDs consistently lie within the IEEE-519-2014 acceptable limit. The elimination of the boost converter from the SPV stage did not affect MPP's performance. Furthermore, the MPP operation was accomplished using the BDC at all radiation levels. As a result, the proposed 3P4W standalone energy system with the MPAPA approach is a feasible alternative for rural electrification.

Author contributions 1) Author 1st has prepared the manuscript. 2) Authors 2nd and 3rd have reviewed the manuscript and help to design the hardware prototype. 3) Author 4th has help to taken the hardware result.

Abstract: *The framework within which the present study, research conducted was descriptive in nature and the target population in this regard is consisting of 100 schoolteachers based in urban and rural areas. Stratified Random sampling method was adopted for selecting the samples. The respondents' age varied from 25 years to 50 years. Data was collected from respondents with the help of self-administered questionnaires. For assessing the Social Intelligence level of teachers, the scale developed by Chadha and Ganeshan was used. The study highlighted that there exists a significant difference in the Social Intelligence level of teachers based on their location status. It also demonstrated that the Social Intelligence level of teachers is average. It is even posited in the study that there exists relationship among variables like Patience and Cooperativeness and therefore it can be inferred that these factors can definitely help predict the Social Intelligence level better.*

Keywords: *Social Intelligence of Schoolteachers, Social Intelligence and leadership quality.*

I. Introduction

In the recent past, social intelligence has become a much talked about term. It is with the advent of leadership issues gaining momentum that it has been realised that Social Intelligence related concepts assume importance. The present study relates to social intelligence in context of school teachers. It is well established fact that students see their faculty as their role model. There are many lessons of life and character building which are primarily learnt from teachers. From this it is evident that if efforts are put in, to raise the level of social intelligence among teachers, the tone for social intelligence among the students may automatically be set.

II. Review of Literature

In 1998 Danial Goleman came up with the exploration of the idea of the Emotional Intelligence (EI) and leadership in his book "What makes a leader?" Since then, vital role of the components of EI; like empathy and self-knowledge has been a subject of talk among diverse communities. But in recent past, researches in the field of 'social- neuroscience: the study of what happens in brain when people interact', has unveiled much of truth about 'what makes a good leader'; and the concept of Social Intelligence (SI) comes into limelight. Though, SI has its origin in Thorndike's (1920) division of intelligence into three facets: the ability to understand and manage ideas (abstract intelligence), concrete objects (mechanical intelligence), and people (social intelligence). The term SI, referred to the person's ability to understand and manage other people and to engage in adaptive social interaction (Thorndike, 1920). More recently, however, Cantor and Kihlstrom (1987) redefined SI as "the individual's fund of knowledge about the social world". A more relationship-based construct for assessing leadership is social intelligence, which we define as a set of interpersonal competencies built on specific neural circuits (Goleman & Boyatzis, 2008). Various researches on social intelligence indicate that how it is linked with everything from student achievement, workplace success to general wellbeing (Bar-on, 2005; Druskatet et.al. 2006). Investigation on various aspects of social intelligence have shown that a high level of social intelligence contributes towards the person's ability to meet the demands of everyday functioning as well as for shouldering responsibility of the welfare of self and others. According to Cantor & Kihlstrom (1987), social intelligences specifically geared for solving the problems of social life, and in particularly managing the life tasks, current concerns or personal projects which the person selects for him or herself, or which other people impose on him or her from outside.

Many researchers reported that social intelligence is multidimensional and distinguished from general intelligence domains (Wong, Day, Maxwell, & Meara, 1995; Jones & Day, 1997; Weis & Süb, 2007) which contributes towards effective leadership. Zirkel (2000) believed that social intelligence is closely related to one's own personality and individual behaviour. SI is the part of individual's mental ability which generates the capacity to adapt him to the society, as such relations are essential for his existence. It is human capacity to understand what is happening in the world and respond to that understanding in personal and social level in effective manner. SI has a great importance for the teachers to interact with students effectively, for better understanding of their personality so as they can be harnessed for shaping up a better personality makeup. Balaghat and Pour (2014) investigated the relationship between social intelligence of high school managers of district-2 of Zahedan and their leadership style and found a positive and significant relationship between SI and relation-oriented managers. Albrecht (2006) suggested that social intelligence is a prerequisite for teachers; education system and teachers respect the rules and behaviours associated with high social intelligence. Jeloudar and Goodarzi (2012) found a significant relationship between teachers' social intelligence and their job satisfaction; and, teachers' social intelligence and five factors of job satisfaction: nature of the work itself, attitudes towards supervisors, relations with co-workers, opportunities for promotion, work condition in the present environment, but the relationship with one factor (salary and benefit) of job satisfaction is low and negligible. Sarvamangala (2012) observed that socio-demographic factors such as gender, age, caste and marital status etc. do not have any influence on social intelligence of school teachers. Toor (2013) found significant difference in social intelligence of male and female secondary school teachers of punjab. McQuade (2013) demonstrated that principals and teachers view social intelligence critical to educational leadership and teachers' improvement. Renugadevi and Nalinilatha (2014) found no significant relationship between social intelligence and teaching competency. Mahaboobvali and Vardhini (2016) studied the social intelligence of school teachers with respect to gender and age; and found no gender influence on social intelligence of teachers whereas a significant variation was found among the age groups of the teachers towards the social intelligence.

Based on the premise that leadership traits can be acquired by raising the level of social intelligence among the students and teachers, the research has been conducted with the following objectives.

1. To find out the social intelligence level of school teachers.
2. To find out the relationship among the various factors contributing to the social intelligence level viz. Patience, Confidence, Cooperativeness, Sensitivity, Recognition in the social environment, Tactfulness, Sense of humour and Memory.
3. To test that whether there is any significant difference in the Social intelligence level of teacher based on the urban or rural areas where schools are located.

III. Hypotheses of the Study:

H1: The School teachers possess high social intelligence.
H2: There exists a positive relationship among the various factors pertaining to social intelligence level.
H3: There is no significant difference in the social intelligence level of teachers based on their locality.

IV. Research Design:

The framework within which the research was conducted was basically descriptive in nature and the target population in this regard is defined as consisting of 100 school teachers based in urban and rural areas. The research was conducted on school teachers. Stratified Random sampling method was adopted for selecting the samples. The respondents' age varied from 25 years to 50 years. Survey methods was used to collect data from respondents with the help of self-administered questionnaires.

A scale comprising of items clubbed into 8 factors was used to determine the Social intelligence level of teachers on 3 point Likert scale. In the process 8 factors were considered for determining the Social intelligence level of teachers. Social intelligence inventory by Chadha and Ganesan were used . The process of data collection took a period of over 4 months. Participation of teachers in the survey was voluntary. Socail intelligence was measured using item scales comprising 5 parts with total of 66 questions. For assessing the Social Intelligence level of teachers, the scale developed by Chadha and Ganesan was used. This was chosen as it is considered as a reliable inventory for assessing the Social intelligence level. On the inventories, reliability analysis was done by using Cronbach alpha test and the score came out to be more than .7 (.85in particular) which indicated that the statements are internally consistent. One way ANOVA was used to measure the significant difference between the factors based on the location status of schools. Karl Pearson's Correlation was used to find the relationship of various factors of social intelligence among each other and Total Social Intelligence score.

For six dimensions of Social Intelligence viz. Patience, Confidence, Sensitivity, Cooperativeness, sense of humour and Recognition of social environment, score of 1 indicated lack of confidence. In case of a dimension tactfulness, the response was in the form of 'yes ' or 'no'. A high score indicated high social intelligence.

The scale comprised 66 items . Each item had options namely “Very high ”, ”high”, ”Average”, “Low”, ”very low”. An individual score is the sum of all the scores of 66 items. The score ranged from 66 to 138. As per manual, the level of social Intelligence has been defined as below:

High Social Intelligence 113 and above
Average Social Intelligence 57 upto 112
Low Social Intelligence 36 to 56

V. Data Analysis

Table 1: Descriptive Statistics

	N	Minimum	Maximum	Mean	Std. Deviation
Social_Int	100	87	123	109.03	7.780
Valid N (listwise)	100				

The data was collected from 100 school teachers and their mean was computed. The mean score of Social Intelligence was computed and the results showed that the school teachers had average social intelligence (According to the interpretation of the scores of the inventory, anyone having a score between 57 to 112 is said to possess Average Social Intelligence.

In the inventory, Social Intelligence is computed as a measure of additive scores of the factors viz. Patience, Confidence, Cooperativeness, Sensitivity, Recognition in the social environment, Tactfulness, Sense of humour and Memory.Therefore the hypothesis stating that social intelligence level of school teachers is high is rejected.

The details of the scores obtained by teachers on individual factors contributing to Social Intelligence level have been given as in Table 2.

Table 2: Descriptive Statistics

	N	Minimum	Maximum	Mean	Std. Deviation
Total_ Social_ Int	100	87	123	109.03	7.780
Patience	100	11	26	20.71	2.931
Confidence	100	14	30	19.90	2.676
Cooperativeness	100	22	31	27.27	2.403
Sensitivity	100	15	25	20.76	2.775
Recog_Soc_env	100	0	3	1.43	.795
Tactfulness	100	1	6	4.02	1.310
Sense_of_humour	100	1	8	4.72	1.676
Memory	100	6	13	10.15	1.828
Valid N (listwise)	100				

Table 3: Correlation between various factors of Social Intelligence

Correlations										
		Patience	Cooperativeness	Confidence	Sensitivity	Recog_Soc_env	Tactfulness	Sense_of_humour	Memory	Total_Social_Int
Patience	Pearson Correlation	**1**	.206*	.251*	.202*	-.041	.133	-.072	.025	.610**

Tactfulness	Pearson Correlation	.133	.338**	-.057	-.021	-.086	**1**	-.108	.121	.340**
	Sig. (2-tailed)	.187	.001	.573	.837	.395		.286	.230	.001
Sense_of_humour	Pearson Correlation	-.072	.139	-.137	-.058	.129	-.108	**1**	-.105	.101
	Sig. (2-tailed)	.475	.167	.174	.566	.200	.286		.299	.316
Memory	Pearson Correlation	.025	.191	-.168	.220*	-.017	.121	-.105	**1**	.339**
	Sig. (2-tailed)	.804	.057	.094	.028	.866	.230	.299		.001
Total_Socil_Int	Pearson Correlation	.610**	.611**	.492**	.569**	.026	.340**	.101	.339**	**1**
	Sig. (2-tailed)	.000	.000	.000	.000	.800	.001	.316	.001	

* Correlation is significant at the 0.05 level (2-tailed).
** Correlation is significant at the 0.01 level (2-tailed).

Table 3 shows Karl Pearson's coefficient of correlation among the various factors of Social intelligence viz. . Patience, Confidence, Cooperativeness, Sensitivity, Recognition in the social environment, Tactfulness, Sense of humour and Memory. The correlation scores obtained by different factors of social intelligence and social intelligence are as given in the Table 3.

The Table clearly shows that patience(r=.610) and cooperativeness (r=.611)have strong positive correlation with social intelligence among the others. It can be seen that Sensitivity, Tactfulness and confidence also show significant positive correlation with spiritual intelligence level but their magnitude of relationship is fairly lesser than the Patience and Cooperativeness. The factors showing positive relationship with Social intelligence were tested at .01 level of significance. Sense of humour and Memory were found to be insignificant to determine Social Intelligence level of the teachers. Therefore, it can be inferred that the Patience, Cooperativeness, Confidence and sensitivity can best predict the Social Intelligence of the teachers.

Table 4
Analysis of Variance for Various Factors of Social Intelligence With Respect to Location of the Schools (Remote and Urban)

Factor Name	Remote		Urban		F value	P value
	Mean	SD	Mean	SD		
Patience	4.31	.58	3.29	.57	.56	.007*
cooperativeness	4.74	.697	3.98	.83	.17	.004*
confidence	4.19	.56	4.18	.72	.25	.77
Sensitivity	4.20	.628	4.27	.58	.77	.46
Recognition in the social environment	2.52	.57	4.79	.60	4.72	.03**
Sense of humor	4.24	.70	4.15	.73	1.07	.34
Memory	4.35	.63	4.24	.84	4.48	.98

*significant at.01 level
**significant at .05 level

One way ANOVA was performed to find that whether there is any significant difference in the social intelligence level among teacher with respect to the location at which they are placed. The result showed that there is a significant difference at 99% confidence level in the Social Intelligence level based on location status of the schools. More specifically the intelligence varied for the factors viz. Patience and Cooperativeness and at 95% confidence level, it is established that recognition to social environment also varies with the location status. The null hypothesis stating that there is a significant difference based on the location status is rejected

V. Findings and Recommendations:

The study highlighted that there exists a significant difference in the Social Intelligence level of teachers based on their location status. It also demonstrated that the Social Intelligence level of teachers is average. It is even posited in the study that there exists relationship among variables like Patience and Cooperativeness and therefore it can be inferred that these factors can definitely help predict the Social Intelligence level better. It is recommended that schools should try to induce Social Intelligence enhancing modules in the course curriculum for teachers and such workshops should become an integral part of the faculty development programmes.

Abstract

With an emphasis on banking industry, this study intends to examine customer satisfaction levels of those who have taken out personal loans from banking institutions. Customer satisfaction is a crucial indicator of success and longevity in the banking industry. This study explores the specifics of customer satisfaction among recipients of personal loans; wherein, the primary goal is to use operational research methods to analyse the intricate topography of customer satisfaction in the personal loan sector. The study's secondary objective is to demonstrate how factor analysis, a well-known dimensionality reduction method, may combine these disparate traits into a condensed set of essential components. The work presents practical insights to guide strategic choices intended to improve customer satisfaction and foster long-term growth in the banking industry, focusing on Banking sector.

Keywords: Banking sector, customer satisfaction, factor analysis, marketing research, personal loan.

1 Introduction

The banking sector provides individuals and businesses with vital financial services, making it a pillar of contemporary economies. Personal loans are critical to these services, providing customers access to money for various uses, including debt reduction, home improvement, education, and medical costs [1]. Understanding and evaluating consumer satisfaction with these financial products is crucial for banks to stay competitive and sustain long-term relationships with their clients as the demand for personal loans rises [2]. Customer satisfaction is a crucial indicator of how successfully a bank meets or exceeds its clients' requirements and expectations. Customer satisfaction in the context of personal loans includes several factors, such as the simplicity of the application process, interest rates, loan terms, level of customer service, openness, and general borrowing experience. The efficiency of banking services can be better understood by looking at customer satisfaction with personal loans. This will enable institutions to customize their products to suit the needs of their clientele better and increase retention rates. In the context of company strategy and consumer-centric methodologies, there is a close relationship between marketing research and customer satisfaction [3].

Customer satisfaction is the result of providing goods and services that meet or exceed the consumer's desires and expectations [4]. Customer satisfaction is a concept in the marketing research field, so it is crucial to understand what marketing research is. Marketing research is essential for comprehending customer preferences, behaviours, and perceptions [5]. Marketing research specifies the information required to address many issues, like designing the method for collecting information, managing and implementing the data collection process, analysing the results, and communicating the findings and their implications [6]. It systematically gathers, records, and analyses data about marketing products and service issues. Marketing research aims to identify and assess how changing elements of the marketing mix impact customer behaviour [7]. The term is commonly interchanged with market research; however, expert practitioners may wish to distinguish between market research is concerned specifically with markets while marketing research is concerned specifically about marketing processes. Also, this process is often partitioned into two sets of categorical pairs: target market, Consumer marketing research, and Business-to-business (B2B) marketing research, or by methodological approach, Qualitative marketing research, and Quantitative marketing research [8]. Consumer marketing research is a form of applied sociology that concentrates on understanding

consumers' preferences, attitudes, and behaviours in a market-based economy. It aims to understand the effects and comparative success of marketing campaigns. Arthur Nielsen pioneered consumer marketing research as a statistical science with the founding of the AC Nielsen Company in 1923 [9].

1.1 Concept of Customer Satisfaction

A fundamental idea in marketing and business management is that customer satisfaction is the level of fulfilment or contentment that consumers feel after interacting with a business, service, or product [10]. It includes their thoughts, emotions, and assessments about several facets of their experience, such as the Caliber of the goods, the promptness of the service, and their general interaction with the business.

Important facets of the customer satisfaction notion consist of:

- Expectations vs. Experience: The degree to which a customer's experience meets or surpasses their initial expectations is a common way to measure customer satisfaction. When a product or service exceeds clients' expectations, they will probably be pleased. If, on the other hand, the experience doesn't live up to expectations, disappointment could result. Customers' perceptions of quality are influenced by their demands, experiences, and preferences [11]. Subjective elements like dependability, effectiveness, beauty, and value for money are important in determining quality. When goods or services match their expectations for quality, customers are most likely to be happy.
- Service Delivery: The way goods or services are delivered can greatly impact customer satisfaction. Prompt and courteous service, customized attention, efficient problem resolution, and general attentiveness influence positive customer experiences and better satisfaction levels. Experiences with the brand at different touchpoints during the consumer journey shape impressions of it [12].
- Emotional Engagement: Satisfaction with customers results from both rational and emotional factors. Positive feelings like joy, delight, and trust foster stronger emotional ties between consumers and brands and are linked to high satisfaction levels [13]. Engaging customers emotionally increases their advocacy and loyalty, encouraging repeat business and positive word-of-mouth referrals.
- Loyalty and Retention: Happy consumers are more likely to stick with a brand over time and make repeat purchases of its goods or services [14]. Additionally, they are more likely to tell others about the company,

which helps with customer acquisition and retention initiatives. Consequently, establishing and sustaining client happiness is essential to long-term company success.

- Continuous Improvement: Due to shifting consumer tastes, industry developments, and competitive pressures, customer satisfaction is dynamic and prone to change. Companies must use performance indicators, market research, and feedback channels to monitor and evaluate customer satisfaction. Businesses may improve customer satisfaction and keep a competitive edge by recognizing areas for improvement and making necessary adjustments to meet changing needs [15]. Customer satisfaction measures how well a client's wants and expectations are satisfied when contacting a business, service, or product.

The banking industry's primary goal is to offer financial services and solutions that satisfy customers' requirements and expectations, and customer satisfaction is intrinsically linked to this goal [16].

1.2 Banking Sector

In the banking sector, many factors contribute to customer satisfaction: service quality, product selection, ease of use, accessibility, and overall customer experience. Maintaining long-term connections with their client and thriving in today's competitive landscape need banks to understand and improve customer satisfaction [17]. The calibre of services offered is one of the main factors influencing client satisfaction in the banking industry. This includes how quickly bank personnel respond to you, how smoothly transactions go, how accurate the information is, and how professionally all of the bank's employees act. Banks must meet various consumer needs, from simple savings and checking accounts to more complicated financial products, including loans, mortgages, and investment possibilities. Customers' satisfaction levels can be raised by offering creative and personalized products at transparent and upfront competitive prices. In the banking industry, accessibility and convenience are also significant determinants of client happiness [18]. Customers now demand smooth online and mobile banking experiences with features like simple account access, bill payment, fund transfers, and round-the-clock customer service, thanks to the development of digital banking technologies. User-friendly interfaces, ATM networks, and branch availability all add to the convenience and happiness of customers. Additionally, relationship management and tailored communication can significantly impact client satisfaction in the banking industry. Proactive relationship managers, tailored advice, and

attentive service can foster customers' trust and loyalty, ultimately increasing their satisfaction with the bank [19].

Customer satisfaction is a complex topic in the banking industry that includes a range of factors such as product choices, ease, trust, and customized relationships. Banks are better positioned to build enduring connections, encourage client loyalty, and prosper in a market that is becoming increasingly competitive when they prioritize comprehending and meeting their customers' needs and preferences. To analyse customer satisfaction with personal loans, the author used factor analysis as a tool. Factor analysis offers a strong foundation for comprehending the fundamental aspects of client contentment and locating workable solutions for raising satisfaction levels inside and outside the banking industry. Factor analysis identifies discrete client groups with comparable satisfaction patterns, which banks can use to segment their customer base better. By customizing their product offers and marketing methods to the distinct requirements and tastes of various client segments, banks can increase customer retention and loyalty through segmentation. In conclusion, factor analysis and marketing research are essential elements of strategic decision-making in the banking industry. Banks can gain valuable insights into the factors that drive customer satisfaction, optimize their offerings, and improve overall customer experiences by utilizing factor analysis techniques and marketing research methodologies. This can lead to developing long-term relationships and a competitive advantage in the market. The study employs OR methods and factor analysis to obtain practical insights to guide strategic choices intended to improve customer satisfaction and foster long-term growth in the banking industry, focusing on Yes Bank.

The rest of the study has been systematized as follows: Section 2 gives an extensive literature review on customer satisfaction in the banking sector. Sections 3 and 3.1 describe the Research Methodology of this study. Section 3.2 interprets the research methodology used, which is Factor Analysis. The final results of this study are described in Section 4. The author has concluded this study in Section 5, and future scopes and limitations of the study are also discussed in the Sections 5.1 and 5.2.

2 Literature Review

This section has extensively reviewed the literature on customer satisfaction in the banking sector to understand the comprehensive construction and research objective. The banking sector mainly relies on customer service

engagement and perspective, and customers, the backbone of the economy, have a significant role in determining their satisfaction.

Parasuraman et al. [20] presented a multi-item scale technique for measuring customer perception in the service industry in their study. They have emphasized the importance of studying customer perception and satisfaction. Hanif et al. [21] studied various factors that affect customer satisfaction. Singh et al. [22] empirically studied customer satisfaction and universal banks. The customer perception and satisfaction towards home loans have been analysed by Chaudhary and Janjhua [23]. Dawar [24] identified critical factors influencing customer satisfaction in banking using factor analysis. Out of the initial 22 attributes, factor analysis was reduced to 6 factors. Linking the banking industry with loan procedure variables, Jain et al. [25] studied the impact of demographic characteristics on customer satisfaction. Customer relationship management is based on increasing customer satisfaction analysed by Tao [26]. In the same year, Kapur et al. [27] presented a study for evaluation based on the expectations of customers and their satisfaction. Using logistic regression in 2016, Anand and Bansal predicted customer satisfaction and dissatisfaction. Begum et al. [28] used a confirmatory factor analysis to determine customer satisfaction with corporate loans. Later, Anand et al. [29] quantified the adopters as satisfied users and dissatisfied customers. In the year 2021, Tien et al. [30] studied customer satisfaction at a bank and used factor analysis for dimension reduction. Agag et al. [31] studied marketing analytics to understand the relationship between customer agility and customer satisfaction. These studies offer a solid framework for examining consumer satisfaction with personal loans in the banking industry. This aligns with the study's goals of employing operational research (OR) to evaluate customer satisfaction with a specific focus on Yes Bank.

3 Research Methodology

For this study, the authors conducted a survey on customers of Yes Bank at Hudson Lane, Kingsway Camp, New Delhi-110009, India, in the age group of 21–60 years, to analyse how satisfied they are with the services of the bank under consideration. They were intentionally chosen as this market is vital, easily influenced by its surroundings, and good at buying power. Two hundred eleven customers were administered randomly, and the area where questionnaires were distributed was the University of Delhi.

Table 1 is a representation of the customers as per their educational/ qualification level:

Table 1 Frequency table of customers' qualification

Education Level	Count of Education Level
Doctorate	6
High School	4
Other	6
Postgraduate	43
Secondary School	5
Undergraduate	146
Grand Total	**210**

In this study, customers were asked to rate their satisfaction with various attributes connected to the dissemination of personal loans. Apart from the different demographic questions, they rated various attributes from 1 to 5, with one being the least satisfied and 5 being the highest satisfaction with a particular attribute.

The authors calculated the weighted mean of those attributes to determine which attributes have the most impact on making the brand more qualitative and valuable among customers. The table below showcases the number of persons catered in the different categories based on their occupation.

Table 2 shows that most of the respondents are private sector employees, followed by the government sector, and so on.

Table 3 describes the various reasons why particular loans have been taken from the bank.

Here, it can be seen that most of the respondents took a loan to finance a new venture after that for medical emergencies, debt consolidation, and so on.

After fetching useful information from the demographics, the next step is moving from demography toward dimensionality reduction. As described

Table 2 Occupation-wise division of the customers

Occupation	Count of Education Level
Business	33
Government Employee	62
Home Maker	4
Other	23
Private Job	70
Retired	1
Self Employed	18
Grand Total	**211**

Table 3 Reasons for availing of personal loans

Purpose for Availing of Personal Loan	Count of Education Level
Debt consolidation	35
Finance a new venture	52
Home remodelling	33
Medical Emergencies	38
Other	25
Vacation Costs	6
Wedding Expenses	22
Grand Total	**211**

above, the various attributes under consideration are presented to the customers, and they are asked to rate them based on their satisfaction level. Before moving toward the analysis, it is essential to understand factor analysis. In the next section, the author briefly describes the methodology used – Factor Analysis.

3.1 Factor Analysis

A statistical method called factor analysis is used to find underlying dimensions or factors that account for patterns of correlations between a group of observed data. Factor analysis can be used in customer satisfaction to determine the main aspects influencing overall satisfaction and the underlying structure of variables connected to satisfaction.

The following actions can be conducted to perform factor analysis on customer satisfaction data:

- Step 1: Data collection: Compile information on a range of customer satisfaction factors, including product characteristics, the calibre of the services, cost, ease of use, and overall experience. Feedback forms, interviews, and surveys can all be used to get this information.
- Step 2: Choose the variables (or survey questions) that best capture the many facets of customer satisfaction. These variables should encompass a broad range of satisfaction parameters and be pertinent to the area of interest.
- Step 3: Data Preparation: Ensure the data satisfies the requirements of factor analysis, including continuous variables, a sizable enough sample size, and no problems with multicollinearity. It can be necessary to attribute or exclude missing data.

- Step 4: Factor Extraction: Use methods for factor extraction, such as joint factor analysis or principal component analysis (PCA), to find the underlying factors that account for the patterns of correlations between the variables. The aim is to reduce the number of dimensions in the data while maintaining the maximum amount of information.
- Step 5: Factor Rotation: After extracting the factors, use rotation techniques like varimax or rotation to create a more straightforward and understandable factor structure. Rotation makes it simpler to see how variables and factors relate to one another.
- Step 6: Factor Interpretation: To understand the results, look at the factor loadings, which show how strongly and in which direction each variable is related to the underlying factors. High-loading variables on a given factor are thought to be closely related to that factor.
- Step 7: Naming & Labelling: Based on the analysis of factor loadings, give the extracted factors that represent the fundamental aspects of customer satisfaction appropriate names or labels. These labels should reflect each component's variables' general themes or traits.
- Step 8: Assessment of Validity and Reliability: Determine the extracted variables' internal consistency and construct validity to assess their validity and reliability. The reliability of the factors can be evaluated using methods like Cronbach's alpha, and the model fit and validity of the factor structure can be examined using confirmatory factor analysis (CFA).
- Step 9: Application and Interpretation: Apply the final factor structure to customer satisfaction and use the insights gained to improve customer experiences. The factors identified have the potential to impact strategic choices about product creation, marketing tactics, improving customer service, and general business operations.

The authors have used 16 variables to perform a factor analysis to analyse customer satisfaction with personal loans. Table 4 represents the descriptive statistics performed on these 16 variables.

But before proceeding with factor analysis, we need to test the KMO and Bartlett's tests to determine the data's suitability. This test measures sampling adequacy for each variable in the model and for the complete model. The statistic measures the proportion of variance among variables that might be common variance. The lower the proportion, the more suitable the collected data is for factor analysis.

Table 4 Descriptive statistics

	Mean	Std. Deviation	Analysis N
Debt to Income Ratio	3.50	1.319	208
Top Up Loan	3.74	1.155	208
Employment History	3.39	1.506	208
Efficient Staff	3.30	1.040	208
Monthly installment	3.41	1.201	208
Rate of Interest	4.09	1.147	208
Time taken for the verification	3.13	1.062	208
Credit Score (CIBIL Score)	3.72	1.448	208
E-Verification	3.53	0.962	208
Penalty fees	2.99	1.026	208
Loan Repayment	2.89	1.331	208
Following RBI Guidelines	3.23	0.994	208
Facility of loan extension	3.77	1.033	208
Quick Loan Approval facility	3.54	1.289	208
Documentation Process	3.08	1.166	208
Low File Closure Charge	3.23	1.356	208

Table 5 KMO and Bartlett's test

Kaiser-Meyer-Olkin Measure of Sampling Adequacy		0.825
Bartlett's Test of Sphericity	Approx. Chi-Square	1035.129
	df	120
	Sig.	$<$0.001

As a rule of thumb for interpreting the statistics:

- KMO values between 0.8 and 1 indicate the sampling is adequate.
- KMO values less than 0.6 indicate inadequate sampling, and that remedial action should be taken. Some authors put this value at 0.5, so use your judgment for values between 0.5 and 0.6.
- KMO values close to zero mean there are large partial correlations compared to the sum of correlations.

For the collected data, the KMO value is 0.825, which can be seen in Table 5, which falls into the excellent range, so we can be confident that the sample size is adequate for factor analysis. Bartlett's test is a statistic used to examine the hypothesis that the variables are uncorrelated in the population. From the data, we have the KMO value of $0.825 > 0.5$. Thus, factor analysis is appropriate for this case. Hence, we can further proceed with the analysis.

Table 6 Communalities

	Initial	Extraction
Debt to Income Ratio	1.000	0.584
Top Up Loan	1.000	0.472
Employment History	1.000	0.607
Efficient Staff	1.000	0.694
Monthly installment	1.000	0.644
Rate of Interest	1.000	0.762
Time taken for the verification	1.000	0.504
Credit Score (CIBIL Score)	1.000	0.419
E-Verification	1.000	0.679
Penalty fees	1.000	0.684
Loan Repayment	1.000	0.584
Following RBI Guidelines	1.000	0.637
Facility of loan extension	1.000	0.537
Quick Loan Approval facility	1.000	0.575
Documentation Process	1.000	0.399
Low File Closure Charge	1.000	0.316

The foundation of factor analysis is to study the various variables under a limited set of technical definitions, which can then be presented to management. Around 16 different variables were considered, and the relevant queries regarding their satisfaction level were sent to the customers. Some findings are presented below in Table 6.

The amount of variance in each variable that is accounted for is shown in this table. Estimates of the variance in each variable accounted for by all components or factors are known as initial communalities. Estimates of the variance in each variable that the components account for are known as extraction communalities. The factors explain all variance, and there is only one communality prior to extraction because there are precisely as many factors as there are variables. Unfortunately, some of the components are eliminated following extraction, which results in the loss of some information. While they can only account for a portion of the variance in the data, the retained components cannot fully explain all of it. Following that, four elements are removed and kept (as shown in Table 7); the communality in the above table is 0.58 for the Debt-to-income ratio, 0.47 for Top-Up loan, and so on. Four factors have been retrieved from the 16 variables; factors with eigenvalues greater than one are presumed to be extracted. The above

Table 7 Total variance explained

	Initial Eigenvalues			Extraction Sums of Squared Loadings			Rotation Sums of Squared Loadings
Component	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total
1	6.402	40.011	40.011	6.402	40.011	40.011	5.709
2	1.283	8.019	48.030	1.283	8.019	48.030	1.334
3	1.222	7.637	55.667	1.222	7.637	55.667	4.289
4	1.012	6.328	61.995	1.012	6.328	61.995	1.222
5	0.816	5.097	67.093				
6	0.776	4.851	71.944				
7	0.713	4.459	76.402				
8	0.694	4.339	80.741				
9	0.561	3.509	84.250				
10	0.545	3.403	87.653				
11	0.443	2.766	90.419				
12	0.397	2.479	92.899				
13	0.375	2.347	95.245				
14	0.312	1.953	97.198				
15	0.255	1.596	98.794				
16	0.193	1.206	100.000				

table (all values are called communality in the above table) shows that the communality is 40% for variable 1, 48% for variable 2, and so on after the factors are extracted and retained. Finding the extracted variables, their Eigenvalues, and the cumulative percentage of variance is the first step in evaluating the results. The cumulative percentage column shows that the four factors extracted—information from the 16 original variables—account for 55% of the variance overall.

Table 8 represents the Rotated Component Matrix, and Table 9 represents the Component Matrix. These tables are required to interpret or summarize the results. These tables report the factor loadings for each variable on the factors or components after rotation. Each number represents the partial correlation between the item and the rotated factor.

The authors are able to reduce the 16 variables to 4 factors that are free from redundancy. After completing the statistical computations factoring, the next step is interpreting these factors. This is achieved by inspecting the pattern of high and low loading of each of the factors on the variables.

Table 8 Rotated component matrix

	Component 1	Component 2	Component 3	Component 4
Debt to Income Ratio			0.720	
Top Up Loan		0.590		
Employment History			0.745	
Efficient Staff	0.773			
Monthly installment				0.557
Rate of Interest		0.786		
Time taken for the verification	0.598			
Credit Score CIBIL Score			0.585	
E- Verification	0.752			
Penalty fees	0.810			
Loan Repayment				0.752
Follow RBI Guidelines	0.731			
Facility of loan extension		0.718		
Quick Loan Approval	0.601			
Documentation Process				
Low Foreclosure Charge	0.537			

Extraction Method: Principal Component Analysis.
Rotation Method: Varimax with Kaiser Normalization.[a]

a. Rotation converged in 7 iterations.

Table 9 Component transformation matrix

Component	1	2	3	4
1	0.816	0.345	0.442	0.140
2	−0.381	0.915	−0.050	0.122
3	−0.244	−0.202	0.325	0.891
4	−0.360	−0.049	0.835	−0.414

Extraction Method: Principal Component Analysis.
Rotation Method: Varimax with Kaiser Normalization.

3.2 Interpretation of Factor Analysis

The results of those above require some discussion. From Table 7 of the total variance explained, it can be seen that the total 16 attributes can be clubbed under the four factors in totality. They can be given specific names to aid the management so that instead of studying the 16 attributes separately, only

four factors can be worked upon. Based on the values obtained in the rotated component matrix, around eight attributes can be clubbed under one canopy based on the values of the factor loadings.

Factor 1: Loan processing efficiency

Attributes	Factor loading
Efficient staff	0.773
Time taken for verification	0.598
E-Verification	0.752
Penalty fees	0.810
Follow RBI Guidelines	0.731
Quick loan Approval	0.601
Low foreclosure charge	0.537

Factor 1 mainly comprises the personal loan processing efficiency attributes influencing the respondents to take a loan. All the attributes have high factor loading. The attribute 'Penalty fees' has the highest factor loading of 0.810, indicating that this factor influences this factor the most.

Similarly, other factors can be created and named accordingly.

Factor 2: Revolving Credit

Attributes	Factor loading
Top-Up Loan	0.590
Rate of Interest	0.786
Facility of loan extension	0.718

Factor 2 mainly comprises the Revolving Credit attributes of the personal loan that influence the respondents to purchase. All the attributes have high factor loading. The attribute 'Rate of Interest' has the highest factor loading of 0.78, which indicates that this attribute influences this factor the most.

Factor 3: Financial Liabilities and Employment History

Attributes	Factor Loading
Debt to income ratio	0.720
Employment history	0.745
Credit Score	0.585

Factor 3 comprises mainly the Financial and employment attributes of the personal loan that influence the respondents' purchase. All the attributes have higher factor loading values. The attribute 'Employment History' has the highest factor loading of 0.74, which indicates that this attribute influences this factor the most. All the attributes within this factor have positive loading.

Factor 4: Payment Mode

Attributes	Factor loading
Monthly installment	0.557
Loan Repayments	0.752

Factor 4 mainly comprises the Payment attributes of the personal loan that influence the respondents to purchase. All the attributes have high factor loading. The attribute 'Loan Repayments' has the highest factor loading of 0.752, indicating that this factor influences this factor the most.

4 Result Discussion

The profile of the related respondents was recorded, wherein it can be seen that out of the 211 customers interviewed for this survey, 75.71% were found to be male, and 25.29% were found to be female. It can be seen that the majority of the loan wishers here are male as loan requirements for business purposes to finance a new venture are more demanded by male people and for medical emergencies, too. To analyze the age buckets under which the customers that were interviewed were falling, the age profiling of the respondents was done. It came out that around 59% of the respondents were falling under the age criteria of 31-40 years, making it the majority, whereas 29% were under 21–30 years, and the rest were under 8.53% and 2.37%, respectively. This shows that most of the customers have proper knowledge about the loan scheme they will take. An educated person makes wiser choices and is aware of the market scenarios. Here, the education level of the respondents showed the results depicting the level of qualification that respondents had. It was seen that 69% of the respondents were graduated and fell under the majority section, with 20% of the customers being postgraduate. This shows that most customers are educated and know about market scenarios well.

4.1 Implications for Practice

The study's conclusions about the banking sector's customer satisfaction with personal loans have important practical implications. First off, banks may better serve their customers by customizing their services by knowing the important factors that influence customer happiness, such as interest rates, loan conditions, and the calibre of customer care. To improve customer delivery, this can entail updating loan products, expediting the application process,

or funding employee training. Second, pinpointing areas of low customer satisfaction gives banks useful information for enhancing their operations. Banks may proactively improve their service offerings and cultivate customer happiness and loyalty by using feedback tools to gain a deeper understanding of client preferences or addressing frequent pain points encountered during the loan application process.

5 Conclusion

The primary purpose of this study is to understand customer satisfaction with Personal loans with reference to Yes Bank. This study found that employees in small ventures or private jobs mostly take personal loans. In most cases, customers are aware of the loan schemes through the telephone from the bank. Most of the respondents have taken loans of 5-10 lakhs. Furthermore, the reason for choosing the respective bank is that the respondent is already a bank customer due to competitive interest rates. Nowadays, Yes Bank takes only one week to sanction the loan. Most customers pay the EMI through Electronic Clearance Services (ECS). Most importantly, Yes Bank charges low for the foreclosure loan. The staff is also efficient in the bank, following RBI guidelines and providing a top-up loan facility with a low-interest rate.

5.1 Limitations

In this study, only exploratory factor analysis was done to summarize the variable. Further, confirmatory factor analysis can be done to delve into the study. The study was only conducted in the Delhi region, so the limited study area may affect the conclusions. Hence, this study can be extended by increasing the sample size, and subsequently, the analysis will be much more appropriate, and results may improve.

5.2 Future Scope

There is an enormous amount of scope for further research and application in the area of customer satisfaction with personal loans in the banking sector. Longitudinal analyses could be carried out to monitor changes in satisfaction over time and identify developing trends and possible areas for development. Furthermore, dividing up the clientele according to different criteria, such as behaviour or demographics, may offer a more in-depth understanding of the disparate needs of separate groups, guiding customized

banking tactics. Cross-cultural comparisons could clarify how cultural differences affect satisfaction levels and help banks provide effective services to diversified customers. In light of the current digital landscape, banks looking to maximize their digital services may find it crucial to examine how technology adoption affects consumer satisfaction with digital lending procedures. Additionally, examining how customer experience, contentment, and service quality interact may help identify areas for development that have the biggest effects on consumer perceptions.

RESEARCH ARTICLE

Analysis of renewable energy and economic growth of Germany

Akanksha Singh, Nand Kumar*

Abstract

The study aims to investigate the effect of energy use, renewable energy consumption, nuclear energy consumption and air transport freight on CO_2 emissions in Germany. Auto-regressive distributed lag (ARDL) technique was used to establish the short and long-term correlations between the dependent (CO_2) and independent variables (Energy use, nuclear consumption, renewable consumption, air transport freight) on a time series data from 1970 to 2021. The results demonstrated the dependence of energy use on non-renewable energy sources by revealing a significant and positive relationship between short and long-term energy use and CO_2 emissions. Similar to energy use, nuclear energy use and air transport freight was also found to be positively correlated with CO_2 emissions. On the other hand, despite the fact that there is a strong negative connection between carbon dioxide emissions and renewable energy, the results reveal that the correlation between the two is not statistically significant. The study aims to investigate the effect of important economic factors on Germany's CO_2 emissions in order to move further in a sustainable manner. The data reveals an astonishing increase in the usage of nuclear energy for power generation between 1965 and 1985, which was followed by a fall in 2012 as a result of the Fukushima tragedy and growing social unease in Germany, which ultimately led to the phase-out of nuclear power. Nonetheless, BAU projections revealed that even with 200 nuclear power plants, CO_2 emissions would still be reduced to 278 by 2070, in part because of the additional power produced by other energy sources.

Keywords: CO_2 emissions, ARDL, Renewable energy consumption, Nuclear consumption, Air transport.

Introduction

One of the most important concerns of mankind today is perhaps climate change. This is clear from the fact that the world is no longer wasting time on theoretical debates and has turned its attention to concrete regulations and environmental laws. Therefore, it has become a matter of tremendous interest to spot and solve the challenges pertaining to reduction in carbon dioxide emission levels. Environmental degradation brought on by human activities that release CO_2 includes ecological problems, global warming, climate change and environmental pollution. According to BP statistics, the G7 nations contributed approximately 25% of global CO_2 emissions in 2019 and slightly less in 2020 to 23.2%. The world's most industrialized economies play a crucial role and their policies and practices are frequently imitated by other nations (B. Li and N. Haneklaus. 2022). We will examine the impact of macroeconomic variables on Germany's CO_2 emissions because it is one of the greatest energy consumers in the world and ranks third in the G-7 countries for overall CO_2 emissions, after the United States and Japan (M. Blesl. *et al*. 2006).

Environmental issues are having a growing impact on German energy policy. The government has set the objective of lowering greenhouse gas (GHG) emissions by at least 55% by 2030 and by 85% by 2050 compared to 1990 emission levels as part of the German Climate Action Plan 2050 (P. Markewitz., *et al*. 2019). The government has promoted initiatives for energy efficiency and renewable energy. The eco-tax was created in 1999 with the intention of promoting energy efficiency, renewable energy use, and conservation. The German Renewable Energy Act (EEG), which went into effect in 2000, established a feed-in tariff (FIT) system for all renewable technologies, which led to an astonishing increase in renewable energy capacity (C. Eui,

C. Marcantonini, and A. D. Ellerman, 2013). However, only an energy shift is not sufficient to reduce GHG emissions significantly. In order to meet the ambitious ideals set by the German government, all sectors, including energy, industry, transport, agriculture and homes, will need to drastically reduce their GHG emissions. For a more comprehensive analysis, we have taken into account a number of sectors, including consumption of renewable energy, nuclear energy and air transportation along with energy use.

As per popular belief, clean energy fuels have a direct impact on the reduction of carbon dioxide levels through production as well as consumption. In this paper, we have emphasized on consumption, so renewable energy consumption is a significant regressor in our analysis. Renewable energy must be able to supply the necessary energy for economic activity and lessen environmental issues brought on by the use of fossil fuels (Y. Fang, 2011). It is worthwhile to mention that clean fuels not only require energy innovation at its pinnacle but also political and social commitment. Therefore, renewable energy consumption's impact may not be as direct and immediate as it seems. Trade is a crucial component of economic growth, which in turn implies that air travel is a crucial component as well. Despite its significance for the advancement of the nation and the creation of jobs, its unfavorable impact on GHG emissions is a serious concern. In fact, 915 million tonnes of CO_2 were created by flights globally in 2019, accounting for 12% of all transport-related CO_2 emissions. This leads us to the inclusion of air transport freight as an essential variable in the study. In an effort to build alternative sources of energy and to avoid the price fluctuations associated with oil import, nuclear power plants have been set up in several countries. Nuclear energy is proposed to offer a significant advantage in terms of reducing CO_2 emissions and curbing the effects of global warming (Y. Wolde-Rufael and K. Menyah, 2010). Hence, the nuclear consumption of Germany has also been taken into account in this study. The use of recent statistics, such as the BP statistics on G7 nation's CO_2 emissions, adds credibility and relevance to the discussion. The mention of Germany's position in global CO_2 emission provides a focused context for the study.

Review of Literature

Chang explored the relationships between energy use, carbon dioxide emissions and economic growth in China. The results of the study indicated that rising economic activity increases energy use and CO_2 emissions (C.C. Chang., 2010). A similar study on Russia's CO_2 emissions, energy use, and economic growth was analyzed by (H.T. Pao., *et al*. 2011). They used the causality test and the co-integration technique to analyze the data between the period of 1990 and 2007. Empirical findings indicated that emissions appear to be elastic in terms of energy use but inelastic in terms of output in the long run (A. Singh., *et al*. 2022) used ARDL analysis on data from 2007 to 2018. The study looks at how economic and environmental factors affect logistic performance in India. The logistics performance index (LPI) is found to be positively impacted by foreign direct investment (FDI) and negatively impacted by the use of fossil fuels, both in the short and long term. While greenhouse gas emissions show a positive correlation with LPI, GDP per capita has a negative correlation, raising worries about the environment. The global economy suffered as India's logistic performance rating fell from 35th to 44th in the world. The report makes suggestions for how to enhance logistics and explains why India

Some of the other studies focussed on factors different from energy use. Apart from energy consumption, Baek also investigated the effects of nuclear energy and income on CO_2 emissions in 12 major nuclear-generating countries. The research demonstrated that nuclear energy typically reduces CO_2 emissions (J. Baek, 2015). Related research by Al-mulai examined the impact of nuclear energy use on GDP growth and CO_2 emissions in 30 nations worldwide. But unlike the previous research, the study's results revealed that nuclear energy use has no long-term impact on CO_2 emissions, but it has a positive long-term impact on GDP growth (U. Al-mulali., 2014)

Some research also studied the relationships of renewable energy use (K. Menyah and Y. Wolde-Rufael, 2010) investigated the relationship between nuclear and renewable energy use and carbon dioxide emissions in the US from 1960 to 2007. The research showed no correlation connecting renewable energy to CO_2 emissions, but it discovered a unidirectional causality between the consumption of nuclear energy and CO_2 emissions. (S. Kumari and N. Kumar., 2023) concludes that while renewable energy boosts the green economy, helps agriculture, and lowers CO_2 emissions, it also highlights the need for better nuclear waste management to avoid environmental risks (A. Singh., *et al*. 2023). The study assesses GDP, nuclear energy consumption, and CO_2 emissions in the United States, France, and Japan from 1965 and 2020 in order to validate the environmental Kuznets curve (EKC) theory. It is demonstrated that nuclear energy greatly lowers CO_2, SO_2, and NOx emissions using the Fourier ARDL and FBTY causality tests. The report recommends boosting the generation of nuclear and tidal energy and making sure that radioactive waste is disposed of safely in order to reach the UN's 2050 net-zero carbon targets.

Similar research was conducted, which studied the causal association between renewable energy use and economic growth in Turkey from 1990 to 2010. The result revealed that there is a unidirectional causal relationship linking economic growth to renewable energy use (O. Ocal and A. Aslan, 2013). Sebri investigated related research for the BRICS countries

between 1971 and 2010 using a multivariate approach. The research showcased that based on the ARDL estimations, empirical data demonstrates that there are long-run equilibrium relationships between the variables (M. Sebri and O. Ben-Salha, 2014). Similar techniques like ARDL and VAR methodology was used to examine the relationship between CO_2 emissions, economic growth, energy consumption and renewable energy consumption in Germany for the years 1975 to 2014 and suggested that the government should create and implement appropriate support programmes to encourage investment in new renewable energy technology by (S. khoshnevis Yazdi and B. Shakouri, 2018).

Different factors from energy use, nuclear energy use, and renewable energy use were analysed in some of the other research. (R. Waheed., *et al*. 2017) Studied the impact of Pakistan's agricultural and forest production on carbon dioxide emissions in addition to renewable energy use. The research showcased that the use of renewable energy and forests have negative and significant effects on CO2 emissions, whereas agricultural production has a positive impact on CO_2 emissions. (Y.Cai., *et al*. 2018) Examined the nexus between clean energy usage, economic growth and CO_2 emissions. The result revealed that in Canada, France, Italy, the US, and the UK there was no correlation between real GDP per capita, clean energy consumption and CO_2 emissions. However, when real GDP per capita and CO_2 emissions are the dependent variables, co-integration occurs in Germany and when CO_2 emissions are the dependent variable, co-integration occurs in Japan.

Methodology

The study establishes a relationship between CO_2 emissions and energy use, renewable energy consumption, nuclear energy consumption and air transport freight over the period 1970–2021 in Germany.

For the purpose of this study, we have used secondary data that was acquired from the World Bank Development Indicators (WDI). Equation 1 establishes the relationship of CO_2 emission with energy use, nuclear consumption, renewable consumption and air transport freight in the context of Germany during the period 1970-2021.

$$\ln CO_2 = f(\ln \text{Energy}, \ln \text{Nuclear}, \ln \text{Renew}, \ln \text{Air}) \quad \ldots.(1)$$

The variables are described in Table 1 and in, the natural log, is used in the equation above.

$$\Delta \ln CO_2 = \alpha_0 + \sum_{i=1}^{n_1} \alpha_{1i} \Delta \ln ENERGY_{t-i} + \sum_{i=1}^{n_2} \alpha_{2i} \Delta \ln NUCLEAR_{t-i} + \sum_{i=1}^{n_3} \alpha_{3i} \Delta \ln RENEW_{t-i} + \sum_{i=1}^{n_4} \alpha_{4i} \Delta \ln AIR_{t-i} + \beta_1 \ln ENERGY_{t-1} + \beta_2 \ln NUCLEAR_{t-1} + \beta_3 \ln RENEW_{t-1} + \beta_4 \ln AIR_{t-1} + \mu_t \quad \ldots. (2)$$

In equation 2 the short-run relationship is represented by α_1 to α_4 whereas the long-run relationship is represented by β_1 to β_4 where α_0 is the drift component and μ_t is the error term and n_i is the optimal lag.

$$\Delta \ln CO_{2t} = \beta_0 + \sum_{i=1}^{n_1} \beta_{1i} \Delta \ln ENERGY_{t-i} + \sum_{i=1}^{n_2} \beta_{2i} \Delta \ln NUCLEAR_{t-i} + \sum_{i=1}^{n_3} \beta_{3i} \Delta \ln RENEW_{t-i} + \sum_{i=1}^{n_4} \beta_{4i} \Delta \ln AIR_{t-i} + \theta ECM_{t-1} + \mu_t \quad \ldots. (3)$$

In order to create an error correction model, the co-integration of the variables was first tested, whereas θ is the speed of adjustment of the long-run equilibrium.

The description of the variable is shown in Table 1 where ENERGY, NUCLEAR, RENEW and AIR are the independent variables affecting CO_2 emission. We discovered that the ARDL technique was best suited for our research since some variables were stationary at the first difference and some at a level.

Results and Discussion

A popular statistical test to determine whether a particular time series is stationary or not is the augmented Dickey-Fuller test (ADF test). In time series analysis, the unit root test is used to determine if a time series is stationary or not. The null hypothesis states that time series have a unit root, whereas the alternative hypothesis states that time series are stationary. Therefore, we require the probability values to be smaller than 0.05 in order to reject the null hypothesis. The outcome of the unit root test is shown in Table 2. The results proved the stationarity of the dependent variable CO_2 at a level as well as 1st difference, whereas the independent variables were stationary at 1st difference.

For the purpose of examining co-integration, Pesaran, Shin and Smith (PSS) created the ARDL bounds test. (A. Montenegro., 2019) The ARDL model is the most suitable for our study since it permits having a mixture of variables at a level and first difference. Another advantage that ARDL test offers is that it is relatively more efficient in the case of small and finite sample data sizes (M. Belloumi, 2014). The ARDL bound test is used to evaluate the long-term connection between the dependent and independent variables prior to performing ARDL co-integration. The upper bound and lower bound are the two essential values that the bound test

characterizes. The lower limit assumes that all variables are at level, while the upper bound presumes that all variables are at first different. The null hypothesis is rejected and co-integration is shown to exist if the upper bound value is less than the F statistic.

Table 3 displays the results of the ARDL bound test; the findings reveal that the dependent and independent variables exhibit considerable co-integration because the F statistic is significantly higher than both the upper bound and lower bound statistic.

The findings of the ARDL short-run test are shown in Table 4. Energy use (0<0.05) and air transport (freight) (0.002<0.05) are significant and have a positive correlation with CO_2 emission, whereas nuclear consumption also has a positive relation with CO_2 emission and is significant at 10% (0.10>0.05). On the other hand, renewable energy has no significant correlation with CO_2 emission in the short run.

Table 5 describes the results of the long-run ARDL test. Energy use, is statistically significant and is positively correlated with carbon dioxide emission. Similarly, nuclear energy is positively correlated with CO_2 emissions and is significant at 10%. Moreover, air transport (freight) is again significant and has a positive correlation with CO_2 emission. On the other hand, renewable energy, an important variable of our study, is not statistically significant and has a negative correlation with carbon dioxide emissions.

Table 6 illustrates the results of the diagnostics tests that were performed to validate our findings. The Jarque-Bera test, which has achieved widespread acceptability among econometricians, is one of the most well-known tests for determining the normality of regressors. (T. Thadewald and H. Büning., 2007) Since normality is the most common presumption when using statistical procedures, we applied the Jarque-Bera test, and the findings indicate that variables are normally distributed.

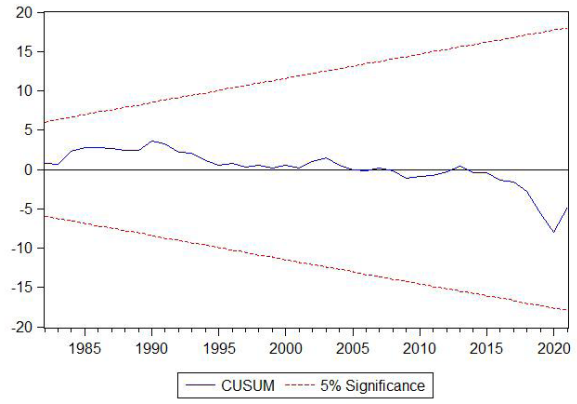
Homoscedasticity is a crucial presumption in statistical analysis. In order to determine if the data are homoscedastic or heteroscedastic, the heteroskedasticity Breusch-Pagan Godfrey test has been used; the results show that the dataset is homoscedastic.

Further Ramsey RESET test was used, and the outcome demonstrates that the model is free from specification error. Specification error means that at least one of the model's fundamental characteristics or presumption is erroneous.



*Significant at 10% level, **significant at 5%, ***significant at 1%

Figure 1: CUSUM test

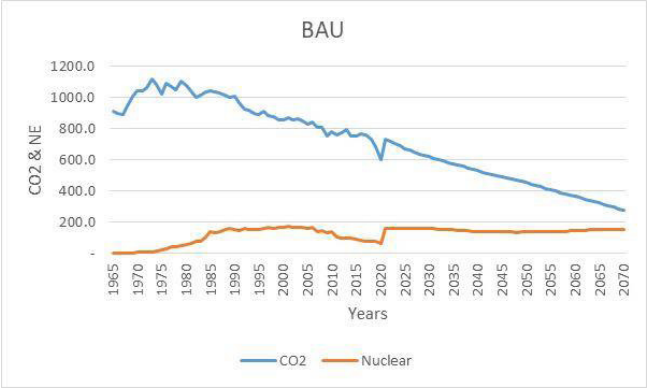


Figure 2: The business usual estimates

As a result, model estimation could produce inaccurate or deceptive results. Lastly, the Breusch-Godfrey Serial Correlation LM test demonstrated that our model's error component is not serially correlated.

Table 7 shows the results of the Granger causality test, the test is applied to time series data to determine whether there is any pronounced predictive power from one variable to the other. In essence, it aids in determining if a variable is helpful or not and whether it is capable of predicting other factors or not. It describes a one-to-one relationship between variables. As per our results, CO_2 - energy use, CO_2 - nuclear consumption, CO_2 - air, energy use - nuclear consumption, energy use - renewable energy consumption, energy use - air transport (Freight), renewable energy - nuclear consumption, nuclear consumption - air transport (Freight), renewable energy - energy use have unidirectional causal relationships.

Figure 1 demonstrates the result of the cumulative sum of the recursive residual stability test (CUSUM). Brown *et al*. invented the CUSUM test in 1975. It is a common statistical tool for analyzing and tracking structural changes in time series models (S. Otto and J. Breitung., 2022). The Figure 1 implies that the model is stable because our graph is within the bounds of 5% significance level.

BAU Estimates

The analysis a trend of sharp increase in the use of nuclear energy for power generation between the years 1965 to 1985. However, the trend started declining from the year 2012 mainly because of the 2012 Fukushima accident and the concerns in German society regarding nuclear accidents were deep, so the government had to completely phase out nuclear power generation. However, the BAU estimates from 2022 to 2070 show that even if the nuclear power generation would have maintained the 200 mark then also the CO_2 emission would have dropped to the mark of 278 by the year 2070. It's also because of the increase in power generation through other sources of renewable energy (Figure 2).

Conclusion

CO_2 emission is a major contributor to climate change and global warming. Substantial increase in CO_2 emission over the years has altered the proportions of our atmosphere and has given rise to global temperatures. The negative effects of this are currently being felt throughout the planet in the form of abrupt changes in weather patterns, extremely high temperatures, rising sea levels and melting ice caps. In this era of widespread recognition of the current issue, countries all over the world are issuing laws and taking precautions, but before one can be sure that these actions are effective, one must first determine whether or not they are even addressing the proper cause. In this paper, we analyzed whether or not the theoretically stated variables had an impact on Germany's CO_2 emissions. One can make some inferences from the empirical testing carried out in this paper.

The focus of the study is to find out whether CO_2 emissions are affected by energy use, renewable energy consumption, nuclear consumption, and air transport (freight) in Germany from the period 1970 to 2021. The results show a substantial and positive correlation between short and long-term energy use and CO_2 emissions, demonstrating the dependence of energy use on non-clean energy sources. The amount of energy used nationwide directly affects carbon dioxide emissions. Similarly there is a positive association between air transport (freight) and CO_2 emissions, indicating that the expansion of the aviation industry has contributed to increased emissions.

Consumption of nuclear energy is positively correlated with CO_2 emissions. It is obvious that Germany's CO_2 emissions will not decrease by switching to nuclear energy. As a result, the country's policy of using nuclear energy as a clean fuel has not been successful. On the contrary, we observe a rise in CO_2 emissions due to other factors such as energy use, industry, population, etc. Although there is a negative correlation between carbon dioxide emissions

and renewable energy, which is a significant variable in our analysis, the test findings show that this correlation is not statistically significant. This suggests that just implementing policies to increase the use of renewable energy has little effect on carbon dioxide emissions. The aforementioned two findings are quite important since they show that, in the case of Germany, the energy industry has no impact at all on CO_2 emissions. Significant CO_2 emissions are not being caused by energy generation or consumption. Other economic sectors like transportation, industrialization, etc, instead influence CO2 emissions. As a result, the nation needs to change its focus on the source of CO_2 emissions. In a complicated economic system, it is exceedingly difficult to comprehend the underlying causes of CO_2 emissions. We can never be certain that our efforts to conserve the environment will be successful if we don't understand the true cause. As a result, ongoing efforts are made in this area, and our work has been essential in understanding some of the real variables influencing Germany's CO_2 emissions. The data demonstrates a strong rise in the usage of nuclear energy for power generation between 1965 and 1985, which was followed by a fall in 2012 as a result of the Fukushima tragedy and growing social unease in Germany, which ultimately led to the phase-out of nuclear power. Due in part to enhanced power generation from other renewable energy sources, BAU projections show that even with 200 units of nuclear power generation, CO_2 emissions will still be reduced to 278 by 2070. Further research can be done on managing the waste disposable generated by nuclear energy.

Abstract

Carbon Nanotube (CNT) arrays and graphene have undergone several investigations to achieve efficient field emission (FE) owing to CNT's remarkable large aspect ratio and graphene's exceptional FE stability. However, when dense CNT arrays and planar graphene layers were used as field emitters, their field enhancement factor reduced dramatically. Therefore, in this paper, we numerically analyze the growth of a dense CNT array with planar graphene layers (PGLs) on top, resulting in a CNT-PGL hybrid and the associated field enhancement factor. The growth of the CNT array is investigated using Plasma Enhanced Chemical Vapor Deposition (PECVD) chamber in C_2H_2/NH_3 environment with variable C_2H_2 flow, Ni catalyst film thickness, and substrate temperature followed by PGL precipitation on its top at an optimized cooling rate and Ni film thickness. The analytical model developed accounts for the number density of ions and neutrals, various surface elementary processes on catalyst film, CNT array growth, and PGLs precipitation. According to our investigation, the average growth rate of CNTs increases and then decreases with increasing C_2H_2 flow rate and catalyst film thickness. CNTs grow at a faster rate when the substrate temperature increases. Furthermore, as the chamber temperature is lowered from 750 °C to 250 °C in N_2 environment and Ni film thickness grows, the number of the graphene layers increases. The field enhancement factors for the CNT array and hybrid are then calculated based on the optimal parameter values. The average height of the nanotubes, their spacing from one another, and the penetration of the electric field due to graphene coverage are considered while computing the field enhancement factor. It has been found that adding planar graphene layers to densely packed CNTs can raise its field enhancement factor. The results obtained match the current experimental observations quite well.

1. Introduction

Carbon nanomaterials having hexagonally arranged sp^2 hybridized carbon atoms are actively used in various application domains. They are divided into three categories based on their dimensional shape: one-dimensional (1D) i.e. carbon nanotube (CNT), two-dimensional (2D) i.e. graphene and three-dimensional (3D) i.e. CNT-graphene hybrid. Carbon nanomaterials have the following set of properties: high electrical and thermal conductivity [1–3], improved surface area, high aspect ratio, field emission stability, flexibility, and low voltage requirement for electron extraction from its surface [4]. They are employed as electron field emitters [5, 6] in x-ray generators [7], flat panel displays [8], microwave amplifiers [9], in electrodes for lithium-ion batteries for enhancing electron and Li-ion transport [10, 11], in supercapacitors [12, 13], in biosensors where CNT's are functionalized with biomolecules [14]. Moreover, they are used as field emitters mounted on hall effect thrusters and in space electric propulsion systems to increase channel wear resistance [15–17].

CNT- Graphene hybrid shows exemplary field emission (FE) owing to the adorable properties of both CNT and graphene, i.e., high aspect ratio, field emission stability and sharp edges of graphene [4, 18, 19].

PECVD (Plasma Enhanced Chemical Vapor Deposition) is the most widespread and versatile method for fabricating carbon nanostructures. In PECVD, the electrostatic force from the applied electric field causes ionization, generating electrons and ions that participate in various reactions (excitation, dissociation), forming radicals. Because of this, the technique can be operated at low temperatures without damaging the substrate and forming vertically aligned carbon nanostructures [20]. The nucleation of the carbon nanostructure in PECVD is controlled by the plasma species (ions, electrons, and neutral atoms) generated, catalyst film thickness, precursor gas flow rate, and plasma control parameters (gas pressure, applied plasma power, bias) [21–24].

Choi *et al* [25] reported that catalyst nanoparticles are formed by plasma pretreatment of the catalyst surface prior to hybrid growth in an optimum growth environment within a PECVD chamber. Extensive studies have shown that the graphene layer number, diameter, and crystallinity of CNT are determined by catalyst film thickness and nanoparticle size [26–28]. It is also scrutinized that CNT array morphology can be directed by properly fixing the growth time, substrate temperature, and gas ratio [29, 30].

Chhowalla *et al* [30] and Bell *et al* [31] studied the effects of the C_2H_2/NH_3 feedstock flow ratio on CNT array growth. It was validated that when the concentration of C_2H_2 is high (>50%), pyramidal structures rather than vertical nanotubes emerge. Choi *et al* [25] and Yu *et al* [26] demonstrated the effects of cooling rate on the yield of graphene from Ni nanoparticles and flat Ni substrate, and proposed an optimal cooling rate for C precipitation. Shurman *et al* [27] simulated the formation of CVD graphene on a thin Ni film at various growth parameters such as growth time, temperature, and Ni film thickness.

Felicitous designing of the CNT array and controlling its dimensions make it worthy as a field emitter in FE devices. Bonard *et al* [32] investigated the effects of geometric configurations (density, height, radius, and distance between CNTs) on the FE properties of CNTs, and found that high-density CNT films are not a prerequisite for optimal field emission. Thapa *et al* [29] investigated that single CNTs or less crowded CNT bundles provide better field emission than crowded CNT bundles. In comparison to pure CNT and graphene films, Kaur *et al* [33] and Hong *et al* [19] observed increased field emission from reduced graphene oxide (rGo) deposited CNT films over Ni foams as well as a decrease in turn on electric field and threshold electric field for graphene embedded CNTs.

Motivated by the aforementioned studies, the author has tried to model and numerically analyze the growth of the CNT-Planar graphene layer (PGL) hybrid. The author determined the optimal dimensions of the hybrid for enhanced field emission by analyzing the favorable C_2H_2 flow rate, Ni film thickness, substrate temperature, and cooling rate.

2. Model

This section works out the kinetics of plasma species and the growth of the CNT-PGL hybrid in C_2H_2/NH_3 plasma using fundamental assumptions and equations. Using the DC-PECVD process, a hybrid of PGLs and CNT arrays is designed over a Silicon (Si) substrate, covered with Ni film as a catalyst. Table 1 lists basic reactants such as ions and neutrals of C_2H_2, NH_3, and H_2 that comprise C_2H_2/NH_3 plasma [34].

In the PECVD technique, when a negatively biased substrate surface with a catalyst film is exposed to a reactive plasma, an electric field arises between the bulk plasma and the substrate surface because of charge separation. The charge separation region is known as the plasma sheath. It is composed of both neutral molecules and positive ions. The electrostatic force arising from the plasma sheath accelerates ions toward the catalyst film surface, i.e., in the vertically downward direction (z-axis) [38], while neutrals undergo Brownian motion across the sheath. The plasma sheath equations (equations (1)–(5)) describe the plasma sheath. The parameters needed for hybrid growth namely the number density and speed of ions, as well as the number density of electrons within the plasma sheath are computed using the following continuity (equations (1) and (2)), momentum balance equations (equations (3) and (4)) for ions and electrons in plasma sheath respectively.

$$\frac{1}{n_{it}}\frac{\partial(n_{it}\nu_{it})}{\partial z} = \tau, \tag{1}$$

Table 2. Symbols with their meanings used in equations (1)–(5).

Symbol	Meaning
m_{it},	Mass of positive ion (t corresponds to type j, k, l)
n_{it},	Number density of positive ions (t corresponds to type j, k, l)
T_{it},	Temperature of positive ions (t corresponds to type j, k, l)
v_{it}	Velocity of positive ions (t corresponds to type j, k, l)
m_e,	Mass of electron
N	Number density of electrons
T_e	Temperature of electrons
v_e	Velocity of electrons
τ	Ionization frequency of neutrals by electrons
$l_\eta = (\sigma_\eta N_u S_\eta)$	Collision frequency computing ions and electrons collisions with the neutrals
η	Refer to electrons and t (type j, k, l) ions
σ_η	Collision cross-section
S_η	Average speed of electrons and positive ions
N_u	Total neutral species number density.
$\beta_{it} = n_{it}/n$	tth ions to electrons number density ratio
ϕ	Electric sheath potential

$$\frac{1}{n}\frac{\partial(nv_e)}{\partial z} = \tau, \tag{2}$$

$$m_{it}v_{it}\frac{\partial v_{ik}}{\partial z} = -e\frac{\partial \phi}{\partial z} - m_{it}\iota_{it}v_{it} - \frac{T_{it}}{n_{it}}\frac{\partial n_{it}}{\partial z}, \tag{3}$$

$$m_e\iota_e v_e = e\frac{\partial \phi}{\partial z} - \frac{T_e}{n}\frac{\partial n}{\partial z}, \tag{4}$$

$$\frac{d^2\phi}{dz^2} = 4\pi e\left(\sum_t \beta_{it}n_{it} - n\right), \tag{5}$$

Poisson's equation (equation (5)), determines the potential distribution within the plasma sheath [39, 40]. Table 2 provides the interpretation of each symbol used in equations (1)–(5).

Ultimately, the sheath equations are resolved by applying the following boundary conditions at plasma sheath interface i.e. at z = 0:

$$\phi = 0,\ \frac{d\phi}{dz} = -\frac{T_e}{e\lambda},\ v_e = 0,\ v_{it} = v_{ito},$$

where $v_{ito} = \sqrt{\frac{T_e}{m_{it}}}$ is the ion –acoustic speed, $\lambda = \frac{T_i}{\sigma_\eta p_o}$ is the mean free path of ion, p_0 is total gas pressure, respectively [39].

Figure 1 illustrates the CNT-PGL hybrid's inculpated growth processes in a plasma environment. Initially under applied plasma power, during pre-etching of the Ni- catalyst film, the dissociation of NH_3 produces energetic electrons, hydrogen and ammonia ions, and neutrals. These plasma species strike at the Ni film due to an induced electric field (E) between the negatively biased substrate and bulk plasma to form Ni catalyst nanoparticles. These nanoparticles serve as nucleation sites for CNT array growth in the C_2H_2/NH_3 plasma environment [41]. The incoming fluxes of positive and neutral ions from the plasma are exposed to the catalyst nanoparticles, which aid in the formation of CNTs. Carbon and hydrogen species in the plasma dissociate and adsorb, across the catalyst surface through surface reactions. Adsorbed carbon atoms diffuse over the catalyst nanoparticle's surface and in bulk up to a diffusion length $\Lambda \approx \sqrt{(D_a t')}$ where t' is the diffusion time. Eventually, carbon atoms in the catalyst bulk begin to precipitate beneath the catalyst surface to direct the tip growth –mode (i.e. lift up of catalyst from the substrate surface) of the CNTs in the CNT array [42], in conjunction with etching by adsorbed hydrogen atoms and incoming nitrogen flux. The electrostatic force present in the plasma sheath causes CNTs to grow vertically [43]. While the array grows, the overall gas pressure is kept at 7 Torr.

After the CNT array growth, C_2H_2/NH_3 flow is terminated, plasma is turned off and the chamber is cooled to 250 °C under N_2 flow with total gas pressure 22 Torr. The cooling rate is assumed linear [25]. Three cooling rates are taken into consideration: 5 °C s^{-1}, 15 °C s^{-1}, and 25 °C s^{-1}. During the cooling period, carbon atoms begin to precipitate out of Ni nanoparticles with a driving force (F) due to the supersaturation of diluted carbon. These carbon atoms form tiny nuclei that expand and meet with one another leading to graphene growth. These

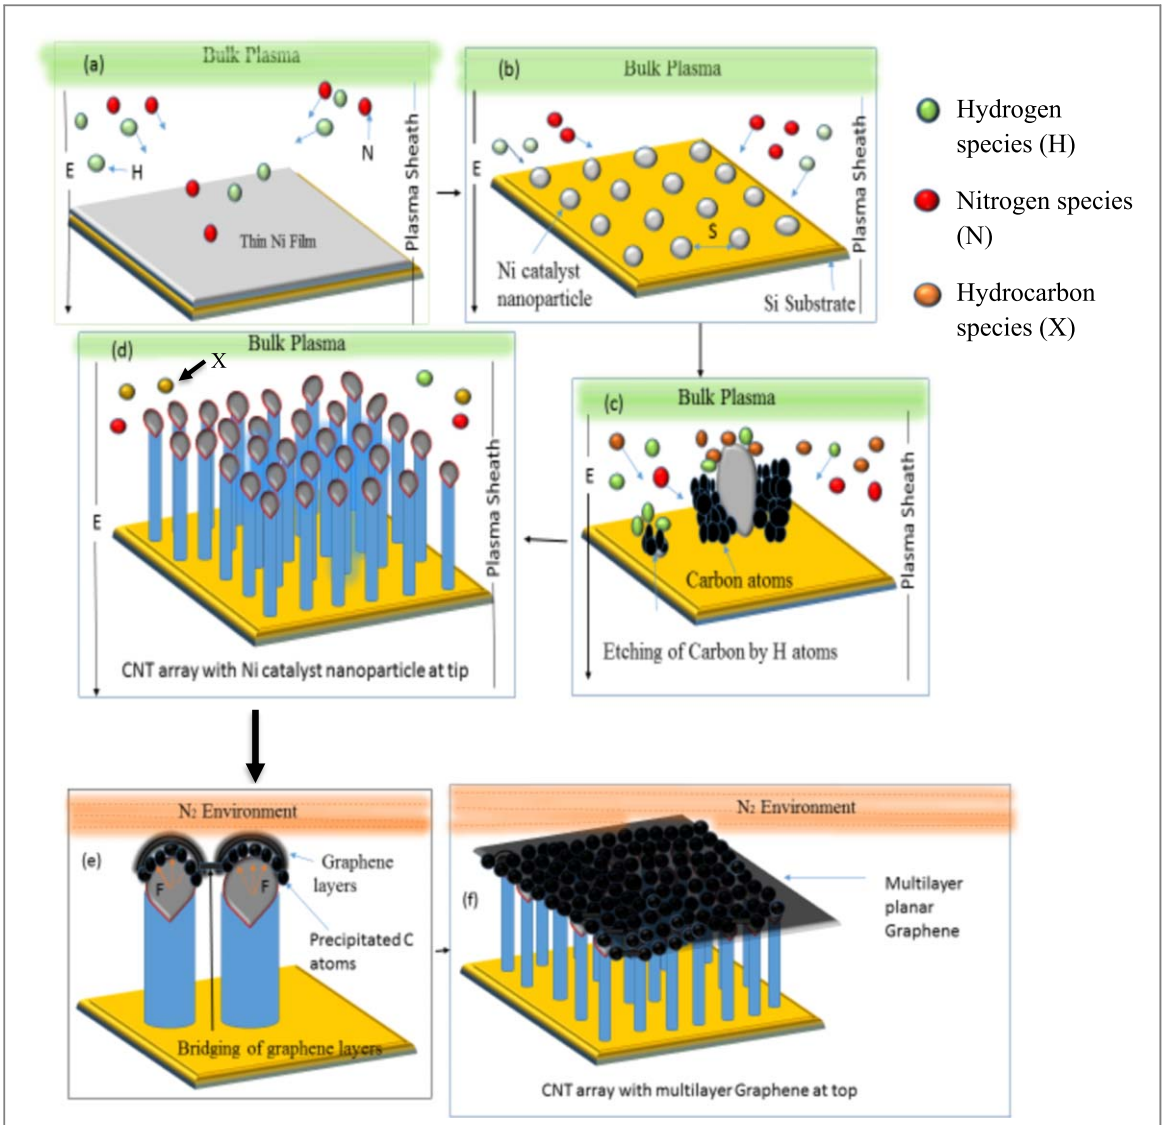

Figure 1. Schematic showing the (a) Pre-etching of the thin Ni film by incident plasma species in NH_3 plasma. (b) Cloven of Ni film into nanoparticles in NH_3 plasma. (c) Etching of carbon on Ni catalyst nanoparticle along with dissociation and adsorption of hydrocarbon and hydrogen species on catalyst nanoparticle surface in C_2H_2/NH_3 plasma. (d) Growth of CNT array via tip growth mode. (e) Precipitation of carbon atoms with driving force (F) to form graphene layers on Ni nanoparticle surface and bridging among graphene layers in N_2 environment. (f) CNT array with multilayer planar graphene at top.

graphene nuclei unite to form a planar graphene sheet by bridging the gaps across the Ni nanoparticles located at the tip of CNTs [25, 44–46]. As a result, a hybrid of CNT and PGL is formed.

2.1. Presumptions considered for simplified modelling [21, 47, 48]

(a) Maxwellian distribution of electrons and ions is considered.

(b) Ion—surface interaction is assumed to be coulomb interaction.

(c) For the sheath to perform its function and repel electrons, the potential must be monotonically decreasing with increase in z. This will occur if $n_{it}(z) > n(z)$ for all z in the sheath.

(d) Catalyst nanoparticle and substrate temperature is considered to be the same

2.2. Precipitation of carbon

Carbon atoms diffuse into Ni forming Ni-C bonds owing to its high solubility in Ni. When the chamber is cooled to a reasonably lower temperature, graphene formation occurs from diluted carbon in the Ni nanoparticles [49, 50]. When the carbon concentration in Ni reaches saturation during cooling, a Ni-C supersaturated solid solution is formed. Consequently, due to the difference in saturation while cooling, a driving force (F) comes into play, diffusing out carbon atoms from Ni bulk to surface and leading to carbon precipitation, following

Arrhenius law. According to Arrhenius law, the dependence of carbon out-diffusion from Ni bulk on temperature is given by

$$D_a = D_o \exp\left(\frac{-U_{voc}}{k_B T_s}\right), \tag{6}$$

where, D_a is bulk diffusion coefficient, $D_o = \frac{D_{Ni} f}{2\pi}$, U_{voc} (=1.74 eV) activation energy for diffusion of carbon atoms in Ni bulk [27, 45], T_s is the catalyst surface temperature , f is thermal vibration frequency ($\approx 10^{13}$Hz).

Let carbon concentration in Ni bulk along z direction, perpendicular to the surface be C_{bulk}(z, t) where t is time. According to Fick's Law of diffusion, the rate of change of concentration at a point within Ni bulk due to diffusion is given by

$$\frac{\partial C_{bulk}}{\partial t} = D_a \nabla^2 C_{bulk}, \tag{7}$$

where, t represents time and C_{bulk} (z, t) is estimated by

$$\frac{C_{bulk}(z,\ t) - C_o}{C_1 - C_o} = erf\left(\frac{z}{2\sqrt{D_a t}}\right), \tag{8}$$

The following boundary conditions are used to compute the C_{bulk} (z, t).

C_{bulk} (z, t) (z > 0, t = 0) = C_1 (Initial bulk concentration in Ni catalyst nanoparticle), C_{bulk} (z, t) (z = 0, t) = C_o (bulk concentration adjacent to the Ni catalyst nanoparticle surface).

The number of planar graphene layers (N_{pg}) obtained at time t is then approximated to

$$N_{pg} \approx \left(\frac{\frac{D_a(C_1 - C_0)}{\sqrt{\pi D_a t}}\frac{V_{Ni}\rho_{Ni}}{M_{Ni}}}{N_a}\right), \tag{9}$$

where, N_a denotes surface concentration of atoms in one graphene layer $\left(\approx 3.8 \times 10^{19}\frac{atoms}{m^2}\right)$. [27, 44, 51, 52], V_{Ni}, ρ_{Ni} (=8.96 g cm^{-3}), and M_{Ni} (=58.69 amu) are the volume, density and mass of Ni catalyst nanoparticle.

2.3. Catalyst nanoparticles formation

During the pre-etching, owing to energy transfer (i.e. input power (P)) by plasma species, the catalyst film gets heated up and segregated. This is the result of multiple energy fluxes contributing viz power transfer due to: striking of plasma species, recombination reactions, chemical etching, incident ion sputtering, and energy loss to surroundings. Therefore the time-varying energy balance equation on Ni film in NH_3 plasma is,

$$P = \frac{\rho_{Ni} C_s T_s}{6}\frac{\partial \pi D_{Ni}^3}{\partial t} = \left[\sum_t^{k,l}[\xi_{it}\varepsilon_{it} + \xi_t\varepsilon_t + \xi_e\varepsilon_e]\right] + \left[\frac{3}{2}k_B T_s\sum_t^{k,l}(1 - \gamma_{it})\xi_{it}\right] + [(\upsilon_o \sigma_{ads} F_k U)A] + \left[\left(\sum_t^{k,l} F_{it}\, Y_I(U_i)(1 - \theta)A\right)\right] - [\sigma A(\eta_s T_s^4 - \eta_{surr} T_{surr}^4)], \tag{10}$$

where, ξ_{it}, ξ_e, ξ_t denotes the collection current at the surface of Ni catalyst film due to positively charged ions of type t (k, l), electrons, and neutrals of type t (k, l) and are defined as,

$$\xi_{it} = \left[n_{it}(z)A\left(\frac{k_B T_{it}}{2\pi^2 m_{it}}\right)^{0.5}\left(\sqrt{\frac{4}{\pi}}\left(\frac{eV_c}{\pi k_B T_{it}}\right)^{0.5} + \exp\left(\frac{eV_c}{k_B T_{it}}\right) erfc\left(\frac{eV_c}{k_B T_{it}}\right)^{0.5}\right)\exp\left(\frac{-eU_c}{k_B T_s}\right)\right], \tag{10a}$$

$$\xi_e = n(z)A\left(\frac{k_B T_e}{2\pi^2 m_e}\right)^{0.5}\exp\left[\frac{eU_c}{k_B T_s} + \frac{eV_C}{k_B T_e}\right], \tag{10b}$$

$$\xi_t = n_t(z)A\left(\frac{k_B T_t}{2\pi^2 m_t}\right)^{0.5}, \tag{10c}$$

Description of other terms used in equations (10)–(10c) is given in table 3.

The left-hand side of equation (10) accounts for the power transfer to Ni film and formation of Ni nanoparticle of diameter (D_{Ni}) with time.

The first term on the right-hand side in equation (10) represents the energy accumulated by striking ions, neutrals, and electrons over the surface. The second term represents energy transfer via neutral formation on the

Table 3. Description of terms in equations (10)–(10*c*).

Terms	Description
$n_{it}(z) = n_{it0}\left(1 - \frac{2e\Phi(z)}{m_{it}v_{ito}^2}\right)$	Spatial dependence of ions within plasma sheath.
$n(z) = n\exp\left(\frac{\lvert e\rvert\ \Phi(z)}{k_B T_e}\right)$	Spatial dependence of electrons within plasma sheath.
$\Phi(z) = \Phi_0\exp\left(\frac{-\lvert z\rvert}{\lambda}\right)$	Positional dependent potential within plasma sheath
$F_t = \left(\frac{n_t v_{thst}}{4}\right)$	Flux of impinging neutrals on the catalyst surface [53].
$F_{it} = \left(n_{it}\left(\frac{k_B T_{it}}{m_{it}}\right)^{0.5}\right)$	Flux of impinging ions on the catalyst surface [53].
$\varepsilon_\varsigma = \left(\left(\frac{2 - qH_\varsigma}{1 - qH_\varsigma}\right) - qH_\varsigma\right)k_B T_\varsigma$	Average energy collected at the surface of Ni catalyst film via ς (ions, neutrals of type t and electrons), $H_\varsigma = \left(\frac{U_B}{k_B T_s}\right)$, U_B is the energy barrier at the catalyst film surface [54].

Table 4. Symbols with their meanings used in equations (10)–(10*c*).

Symbol	Meaning
C_s(=0.104 cal g^{-1} $°C^{-1}$)	Specific heat of Ni catalyst film
A	Area of Ni catalyst film
$\gamma_{it}(\approx 1)$	Sticking coefficient of positive ions of type t (j, k, l)
σ_{ads}(=6.8 × 10^{-16} cm^2)	Cross-section for reaction with atomic hydrogen
υ_o(≈10^{15} cm^{-2})	Number of adsorption sites per unit area
η_{surr}(=1) and η_s(=0.12)	Environment emissivity and Ni catalyst film emissivity
σ(5.67 × 10^{-5} *ergs* $cm^{-2}s^{-1}K^{-4}$)	Stefan's constant
$Y_I(U_i)$	Sputtering yield, dependent on ion energy [55]
V_C	Potential at surface of Ni catalyst film
Uc = φ_o	Substrate potential
k_B	Boltzmann constant
θ = 0.01	Total surface coverage
U (=3.74 eV for Ni)	Binding energy of material surface [53]
T_S and T_{surr}	Substrate temperature and temperature of plasma environment
ν_{thst}	Thermal velocity of neutral species.

surface. Energy transfer from chemical etching and incident ion sputtering is represented by the third and fourth terms. The last term accounts for energy loss from the surface to the surroundings.

Table 4 provides the interpretation of each symbol used in equations (10)–(10*c*).

2.4. Charging of CNT-PGL hybrid

Charge (Z') is evolved over the surface of the CNT- PGL hybrid because of the augmentation of positive charges and electrons, and is computed through equation,

$$\dot{Z'} = \sum_{w=1}^{r}\left(\sum_{t}^{j,k,l}\xi_{it}^{tipw} + \sum_{t}^{j,k,l}\xi_{it}^{curw} + \sum_{t}^{j,k,l}\xi_{it}^{pgw} - \Upsilon_e(\xi_e^{tipw} + \xi_e^{curw} + \xi_e^{pgw})\right), \tag{11}$$

where, r represents number of CNTs , ξ_{it}^{tipw}, ξ_{it}^{curw}, ξ_{it}^{pgw} represents the ion collection current at w^{th} - CNT tip, curved surface and PGL and are defined as,

$$\xi_{it}^{tipw} = \left[\frac{\pi D_w^2}{4}\left(\frac{8k_B T_{it}}{\pi m_{it}}\right)^{\sqrt{0.25}} n_{it}(z)(1 - Z_{CNT}\Psi_V)\exp\left(\frac{-eU_c}{k_B T_s}\right)\right], \tag{11a}$$

$$\xi_{it}^{curw} = \left[n_{it}(z) \frac{D_w}{2} L_w \left(\frac{2\pi k_B T_{it}}{m_{it}} \right)^{\sqrt{0.25}} \left(2 \left(\frac{eV_{cur}}{\pi k_B T_{it}} \right)^{\sqrt{0.25}} + \exp\left(\frac{eV_{cur}}{k_B T_{it}} \right) erfc \left(\frac{eV_{cur}}{k_B T_{it}} \right)^{\sqrt{0.25}} \right) \exp\left(\frac{-eU_c}{k_B T_s} \right) \right], \tag{11b}$$

$$\xi_{it}^{pgw} = n_{it}(z) \begin{pmatrix} l_{pgw} t_{pgw} \\ + t_{pgw} h_{pgw} \\ + h_{pgw} l_{pgw} \end{pmatrix} \left(\frac{k_B T_{it}}{2\pi^2 m_{it}} \right)^{\sqrt{0.25}} \times \begin{pmatrix} \frac{2}{\sqrt{\pi}} \left(\frac{eV_{pg}}{k_B T_{it}} \right) \\ + \exp\left(\frac{eV_{pg}}{k_B T_{it}} \right) erfc \left(\frac{eV_{pg}}{k_B T_{it}} \right) \end{pmatrix} \times \exp\left(\frac{-eU_c}{k_B T_s} \right), \tag{11c}$$

D_w and L_w are the average height and diameter of the wth CNT in CNT array. l_{pgw},t_{pgw} and h_{pgw} are the length, thickness and height of PGL on wth catalyst nanoparticle. $\psi_v = \frac{2e^2}{D_w 4\pi\varepsilon_\circ}$, V_{cur} and V_{pg} denotes potential at tip, curved surface of wth CNT (refer equation (A1) of the appendix) and at surface of PGL on wth catalyst nanoparticle [56].

ξ_e^{tipw}, ξ_e^{curw}, ξ_e^{pgw} represents the electron collection current at wth - CNT tip, curved surface and PGL and are defined as,

$$\xi_e^{tipw} = \left[n(z) \pi \frac{D_w^2}{4} \sqrt{\left(\frac{8k_B T_e}{\pi m_e} \right)} \exp\left[\frac{Z_{CNT} \psi_V}{k_B T_e} + \frac{eU_c}{k_B T_s} \right] \right], \tag{11d}$$

$$\xi_e^{curw} = \left[n(z) \frac{D_w}{2} L_w \sqrt{\left(\frac{2\pi k_B T_e}{m_e} \right)} \exp\left[\frac{eV_{cur}}{k_B T_e} + \frac{eU_c}{k_B T_s} \right] \right], \tag{11e}$$

$$\xi_e^{pgw} = n(z)(l_{pgw} t_{pgw} + t_{pgw} h_{pgw} + h_{pgw} l_{pgw}) \left(\frac{k_B T_e}{2\pi^2 m_e} \right)^{\sqrt{0.25}} \left(\exp\left(\frac{eV_{pg}}{k_B T_e} + \frac{eU_c}{k_B T_s} \right) \right), \tag{11f}$$

In equation (11), on right-hand side, the first, second, and third term outlines the accreting positive charges of type j, k, l on CNT array and PGL with time whereas the last term depicts a decrease in charge due to electron accumulation with time.

2.5. Kinetics of electrons in plasma

The time evolution of electrons in the bulk plasma is attributed to ionization of neutral atoms, ion-electron recombination, electron collection current on the hybrid surface, and electron loss to the chamber wall. It is computed using the following equation,

$$\dot{n} = \sum_{t}^{j,k,l} \delta_t n_t - \sum_{t}^{j,k,l} \alpha_t n n_{it} - \gamma_e \Lambda_{hyb} \sum_{w=1}^{r} \begin{pmatrix} \xi_e^{tipw} + \xi_e^{curw} \\ + \xi_e^{pgw} \end{pmatrix} - K_{wall}^e n, \tag{12}$$

where, δ_t is the ionization coefficient of neutral atoms. α_t is the recombination coefficient of electrons and ions, and is expressed as $\alpha_t \left(= \alpha_{to} \left(\frac{300}{T_e} \right)^q \right)$cm^{3}sec^{-1} with q (= −1.2) constant, α_{to} =1.12 × 10^{-7} cm^{3}sec^{-1}. γ_e(≈1) is the sticking coefficient of electrons, Λ_{hyb} represents hybrid number density. $K_{wall}^e n = \left(\frac{\gamma_e \nu_{the} Sn}{4V} \right)$ is the loss of electrons per unit time per unit volume on the chamber wall, ν_{the} is the thermal velocity of electrons (≈5.13 × 10^7 cm sec^{-1}) S is the chamber surface area with inner diameter 32 cm and length 23 cm [57], V denotes the chamber volume (≈1.05 × 10^{4}cm^3).

The first term on the right-hand side of equation (12) represents the increase in electron density over time as a result of ionization of neutral atoms in plasma. The second and third terms represent the electron density timely decay induced by ion-electron recombination and collection current on the CNT-PGL Hybrid The final term represents the electron density loss on the chamber wall per unit time. For electron impact reactions [cf. 58, 59].

Table 5. Description of the terms in equations (13a)–(13c).

Terms	Description
$A_t = \delta_t n_t$	The rate of gain of ions of type t (t corresponds to type j, k, l) due to neutral atom ionization in plasma
$B_t = \alpha_t n n_{it}$	The rate of loss of ions of type t (t corresponds to type j, k, l) due to ion-electron recombination.
$C_t = \Lambda_{hyb} \sum_{w=1}^{r} \begin{pmatrix} \xi_{it}^{tipw} + \xi_{it}^{curw} \\ + \xi_{it}^{pgw} \end{pmatrix}$	The rate of loss of ion of type t (t corresponds to type j, k, l) due to the ion collection current at the hybrid surface.
$D_t = K_{wall}^{it} n_{it} = \left(\frac{\gamma_{it} \nu_{thit} S n_{it}}{4V} \right)$	The rate of loss of ions of type t (t corresponds to type j, k, l) to chamber wall
$E_j = \sum_i P_{ij} n_j n_{il}$	The rate of gain of ions of type j due to reaction between neutral of type j and ion of type l , as listed in table 6
$F_j = \sum_i P_{ij} n_j n_{ik}$	The rate of gain of ions of type j due to reaction between neutral of type j and ion of type k, as listed in table 6.
$G_j = \sum_i P_{il} n_l n_{ij}$	The rate of loss of ions of type l due to reaction between neutral of type l and ion of type j, as listed in table 6.
$E_k = F_{th}$	The rate of gain of ions of type k due to thermal dehydrogenation
$F_k = \sum_i P_{ij} n_j n_{ik}$	The rate of loss of ions of type j due to reaction between neutral of type j and ion of type k, as listed in table 6.
$G_k = \sum_i P_{ik} n_k n_{ik}$	The rate of gain of ions of type k due to reaction between neutral of type k and ion of type k, as listed in table 6.
$E_l = \sum_i P_{il} n_l n_{ij}$	The rate of gain of ions of type l due to reaction between neutral of type l and ion of type j, as listed in table 6.
$F_l = \sum_i P_{il} n_l n_{il}$	The rate of gain of ions of type l due to reaction between neutral of type l and ion of type l, as listed in table 6.
$G_l = \sum_i P_{ij} n_j n_{il}$	The rate of loss of ions of type j due to reaction between neutral of type j and ion of type l, as listed in table 6.
P_{it}	Rate constant for ion-neutral reactions, as listed in table 6.
ν_{thit}	Thermal velocity of ions of type t (t corresponds to type j, k, l) [59]

2.6. Kinetics of positive ions in plasma

The following equations describe the time evolution of positive ions in the bulk plasma due to, the ionization of neutral atoms, electron–ion recombination, ion collection current at the hybrid's surface, loss of ions to the chamber wall, thermal dehydrogenation, and ion-neutral reactions.

$$n_{ij}^{\cdot} = A_j - B_j - C_j - D_j + E_j + F_j - G_j, \tag{13a}$$

$$n_{ik}^{\cdot} = A_k - B_k - C_k - D_k + E_k - F_k + G_k, \tag{13b}$$

$$n_{il}^{\cdot} = A_l - B_l - C_l - D_l + E_l + F_l - G_l, \tag{13c}$$

Description of the terms in equations (13*a*)–(13*c*) is provided in table 5.

2.7. Kinetics of neutrals in plasma

The following equations describe the time evolution of neutrals in bulk plasma due to, electron–ion recombination, neutralization of ions at the hybrid's surface, ionization of neutral atoms followed by neutrals loss to the chamber wall, their accretion, adsorption, desorption over the hybrid surface, and numerous ion-neutral processes.

$$n_j^{\cdot} = H_j + I_j - J_j - K_j - L_j - M_j + N_j - O_j - P_j + Q_j, \tag{14a}$$

$$n_k^{\cdot} = H_k + I_k - J_k - K_k - L_k - M_k + N_k + O_k - P_k, \tag{14b}$$

$$n_l^{\cdot} = H_l + I_l - J_l - K_l - L_l - M_l + N_l - O_l - P_l + Q_l, \tag{14c}$$

Description of the terms in equations (14*a*)–(14*c*) is provided in table 7.

2.8. Generation of hydrogen and carbon species over catalysts surface

The interaction of neutrals and ions of type j, k, and l with catalyst nanoparticles results in the formation of hydrogen radicals (H_a) and carbon species (C_a) on the catalyst surface, as explained in the supplementary information.

See the supplementary information for specifics on the generation of hydrogen and carbon species on the surface of the catalyst.

Table 6. Ion-neutral reactions between various species considered in the present plasma model [59, 60].

Reactions	Rate Constant (P_{it}) (cm^3/sec)
$H^+ + CH_4 \rightarrow CH_3^+ + H_2$	2.30×10^{-9} [60]
$H^+ + CH_3 \rightarrow CH_3^+ + H$	3.40×10^{-9} [60]
$H^+ + NH_3 \rightarrow NH_3^+ + H$	5.20×10^{-9} [60]
$H^+ + C_2H_3 \rightarrow C_2H_3^+ + H$	2.00×10^{-9} [60]
$H_2^+ + H \rightarrow H^+ + H_2$	6.40×10^{-10} [60]
$H_2^+ + H_2 \rightarrow H_3^+ + H$	2.50×10^{-9} [60]
$H_2^+ + C_2H_2 \rightarrow C_2H_2^+ + H_2$	5.30×10^{-9} [60]
$CH_3^+ + C_2H_2 \rightarrow C_3H_3^+ + H_2$	1.15×10^{-9} [60]
$CH_3^+ + NH_3 \rightarrow NH_4^+ + CH_2$	3.04×10^{-10} [60]
$CH_4^+ + H_2 \rightarrow CH_5^+ + H$	3.50×10^{-11} [59]
$CH_4^+ + CH_4 \rightarrow CH_5^+ + CH_3$	1.50×10^{-9} [59]
$CH_4^+ + C_2H_2 \rightarrow C_2H_2^+ + CH_4$	2.72×10^{-9} [59]
$CH_4^+ + C_2H_2 \rightarrow C_2H_3^+ + CH_3$	2.45×10^{-9} [60]
$CH_4^+ + NH_3 \rightarrow NH_3^+ + CH_4$	2.70×10^{-9} [60]
$CH_4^+ + HCN \rightarrow HCNH^+ + CH_3$	1.20×10^{-9} [60]
$C_2H^+ + H_2 \rightarrow C_2H_2^+ + H$	1.25×10^{-9} [60]
$C_2H^+ + CH_4 \rightarrow C_2H_2^+ + CH_3$	3.70×10^{-10} [60]
$C_2H^+ + C_2H_2 \rightarrow C_4H_2^+ + H$	1.85×10^{-9} [60]
$C_2H^+ + HCN \rightarrow C_2H_2^+ + CN$	2.70×10^{-9} [60]
$C_2H_2^+ + H_2 \rightarrow C_2H_3^+ + H$	1.00×10^{-11} [60]
$C_2H_2^+ + CH_4 \rightarrow C_3H_4^+ + H_2$	6.25×10^{-10} [59]
$C_2H_2^+ + C_2H_2 \rightarrow C_4H_2^+ + H_2$	4.90×10^{-10} [60]
$C_2H_2^+ + NH_3 \rightarrow NH_3^+ + C_2H_2$	2.14×10^{-9} [60]
$C_2H_3^+ + HCN \rightarrow HCNH^+ + C_2H_2$	2.90×10^{-9} [60]
$C_2H_3^+ + NH_3 \rightarrow NH_4^+ + C_2H_2$	2.50×10^{-9} [60]
$H^+ + C_4H_2 \rightarrow C_4H_2^+ + H$	2.06×10^{-9} [60]
$C_3H_2^+ + C_3H_4 \rightarrow C_4H_3^+ + C_2H_3$	1.96×10^{-10} [60]
$HCN^+ + CH_4 \rightarrow C_2H_3^+ + NH_2$	2.60×10^{-10} [60]
$NH_3^+ + NH_3 \rightarrow NH_4^+ + NH_2$	2.10×10^{-9} [60]
$N_2^+ + NH_3 \rightarrow NH_3^+ + N_2$	1.94×10^{-9} [60]
$N_2^+ + CH_4 \rightarrow CH_3^+ + N_2 + H$	9.30×10^{-10} [60]
$CN^+ + NH_2 \rightarrow NH_2^+ + CN$	9.10×10^{-10} [60]
$CN^+ + NH_3 \rightarrow HCN^+ + NH_2$	2.00×10^{-9} [59]
$CN^+ + HCN \rightarrow HCN^+ + CN$	2.70×10^{-9} [60]
$HCN^+ + C_2H_2 \rightarrow C_2H_2^+ + HCN$	1.50×10^{-9} [60]
$HCN^+ + NH_3 \rightarrow NH_3^+ + HCN$	1.68×10^{-9} [60]

2.9. Growth rate equation of CNT array

The average growth rate of wth CNT in the CNT array is assessed by the change in the average volume of wth CNT, represented by the left-hand side of equation (15). The outer diameter of the wth CNT is comparable to the diameter of the w^{th} catalyst nanoparticle (D_{Ni}).

The right-hand side of equation (15) evaluates the growth processes of wth CNT in the CNT array. The carbon monomers and carbon clusters that are generated on the catalyst surface because of several surface processes - such as hydrocarbon adsorption, ion-induced and thermal dissociation of adsorbed hydrocarbons, decomposition of hydrocarbon ions, hydrocarbon and hydrogen ions interaction, diffuse over the surface and into the bulk of the wth Ni catalyst nanoparticle with different energy barriers. The temperature of the catalyst nanoparticles has a considerable impact on these diffusion processes. At lower catalyst temperatures, the surface diffusion process dominates CNT array growth, whereas at higher catalyst temperatures, CNT array growth is primarily owing to the bulk diffusion process, and at intermediate temperatures, both processes contribute. As a result, in this paper, we have studied both the diffusion process in CNT array growth because the temperature of the catalyst nanoparticle is assumed constant.

After this, the carbon atoms in wth Ni catalyst bulk precipitate out with an energy barrier for incorporation along the CNT-Ni interface and result in the formation of a graphitic cylindrical tube. The highly active hydrogen species contribute to array expansion by eliminating amorphous carbon from the wth catalyst surface during array formation. The expansion also incorporates the accumulation of neutrals of type j and l throughout the surface of wth CNT [55, 62]. The accumulated neutrals of type l in the CNTs lattice significantly affect the growth of CNTs.

Table 7. Description of the terms in equations (14a)–(14c).

Terms	Description
$H_t = \alpha_t n n_{it}$	The rate of gain of neutrals of type t (t corresponds to type j, k, l) due to electron- ion combination.
$I_t = \Lambda_{hyb}(1-\gamma_{it})\sum_{w=1}^{r}\begin{pmatrix}\xi_{it}^{tipw}+\xi_{it}^{curw}\\+\xi_{it}^{pgrw}\end{pmatrix}$	The rate of gain of neutrals of type t (t corresponds to type j, k, l) due to ion neutralization on hybrid surface.
$J_j = K_{wall}^{t} n_t = \left(\frac{\gamma_t D_t}{\ell}\right)$	The rate of loss of neutrals of type t to chamber wall. (t corresponds to type j, k, l) D_t= Diffusion coefficient of neutrals within plasma, ℓ= Effective diffusion length of cylindrical chamber [34, 61].
$K_t = \delta_t n_t$	The rate of loss of neutrals of type t due to ionization of neutral atoms (t corresponds to type j, k, l).
$L_t = \Lambda_{hyb}(\gamma_t)\sum_{w=1}^{r}\begin{pmatrix}j_{it}^{tipw}+j_{it}^{curw}\\+j_{it}^{pgw}\end{pmatrix}$	The rate of loss of neutrals of type t due to their accretion at hybrid's surface (t corresponds to type j, k, l).
$M_t = F_{adt} = \frac{p_t}{(2\pi m_{it} k_B T_{it})^{\sqrt{0.25}}} \times \frac{n_t}{F_t}$	The rate of loss of neutrals of type t due to their adsorption at hybrid's surface. p_t = partial pressure of adsorbing species (t corresponds to type j, k, l).
$N_t = F_{dest} = n_t f \exp\left(-\frac{U_{ads}}{k_B T_{it}}\right)$	The rate of gain of neutrals of type j due to their desorption from hybrid's surface with adsorption energy $U_{ads;}$ (t corresponds to type j, k, l).
$O_j = \sum_i P_{ij} n_j n_{il}$	The loss of neutrals of type j due to reaction between neutral of type j and ion of type l, as listed in table 6.
$P_j = \sum_i P_{ij} n_j n_{ik}$	The loss of neutrals of type j due to reaction between neutral of type j and ion of type k, as listed in table 6.
$Q_j = \sum_i P_{il} n_l n_{ij}$	The gain of neutrals of type l due to reaction between neutral of type l and ion of type j, as listed in table 6.
$Q_k = \sum_i P_{ij} n_j n_{ik}$	The gain of neutrals of type j due to reaction between neutral of type j and ion of type k, as listed in table 6.
$P_k = \sum_i P_{ik} n_k n_{ik}$	The loss of neutrals of type k due to reaction between neutral of type k and ion of type k, as listed in table 6.
$O_l = \sum_i P_{il} n_l n_{ij}$	The loss of neutrals of type l due to reaction between neutral of type l and ion of type j, as listed in table 6.
$P_l = \sum_i P_{il} n_l n_{il}$	The loss of neutrals of type l due to reaction between neutral of type l and ion of type l, as listed in table 6.
$Q_l = \sum_i P_{ij} n_j n_{il}$	The gain of neutrals of type j due to reaction between neutral of type j and ion of type l, as listed in table 6.

$$\frac{\pi}{4}\frac{d(D_{Niw}^2 - D_w^2)L_w}{dt} = \frac{1}{r}$$
$$\sum_{w=1}^{r}\left[\begin{pmatrix}\frac{D_a D_{Niw}}{f}\exp\left(\frac{-U_{voc}}{k_B T_s}\right)\\+\frac{D_b}{f}\exp\left(\frac{-U_{arc}}{k_B T_s}\right)\\+\frac{D_c}{f}\exp\left(\frac{-U_{arcl}}{k_B T_s}\right)\\\frac{A_s D_{Ni} w}{f}\exp\left(\frac{-\delta U_{INc}}{k_B T_s}\right)\end{pmatrix}\times\left(C_a \times \xi_{ij} \times \left(\frac{M}{\rho}\right)_w\right)\right.$$
$$\left.+\left(\left[\pi D_{Niw} L_w \times H_a \times \xi_{ik} \times \left(\frac{M_{Ni}}{\rho_{Ni}}\right)_w\right] + \left[(\Upsilon_j \xi_j + \Upsilon_l \xi_l) \times \left(\frac{M}{\rho}\right)_w\right]\right)\right], \quad (15)$$

The details of growth processes integrated in equation (15) are in given table 8.

2.10. Growth rate equation of PGL

When the chamber is cooled, carbon atoms begin to diffuse out from the bulk of the wth catalyst nanoparticles and onto its surface, forming graphene nuclei. These nuclei combine and bridge the spaces between nanoparticles to produce PGLs. Subsequently, the adsorbed carbon is then etched over the catalyst surface, resulting in clean graphene layers.

The growth of PGL is computed in terms of areal (thickness (t_{pg}), and height (h_{pg})) change with time, as expressed by the left-hand side of equation (16).

Table 8. Details of growth processes and parameters integrated in equation (15).

Functions/Parameters	Description
$\frac{D_a D_{Niw}}{f}\exp\left(\frac{-U_{voc}}{k_B T_s}\right)$	Bulk diffusion of carbon monomer into wth catalyst nanoparticle.
$\frac{D_b}{f}\exp\left(\frac{-U_{arc}}{k_B T_s}\right)$	Diffusion of carbon monomer over surface of wth catalyst nanoparticle.
$\frac{D_c}{f}\exp\left(\frac{-U_{arcl}}{k_B T_s}\right)$	Diffusion of carbon cluster over surface of wth catalyst nanoparticle.
$\frac{A_s D_{Niw}}{f}\exp\left(\frac{-\delta U_{INc}}{k_B T_s}\right)$	Incorporation of carbon monomer into wth CNT through wth CNT - Ni confluence.
$\left[\pi D_{Niw} L_w \times H_a \times \xi_{ik} \times \left(\frac{M_{Ni}}{\rho_{Ni}}\right)_w\right]$	Etching of amorphous carbon over the wth catalyst nanoparticle surface.
$\left[(\Upsilon_j \xi_j + \Upsilon_l \xi_l) \times \left(\frac{M}{\rho}\right)_w\right]$	Accumulation of neutrals of type j and l throughout the surface of wth CNT
$U_{voc} = (1.6\ eV)$	Energy barriers for bulk diffusion in catalyst nanoparticle [62]
$U_{arc} = (0.3\ eV)$	Energy barriers for surface diffusion of carbon monomer over catalyst surface [62].
$U_{arcl} = (0.48\ eV)$	Energy barriers for surface diffusion of carbon clusters over catalyst surface [63].
$U_{Inc} = (0.4\ eV)$	Energy barrier for incorporation along CNT- Ni interface [62]
D_a	Bulk diffusion coefficients [62]
D_b, D_c	Surface diffusion coefficients [62]
A_s	Incorporation speed of carbon monomer into wth CNT
M (≈12 g)	Mass of wth CNT
ρ	Density of wth CNT
Y_t(≈1)	Sticking coefficient of neutrals of type j and l [62]

$$l_{pg}\frac{d(h_{pg}\times t_{pg})}{dt} = \sum_{w=1}^{r}\left[\left(D_a\frac{(C_1-C_0)}{\sqrt{\pi D_a t}}\pi D_{Niw}^2 + \frac{(C_1-C_0)}{\sqrt{\pi D_a t}}D_b\pi D_{Niw}^2 + y_i I_K n_{it}\vartheta_0\theta_c l_{pgw} h_{pgw}\right)\frac{M_{wpg}}{\rho_{wpg}}\right], \quad (16)$$

where, M_{wpg} (≈12 g) and ρ_{wpg} are the mass and density of graphene layer on wth catalyst nanoparticle. y_i and I_K are the etching yield and rate coefficient for ions incident on the catalyst nanoparticle [64].

The right-hand side of equation (16) includes the growth processes involved in PGL growth. The first phrase refers to the outward diffusion of carbon atoms from the bulk of the wth Ni catalyst nanoparticle, followed by diffusion over the catalyst surface to generate graphene layers with activation energy barriers [65]. The final part of the equation represents the etching of adsorbed carbon atoms over the catalyst surface, promoting the formation of clean graphene.

2.11. Field enhancement factor

Understanding the field emission characteristics requires the study of the field enhancement factor. Equations (17) and (18) show the approximated field enhancement factor of the CNT array and CNT-PGL hybrid.

$$\beta_a \approx \beta\left\{1 - \exp\left(-2.3172\frac{s}{L_w}\right)\right\}, \quad (17)$$

$$\beta_{hyb} \approx \beta_a \times \beta_g \times \exp(-\phi'), \quad (18)$$

where β_a and $\beta_{hy\,b}$ denotes the field enhancement factor of CNT array and CNT-PGL hybrid. Exp $(-\phi')$ refers to the exponential fall in field enhancement factor owing to a decrease in electric field penetration due to graphene coverage over the CNT array, with $\phi = \sigma'\sqrt{\mu}/\sqrt{\varepsilon}$. σ', μ, ε, β_g are the conductivity, electric dipole moment, dielectric constant, and field enhancement factor of PGL. s is the spacing among CNTs [32, 66–71].

3. Results and discussion

In this paper, an analytical model is used to describe the growth of the CNT-PGL hybrid under appropriate conditions i.e., C_2H_2 flow rate, catalyst film thickness, substrate temperature, and cooling rate. The analytical model incorporates first-order simultaneous differential equations for plasma sheath, plasma species densities, carbon and hydrogen species surface concentration, growth rate of CNT array and PGL as well as field enhancement factor of CNT and CNT-PGL hybrid. The equations are solved via Mathematica software. In computations, we use substrate area to be 500 × 500 μm^2 covered with Ni film, with average centre-to-centre

Table 9. Initial number density of various plasma species considered in present model [47, 65, 72, 73].

Species	Mass (1 amu = 1.66×10^{-27} kg)	Number density (cm^{-3})
Electron	0.0005486 amu	7×10^{10}
C_2H_2	26 amu	7×10^{13}
CH_4	16 amu	2×10^{14}
CH_3	15 amu	1×10^{13}

Table 10. Parameters used in present model [25, 36].

Parameters	Value
Electron temperature (T_{eo})	2.2 eV
Neutral temperature (T_{no})	0.17 eV
Ion temperature (T_{io})	0.15 eV
Plasma Power	120 W
Substrate Potential (U_c)	−500 V
Substrate temperature (T_s)	750 °C
sGas pressure while CNT array growth	7 Torr
Gas pressure while graphene growth	22 Torr
Initial bulk concentration in Ni catalyst nanoparticle (C_1)	0
NH_3 gas flow rate	200 sccm
N_2 flow rate	10,000 sccm

spacing (s) of 1 μm among the catalyst nanoparticles formed. Tables 9 and 10 list relevant initial conditions and parameters that were determined experimentally. They are utilized to solve equations presented in section (2) at t = 0.

In the present analysis, the obtained potential distribution inside the plasma sheath, ion, and neutral density are used to compute the average diameter (D_{Ni}) of the catalyst nanoparticle together with hydrogen and carbon flux over the catalyst surface. The obtained carbon and hydrogen flux are used to calculate the growth rates of planar graphene and CNT arrays. Then we start the next time by solving the differential equations again, with new boundary conditions derived from the dimensions of the recently acquired hybrid.

First, we analyze the effect of C_2H_2 flow rate, catalyst film thickness, and substrate temperature on the growth of the CNT array, followed by an analysis of the growth of PGL over the CNT array by cooling the chamber.

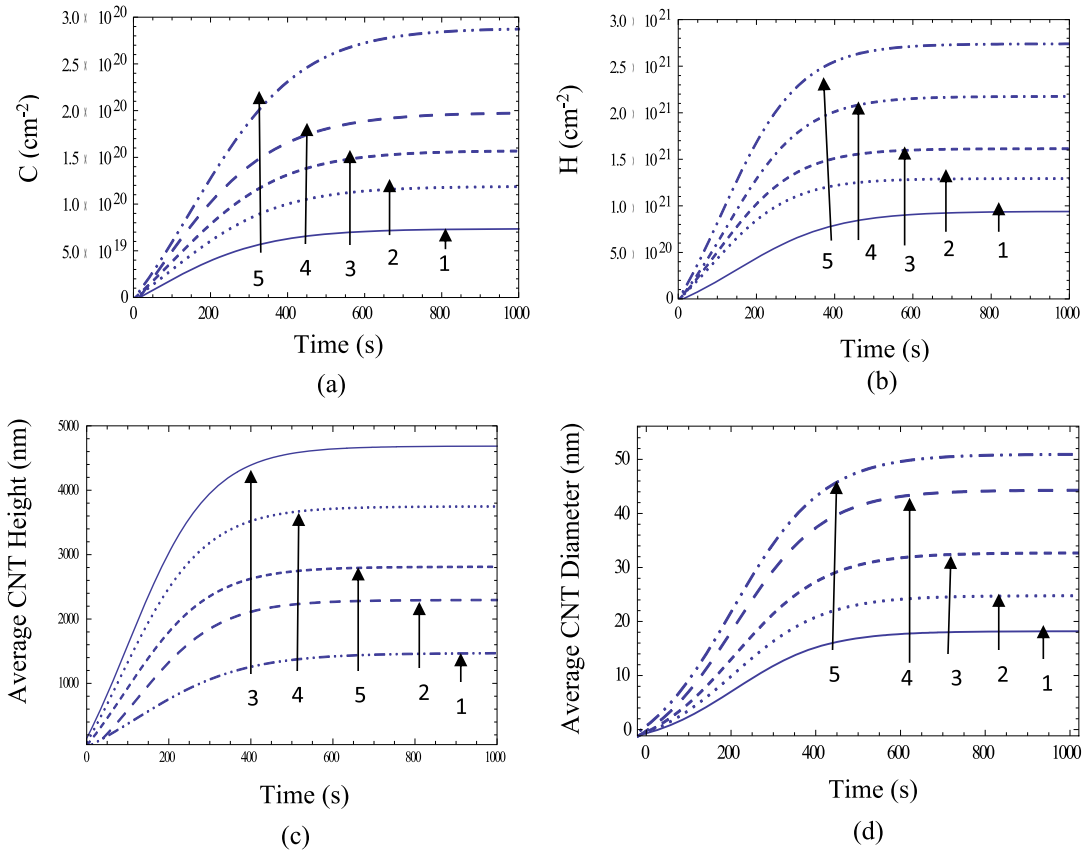

Figure 3. Time varying (a) Surface concentration of Carbon (C_a), (b) Surface concentration of Hydrogen (H_a), (c) Average CNT Height, (d) Average CNT diameter for varying C_2H_2 flow rate and constant NH_3 flow rate (200 sccm). (1 = 20 sccm), (2 = 40 sccm), (3 = 60 sccm), (4 = 100 sccm) (5 = 150 sccm).

3.1. Time variation of CNT array growth with C_2H_2 gas flow rate

Lighter and etchant ions (NH_4^+, HCN^+, $C_2H_2^+$, $C_2H_3^+$, H_2^+) are predominant under low C_2H_2 gas flow rate [cf. figures 2(a)–(e)] assisting in the formation of a clean CNT array [74]. With further increase in C_2H_2 gas flow rate, the neutral number density of type j in plasma bulk increases [cf. figures 2(f)–(i)] leading to their increased adsorption on the catalyst surface. In addition, NH_3 is insufficient to suppress the decomposition of C_2H_2. So low etchant ion density and insufficient NH_3 at high C_2H_2 flow rate results in excess carbon deposition as amorphous carbon, poisoning the catalyst particle, retarding the CNT array growth. Hence, at a low C_2H_2 gas flow rate (i.e. up to 60 sccm) the relative carbon and hydrogen radical surface concentration [cf. figures 3(a), (b)] is competent for an increase in the growth rate of CNT, as carbon species generated over the surface of the catalyst are deposited and amorphous carbon is etched.

Figure 3(c) shows that the average CNT height in the CNT array increases up to a C_2H_2 flow rate of 60 sccm and then it declines with a further rise in C_2H_2 flow at fixed ammonia (NH_3) gas flow rate (200 sccm). Chhowalla *et al* [30] reported an initial increase in CNT growth rate up to 30% C_2H_2 concentration then it dropped further and according to Bell *et al* [31], CNTs are well aligned between 4 and 20% of C_2H_2, with a growth peak at 20%. At 29% C_2H_2, CNTs resemble obelisks while at 38%, amorphous C deposition was detected.

Because of carbon deposition on the catalyst nanoparticle surface, the average diameter of CNTs in an array increases as the flow rate of C_2H_2 increases [cf. figure 3(d)]. The findings are in line with Merkulov *et al* [75], who found a 36 nm tip diameter at a C_2H_2/NH_3 ratio of 0.625 and a 46 nm tip diameter at a ratio of 0.80.

3.2. Variation of CNT array length and diameter with catalyst thickness

Figure 4(a) shows the average CNT height in array with increasing Ni film thickness. As thickness increases (upto 10 nm), catalyst particle size increases, raising average

3.3. Variation of CNT array length and diameter with catalyst thickness

Figure 4(a) shows the average CNT height in an array with increasing Ni film thickness. As thickness increases (up to 10 nm), catalyst particle size increases, raising average CNT height because catalyst particle remain active for dissolution, surface, and bulk diffusion of C- atoms [76]. Above 10 nm thickness, a decrease in average CNT

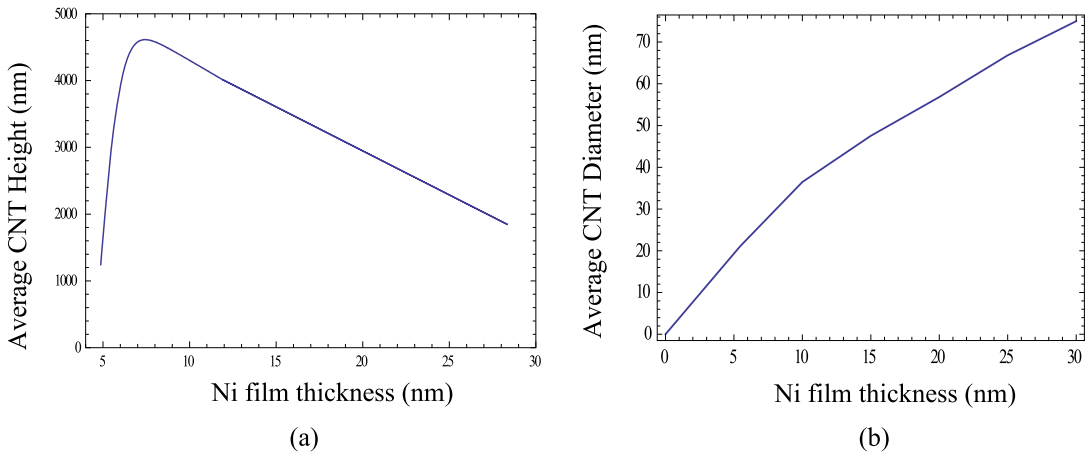

Figure 4. (a) Average CNT Height, (b) Average CNT diameter for varying Ni film thickness.

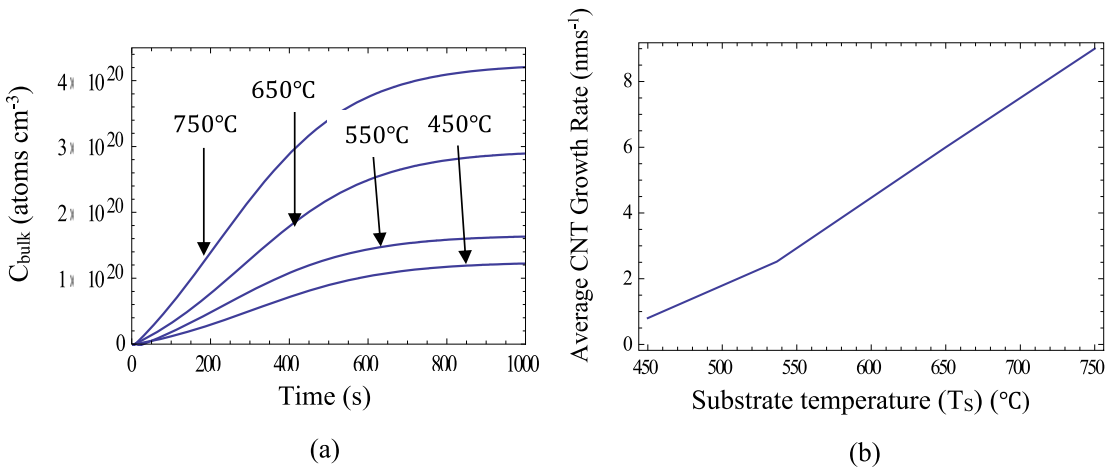

Figure 5. (a) Time varying Carbon atom concentration (C_{bulk}) in Ni nanoparticle. (b) Average CNT growth rate with substrate temperature.

height is observed owing to an increase in diffusion length of carbon inside the catalyst particle, so not enough particles can diffuse out from the catalyst bulk; consequently, shorter nanotubes are obtained. The obtained results comply with the studies of Lee *et al* [76] where an increase of Ni catalyst thickness from 4 to 10 nm, enhances the length and growth rate of CNT by a factor of 0.7. As per Han *et al* [77], the acquired data indicate that, in the case of a 100 nm Ni layer, carbon nanoparticles rather than carbon nanotubes appear in the SEM pictures [cf. figure 2 of Han *et al* [77]]. Ma *et al* [78] conducted an experiment wherein they noticed that the average length of CNTs decreased with increasing Ni film thickness up to 20 nm [cf. figure 4 of Ma *et al* [78]].

Additionally, the size of the Ni nanoparticles, which grow with Ni film thickness, controls the average diameter of CNT [cf. figure 4(b)]. This comes after Han *et al*'s study [77], in which the mean diameter of CNTs increased from 32 to 113 nm when the thickness of the Ni film increased from 10 to 100 nm.

3.4. Variation of growth rate of CNT array with substrate temperature

With increasing substrate temperature, the concentration of carbon atoms (C_{bulk}) inside Ni catalyst nanoparticles increases [cf. figure 5(a)]. This can be attributed to an increase in ion-driven hydrocarbon and ammonia species dissociation and decomposition over Ni catalyst nanoparticle. As a result, C_a and H_a increases across Ni nanoparticle surface. Increases in H_a cause etching, which removes excess carbon from the Ni surface. This opens up the catalyst surface area, allowing a larger intake of carbon and a rise in carbon atom solubility [79]

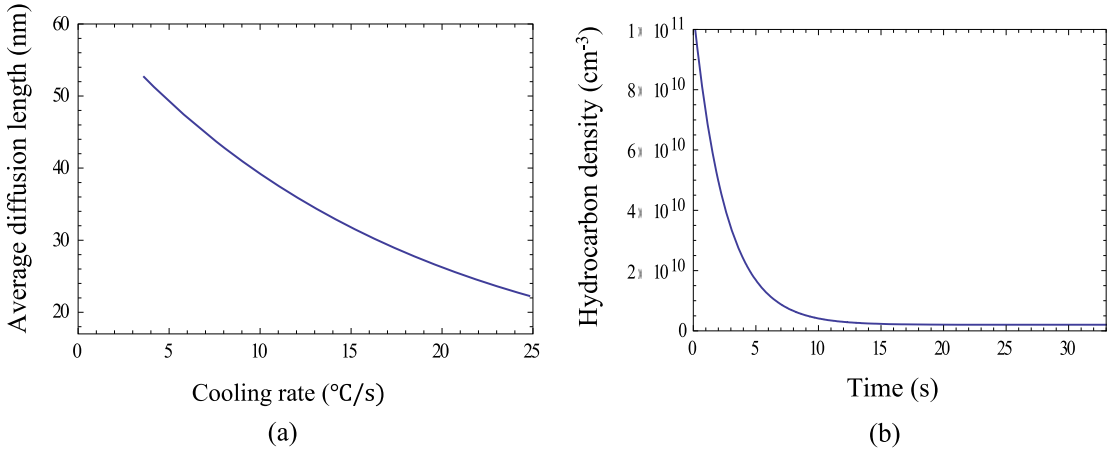

Figure 6. (a) Average diffusion length with varying cooling rates (b) Time varying hydrocarbon density.

and diffusivity. Studies by Bleu *et al* [80], Shurman *et al* [27], have shown that the concentration of carbon in the Ni bulk increases with substrate temperature.

As a result, the average growth rate of CNT in the array rises [cf. figure 5(b)]. This is in line with research done by Chhowalla *et al* who found that CNT height increased between 520 °C and 700 °C [30].

3.5. Variation of: diffusion length with cooling rate, hydrocarbon density with time in N_2 environment to obtain PGL

The carbon diffusion length inside Ni nanoparticles is explored for graphene precipitation. This is done in the N_2 environment after stopping C_2H_2/NH_3 flow. At a slow cooling rate (5 °C s^{-1}), the diffusion length is larger than the size of Ni nanoparticles, which leads to Ni completely carburizing and inhibits the formation of graphene [45]. At a rapid cooling rate (25 °C s^{-1}), a shorter diffusion length is obtained. Therefore, carbon atoms near the Ni surface precipitate more quickly than they diffuse in the Ni bulk, resulting in the formation of amorphous carbon [81]. Figure 6(a) illustrates the effective average diffusion length of carbon into Ni nanoparticle bulk at slow, moderate (15 °C s^{-1}), and fast cooling rates. The calculated diffusion lengths agree with the results of Gkouzou *et al* [45]. According to Yu *et al* [26] and Reina *et al* [81], the average diffusion length decreases with a rise in cooling rates.

Starting N_2 flow and stopping C_2H_2/NH_3 flow after the formation of the CNT array, causes a gradual decrease for species remaining in the chamber [cf. figure 6(b)]. This is explained by the fact that N_2 helps to eliminate volatile byproducts such as HCN, C_2N_2, CN, and volatile hydrocarbons as well as any remaining unreacted precursors [82, 83]. This prevents the catalyst from contamination during the precipitation process. As a result, precipitation processes dominate surface reaction processes in the formation of PGL.

With time as the temperature of the chamber decreases at a rate of 15 °C s^{-1}, the carbon atoms start precipitating out from the Ni nanoparticle catalyst bulk. The excess carbon atoms that precipitate out to form graphene layers are proportionate to the difference in concentration of the saturated (C_1) and supersaturated (C_0) solution of carbon atoms inside the Ni catalyst [45]. More carbon precipitates out when the temperature drops because the concentration difference between saturated and supersaturated solutions increases and acts as a constant driving force [44, 45].

Consequently, the synthesis of graphene is guided by the outward and surface diffusion of carbon atoms from and on the Ni surface [46, 64, 84]. Therefore, we can depict that the number of graphene layers; hence the thickness of graphene increases with time on cooling [27, 49], [cf. figures 7(a), (b)]. The experimental work of Choi *et al* [25] regarding number of graphene layers (4–7 layers), is similar to the obtained value (≈5 layers). Reina *et al* [49] have obtained thickness within the range of 1–5 nm corresponding to approximately 1–12 graphene layers. Gupta *et al* [85] have plotted the thickness of the graphene layer for different values of graphene layer number [cf. figure 1 of Gupta *et al* [85]].

3.6. Variation of graphene layer number with Ni film thickness

At Ni film thicknesses of less than 3 nm, small catalyst nanoparticles form. Carbon atoms rapidly saturate these catalyst nanoparticles by forming a carbon shell around them [76]. The catalyst nanoparticle size rises with the thickness of the Ni film, causing the CNT array to grow due to increased carbon atom dissolution and diffusion [76]. This simultaneously increases the number of carbon atoms available for precipitation, eventually leading to

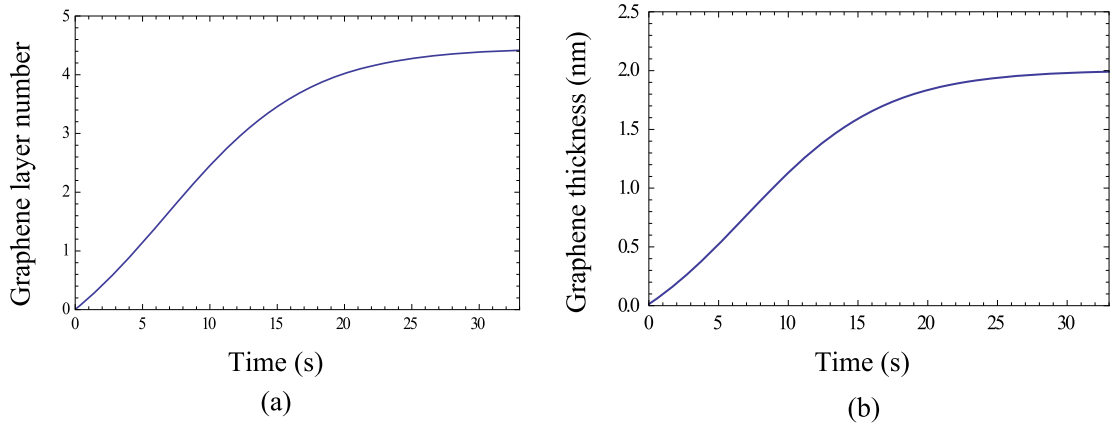

Figure 7. (a) Time varying (a) graphene layer number (b) graphene thickness.

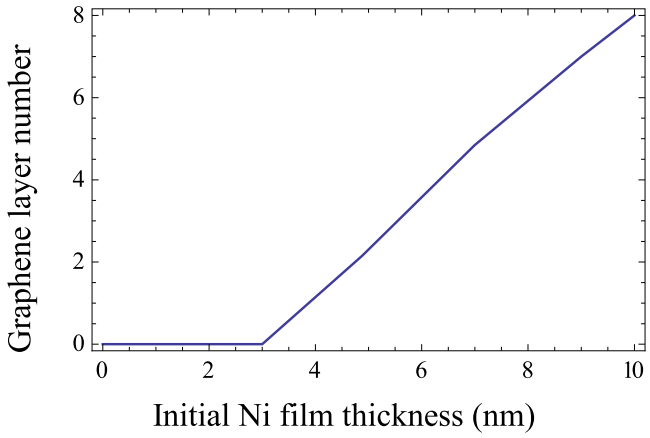

Figure 8. Varying graphene layer number with initial Ni film thickness.

Table 11. Optimized dimensions of CNT array and CNT-PGL hybrid considered.

CNT array	CNT –PGL Hybrid
Average height of CNT (L_w) ≈ 5 μm	Thickness of graphene (t_{pg}) ≈ 2 nm
Average diameter of CNT (D_w) ≈ 32 nm	Average height of CNT ≈ 5 μm
Spacing among CNT ≈ 1 μm	Average diameter of CNT ≈ 32 nm

the formation of graphene layers [46]. Up to a film thickness of 3 nm, figure 8 displays no graphene layer; beyond that, the layer number starts to rise with an increase in film thickness. For a 7 nm thick Ni film, Choi *et al* [25] got 4–7 graphene layers; Peng *et al* [46] and Kim *et al* [86], have shown that the number of graphene layers increases with the thickness of the Ni film.

3.7. Field enhancement factor of CNT array and CNT-PGL hybrid

The procured results from the present study are utilized to determine the field enhancement factor of the CNT-PGL hybrid (β_{hyb}) and to compare it with the field enhancement factor of CNT array (β_a). Table 11 lists the dimensions of the CNT array and CNT-PGL hybrid obtained at a C_2H_2 flow rate of 60 sccm, Ni film thickness of 8 nm, substrate temperature 750 °C, cooling rate 15 °C s^{-1}.

The obtained β_a [cf. figure 9] is consistent with the experimental results of Bonard *et al* [32], who got β_a (≈800) for the following parameters of CNT film: mean height 3 μm, mean tube radius 19 nm, and inter-tube distance 1.02 μm. Furthermore, it is observed that β_a is less than β_{hyb}. Because CNTs are densely packed, the higher coulomb-repelling force of neighboring CNTs results in a significant reduction of β_a. The large β_{hyb} is

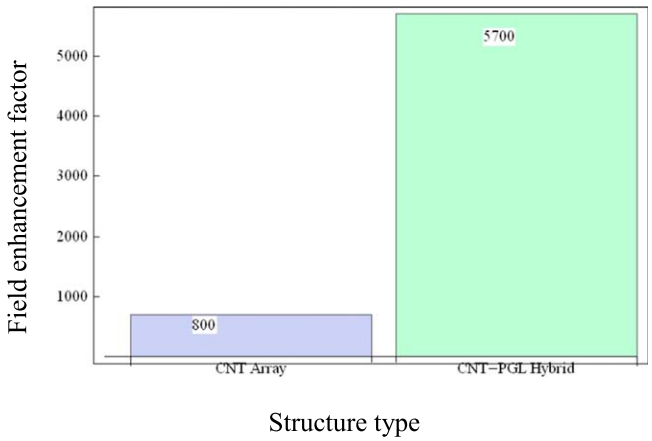

Figure 9. Field enhancement factor of CNT array and CNT-PGL Hybrid.

ascribed to the field emission from (i) the PGL's edges and (ii) the spaces between CNTs since PGL is present on CNT [86, 87]. Therefore, precipitating PGL across a CNT array considerably increases the field enhancement factor, exceeding βa. Obtained β_{hyb} is following Qu *et al* [88] who have obtained β_{hyb} ($\approx$ 5780). Kaur *et al* [33] [cf. table 2 of Kaur *et al* [33]], Hong *et al* [19], Kaushik *et al* [87] [cf. table 3 of Kaushik *et al* [87]] have also reported an escalation in β_{hyb} than β_a.

4. Conclusion

The model can configure and characterize the growth of the CNT-PGL hybrid by adjusting the C_2H_2 flow rate, catalyst film thickness, substrate temperature, and cooling rate. The effect of varying C_2H_2 flow rates on ion and neutral number density, as well as on carbon and hydrogen radical surface concentration is evaluated, to investigate their influence on the growth of the CNT array. It has been noted that as the C_2H_2 flow rate and Ni film thickness increase, the growth rate of the CNT array first increases and subsequently drops. Furthermore, the solubility and diffusivity of carbon atoms inside the Ni catalyst increase with substrate temperature, enhancing the average growth rate of CNTs. Moreover, as chamber temperature decreases at a rate of 15 °C s^{-1} and catalyst film thickness increases the number of graphene layers grows. The procured results are employed to determine the field enhancement factor of densely packed CNT array and CNT-PGL hybrid and it is concluded that precipitated graphene layers on the CNT array top can enhance the field enhancement factor of the densely packed CNTs. Thus gas flow rate, catalyst film thickness, substrate temperature, and cooling rate may all be regulated to control the formation of a CNT-PGL hybrid, which may then be employed in efficient field emission devices.

Abstract
A novel Segmented Clad-Graded Index (SC-GI) photonic crystal fiber with a circular core composed of $As_{38}Se_{62}$ is proposed to realize the supercontinuum spectrum in the entire transparency range of $As_{38}Se_{62}$ (2–10 μm). SC-GI PCF conveys dual Zero Dispersion Wavelengths at around 2.4 μm and 6.4 μm. The devised PCF also offers a very small effective mode area of 2.46 μm^2 and a very high nonlinear coefficient of 12,005 W^{-1} km^{-1} at the pump wavelength of 2.4 μm. Detailed numerical simulations reveal that a short length of SC-GI PCF (~28 mm) is capable of showing a broad SC spectrum ranging from 3 to 9.5 μm (−30 dB level of power) using an input source of moderate peak power (1.8 kW) pumping at 3.4 μm. To the best of the author's knowledge, this is the first time report of SCG in Segmented Cladding Fiber design. The evaluated SC covers the transparency window of the background material and also covers the mid-IR region. This type of high broadening opens the gateway for applications like optical metrology, optical coherence tomography (OCT), food quality control, telecommunications and future applications covering the Mid-IR region.Please confirm the corresponding author is correctly identified and amend if necessary.Yes, Corresponding author is correctly mentioned.

1 Introduction

Over the last fifty years, communication and data transmission have perceived a huge technological advancement. One of the reasons behind such advancement is the invention of optical fibers. Optical fibers work on the principle of total internal reflection which is maintained by refractive index difference between core-cladding interfaces. For increasing the

influence of refractive indices of materials, optical fibers are upgraded and transformed into a new substitute—photonic crystal fibers. PCFs are designed by incorporating different type of holes composed of air or material with low refractive index arranged in ordered manner around the core. Photonic crystal fiber delivers extraordinary properties like extremely large-mode-area, extremely small-mode-area, low confinement loss, high birefringence, tailored dispersion properties and high magnitude of nonlinearity and many more (She et al. 2021; Matsui 2005; Medjouri 2021; Kim 2020; Dussardier 2011). Quality to provide an extremely small mode area for light confinement and flexibility to choose high nonlinear material guarantees the presence of fascinating various nonlinear effects like self-phase modulation (SPM), cross-phase modulation (XPM), four-wave mixing (FWM), stimulated Raman and Brillouin scattering (SBS-SRS) in PCF. These nonlinear effects can play simultaneously to give rise to a wide band of supercontinuum spectra. When any picosecond or femtosecond laser pulse interacts with media containing inherent nonlinear properties results in the generation of broadband SC covering the whole Mid-IR (MIR) region. Such broadband SC mainly wraps MIR regime applicable in various fields like telecommunications, optical coherence tomography (OCT) (Hartl et al. 2001), generation of frequency combs, and optical metrology (Ye 2003). To gather the best results of SC, one need to take care of two aspects in PCF: i) arrangement of the air-holes around the core. These air holes altogether control the dispersion characteristics of fiber and hence help in broadening of spectrum. ii) Material selection for composition of core and cladding. For enhancing nonlinear effects such as SCG, core should be composed of material inherits very high refractive index and high nonlinearity. Nonlinearity of silica is in the range of 10^{-20} m^2W^{-1} which bounds its application only within near-IR range (Wang 2023). Dudley et al. had designed ASMF (Air-Silica Micro-structured Fibers) and simulated at pumping of pulse-width 100 fs at 780 nm resulted SC spectra of 500–1400 nm (Alfano and Shapiro 1970). To exaggerate the SC in Mid-IR or Far-IR regions, silica is begun to be replaced with tellurite (Xu et al. 2018; Zheng 2021; Liao 2009), chalcogenide (Siwach 2018; Saini 2017; Saini 2015) chalcopyrite (Salimullah 2023) etc. In recent times, chalcogenide glass formed PCFs are at boom for creation of SC as they offer transparency range of 2–25 µm and inherits high nonlinearity of range 10^{-17} m^2W^{-1}. Diouf et al. had presented two optical structures (one is PCF and another is rib waveguide) composed of $AsSe_2/As_2Se_5$ glasses offering SC band expanded up to 13 µm for the former structure and 16 µm for the latter (Diouf et al. 2019a, b). Van et al. had proposed a hexagonal core PCF with the composition of As_2Se_3 as a background component delivering SC spanning up to 10 µm with the input of 3.5 µm pumping (Chu et al. 2022). $Ge_{15}Sb_{15}Se_{70}$ fabricated PCF giving the spanned SC of 1–7 µm by Medjouri et al. 2019. By the doping of iodine in $Ge_{10}As_{22}Se_{68}$ chalcogenide glass, Zero dispersion wavelength was shifted from 7 µm to 5.5 µm and SC broadens from 1.2 to 15.2 µm at 12 cm fiber reported by Jiao et al. (2019). Wang et al. simulated the SC spectra (2.3–14.5 µm) with a 17 cm long Te-rich chalk ogenide PCF (Wang et al. 2019). $Ge_{11.5}As_{24}Se_{64.5}$ based PCF was proposed by Vyas et al. which provides SC of 1–15 µm at fiber length of 100 mm with a pulse peak power of 3 kW (Vyas 2016). Among all the Selenium (Se) composed glasses $As_{38}Se_{62}$ show high nonlinearity, deliver a nonlinear refractive index of high magnitude (Khamaru 2023) and offer a range of transparency of 2–10 µm. Moller et al. were the first to propose this particular material for SC formation and gave proven results of 1.7–7.5 µm SC band (Møller et al. 2015) In very recent times, Vyas et al. showed a broadband SC of 2–9 µm in the same material at 4 µm pump wavelength with 200 mm of fiber length (Vyas et al. 2021).

In the present work, we have designed a segmented clad-graded index (SC-GI) circular core PCF to realize the SCG. In the author's knowledge, this is the first time when a PCF

having segmented cladding is being explored for SCG. Our numerical simulations deliver favorable dispersion properties consisting of dual zero dispersion wavelengths (2.4 μm and 6.4 μm). This empowers SC-GI PCF to achieve SCG in a broadband range spanning from 3 to 9.5 μm with low peak power (1.8 kW) and short fiber length (~28 mm), which totally covers the transparency regime of $As_{38}Se_{62}$ glass and almost covers the Mid-IR region and opens the gateway for new applications and advancements over them.

The paper is organized into broad five parts. Section 1 comprises the introduction and brief survey of past works presented on SCG in PCFs. The methodology for the analysis is given in Sect. 2. Section 3 gives the structural explanation of the proposed SC-GI PCF for SCG applications. All the results of the simulation and respective discussions are done in Sect. 4. Finally, conclusions are drawn and encapsulated in Sect. 5.

2 Methodology

For simulating SC-GI PCF, we have utilized the FEM-based full vectorial modelling software package COMSOL Multiphysics. The FEM method has been used for the complete modal analysis of the design. Supercontinuum is generated with the inclusion of both linear and nonlinear characteristics of the fiber which are described in further sub-sections.

2.1 Linear properties of PCF

The SC-GI PCF consists of a circular core bounded by segmented cladding. Segmented cladding is characterized by the special arrangement of air holes along the radial and angular directions. $As_{38}Se_{62}$, a variant of selenide chalcogenide material is chosen as the core material. The refractive index of $As_{38}Se_{62}$ as a function of wavelength is described by Sellmeier Equation (Vyas et al. 2021):

$$n^2(\lambda) = 3.7464 + \frac{\left(3.9057 \times \lambda^2\right)}{\lambda^2 - 0.4073^2} + \frac{\left(0.9466 \times \lambda^2\right)}{\left(\lambda^2 - 40.082^2\right)} \tag{1}$$

Since the Sellmeier equation is included for defining refractive index, the involvement of both dispersion factors like material and waveguide takes place and total dispersion is calculated by the formula given as follows:

$$D(\lambda) = -\frac{\lambda}{c}\frac{d^2 n_{eff}}{d\lambda^2} \tag{2}$$

After the calculation of dispersion, Eq. (3) will provide the idea of a set of parameters related to dispersion which are evolved and termed as Taylor series expansion. In this given series, the first term of RHS defines the effective R.I. of the mode under propagation. Group wave velocity and group velocity dispersion are defined in the second and third terms of equation respectively. Consideration is taken up to the 9th order for the dispersion parameters.

$$\beta(\omega) = \beta(\omega_o) + \beta_1(\omega_o)(\omega - \omega_o) + \frac{1}{2!}\beta_2(\omega_o)(\omega - \omega_o)^2 + \frac{1}{3!}\beta_2(\omega_o)(\omega - \omega_o)^2 \ldots \tag{3}$$

2.2 Nonlinear properties of PCF

After including all the linear factors, nonlinear factors are also included for the formation of broadband SC pattern which comprises of SPM, FWM, SRS, CPM and many more. For quantifying the nonlinear effects, the nonlinear coefficient is extracted by solving the given equation:

$$\gamma = \frac{2\pi n_2}{\lambda A_{\text{eff}}} \tag{4}$$

The above equation is governed by two important specifications. One of the specifications is a nonlinear refractive index n_2. The chalcogenide glass $As_{38}Se_{62}$ has the value of n_2 as 1.13×10^{-17} m^2W^{-1} (Vyas et al. 2021). Another specification is the effective-mode-area (EMA) which is formulated below. For output of highly broadband SCG, a high magnitude of n_2 and a small EMA are favourable conditions.

$$A_{\text{eff}} = \frac{\left(\iint_{-\infty}^{\infty} |E|^2 dxdy\right)^2}{\left(\iint_{-\infty}^{\infty} |E|^4 dxdy\right)} \tag{5}$$

Incorporation of the Raman response function ($R(t\prime)$) is also done in the SC generating algorithm which includes the reliance on electronic, vibrational and nuclear contributions during the mode propagation through the PCF. Incorporation of parameters like fractional contributions, Raman period and lifetime as f_r, τ_1, τ_2 whose magnitude for material like $As_{38}Se_{62}$ are 0.1, 23.14 fs, 157 fs (Ghosh et al. 2019) are described in the following equations:

$$R(t') = (1 - f_r)\delta(t) + f_r h_r(t\prime) \tag{6}$$

$$h_r = \frac{\tau_i^2 + \tau_2^2}{\tau_1 \tau_2} \exp\left(-\frac{t\prime}{\tau_2}\right) \sin\left(\frac{t\prime}{\tau_1}\right) \tag{7}$$

2.3 Supercontinuum generation

After the interaction of all the linear and nonlinear effects which have taken participation during mode propagation, an ultra-highly spanned SC is formed. Numerically, a generalized nonlinear Schrodinger equation abbreviated as GNLSE is going to be solved with the reference of split-step Fourier Method and same is described below:

$$\frac{dA}{dz} + \frac{\alpha}{2}A - \left(\sum_{n\geq 2} \beta_n \frac{i^{n+1}}{n!} \frac{\partial^n A}{\partial t^n}\right) = i\gamma \left(1 + \frac{i}{\omega_o}\frac{\partial}{\partial t}\right) A(z,\ t) \int_{-\infty}^{\infty} R(t') \left|A(z, t - t')\right|^2 dt' \tag{8}$$

The above equation is the blend of linear and nonlinear properties organized in LHS and RHS respectively where $A(z,\ t)$ is the envelope of the optical field and α denotes the attenuation loss of $As_{38}Se_{62}$ composed PCF and having the value of 0.9 dB/m at ZDW (Le et al. 2011). All the other terms like dispersion components (β), and Raman response function $R(t')$ are already discussed in the above sections. The alterations in spectral phase across

supercontinuum are measured by relative coherence among successive spectral evolutions of SC. The first-order relative coherence is measured by the given equation:

$$\left|g_{12}^{(1)}(\lambda, t_1 - t_2)\right| = \left| \frac{\left\langle E_1^*(\lambda, t_1) E_2(\lambda, t_1) \right\rangle}{\sqrt{\left\langle \left|E_1(\lambda, t_1)\right|^2 \right\rangle \left\langle \left|E_2(\lambda, t_2)\right|^2 \right\rangle}} \right| \tag{9}$$

The numerical magnitude for coherence should be nearest to unity which verifies the degree of coherency of generated SC spectra at optimized parameters. For good agreement with SC, average coherency must be approximate to 1. Coherence must be calculated at different fiber lengths for examining the coherent nature of generated SC at maximum fiber length.

3 Designed SC-GI PCF

We have designed a Segmented Clad-Graded Index (SC-GI) photonic crystal fiber shown in Fig. 1a. The SC-GI PCF consists of a circular core bounded by segmented cladding. The radius of the solid circular core is denoted as r_c. Segmented cladding represents the low- and high-index region in angular direction (Rastogi 2001; Kumar 2012).

Here, we have realized low-index region in angular direction by incorporating three bunches of air holes whose radii are gradually increasing in radial direction. The Radii of these air holes are represented by r_{1n} (n represents the no. of the ring as clearly shown in the inset of Fig. 1a. Δr_1 represents the constant increase in radius. Λ is defined as the

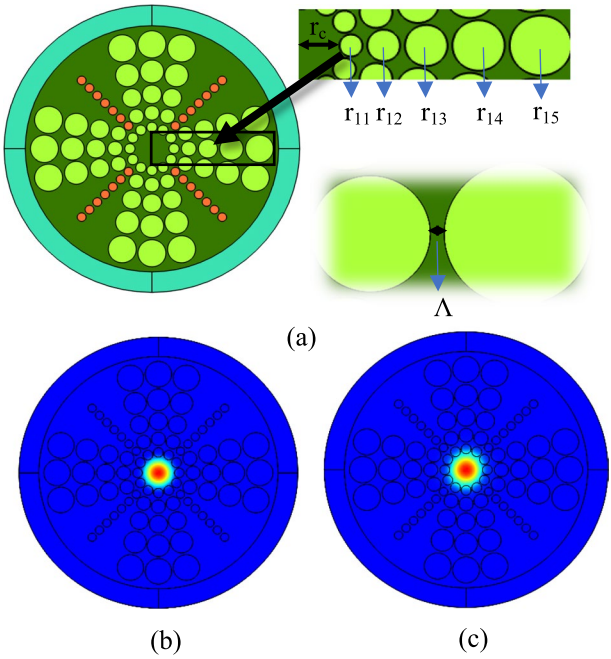

Fig. 1 **a** Proposed SC-GI PCF Design **b** Mode field at 2 μm **c** Mode field at 4 μm

constant separation between the two consecutive graded air holes as shown in the inset of Fig. 1a. Such four segmented claddings are introduced symmetrically at angles of 0, π/2, π, 3π/2 and shown in Fig. 1a. Apart from four sets of segmented cladding, another four sets of air holes of radius r_2 are placed at angles of π/4, 3π/4, 5π/4 and 7π/4. These air holes of the same radii are introduced to confine the mode properly within the core. $As_{38}Se_{62}$ chalcogenide material is used as high-index material for core and cladding region.

Apart from the PCF structure, a PML with cylindrical geometry is applied on the cross-section of fiber to eliminate the reflection back effect. We have designed our PCF to extract a nearly flat dispersion curve (with a small dispersion value) in the normal and anomalous regime. Figure 1b and c shows the fundamental modal field at 2 μm and 4 μm. In this proposed work, we have chosen anomalous region of interest which maximizes the chances of participation of soliton fission on SC.

3.1 Simulation results and discussions

This section is broken down into two sub-parts which deals with the optimization of the designed parameters (r_{11}, Δr_1 and Λ) to achieve favorable flat dispersion and hence desired broad SCG spectrum.

3.2 Evaluation of dispersion characteristics

The dispersion characteristics give the overview of the positioning of normal and anomalous regime by evaluating dispersion at broad spectral region and help in extracting the zero-dispersion wavelength (ZDW) which directly gives the information about the suitable pump wavelength that one should choose. For optimizing our parameters, first, we have seen the effect of all the designed parameters on the dispersion characteristics of the designed PCF. At the initial stage of the study, we kept our parameters at the constant value $r_{11} = 350$ nm and $\Delta r_1 = 100$ nm and varied the dimension of pitch (Λ) from 100 to 200 nm in the step of 50 nm and assessed the dispersion curves respectively. The assessment is illustrated in Fig. 2a. From the observation, we have obtained two values of zero dispersion wavelength in 2000–7000 nm spectral wavelength. The first ZDW is found around 2300 nm which keeps on increasing on the increment of Λ and another ZDW which falls around 6300 nm is on the verge of decrement in the same set of observations. Next, we have seen the effect of r_{11} while keeping $\Delta r_1 = 100$ nm and $\Lambda = 150$ nm and shown in Fig. 2b.

On the increment of r_{11}, both the ZDWs shift towards high wavelengths (red-shifted). After that, we have taken $r_{11} = 350$ nm and $\Lambda = 150$ nm as constant parameters and changed the grading (Δr_1) from 100 to 200 nm. We have noticed that there is no significant change in the first ZDW but the increment is observed in the second ZDW (Fig. 2c). At the next step of observation we have influenced the radius of circular core denoted as r_c and changed the magnitude from 900 to 1100 nm at a step of 100 nm. The observation displayed in Fig. 2d shows that first ZDW got red shifted and increased by 100 nm at increment of the r_c. The respective second ZDW got blue shifted by the same influence. After that, we introduced an increment in the magnitude of r_2 by 50 nm from 250 to 350 nm. The observation shown in Fig. 2e concludes that there is no change in first ZDW, whereas second ZDW experienced a negligible change. In the final step of study, we have varied the angle of rotation of three bunches of cladding holes by 45° and no variation has been observed in dispersion characteristics displayed in Fig. 2f because of the symmetricity of the structure. With the above analysis, we have fixed our optimized design parameters as

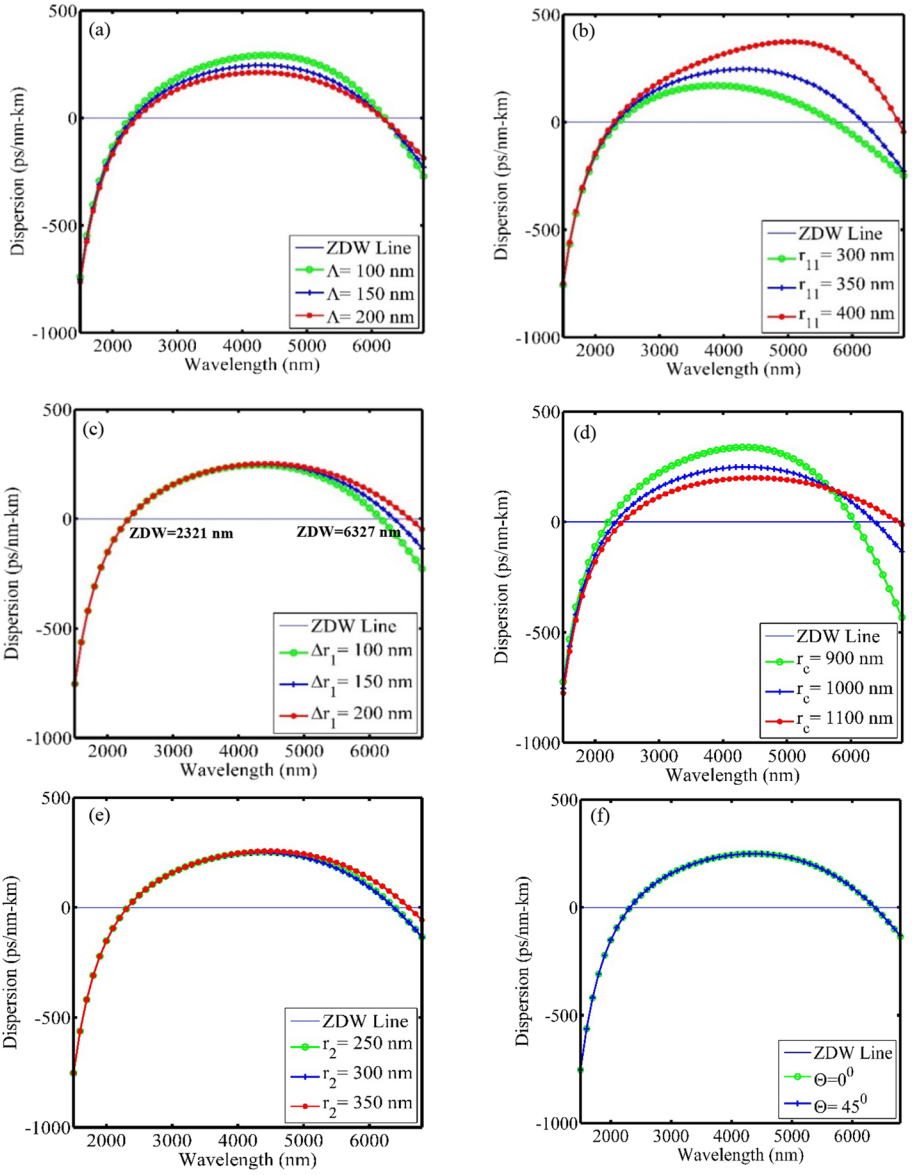

Fig. 2 Dispersion Characteristics with variation of **a** Pitch (Λ) **b** Radius (r_{11}) **c** Grading (Δr_1) **d** Radius of circular core (r_c) **e** Radius (r_2) **f** Angle of rotation of segmented cladding (Θ)

shown in Table 1. The reason behind the optimization is the selection of ZDW. We have extracted values of ZDW as 2321 nm and 6367 nm at our optimized parameters which helps us to choose our pump wavelength as 3.4 μm laser source (anomalous region) which is readily available OPCPA Laser (Petrov 2001; Mayer et al. 2013).

Figure 3 shows the spectral variation of EMA and the nonlinear coefficient. EMA keeps on increasing with wavelength due to the weak confinement of light at higher wavelengths.

Table 1 Optimized design parameters

	Pitch (Λ)	Radius (r_{11})	Change in radius (Δr_1)	Radius of circular core (r_c)	Radius (r_2)	Segmented Clad's angle of rotation (Θ)
PCF parameters	150 nm	350 nm	150 nm	1000 nm	300 nm	0°

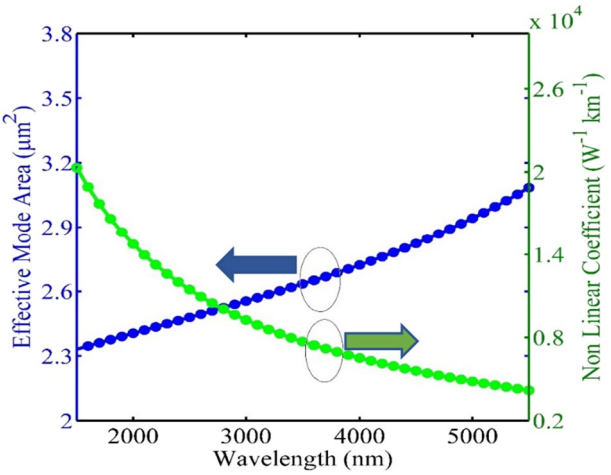

Fig. 3 Variation of effective mode area and nonlinear coefficient with respect to wavelength at optimized parameters

In response to this, the nonlinear coefficient that inversely depends on A_{eff} keeps on decreasing. At pump wavelength $\lambda = 3.4$ μm, the proposed fiber (at optimized parameters) shows a small magnitude of A_{eff} (2.46 μm^2) and a correspondingly large nonlinear coefficient attaining (12,005 W^{-1} km^{-1}).

3.3 Evolution of supercontinuum at anomalous region

For the formation of broadband SC, a secant hyperbolic laser pulse is fed to the PCF containing all the optimizing parameters. Numerically, we have solved GNLSE already discussed in Sec. II. B. with the help of MATLAB software at different peak powers (kW), pulse widths (femtoseconds) and different fiber lengths (mm). The appropriate action of the nonlinearities participating in spectral broadening is clarified by calculated values of the distinct time scales tabulated in Table 2

During the pumping of femtosecond pulse at 3.4 μm which falls at anomalous region, an ultra-broadband SC spectrum is generated at relatively low peak powers 1.8 kW which are displayed in Fig. 4.

Table 2 Length scales and other nonlinear parameters

Length scale/parameter	Formula	Calculated value
Peak power	P_0	1.8 kW
Pulse width	T_{FWHM}	50 fs
Pulse duration	$T_0 = \frac{T_{FWHM}}{1.763}$	28.3 fs
Group velocity dispersion	β_2	1.37 ps^2/m
Nonlinear length	$L_{NL} = \frac{1}{\gamma P_0}$	0.0463 mm
Dispersion length	$L_D = \frac{T_0^2}{\lvert\beta_2\rvert}$	0.585 mm
Soliton order	$N = \sqrt{\frac{L_D}{L_{NL}}}$	≈ 4
Soliton fission length	$L_{fs} = \frac{L_D}{N}$	0.1463 mm

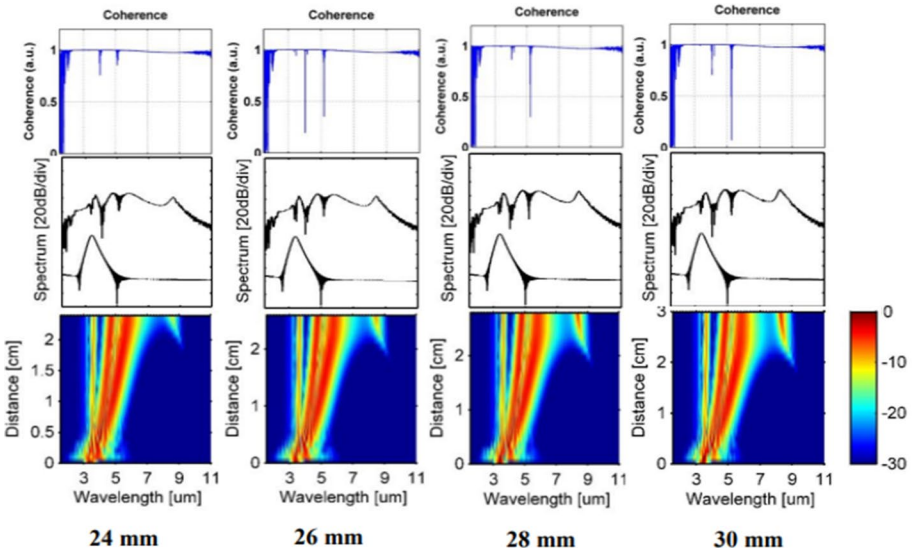

Fig. 4 Numerically simulated SC spectra at the pumping of 3.4 µm at different fiber lengths

Figure 4 shows the change in SC broadening with fiber length. SCG bandwidth increases as fiber length is increased from 24 to 28 mm. Due to the small effective mode area and higher nonlinear coefficient, nonlinear effects like SPM and XPM participate very early in respective SC broadening at millimeter scale of length. In quantitative speaking, nonlinear effects started to participate after pulse propagation around 0.05 mm (because $L_{NL}=0.0463$ mm) and dispersive effects begin to participate after propagating 0.6 mm (because $L_D=0.585$ mm) along fiber length. Since we have worked on anomalous region, soliton fission is the main attraction for SC broadening alongwith SPM and XPM. At anomalous dispersion, there exhibits some instability in the nonlinear medium which modulates the steady state in such a way that gives birth to train of ultrashort pulses known as solitons which remain unaffected in propagation of longer lengths. Due to the undistorted nature of solitons, they got entangled at certain length and generate new frequency components in lower frequency range which basically defined as soliton fission. The soliton order is (~4) and the respective soliton fission length (L_{fs}) is 0.15 mm. Raman Scattering and higher order dispersion are the main two factors that can perturb periodic evolution ideally and respective induction of pulse breakdown with the aid of soliton fission. But further increment in the fiber length does not influence the broadening of the SC spectra. Thus, we have taken 28 mm as an optimum fiber length to achieve the favorable SCG bandwidth spanning from 3000 to 9500 nm which fully wraps the transparency region at very low peak power of 1.8 kW.

Figure 5 shows the SC spectrum at variable peak powers (1.6 kW to 1.8 kW) with a constant fiber length of 28 mm and pulse width of 50 fs. The quantitative understanding from nonlinear length given in Table 2 is gathered as increment in peak power results in introduction of nonlinear effects faster at a small length of the fiber. Therefore, a significant increase in the SCG bandwidth is observed with the increase in peak power till 1.8 kW. It has also been observed that further increase in peak power (> 1.8 kW) is not showing any significant improvement in the SCG bandwidth and the coherence of

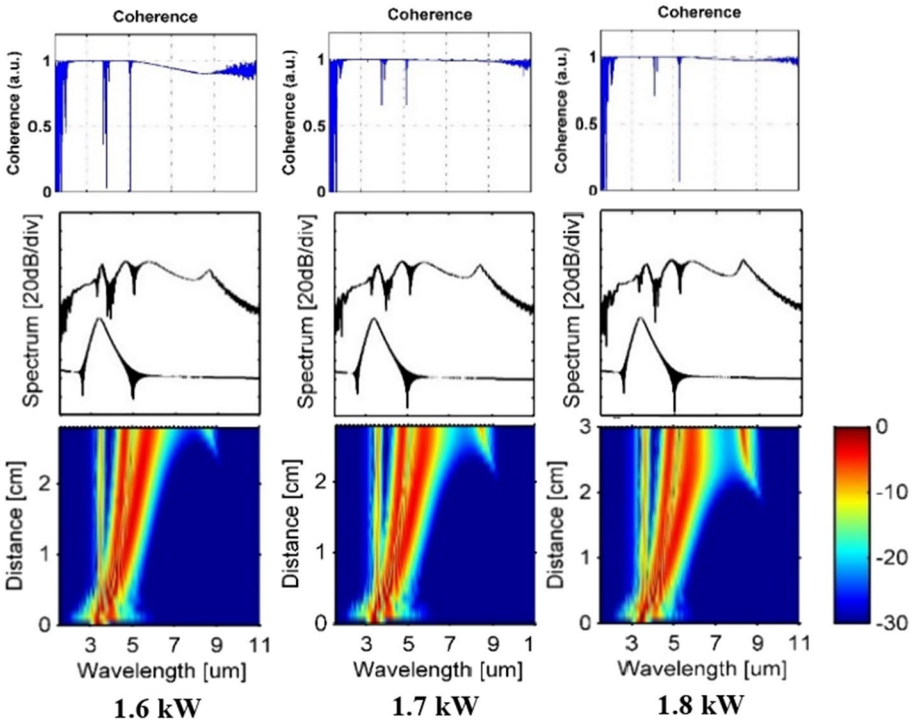

Fig. 5 Numerically simulated SC spectra at the pumping of 3.4 μm at different peak powers

the spectrum is also get disturbed. Thus, we have kept 1.8 kW peak power as optimum peak power of input pulse for analysis. The effect of pulse width (50 fs to 90 fs) on the SCG spectrum is shown in Fig. 6. Since, increase in pulse width (T_{FWHM}) and respective increase in pulse duration (T_0) causes the delay in nonlinear effects by which an intense broadband spectrum is not visible with the increment of the pulse width. Either the band

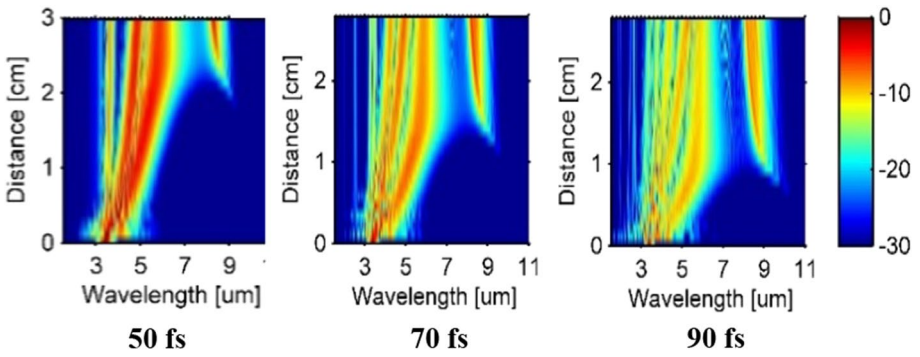

Fig. 6 Spectral Evolution at different pulse width

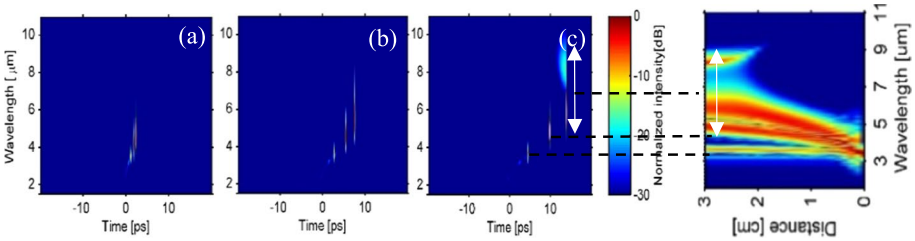

Fig. 7 Time-Wavelength FROG spectrogram at **a** 8 mm **b** 18 mm **c** 28 mm

is spanning in red-shifted side but a poor intensity (approximate half amplitude) or distorted coherence pattern is observed with pulse width.

Figure 7 displayed the time-wavelength relationship known as FROG spectrogram at the desired laser input fed to different lengths of fiber. The FROG spectrogram helps to identify the dispersive components along with soliton fission components distinctly and also tells about their mutual correlation. Time-delayed spectral components are observable at respective spectrograms.

The proposed PCF can be fabricated by the methods of extrusion and drilling techniques. The extrusion method offers an advantage over drilling techniques because the extrusion approach can tolerate high dopant concentrations, which provide a route, it offers greater flexibility in the construction of PCFs made from chalcogenide glasses to more readily change the mechanical and optical characteristics in contrast to silica glass (Chauhan 2020; Zhang 2015; Ruan 2010).

From all the outputs, we can conclude that a broad spectral evolution of SC of 3000–9500 nm is generated at 1.8 kW of peak power, when pumped by 3.4 μm femtosecond laser of 50 kHz repetition rate and pulse width of 50 fs is fed to 28 mm proposed PC fiber. In comparison to previous works as described in Table 3, our PCF can deliver broad SC spectra at relatively low peak power and with small fiber length.

4 Conclusion

We have devised for the first time SCG analysis in Segmented Cladding Design in the author's knowledge. The presented The SC-GI PCF consists of a circular core bounded by segmented cladding. The low-index region in angular direction of the Segmented Cladding is achieved by a specially designed air holes whose diameters increases gradually achieved and high-index regions is realized by $As_{38}Se_{62}$ chalcogenide material. The presented novel fiber design offers two ZDWs at 2321 nm and 6367 nm at optimized design parameters. Correspondingly we have chosen 3.4 μm as our pump wavelength which falls in anomalous regime. At revamped parameters shown in Table 2, our PCF results in achieving a very small effective mode area having magnitude 2.46 μm^2 and high nonlinear coefficient of 12,005 W^{-1} km^{-1}. The Supercontinuum spanning from 2 to 9.5 μm at 3.4 μm pumping at level of − 30 dB is reported which completely covers the transparency limit of proposed material and also covers the Mid-IR region in some extant. Applications like optical metrology, optical coherence tomography (OCT), food quality control & telecommunications has the need of broadband SC spectra which we have simulated in this work.

Table 3 Comparison of our results with previously done works

Sr. No	Material used	SCG Spectra	Broadening	PeakPower & Fiber length	References
1	As_2Se_3	2.53–16.6 µm	14 µm	4000 W & 47 mm	Feng et al. (2020)
2	$Ge_{12}As_{24}Se_{64}$-$Ge_{10}As_{24}S_{66}$	1.8–10 µm	8.2 µm	3000 W & 3.61 cm	Yu et al. (2013)
3	$As_{39}Se_{61}$	1.95–6.58 µm	4.63 µm	880 W & 1 cm	Medjouri and Abed (2019)
4	$Ge_{10}As_{22}Se_{68}$-As_2S_3	2–8 µm	6 µm	5000 W & 10 mm	Karim (2020)
5	As_2S_5	0.7–5.2 µm	4.5 µm	25,000 W & 5 mm	Diouf (2019a, b)
6	$As_{38}Se_{62}$	2–10 µm	8 µm	1330 W & 200 mm	Vyas et al. (2021)
7	$As_{38}Se_{62}$	3–9.5 µm	6.5 µm	1800 W & 28 mm	This work

Author contributions A Khamaru has done the simulation work, analyses the results and written the original manuscript and A Kumar has given ideas and review the manuscript.

***Abstract*—Natural Language Processing models are now being used more than ever before and they have been quite remarkable in applications like sentiment classification, text generation, generative AI, etc. The deep learning models behind these applications of Natural Language Processing are the reason why these models can understand the complex relation between the variables and apply those learning for the applications of NLP. But, similar to all the other applications of deep learning, NLP models are also equally susceptible to external attacks which can hamper the accuracy and the credibility of the model, which in the end poses a big question on the reliability of these models. Textual adversarial attacks can deviate the model from giving the correct answer to giving an incorrect output, just because of a small perturbation made in the input. These perturbations, often involving synonyms of the original word, are still able to successfully fool these models. This paper, in a similar context, proposes BEACOMP, a novel textual adversarial attack that uses composite transformation functions from the TextAttack library, in a black box setting, to successfully fool the model. The accuracy and the success rate of the attack are validated through three different models Distilled BERT, BERT uncased, and RoBERTa, on 4 different datasets including IMDB, SST2, Rotten Tomatoes, and AG news. The use of the attack proposed showed an increase in the attack success rate, which in the end improves the model's preparedness for adversarial attacks. On average, for the models tested in the research, their accuracy dropped from 97.16% to 1.91%. This demonstrates the effectiveness of the TextAttack library in generating attack patterns for text classification patterns while adhering to certain constraints.**

***Index Terms*—Natural Language Processing, Adversarial Machine Learning, Robustness of AI Models, Deep Learning, TextAttack**

I. INTRODUCTION

Applications of NLP models are endless in today's era, ranging from sentiment analysis, chatbots, machine translation, etc. to the latest developments in the AI world like generative AI and LLMs. Products like ChatGPT and BardAI have expressed the significant impact NLP can make in today's world of deep learning. The acceptability and awareness of NLP models being used in our daily lives have been increasing significantly day by day, in which the LLM models discussed above have a substantial part to play. It is evident that with the rapid increase in the utilization of these NLP models, the threat to these models is an issue that needs to be tackled while working on them. These models, if not calibrated for these adversarial attacks [1] carefully, can not only be an issue in the accuracy of these models but more importantly can be a massive pool of misinformation. With small perturbations, these models can be fooled very easily which poses serious concerns over the reliability of the models [2]. If compared to a real-life scenario, with the ever-increasing popularity and usage of LLM models, with changes as small as character level changes in the input, the algorithm behind the LLMs can be easily fooled and can give a completely different answer than what should be the correct answer [3]. One of the problems is also that most of the attacks which have been discussed in the context of TextAttack have been single parametric attacks, i.e, little to no research has been done on the possibility of using composite attacks combining different parameters of the four pillars of the TextAttack library(Goal function, Transformation Function, Constraint Definition, and Search Method Selection), into a single attack. This possibility has several possible advantages over single parametric attacks which have been discussed before. Extending on the possibility of increased perturbations, as there will be a better quality adversarial example generated, the Attack Success rate will be increased as more words will be changed.

The purpose of the study is to create a **novel attack** using the TextAttack library which covers a large number of words and symbols so that a more robust attack function could be created. It also allows the attack to be used in a variety of applications pertaining to different industries [4] as the attack function is capable of generating adversarial examples which are very effective with a high attack success rate and a high average perturbed rate.

As shown in Figure 1, one of the key areas of adversarial machine learning is untargeted classification in NLP models and this study dis- cusses a novel adversarial attack 'BEACOMP' which in a nutshell uses beam search and a composite transformation function for untargeted classification of various NLP models like RoBERTa, Distilled BERT, BERT Uncased, etc. The unique features of the above adversarial attack are discussed below:

A. Composite Transformation Function

The previous works in the area have used a single trans- formation function to run the attacks whereas in this study, a combination of various transformation functions is used along with Beam Search to enhance the efficiency of the attack on the NLP models. Using a composite transformation function rather than a single transformation function increases the vari- ability of usage of the attack as the composite transformation function involves perturbations using WordSwap Embedding, Word Deletion, WordSwap Change Number, etc.

B. Attack Success Rate

Due to the uniqueness of the transformation function, an increase in success rate was seen. This can also be held accountable due to the fact that even the embedding distance was not kept less than 0.7 so as to not lose the semantic meaning of an input, therefore, the attack was able to perform better and hence the attack success rate was seen to be increased as compared to the precious studies.

C. Usability

Due to the seamless integration of the text attack library with various pre-trained models, it makes it very efficient to implement BEACOMP with various NLP models, even the models and datasets other than those discussed in this study. This makes the potential usage of BEACOMP attack for untargeted classification very seamless with various NLP models.

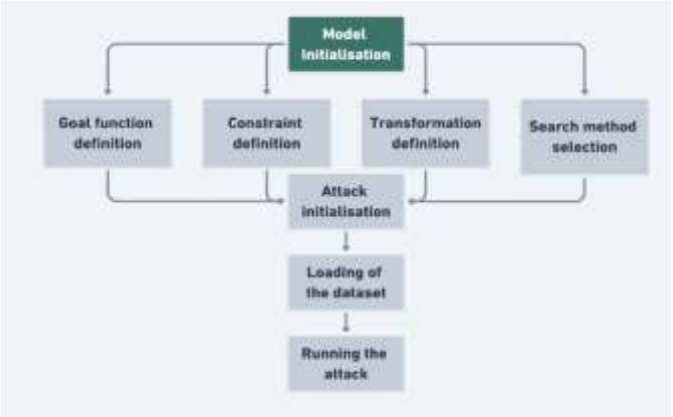

Fig. 2. Proposed Approach of the Attack

II. PROPOSED APPROACH

BEACOMP is a novel architecture designed to launch tex- tual adversarial attacks, which aim to expose the vulnerability of neural text classifiers. As shown in Figure 2, the approach for the BEACOMP attack can be described in 7 different steps ranging from Model initialisation, Goal function definition, Constraint definition, Transformation definition, Search method selection, Attack initialization, loading of the dataset, and then finally running the attack. The figure 2 clearly shows the step-by-step process
[5] of the entire attack as the steps of initialising the attack specifications:

A. Model Initialisation

The attack initialization starts with deciding on a pre- trained model from the TextAttack library for sequence classification. Along with the model, a tokenizer is also initialized for the attack according to the model selected, using the HuggingFace transformers library. Both of these entities are then wrapped in an interface named model wrapper using the 'Hugging- FaceModelWrapper'. This wrapper acts as a bridge, allowing seamless integration of th pre-trained BERT model [6] into the TextAttack framework for text-based attacks and evaluations.

B. Goal Function Definition

The goal function explains the target of our attack, based on our choice, The goal function can be divided into two parts: the first one is Untargeted Classification, in which our primary goal is perturbation the input just enough to deviate the output to anything but the original correct output. The other one is targeted classification where we are responsible for dictating the output classification label of the attack, and the output is controlled by the attack. For this study, we have focused on using Untargeted Classification for our attack.

c) Constraint Definition

The constraints are one of the most vital aspects of the attack as they basically outline the transformation limits of the input text so as to semantically make sense and be as close to the input text as possible. For this research work, a combination of 3 different constraints has been used so as to cover the maximum number of constraints as possible.

a. Repeat Modification

Repeat Modification constraints the modification of words which have already been modified. The RepeatModification Constraint tracks the words which have already been modified so as to prevent unnatural and irrelevant responses and also to save on computational time.

b. StopWordModification

StopWords in the context of NLP are defined by words which are not semantically relevant to the sentence for its understanding and hence are omitted when performing modifications in the sentence. StopWordModification constraint does exactly this, i.e., prevents the modification of stopwords in a sentence.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 20,2024 at 06:19:33 UTC from IEEE Xplore. Restrictions apply.

c. WordEmbeddingDistance

As shown in Figure 3, the WordEmbeddingDistance uses the concept of 'Cosine Similarity' [7] to determine how sim- ilar words are by comparing the cosine angle between their vectors in multi-dimensional space. As shown in Figure 4, this helps in finding the most semantically relevant words for the modification to the input text. Now, the WordEmbed- dingDistance should generally not have a low value as that will produce irrelevant words as the modification. On the other side, the WordEmbeddingDistance cannot be very high either as that will make the process of finding a word which is semantically similar yet different very difficult. Hence, for this research study, we took the WordEmbeddingDistance to be equal to or greater than 0.7.

D. Transformation Definition

The transformation functions defined in each attack are the main functions which control the transformation of the input text and the type of perturbations allowed with the input. As shown in Figure 5, These modifications may be in the form of numbers in case of numerical input or alphabetical modifications in case of textual input and the types of transformations allowed are guided by the transformation functions defined in the attack.

As shown in figure 6, For this research work, a composite function of 3 transfor- mation functions has been used with the functions being used as follows:

a. WordSwapEmbedding

As discussed in the section on WordEmbeddingDistance constraint, the semantically nearest according to the Word embedding [8] distance is then swapped with the original word. The swapping takes place according to the word embedding distance defined in the WordEmbeddingDistance constraint definition and only then the modification of the original input takes place with perturbation.

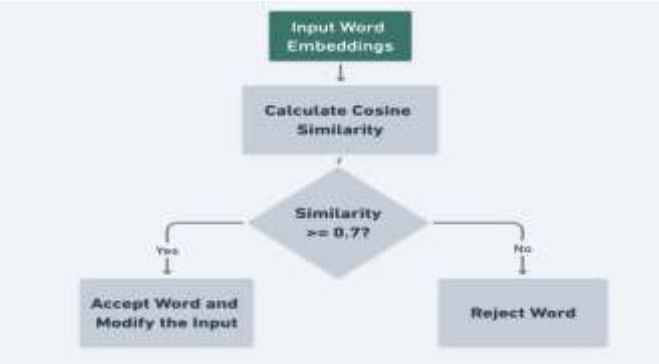

Fig. 3. Calculating world Embedding distance.

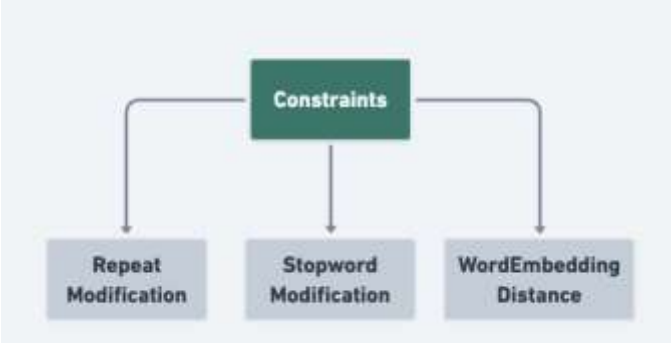

Fig. 4. Characteristics of the Constraints put on novel attack.

b. Word Deletion

Word Deletion is a transformation method that takes a sentence and transforms it by deleting a single word. This transformation function helps in increasing the randomness of the input text as there are no pre-defined criteria as to which word will get deleted, yet retaining the semantic structure and the meaning of the sentence.

c. WordSwapChangeNumber

More often than not, inputs involve numbers as part of the sentence and the WordSwapChangeNumber is used to change any random number in the sentence to make a valid perturbation input. One of the key examples in the classification space for this transformation could be movie ratings, for example, if "I give 1.5 out of 5 stars to the movie" is changed to "I give 4.5 out of 5 stars to the movie", this makes a valid perturbed sentence which will dis-classify the output.

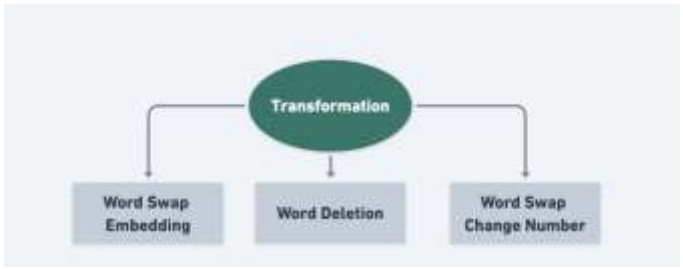

Fig. 5. Characteristics of Transformations put on novel attack.

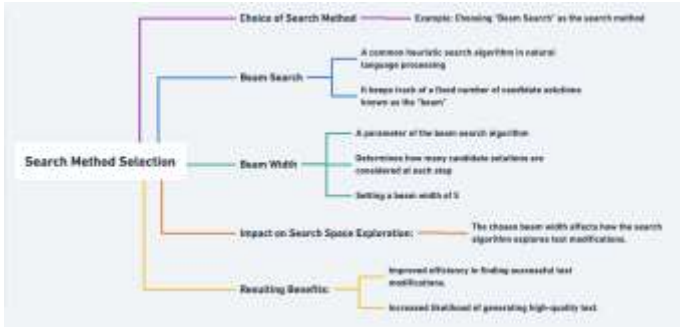

Fig. 6. Characteristics of Transformations put on novel attack.

E. Search Method Selection

For the context of this research, Beam-Search was used as the search method for searching possible text modifica- tions during the attack. BeamSearch [9] was used instead of GreedySearch as BeamSearch, even if it takes a higher computational power, produces more accurate results.

The algorithm uses a parameter called "beamwidth" that determines the number of adjustments required at each step of the search. For example, choosing a beam width of 5 means that the algorithm searches for and evaluates up to five different text editors simultaneously. This approach increases the risk of effectively detecting text changes by effectively searching the

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 20,2024 at 06:19:33 UTC from IEEE Xplore. Restrictions apply.

search space. In general, the choice of the search method and its settings affect the effectiveness and efficiency of creating enemy attacks in the TextAttack library [10]. For our research, the beam width was kept to be 5.

F. Attack Initialisation

The novel attack is then initialized with all the parameters i.e., Goal Function, Constraints, Transformations, and Search method, written in the definition part of the attack. An object of 'attack' is then created containing all the parameters. The attack encapsulates the entire attack configuration which will be applied to the datasets, the process of which, is discussed in the next section.

G. Loading of the Dataset

The next process comprises deciding the dataset on which the attack will be tested. For this study, datasets which have been used over here have variety in terms of having binary output, multiple classification output, etc. Some of the exam- ples include sentiment classification as positive or negative, or Deciding the category of the news according to the text as sci-tech, business, or world news, etc.

Nonetheless, in both the types of the above datasets, untar-geted classification was used and the goal was to use famous models like Distilled BERT, BERT uncased, and RoBERTa on these datasets to testify to the accuracy and efficiency of the attack [11]. The datasets which were used for this study were described in Table 1.

TABLE I. DATASET DESCRIPTION AND OUTPUT TYPE

Dataset Name	Description	Output Type
AG News	AG is a collection of more than 1 million news ar- ticles. News articles have been gathered from more than 2000 news sources by ComeToMyHead in more than 1 year of activity. 4 labels: World, Business, Sports, and Sci-tech	Classification (World, Business, Sports, Sci-tech)
Rotten Tomatoes	Rotten Tomatoes is a dataset containing 5,331 positive and 5,331 negative processed sentences from Rotten Tomatoes movie reviews. (Positive, Negative)	Binary
SST2	SST2 consists of 11,855 single sentences extracted from movie reviews. It was parsed with the Stanford parser and includes a total of 215,154 unique phrases from those parsed trees. (Positive, Negative)	Binary
Yelp Polarity	The Yelp reviews polarity dataset is constructed by considering stars 1 and 2 as negative, and 3 and 4 as positive. In total, there are 560,000 training samples and 38,000 testing samples. Negative polarity is class 1, and positive class 2. (1, 2)	Binary

H. Running the Attack

After finally deciding on the datasets to be used, models to be tested, and the attack configuration, the attack is then run and tested. For this research, we kept the number of examples to 100 which means the attack will target 100 examples in the dataset.

The 'attackargs' function sets the attackargs value, spec-ifying that the attack should be used for 100 samples, and disables the output model. Finally, it performs an attack on the data using the Attacker category, attempting to modify the input texts to reduce the model's classification accuracy.

Algorithm 1: BEACOMP Adversarial Attack
Aim: Adversarial attack framework to fool neural text classifier
Input: legitimate input X and its ground truth label Y, classifier $F(.)$, threshold δ, semantic similarity $S(.)$.
Output: Generated an adversarial sequence X_{adv}

1. Initialization: $X^* \Leftarrow X$
2. for X_i in x do
3. Compute score (X_i^*) according to Equation (5)
4. end for
5. $W_{Ordered} \Leftarrow Sort(X_1, X_2, X_3 \ldots\ldots\ldots\ldots X_n)$ in descending order
6. Remove the stop words in $W_{Ordered}$

14. end for
15. return None

III. RESULTS

Before discussing, the results, let us get into what a Beacomp attack looks like. Shown in BEMOCOMP algorithm, is the snippet of one of the attacks made on the Yelp-polarity dataset using the BERT Uncased model in which it is clearly shown how many and what words are being changed in order to produce a successful adversarial input to the model. For instance, in the example given below, 4 words were changed from their original words through which, the attack was able to successfully fool the model and was able to hence, produce a successful adversarial attack. Through this, it can also be seen that the Average perturbed rate is not a very efficient way of discussing the efficiency of the attack as even with a low APR rate in this example, the attack was successful. However, APR is important in order to understand the overall working, the robustness, and to understand the efficiency of the model. This is the reason that we have kept APR as one of the parameters while evaluating the success rate of the attack.

TABLE II. ACCURACY OF THE MODEL BEFORE AND AFTER THE ATTACK (IN %)

Model	**Distilled BERT**		**BERT Uncased**		**RoBERTa**	
	Before	**After**	**Before**	**After**	**Before**	**After**

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 20,2024 at 06:19:33 UTC from IEEE Xplore. Restrictions apply.

AG News	99.0	1.0	98.0	2	100.0	0
Rotten Tomatoe	98.0	0	100.0	10	85.0	1.0
SST2	99.0	2.0	100.0	0	92.0	4.0
Yelp Polarity	99.0	1	100.0	0	96.0	2.0

TABLE III. ASR (ATTACK SUCCESS RATE) AND APR (AVERAGE PERTURBED RATE) OF THE ATTACK

Model	**Distilled BERT**		**BERT Uncased**		**RoBERT**	
	ASR	**APR**	**ASR**	**APR**	**ASR**	**APR**
AG News	98.99	37.36	100	58.11	97.92	14.24
Rotten Tomatoe	92.28	15.36	90	18.56	98.82	14.50
SST2	90.0	9.64	100	38.08	93.59	9.88
Yelp Polarity	96.62	32.34	100.0	4.01	99.26	11.42

The success of the attack was measured on three different parameters, namely the change in accuracy of the model before and after the attack, the attack success rate(APR), and the Average perturbed rate(APR). By seeing the results, it is pretty evident that the attack was able to significantly lower the accuracies of all three different models tested. Also, as one of the parameters taken into consideration while measuring the success of the attack, the attack success rate was seen to be at an average of 96.46%, which showcases a very high percentage of attacks being successful.

IV. CONCLUSION

With all the results of the attack discussed above shown in table number 2 and 3, it is pretty evident that the novel attack BEACOMP attack was successfully able to fool all the models with a very good efficiency, and Attack success rate. The attack was able to differentiate itself from the previously discussed attack algo- rithms by including a composite attack composition which also

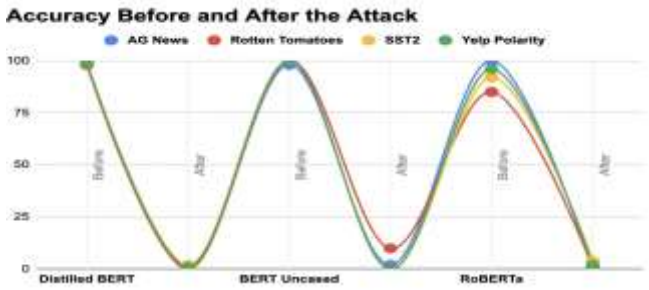

Fig. 8. Accuracy Before and After the attack

resulted in an increased efficiency of the attack on all three models. There was also a conclusion that the average perturbed word does not play a very large impact on the success of the attack. Ultimately, the attack was successful and on average, the model's accuracy dropped from 97.16% to 1.91%. This demonstrates the effectiveness of the TextAttack library in generating attack patterns for text classification patterns while adhering to certain constraints. This attack achieved a negative trend in altering inputs, highlighting the importance of trying to strengthen and prevent attacks such as attacks on natural language use.

V. DISCUSSION AND FUTURE WORK

The robustness and the accuracy of NLP models are be- coming a significant area of research which is vital to all the applications of NLP in today's world. With the increasing usage of NLP models, it is important that the vulnerability of these models are taken into consideration when working with them. In the future, many possibilities of research in the same area are needed and possible, some of the areas plausible are:

A. *Adversarial Attack Variants :* Different variants of attack recipes are possible through the textattack library which will help in discussing and comparing the robustness of NLP models on different attack compositions. The composition of different at- tacks will also help in creating a more robust attack composition for future research studies. New types of attacks can also be developed such as targetted attacks, where the attacker aims to make the model classify the input as a specific class, knowledge-based attacks, where the attacker has access to additional information about the model, data, or training process, or developing attacks for models other than binary outputs.

B. *Adversarial Defense Mechanisms:* Along with the dif- ferent variants of attack recipes, the defence mech- anisms of these models to these adversarial attacks also play a large part to play. Different mechanisms can be developed for models in order to successfully defend themselves from the adversarial attacks and will hence, increase the robustness, and will decrease the vulnerability of these models. Different techniques like including adversarial training in building the model, in- put preprocessing, and model architecture improvements can be implemented in order to increase the quality of the defence mechanisms of these models.

C. *Ethical and Security Considerations:* With the rapid increase in the usage of NLP models, the ethical and security considerations become a very vital part to take into consideration when dealing with them. While improving the defense mechanism, or introducing new attack variants, the privacy of the data incorporated in the data should not be hampered. Also, through these attacks, it should be taken into consideration that the personal data in the data should not be made vulnerable to cyber attacks, so as to prevent distrust in using NLP models.

D. *Adversarial Attacks on Neural Language Generation:* Generative AI is one of the fastest emerging fields currently in the field and it is very important to consider the possibility of applications made based on Generative AI to be robust to these adversarial attacks. Hence, robustness to adversarial attacks should be incorporated into training these applications. Some of the fields in which this can be done include text generation and machine translation, both of which are very important fields in Natural language processing and are used on a large scale by many companies and people around the world.

E. *Adversarial Attacks in Multilingual:* Settings More often than not, the idea of Multilingual attacks is left out while discussing new research ideas and as the majority of the population of the world does not have English as their primary language, it is very important to include different geographies and languages while discussing and developing these attacks.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 20,2024 at 06:19:33 UTC from IEEE Xplore. Restrictions apply.

For instance, machine translation is one of the most prominent fields applicable for using adversarial attacks in Multilingual settings.

Abstract.

Heavy metals even in a very low quantity can be hazardous which can cause significant ecological and health consequences affecting the physiological functioning and structural makeup of all the living things. The elevated level of heavy metals in the environment causes biodiversity loss, environmental pollution, and ecosystem alteration. thus, it is imperative to remove heavy metals from contaminated region through detoxification. Using microorganisms such as fungi, bacteria, algae and yeast is a cost-effective, sustainable, and promising method in order to bioremediate heavy metals. Living organisms can alter contaminants as part of their metabolic processes, breaking them down into less toxic substances. The distinct advantage of microbial remediation is the rate of heavy metal cleanup, which is much faster than phytoremediation. Microorganisms absorb and detoxify heavy metals faster than plants, avoiding the spread of contaminants in the surrounding environment. The ability of microorganisms to execute the detoxification of harmful metal ions by reducing the metal ion into metal nanoparticles makes them appropriate for use in the simultaneous elimination of harmful chemicals from the polluted area and biosynthesis of nanoparticles which holds an immense potential to be used in biomedical and industrial applications. This review focuses the process of detoxifying heavy metals by using microorganisms to synthesize nanoparticles and remediate the affected areas simultaneously.

Keywords: heavy metals, bioremediation, bioaccumulation, synergy, nanoparticles biosynthesis

1. Introduction.

During the last hundred years, industrialization has grown at a tremendous rate. This also increased the requirement for the earth's natural resources; these resources are utilized at a careless rate, which leads to huge contamination of the earth's environment. The biggest contributors to environmental contamination are pesticides and the dumping of industrial waste into water bodies which leads to water pollution. The xenobiotic substances, which are produced by humans, are resistant to natural degradation thus, it's a matter of great concern because accumulation of the xenobiotic substances can lead to environmental pollution and can affect various life forms. These pollutants are classified as either organic or inorganic pollutants. Some examples of typical organic pollutants are azo dyes, petroleum hydrocarbons, chlorinated phenol, persistent organic pollutants (POPs), insecticides, etc. Heavy metals are inorganic pollutants, which include, lead (Pb), chromium (Cr), mercury (Hg), nickel (Ni), copper (Cu), cadmium (Cd), manganese (Mn), cobalt (Co), iron (Fe) (Pavan Kumar Gautam & Ravindra Kuma, 2022). Metallic elements that have large atomic weights or high atomic numbers, and high densities, are classified as heavy metals. These metallic elements have greater density than $5g/cm^3$ (Duruibe et al., 2007). Due to their occurrence in microscopic amounts, heavy metals are often referred to as trace elements. Heavy metals even in a very low quantity can be hazardous and can cause significant ecological and health consequences affecting the physiological functioning and structural makeup of all living things. The heavy metals are quite toxic to various life forms and thus, it is necessary to carry out the detoxification or elimination of the heavy metal from the polluted site. The Conventional physical and chemical method used for removing the pollutants from wastewater can lead to the generation of by-products and secondary pollutants and is thus not a cost-effective and sustainable method for the elimination of heavy metals from the polluted sites (Chibuike & Obiora, 2014). An economical and ecologically sustainable approach needs to be used for the detoxification of heavy metals. Bioremediation is a method that involves utilizing living things like microorganisms and plants, that can break down a broad spectrum of xenobiotics compounds and can convert contaminants into less hazardous forms (Vidali, 2001a). Living organisms can alter contaminants compounds as part of their metabolic processes, breaking them down into less toxic substances. Bioremediation involves phytoremediation which involves the use of plants for the purpose of remediation and micro-remediation involves the use of microorganisms involving fungi, bacteria, and algae. Phytoremediation, despite being a potentially effective and environmentally friendly approach, has several drawbacks and limitations. One of its limitations is that the process takes a lot of time that may require months or years to achieve a substantial reduction in contaminants (Vidali, 2001b). Another safe, effective, and substitute approach for heavy metal eradication is micro remediation. Micro remediation involves the use of fungi, bacteria, and algae for the elimination of heavy metals from the polluted site by converting harmful heavy metals into less harmful forms or immobilizing them making them less toxic(Zhang & Zhang, 2022). Microbes are the preferred choice for this task as they are convenient to handle, cultivate, and implement. Instead of planting lots of plants, microorganisms might be introduced directly to the polluted sites. This

eliminates extensive planting and maintenance work, making it practical for the urban environment. The biosynthesis of nanoparticles can be performed using fungi, bacteria, algae, and plants. The biosynthetic process involves the reduction of metal ions into metal nanoparticles. The compounds present in microbes act as stabilizing and reducing agents for the biogenic synthesis of nanoparticles. Due to the high exposure to hazardous chemicals and elevated concentrations of heavy metals, the microorganism has developed some defense mechanisms to survive in such a harsh condition. This review focuses on the synergy of bioremediation of heavy metal by simultaneously synthesizing the nanoparticles using microbes. The microorganism has the ability to detoxify the harmful metal ions by either reducing the metal ion into zero valent state or metal nanoparticles making them suitable to be use for the simultaneous removal of harmful chemicals from wastewater and other contaminated sources and reducing the heavy metal ion into metal nanoparticles.

2. Sources of heavy metal

The earth's crust naturally contains heavy metals. Due to the dramatic growth in the usage of heavy metals, there is an increase in the concentration of metallic components in terrestrial and aquatic ecosystems. Anthropogenic activities including fossil fuel combustion, mining, metal leaching, sewage, oil refinery, lime, industrial waste, inorganic fertilizer, electronic waste, pesticides, and fungicides pesticides are the primary sources of heavy metal pollution (Yadav & Sharma, 2023). Higher quantities of Cr, Ni, Pb, and Cd can be found in inorganic fertilizers, especially in phosphate fertilizers. Cadmium is particularly a dangerous element for plants due to its higher degree of accumulation in leaves, which can be ingested by humans or animals. The excess of Cd causes kidney dysfunction, hypertension, bone fractures, and lung cancer in humans (Kumar Sharma & Agrawal, 2005). Natural sources of heavy metal pollution are soil erosion due to heavy rainfall, volcanic eruptions, comets, metal corrosion, decomposition, and geological weathering. When rocks, minerals, and soil establish a connection with water, atmosphere, and living things, a process known as weathering occurs that breaks them down. It is a site-specific process in which heavy metals are released from the host rock into the surrounding environment by the activity of microorganisms or micro-climatic factors including pressure, ice, water, and heat. (Wen et al., 2021) carried out a study and their findings revealed that weathering causes the release of heavy metals As, Hg, and Tl from the argillaceous sandstone. FTIR and Raman spectroscopy showed that prolonged weathering broke down carbonyl and hydroxyl functional groups, resulting in the release of bound heavy metals from the rocks (Wen et al., 2021). Metals and other substances are taken up as nutrition by the living things from their surroundings. These nutrients and metals are crucial for their development. These nutrients are returned to the environment after their death and decomposition. The most frequent heavy metals present in decomposing organic matter are Hg, Cd, Cr, Pb, As, and Zn (Stefanowicz et al., 2020). Volcanic eruptions are a natural process. It causes particles to be released onto the earth's surface. volcanic ash and pyroclastic material are emitted during eruptions of volcanoes. heavy metals are also found in volcanic ash because volcanoes are created by the metal dissolution from the earth's crust. Cd, Fe, Zn, Pb, Cu, and Cr can be found in volcanic ash (L, 2010). During rainfall,

they are frequently transmitted to the environment. Volcanic ash also contains volcanic dust, which is carried by the wind and lands on the ground when it rains. The trace metals that are present in volcanic dust go to the soil, and depending upon temperature, pH, and redox they dissolve in water and get absorbed by the soil particles (Ilyinskaya et al., 2021; Ma et al., 2019).

3. Approaches for the removal of heavy metals.

The elevated level of heavy metals in the environment causes biodiversity loss, environmental pollution, and ecosystem alteration. To keep the environment safer for living organisms, the high concentration of trace elements and heavy metals must be eliminated from polluted water bodies and soil. There are various chemical, biological, and physical methods that can be used for the purpose of remediation. It is possible to eliminate these heavy metals using a variety of techniques, reverse osmosis, membrane technology, oxidation, reduction, filtration, ion exchanges, membrane technology, electrochemical treatment, and evaporation. However, many of these strategies lose their effectiveness at heavy metals concentrations below 100 mg/L (Nourbakhsh et al., 1994). These Physio-chemicals methods are not ecologically friendly and relatively expensive for heavy metals remediation and have other drawbacks also such as inadequate metal removal rates, increased need for energy, and reagents, and the production of hazardous sludge. Additionally, these physio-chemical methods are not suitable for extensive contaminated sites such as industrial waste sites, agriculturally polluted soils, and mining areas due to their high costs.

Hence, ecologically friendly and inexpensive techniques are required for the remediation of metal-contaminated water and soil.

3.1. Biological approach for remediation.

A biological technique called bioremediation in which environmental contaminants are excluded with the assistance of living things including microorganisms and plants which can break down a broad spectrum of xenobiotics compounds and convert contaminants into less hazardous forms (Vidali, 2001a). Living organisms can alter contaminants compounds as part of their metabolic processes, breaking them down into less toxic substances.

Bioremediation has many advantages over physio-chemical techniques, they are less costly when compared to the conventional methods, and they offer a permanent approach that could result in the complete mineralization of contaminants. Physio-chemical methods have a major disadvantage in that they cannot remove contaminants when they are present in a very low concentration, but with the help of bioremediation low concentration contaminants can be treated effectively (Kour et al., 2021).

Phyto-remediation and micro-remediation are the two different terms for bioremediation, in phytoremediation an essential part is played by the plants in the remediation of contaminants. On the other hand, micro remediation is conducted by microorganisms such as fungi, algae, and bacteria.

3.1.1. Phytoremediation

The word “phytoremediation” was introduced in 1991, and is composed of the fusion of two words: Greek phyton (meaning plant) and Latin remediare (meaning remedy). Plants have

natural inherent capabilities to absorb, bioaccumulate, preserve, or decompose inorganic or organic chemical compounds (Ali et al., 2013). When compared to other remediation methods, phytoremediation has very low Maintenance and installation costs also applicable for enormous, contaminated area where other alternative remediation methods are neither practical nor economical (Van Aken, 2009). Furthermore, phytoremediation not only cleans up polluted environments but also provides benefits such as biofuel production and carbon sequestration (Doty et al., 2007). (Ranieri et al., 2016) used the plant species *Phragmites Australis* and *Ailanthus Altissima* and removed between 55 to 61% of Cr^{3+} from the water. In both plants, a significant amount of chromium is absorbed by the roots (Ranieri et al., 2016). For heavy metal phytoremediation, hyperaccumulators are most appropriate. Hyperaccumulators are the plant species that have higher efficiency for the metal's accumulation from the soil and storage in their tissues as compared to normal plants (Dinh et al., 2004). They can accumulate concentrations 100 times higher than those of regular plants growing on sites contaminated with metals (Liu et al., 2022). Over 400 species renowned for their exceptional ability to hyperaccumulate metals are from the families Brassicaceae, Asteraceae, Rubiaceae, and Euphobiaceae (McGrath & Zhao, 2003). Hyperaccumulator plants also demonstrate efficient metal transport from roots to shoots. The transport efficiency of non-hyperaccumulators from roots to shoot when compared with the efficiency of hyperaccumulators is less although they accumulate metals in their root in higher concentration. (Robinson et al., 2003) used the rapidly growing hyperaccumulator plant *Berkheya coddii* for the remediation of nickel. They grew the plants hydroponically, and the nutrient solution carries varying concentrations of Ni. To find the concentration of Ni, they employed inductively coupled plasma emission spectroscopy (ICP-AES) and found that the highest Ni concentration was in the leaves and accumulated in a water-soluble state. Ni concentration was greater in the shoot than in the roots (Robinson et al., 2003). Heavy metals accumulation efficiency of plants could be increased by supplying chelators such as EDTA, oxalic acid, and DTPA. Together with the metals in the contaminated soil, they form a complex and enhance the rate of transfer of metals to plant roots and above-ground components. (Ehsan et al., 2014)experimented to investigate, Citric acid effects on the phytoremediation of Cd in *Brassica napus L.* They grow the plants hydroponically and Two weeks later, $CdCl_2$ and citric acid were introduced into the nutrient solution. Plants were then taken out of the solution after 8 weeks. They used flame atomic absorption spectroscopy to measure the amount of Cd in the different parts of the plant and found that, in comparison to plants grown without citric acid, there was a high concentration of Cd in the plant's roots and shoot (Ehsan et al., 2014).

Phytoremediation, despite being a potentially effective and environmentally friendly approach, has several drawbacks and limitations. One of its limitations is that it is a long process that may require months or years to achieve a substantial reduction in contaminants. Also, the selection of suitable plants is important, as not all plants possess the ability to effectively absorb contaminants. It is appropriate for minimal to moderately heavy metal-contaminated regions, since extremely contaminated sites don't promote plant growth and there are concerns regarding the transfer of heavy metals to the food chain if not properly monitored (Vidali, 2001b).

(Bañuelos et al., 2002) carried out various studies, and their findings highlighted that the plants used in the phytoremediation of selenium could transfer Se to animals and insects unintentionally. Insects feeding on these plants have the capacity to accumulate large amounts of selenium. The accumulated high selenium could harm animals and birds that feed on these insects (Bañuelos et al., 2002).

Another safe, effective, and substitute approach for heavy metal eradication is micro remediation, which utilizes fungi, bacteria, and algae to convert harmful heavy metals into less harmful forms or immobilize them making them less toxic. Microbes are the preferred choice for this task as they are convenient to handle, cultivation, and implementation. Microbes are ubiquitous and can survive even in adverse environmental situations such as high pH, temperature, and salt concentration. The microbes are incredibly tiny; their ratio of surface area to volume is high, so their rate of absorption is very high (Zouboulis et al., 2004). They have a rapid multiplication rate and can even work in conditions when extremely low concentrations of heavy metals are found.

The distinct advantage of microbial remediation is the rate of heavy metal cleanup, which is much faster than phytoremediation. Microorganisms absorb and detoxify heavy metals faster than plants, avoiding the spread of contaminants in the surrounding environment. Micro remediation is ideal for cities or small areas to clean polluted water or soil. Instead of planting lots of plants, microorganisms might be introduced directly to the polluted sites. This eliminates extensive planting and maintenance work, making it practical for the urban environment.

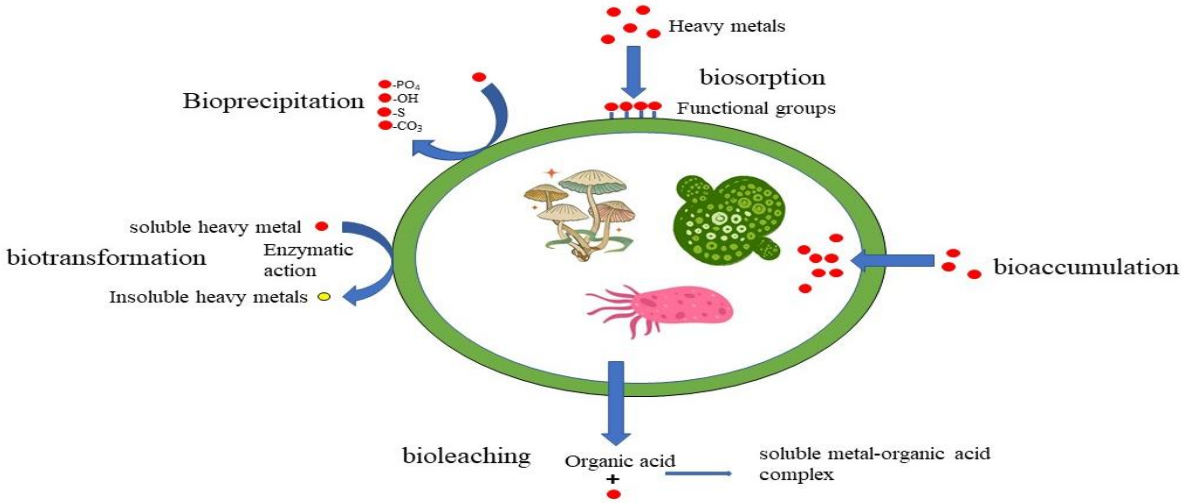

Figure 1. Mechanism of heavy metals remediation in fungi, algae, and bacteria.

3.1.2. Bacteria

Heavy metals also have a toxic effect on bacteria when they are growing in an environment containing high quantity of heavy metals beyond the threshold limit. Bacteria developed distinct mechanisms including biosorption, bioaccumulation, bio-precipitation, and bioleaching to protect themselves against toxic metals, and these metal-resistant bacteria can be utilized as effective bioremediation agents. The first line of defense against heavy metal toxicity is adsorption, in which metal ions bind nonspecifically to the surface of cells. Bacterial cell walls

have various types of functional groups, like phosphoryl, sulfate, amino, and carboxyl groups, with which heavy metals interact and get accumulated on the bacterial cell wall's surface. (Musa Jibrin et al., 2020) used *Lysinibacillus fusiformis* 5B for the biosorption of Cr, Ni, Pb, and Cd. Different concentrations of heavy metal-containing culture broths were prepared and inoculated with L. *fusiformis* 5B. For 35 days, inoculated culture broths are kept at 37C^{o} in a shaker incubator. Atomic absorption spectroscopy was used to quantify the amount of heavy metal biosorption, L. *fusiformis* 5B effectively removed heavy metals from the culture broths and can be used as biosorption agents (Musa Jibrin et al., 2020). Biosorption was observed in both live and dead bacteria cells. dead microbial biomass could be used for bioremediation. (Mohapatra et al., 2019) carried out a study, that used high Pb (II) concentration resistance *Bacillus xiamenensis* PbRPSD202 and analyzed biosorption capacity. Dead and active biomass of bacteria is employed for the elimination of Pb (II) from the aqueous solution. They used the XRD and FTIR techniques to investigate the function of ligands like, hydroxyl, amino, carboxyl, and carbonyl groups present on the bacterial surface in Pb (II) biosorption. Under optimum situations, dead and active biomass of bacteria removed 97.18% and 99.19% lead (II) from the solution (Mohapatra et al., 2019). Utilization of dead biomass of bacteria for bioremediation is becoming more prevalent as no nutrition is required for the bacterial cell's growth, thus reducing the cost of operation. Many bacteria produce extracellular polymeric substances (EPS) that have a major role in the production of biofilms and the adherence of bacteria to different surfaces. The essential components of these substances are polysaccharides, lipids, nucleic acids, and proteins. EPS are engaged in the defense of bacteria against toxic heavy metals, as they consist of various types of anionic and cationic functional groups. These functional groups on EPS interact with the heavy metals, preventing their entry into the bacterial cell, and accumulating them. (Cui et al., 2020) extracted the EPS from *Agrobacterium tumefaciens* F2 that showed effective absorption efficiency for the three heavy metals. Absorption efficiency of Ni^{2+}, Pb^{2+}, Cd^{2+} on EPS was found to be 77.95%, 94.67%, and 94.41% respectively. FTIR analysis showed that polysaccharides are the primary component in the EPS extracted from *Agrobacterium tumefaciens* F2 and have a crucial role in the absorption of Cd^{2+}, Ni^{2+}, and Pb^{2+} ions (Cui et al., 2020). Bacterial cells could alter the ionic state of heavy metals after adsorption, hence lowering their toxicity. Another bioremediation mechanism observed in bacteria is bioaccumulation in which heavy metals are accumulated inside the bacterial cells. When compared to biosorption, bioaccumulation is a more time-consuming and energy-dependent process. (Ahemad & Malik, 2011) isolated 34 bacteria from the heavy metal-contaminated soil, from which pseudomonas isolate SN30, pseudomonas isolate SN7, and pseudomonas isolate SN28 were the zinc-resistant bacteria and shown resistant against Cr^{3+}, Cr^{6}, Hg^{2+}, Cu^{2+} Ni^{2+}, Pb^{2+}, and Cd^{2+}. These bacterial isolates have shown the ability for the accumulation of zinc and copper. When the concentration of copper in the medium is 2.92 mM, bacterial isolates SN30, SN7, and SN28 accumulated 22, 20, and 25 mg/g dry weight of cells. Similarly, when the concentration of zinc is 1.6 mM, zinc resistance bacteria SN30, SN7, and SN28 accumulated 26, 29, and 25mg/g dry weight of cells (Ahemad & Malik, 2011).

3.1.3. Fungi

Fungi are an excellent option for the biological remediation of heavy metals, as they exhibit high-level metal tolerance and impressive wall and intracellular binding of metals. compared to other microorganisms, they are easier to grow, high biomass producers and low-cost media can be used for their growth (White et al., 1995). The Fungal cell wall usually consists of chitin, proteins, polysaccharides (80- 90%), lipids, inorganic ions, and phosphates. These components of fungal cell walls play a crucial part in heavy metal adsorption. There are various negatively charged functional groups like carboxyl, phosphate, amino, sulphate, hydroxyl, and amino groups present on the fungal cell wall. During adsorption, these functional groups bind with various metal cations. (Narolkar et al., 2022) isolated 9 fungal isolates from the metal-polluted site. At 150 ppm of Cr (VI), fungal isolate *Aspergillus candidus* demonstrated an impressive potential for adsorption of 5.49 mg/g and a chromium removal efficacy of 98.75% (Narolkar et al., 2022). (Kurniati et al., 2014) isolated filamentous fungi from the forest soil and investigated the potential of filamentous fungi for mercury bioremediation. *Aspergillus flavus* strain KRP1 exhibited high mercury resistance and demonstrated tolerance up to 100 mg/L. Mercury (II) was eliminated from the PBD media by strain KRP1 via biosorption. After incubating for 7 days, the Removal efficiency of KRP1 in static and shaken conditions is 98.73% and 97.50% in the PBD media containing 10 mg/L mercury (II) (Kurniati et al., 2014). Dead and live fungal biomass could be used as effective bio-sorbents because both have a variety of functional groups on their cell walls which can effectively used for getting rid of harmful heavy metals. (Ranjani, 2019) carried out a study and evaluated the biosorption ability of dead and live biomass of *Rhizopus stolinifer* and *Aspergillus niger* for chromium (VI), isolated from the metal-polluted leather tannery location. *Aspergillus niger* has demonstrated tolerance for chromium (VI) up to 100 ppm and Rhizopus *stolinifer* had a tolerance of up to 1000 ppm. The removal ability of dead and live biomass of *Aspergillus niger* was 45% and 25% and that of Rhizopus *stolinifer* was 83% and 45% at 100 ppm of chromium (VI) (Ranjani, 2019). Fungi exhibit another process by which heavy metals are bioremediated i.e bioaccumulation. It deals with the movement of metals through the cell membrane and accumulation inside the fungal cell. (Dursun et al., 2003) studied the bioaccumulation capability of *Aspergillus niger* and the effect of pH on the growth and bioaccumulation of lead (II), chromium (VI), and copper (II). The ideal pH for the bioaccumulation of lead (II), chromium (VI), and copper (II) and the growth of *Aspergillus niger* were 4.5, 3.5, and 5.0. At concentrations of 100 mg dm^{-3} of lead (II) and copper (II), the maximum accumulation capability of *Aspergillus niger* was 34.4 and 15.6 mg/g, respectively. It was observed that an increase in the concentration of chromium (VI) from 50 to 75, there is no fungal growth, and chromium (VI) uptake occurs. The maximum accumulation capability of *Aspergillus niger* at 50 mg dm^{-3} was 6.6 mg/g (Dursun et al., 2003).

3.1.4. Algae

Algae are quite effective in eliminating heavy metals from polluted environments. The majority of heavy metals are eliminated by algae via biosorption, accumulation, or biotransformation. On the surface of Algal cells, there are a variety of functional moieties present, metal ions bind with

these functional groups and get adsorbed at the cell wall. Biosorption is a passive process; dead and living algal biomass can be used as biosorbent. (El-Naggar et al., 2018) used the dried biomass of *Gelidium amansii* for the eradication of lead from the aqueous solution. The FTIR investigation indicated the presence of phosphate, carbonate, methylene, phenolic, and carbonyl groups on the cell wall; these functional groups have a key role in the biosorption of lead. Under optimal conditions, *Gelidium amansii* demonstrated 100% lead removal efficiency from the aqueous solution (El-Naggar et al., 2018). (Shamshad et al., 2016) evaluated the biosorption capacity of *Oedogonium westti* for Cr, Ni, Pb, and Cd. *Oedogonium westti* was cultured in a selected heavy metal-containing aqueous solution for 7 days. The findings of this investigation showed that the adsorption capacity of *Oedogonium westti* for Cr, Ni, Pb, and Cd was 0.620, 0.418, 0.261, and 0.974 mg/g, respectively. Concentrations of metal and pH greatly affect the removal capacity. When pH was 4 and Cr and Cd were present in low concentrations, the removal capacity of *O. westti* was 93% and 95%, respectively. In the case of Ni, increasing the amount of Ni in the aqueous solution also enhanced the removal capacity and reached 87%. The removal capacity for Pb increases with a rise in the pH and metal concentration; at pH 6, the removal capacity for Pb was between 91-96% (Shamshad et al., 2016). Biosorption inhibits the penetration of heavy metals in the algal cell, but when extremely high concentrations of heavy metals exist, they can enter the algal cell. Then algal cells exhibit another mechanism known as bioaccumulation, in which heavy metals are accumulated in the algal cell to mitigate their toxic effects. Bioaccumulation is an energy-dependent and slow process, only living cells can carry out this mechanism. (Pham, 2019) Carried out a study, and their findings revealed that *Scenedesmus sp.* is Able to bioaccumulate Cu. when the amount of Cu in the solution is 2 mg/l, Scenedesmus sp. demonstrated 89.5% Cu removal efficiency within 7 days (Pham, 2019). Similar findings were provided by (Vigara Fernández et al., 2021) that *Chlorella sorokiniana* accumulated 11232 mg/kg of Cd, and demonstrated 65% removal efficiency (Vigara Fernández et al., 2021).

Table 1. Microbial mediated bioremediation of heavy metals.

Type of microorganism used	**Heavy metal to be removed**	**Mechanism of bioremediation used to detoxify the heavy metal**	**Performance of bioremediation**	**Time taken for bioremediation**	**Reference**
Bacteria:					
Arthrobacter viscosus	Cr	Biosorption.	100%	144h	(Hlihor et al., 2017)
EB L14	Cd, Cu, Pb.	Bioaccumulation, biosorption.	75.78%,21.25%, 80.48%.	24h	(Guo et al., 2010)

Bacillus cereus	Hg	Biosorption.	104.4 mg/g.	72h	(Sinha et al., 2012)
Bacillus anthracis PS2010	Co, Zn, Pb, Cd, Cu	bioaccumulation	4.75, 5.22, 6.44, 3.41, 2.03 mg/g.	-	(Sobhy et al., 2014)
Acidithiobacillus ferrooxidans	Fe, Zn, Cu, Pb	Bioleaching	85.42%, 98.73%, 96.44%, 88.90%	28 days	(Rouchalova et al., 2020)
Micrococcus luteus DE2008	Cu, Pb	Biosorption.	408mg/g, 1965mg/g.	12h	(Puyen et al., 2012)
Lactobacillus plantarum MF042018	Cr, Ni	Bioaccumulation	30.2 %, 33.8%	24h	(Ameen et al., 2020)
Variovorax boronicumulans	Zn, Pb, Cd	Bioprecipitation	73.81%, 95.93, 73.81%.	72h	(Jalilvand et al., 2020)
Stenotrophomonas rhizophila	Zn, Pb, Cd	Bioprecipitation	63.91%, 96.25%, 71.3%	72h	(Jalilvand et al., 2020)
Sporosarcina pasteurii	Zn, Pb, Cd	Bioprecipitation	94.83%,98.71%, 97.15%	72h	(Jalilvand et al., 2020)
Pseudomonas fluorescens	Cd	Biosorption	99%	5 min	(Sankarammal et al., 2014)
Oceanobacillus profundus	Pb, Zn	Biosorption	94%, 54%	24h	(Mwandira et al., 2020)
Fungi					

Trichoderma fungus	Cd	Biosorption	78.46%	120 min	(Bazrafshan et al., 2016)
Pleurotus ostreatus	Zn, Ni, Cr, Cu	Biosorption	3.22, 20.40, 10.75, 8.06 mg/g	150 min	(Javaid et al., 2011)
Aspergillus lentulus FJ172995	Ni, Pb, Cu, Cr	Bioaccumulation	42%, 100%, 78%,79%	5 days	(Mishra & Malik, 2012)
Alternaria alternata	Ag, Hg, Cu, Pb	Bioaccumulation	63.1%, 68.5%, 76.4%, 80%	7 days	(Verma et al., 2016)
Komagataella phaffi	Cu, Pb, Cd	Bioaccumulation	21.63, 20.63, 25.23 mg/g.	7 days	(Liaquat et al., 2020)
Fusarium sp. MMT1	Cr	Bioaccumulation ,Biotransformation	100%	72h	(Guria et al., 2014)
Neurospora crassa	Cu, Pb	Biosorption	12.28,49.06 mg/g	15 min	(Kiran et al., 2005)
Neosartorya fischeri	Tl	Biosorption, Bioaccumulation	62.01, 432.91 mg/kg	30 days	(Urík et al., 2010)
Trichoderma gamsii	Cr	Biosorption	89%	420 min	(Kavita & Keharia, 2012)
Algae					
Porphyra leucosticta	Pb, Cd	Biosorption	95%, 75%	120 min	(Ye et al., 2015)
Scenedesmus sp.	Pb	Bioaccumulation	83.5-84.2%	7 days	(Pham et al., 2020)
Spirulina sp.	Mn, Se, Zn,		99.73%,98.83%,		(Mane & Bhosle, 2012)

Spirogyra sp.	Fe, Cr, Cu	Biosorption	79%, 98.93%, 98.3%, 81.2%	7 days	(Mane & Bhosle, 2012)
Botryococusbrur auni	Mn, Se, Zn, Fe, Cr, Cu	Biosorption	99.6%, 98.16%, 81.53%, 99.73%, 98.23%, 89.6%	7 days	(Uddin & Lall, 2019)
Spirulina platensis	Cu, Pb, Cd	bioaccumulation	82%, 93%, 89%	90 min	(Al-Homaidan et al., 2014)
Desmodesmus sp.	Cu	Biosorption	90.6%	90 min	(Rugnini L et al., 2018)
Scenedesmus obliquus	Ni, Cu	Biosorption	85%, 94%.	2 days	(Rinanti et al., 2018)
Phacus genera	Cu	Biosorption, Bioaccumulation	65.54% ± 8.04	240 min	(Ahmad et al., 2020)
Spirulina (Arthrospira) platensis	Al, Pb, Ni	Bioaccumulation	64.28%, 79.17%, 66.67%	7 days	(Arunakumara et al., 2008)
Chlorococcum sp.	Pb	Bioaccumulation	188 mg/g	2 days	(Upadhyay et al., 2022)
	As	Bioaccumulation	322.43±2.95µg/g	10 days	

4. Simultaneous bioremediation and nanoparticle synthesis; synergy

Due to an increased exposure to hazardous chemicals and the elevated levels of heavy metals, certain defence mechanisms have been developed by microorganisms in order to survive in such harsh conditions, such as intracellular bioaccumulation, extracellular precipitation, and changes in efflux pumps. The microorganism has the ability to detoxify the harmful metal ions by either reducing the metal ion into a zero-valent state or metal nanoparticles, making them suitable for the simultaneous removal of harmful chemicals from wastewater and other contaminated sources and the biosynthesis of nanoparticles that have a potential to be used in different biomedical applications (Jadoun et al., 2022). The biosynthesis of nanoparticles can be executed using fungi, bacteria, algae, and plants. The microorganism provides a benefit over plant-mediated synthesis of nanoparticles i.e. they can reproduce easily when compared with plants. Microbes in the

presence of metal oxides can synthesize metal nanoparticles as well as they can be used for the biological remediation of heavy metals this synergy is due to the capability of microorganisms to tolerate the high concentration of heavy metals because of the presence of intracellular and extracellular proteins that mediate the adsorption and chelation of metal (Gomaa, 2022). The synthesis of metallic nanoparticles can occur either within the microbial cell or using the supernatant of the microbial cell which consists of different proteins, enzymes, and polysaccharides of the microorganism that act as reducing agents and are in charge for converting metal ions into metal nanoparticles.

The intracellular synthesis of nanoparticles involves three steps; trapping of metal ions onto the cell wall of microorganisms, bio-reduction by enzymes present in the cytoplasm, and capping and stabilization by organic molecules within the cell (Fariq et al., 2017). (Salvadori et al., 2014) using the dead biomass *of Rhodotorula mucilaginosa* carried out the intracellular synthesis of Cu nanoparticles. The copper ions were reduced by the dead biomass of red yeast into copper nanoparticles and apart from acting as a reducing agent the dead biomass also contributed in stabilizing the formed copper nanoparticles. The average diameter of the synthesized copper nanoparticles was observed to be 10.5nm and hence they concluded that the dead yeast biomass can be successfully used for the biosynthesis of copper nanoparticles with subsequent bioremediation of wastewater by removing copper from wastewater (Salvadori et al., 2014).

Some enzymes such as NADH-dependent enzymes which are released into the culture medium as extracellular enzymes serve in the metal ion reduction. The proteins, peptides, and other organic molecules found in the supernatant which is released by the microbial cell serve as capping and stabilizing agent for the synthesized nanoparticles (Murali et al., 2023). (Tyagi et al., 2019) used an entomopathogenic fungus, *Beauveria bassiana* for the biosynthesis of Ag nanoparticles. They used the extracellular synthesis approach for manufacturing Ag nanoparticles. The Supernatant was separated from the fungal biomass and in the supernatant silver nitrate was added which was further reduced to Ag nanoparticles. The color change of the solution to dark brown from white color was the first indication that confirmed the synthesis of Ag nanoparticles, further analysis of nanoparticles revealed that their size was in a range of 10-50nm and the Ag nanoparticles exhibit antimicrobial efficacy against different bacterial strains(Tyagi et al., 2019). (Ramanathan et al., 2013) used silver-resistant bacterium, *Morganella morganii* for the biosynthesis of copper nanoparticles and they evaluated the link between the biosynthesis of copper nanoparticles and the resistance that bacteria exert against heavy metal. Bacteria synthesize metalloproteins by utilizing copper, thus copper is a trace element that is utilized by bacteria in several ways however, at high concentrations, Cu (II) is toxic for the cell, and it can induce hydroxyl radical generation which can damage the cell in a different manner and can lead to microbial cell toxicity (Brow et al., 1992). Hence it is necessary for the bacterium to protect itself from the toxic concentration of copper ions and simultaneously must regulate the supply of copper to be utilized for the synthesis of metalloprotein. Further, their results indicated that the copper ions penetrate within the bacterial cell which within the cell associates with the biomolecules and is reduced to copper nanoparticles which are released out of the cells into the

medium. Their result also suggested that the Ag^{+} ions binding protein, SilE was involved in the uptake of Cu^{2+} ions inside the bacterial cell which further reduced into zero-valent Cu nanoparticles(Ramanathan et al., 2013). Bacteria, fungi, and algae can be effectively used in the bioremediation of heavy metals as well as in the synthesis of metal nanoparticles. Nitrate and silver are the common pollutants that are found in waste from ink, porcelain, and photographic manufacturing industries. (Eltarahony et al., 2016) used *Achromobacter sp.* MMT, which is a bacterial strain for the bioremediation of silver and nitrate pollutants, and due to the presence of periplasmic nitrate reductase enzyme the silver ions were simultaneously reduced to silver nanoparticles. For this purpose, they immobilized the bacteria and nitrate reductase enzyme so that they could withstand the harsh environmental condition of wastewater that was artificially made which contained $AgNO_3$. They observed that the immobilized bacterial cells were found to completely eliminate nitrate within 192 hours and simultaneously reduced Ag^{+} ions into Ag nanoparticles that had a size range between 23.26nm and 58.14 nm. The immobilized nitrate reductase enzyme had a lower efficiency in removing the nitrate from wastewater and the synthesized Ag nanoparticles by the enzyme were having a size range between 94.44 nm-172.22 nm(Eltarahony et al., 2016). (Sundararaju et al., 2020) used *Microbacterium sp.* for the removal of heavy metals from the surroundings, *Microbacterium sp.* is a bacterium that exhibits resistance to heavy metal and this bacterium was isolated from electroplating industrial effluent. Cobalt is a heavy metal that is released by some of the industries to the water bodies which can lead to a significant threat to the environment. The bacterium has shown resistance to Co (II) ions and is thus employed for the reduction of Co (II) ions to Cobalt oxide nanoparticles. Co_3O_4 nanoparticles were synthesized extracellularly using the *Microbacterium sp.* The Co_3O_4 nanoparticles were further characterized using different techniques and their analysis revealed their spherical morphology and the size range was observed to be 10–70 nm. These biosynthesized cobalt oxide nanoparticles can be utilized in the field of various industrial and clinical applications(Sundararaju et al., 2020). Phenol is an organic aromatic compound that at high concentrations is a toxic, carcinogenic, mutagenic compound it is released by pharmaceutic, petroleum, and other industries as a byproduct to the waterbodies and it can't degrade naturally. Thus, an ecologically friendly and economical method is employed for the bioremediation of phenol and tellurite oxyanions by (Hosseini, Lashani, et al., 2023). They used a bacterium, *Lysinibacillus sp.* which has an ability for the bioremediation of phenol and Te oxyanions. The bacteria utilized phenol as a source of carbon and reduced Te oxyanions to Te nanoparticles. The formation of Te nanoparticles was executed using an intracellular synthesis approach where the synthesized Te nanoparticles accumulate within the bacterial cell which was later on separated from the bacteria. The bacterium successfully degraded phenol by using it as a source of carbon and reduced tellurite oxyanions to Te nanoparticles and the formation of a black color of biomass indicated the formation of Te nanoparticles. The nanoparticles characterization indicated that the nanoparticles were observed to be spherical and their size range was observed to be 22 nm-148 nm. Thus, their study concluded that this biological method of bioremediation of these toxic

compounds is an effective mechanism for simultaneous bioremediation and nanoparticle synthesis(Hosseini, Lashani, et al., 2023) .

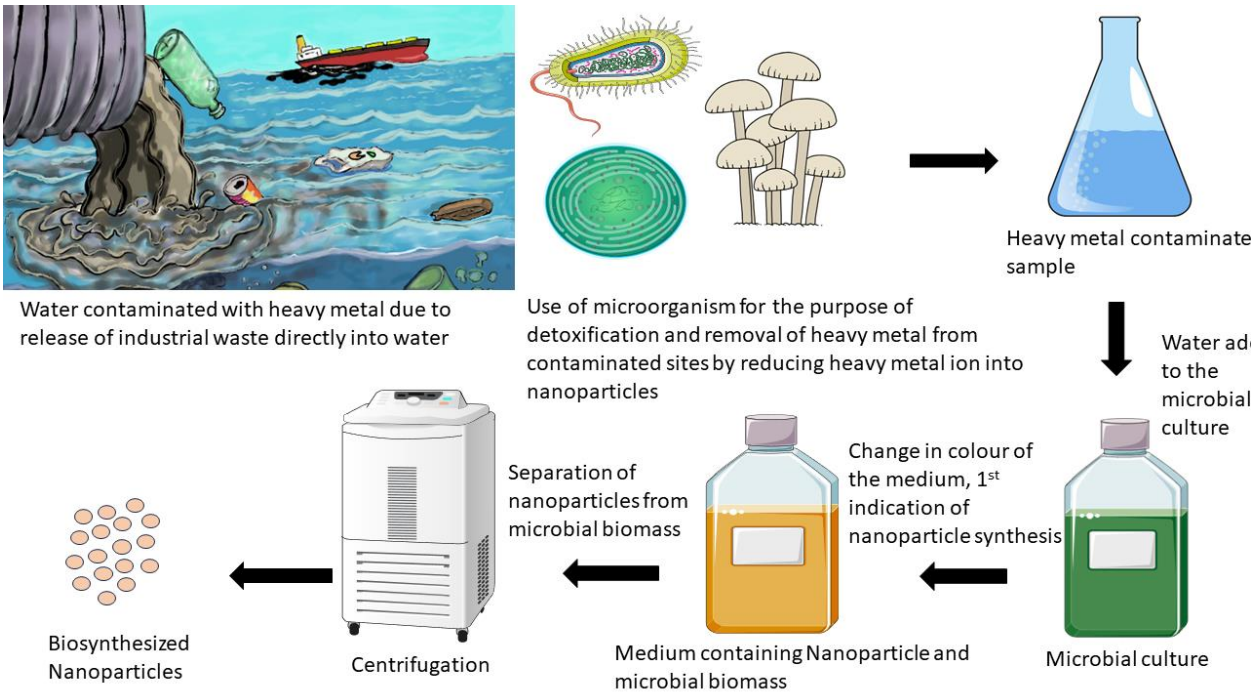

Figure 2. Schematic diagram illustrating simultaneous bioremediation of heavy metals from the contaminated sites and nanoparticle synthesis by reducing the heavy metal ion into nanoparticles

The presence of Cd in water and soil can lead to a significant danger to human life as it is a potent human carcinogen. Cadmium is a heavy metal and is quite toxic and thus it should be removed from the environment in order to prevent its exposure to humans through food and water. (Chakraborty et al., 2018) utilized extracellular polymeric substances released by *Pseudomonas aeruginosa* which is a bacterium isolated from marine areas for the bio-reduction of Cd^{2+}ions to CdS nanoparticles. The Extracellular polymeric substance released by *Pseudomonas aeruginosa* consists of polysaccharides, nucleic acids, proteins, and lipids which are accountable for the reduction of Cd^{2+} ions into CdS nanoparticles. The CdS nanoparticles were further analyzed using various techniques and they were characterized to be spherical and their size was observed to be around 10nm. They concluded that EPS secreted by *Pseudomonas aeruginosa* serves to be a sustainable method for the simultaneous removal of cd ions from the sample and the reduction of these cadmium ions to cadmium sulphide nanoparticles (Chakraborty et al., 2018). (Annamalai et al., 2013) used a biological method for the removal of chromium ions using *Bacillus subtilis.* At first, the biosorption of Cr (VI) was done to Cr (III) and was subsequently reduced to Cr nanoparticles using *Bacillus subtilis*. The manufacturing of Cr nanoparticles was done using an intracellular synthesis approach in which the Cr ions penetrate within the bacterial cell and subsequently inside the cell get reduced to Cr nanoparticles. Their results indicated that at pH 7 maximum chromium ions were removed by

Bacillus subtilis, further, the Cr nanoparticles were characterized to be spherical and their size ranges from 50 nm-78 nm. Thus, they provide sustainable and alternative approach for the detoxifying chromium ions from industrial effluents (Annamalai et al., 2013). Mercury is a heavy metal whose accumulation in the environment can lead to major problems in various life forms. Numerous human activities result in the release of Hg2+ ions into the environment such as the burning of coal, some industrial operations, and mining. Detoxification of Hg^{2+} ions can be done by carrying out the reduction of Hg^{2+} ions into HgS nanoparticles using various microorganisms. (Sathyavathi et al., 2013) used *Bacillus cereus* MRS-1 for the bioremediation of mercury by reducing Hg^{2+} ions into HgS nanoparticles. The major derivative of mercury is $HgCl_2$ which is released into the environment via various human activities. The bacterium has the ability to detoxify mercury chloride into HgS nanoparticles. In this study, $HgCl_2$ was added to *Bacillus cereus* MRS-1 culture, and the HgS nanoparticles were extracellularly precipitated. The biosynthesized HgS nanoparticles were observed to be spherical and their size ranges from 10 nm-100 nm. Thus, the *Bacillus cereus* strain which was isolated from industrial effluent of electroplating can be successfully used for the bioremediation of Hg which is present in the contaminated sites(Sathyavathi et al., 2013). (Chandrakant Vaigankar et al., 2020) carried out the detoxification of Selenite, using the bacterium *Halomonas venusta* which is a salt-tolerant bacterium. The bioremediation of selenite was done by reducing selenite to selenium nanoparticles by the salt-tolerant bacterium. The bacteria carried out the reduction of selenite oxyanions intracellularly and the fabrication of Selenium nanoparticles was first indicated when the color of the medium was changed to brick red from yellow. it was observed that the nanoparticles were spherical in shape and their size was observed in the range of 20 nm-80 nm also hexagonal crystal lattice was exhibited by them. They also evaluated anti-cancer, anti-oxidant, and also their potential against larvicidal mosquitoes (Chandrakant Vaigankar et al., 2020). Selenate and Selenite which are the oxyanions of selenium, these oxyanions are quite toxic at a high concentration to the aquatic and terrestrial life forms. However, some bacteria can withstand a high concentration of selenium ions and can reduce the oxyanions of selenium into selenium nanoparticles.(Pandey et al., 2021) carried out the biosynthesis of selenium nanoparticles in order to eliminate the toxic effect of selenium ions upon various life forms. They cultured *Anabaena sp.* For the biosynthesis of selenium nanoparticles. Sodium selenite was added to the cyanobacterial biomass and the solution was incubated. The nanoparticles were separated as supernatant and cyanobacterial biomass as pellets. Further, the selenium nanoparticles were characterized using different techniques, and the average diameter of the synthesized selenium nanoparticles was observed to be 25nm. The biosynthesized Se nanoparticles exhibited potent anti-bacterial activity and can be employed in the textile industry in the decolorization of dye (Pandey et al., 2021).

(Bedi et al., 2018) carried out the biosynthesis of iron-containing metal nanoparticles via bioremediation of mining waste. A significant amount of the mining waste is produced by the iron ore. They isolated a fungal strain from the mining site containing iron ore tailings *Aspergillus aculeatus*, which able to withstand elevated metal ion concentrations without leading

to its cell toxicity and can effectively convert the iron ore into metal nanoparticles. Their results indicated that the iron nanoparticles were highly effective in seed germination as these iron nanoparticles can be uptake by plants as a source of iron. Also, at low concentrations, they positively enhanced root and shoot development, however, they exerted toxic effects at higher concentrations on seedling growth (Bedi et al., 2018). Copper is the most common pollutant found in municipal wastewater, the presence of high concentrations of cupric ions can cause severe toxicity to various life forms. Conventional chemical and physical methods of removing pollutants from wastewater can lead to the generation of by-products and secondary pollutants. (Žvab et al., 2021) utilized the ability of *Chlamydomonas reinhardtii*, a microalga, for the bioremediation of nutrient media which is considered wastewater rich in Cu^{2+} ions. *C. reinhardtii* is used for the bioremediation of cupric ions by simultaneously biosynthesizing Cu nanoparticles. Further characterization of nanoparticles was done and the synthesized nanoparticles were observed to be spherical, and polydisperse and their size was observed to be 10nm. Thus, they effectively carried out the bioremediation of the Cu^{2+} polluted media and evaluated the potential of *Chlamydomonas reinhardtii* for the detoxification of metal ions by reducing it to metal nanoparticles (Žvab et al., 2021). Some natural activities such as the industrial activity, mining, burning of coal, and weathering of rocks can lead to the development of selenite and tellurite oxyanions which are quite toxic for living organisms. Thus, these oxyanions need to be removed from the environment. For this purpose, (Hosseini, Hadian, et al., 2023) carried out the bioremediation of selenite and tellurite oxyanions using *Trichosporon cutaneum* and *Yarrowia lipolytica*, these yeast strains reduced Se and Te ions into Se-Te nanoparticles. The nanoparticles were biosynthesized intracellularly by the yeast. The size of the Se-Te nanoparticles synthesized by *Yarrowia lipolytica* was found in a range of 46 nm-171 nm while the size of nanoparticles biosynthesized by *Trichosporon cutaneum* was observed in a range of 25 nm-53 nm. The analysis of synthesized nanoparticles revealed that the synthesized nanoparticles were covered by carbohydrates, proteins, and lipids and thus they successfully removed the oxyanions from the polluted environment by simultaneously synthesizing Se-Te nanoparticles which can be used in biomedical applications (Hosseini, Hadian, et al., 2023).

5. Future prospect

Research needs to be conducted in order to identify what can be done to improve the rate of biosynthesis of nanoparticles and increase the efficiency of microorganisms to more effectively carry out the bioremediation and detoxification of heavy metals. Additionally, some microorganisms used for simultaneous bioremediation and nanoparticle production could be pathogenic, so they could not be widely employed. Genetic engineering can be used to overcome these challenges. Modification in the genome of organisms can be done to alter the genes, and microorganisms with enhanced bioremediation capacities and less potential to cause diseases can be produced. The majority of these heavy metal remediation techniques are limited to the laboratory scale, employment of simultaneous bioremediation and nanoparticle synthesis at large a scale would be a major challenge. Apart from the biosynthesized nanoparticles have several benefits in different areas however, the nanoparticles can serve to some major health

complications if accumulated inside the human body in a high concentration. Thus, apart from the positive applications of nanoparticles the negative impact of nanoparticles on living organisms must also be evaluated.

6. Conclusion

The use of microorganisms such as fungi, yeast, bacteria, and algae is an economical, sustainable, and promising method for the bioremediation, detoxification, or elimination of heavy metals such as copper, cobalt, chromium, tellurite, selenite, cadmium, mercury and other contaminants from the contaminated sites in the environment. Some natural and anthropogenic activities cause these highly toxic heavy metals to release into the surroundings which could pose a significant danger to various life forms, thus it is essential to remove heavy metals from contaminated areas such as wastewater. The use of microorganisms has a dual benefit, they can effectively remove heavy metal from the surroundings by reducing it to nanoparticles, and the biosynthesized nanoparticles due to their smaller size can be employed in various biomedical applications such as antibacterial, anti-oxidant, anti-cancer, etc. thus this dual benefit can largely benefit the society in the removal of contaminants from the contaminated areas and also in the field of medicine, nanotechnology ad industrial applications.

Abstract. This paper presents the results of the experimental investigations carried out on two intricate plan-shaped buildings to evaluate the aerodynamic performance of the building. The intention is to explore the associated environment resulting from wind forces in both solitary and obstructing situations using a prototype model at a scale of 1:300 with a prototype having 180m height. Experimental tests were carried out at the boundary layer wind tunnel considering isolated conditions with 0° to 180° isolated wind directions and four interference conditions of twin buildings (separately for both the models). The research has been undertaken in Terrain Category II, which is the most widely available terrain in India. A comparative assessment of the two models is performed in an attempt to comprehend the various consequences of diverse conditions that may emerge in real-life situations, as well as the discrepancies among them. Experimental results of wind pressure coefficients of Model-1 and Model-2 show good agreement with various wind incidence conditions with the minute difference in the magnitudes of Cp. On the basis of wind tunnel studies, it is distinguished that the performance of Model-2 is better than Model-1in both isolated as well as interference conditions for all wind incidences and orientations respectively.

Keywords: Tall buildings; wind directions; interference factor; mean pressure-coefficients

1. Introduction

Impelled by the developing need of the present era, the trend calls for the construction of tall buildings. Buildings, according to Hassanli et al. (2017), do provide shelter and also operate as a barrier between both the outdoor and inside surroundings, as well as the residents who live within. Amin and Ahuja (2010) said the barrier i.e., the tall structures are generally slender in nature and are induced by wind load and can cause discomfort to the inhabitants on a psychological level and the symptoms may range from concern, anxiety, and fear to headaches. Kalehsar and Khodaie (2017) and (2018) modeled a structural design for super-tall buildings for the reduction of excessive vibration due to wind loads by inducing damping devices. An ample amount of information is available with different international standards (AS/ NZS: 1170.2:2011, ASCE: 7-02 (2002), IS: 875 (Part 3): 2015) for regular symmetrical cross- sectional plan shape buildings with similar cross-section throughout its height around the world. As necessary as the study of aerodynamic effects on the isolated structures is, seldom these structures are constructed as a unit. Only a small amount of investigation has been executed out over indifferent planned structures. Chakraborty et al. (2013), Cheng et al. (2015), Li (2017), Gomes et al. (2005), Bhattacharyya et al. (2014) and Paul and Dalui (2016) studied through experiments the wind pressures on '+' shaped, "H" shaped "L" shaped, L‟ and „U‟ plan shaped, L- and T-shaped, E- plan shaped and Z-plan shaped models of tall structures respectively, for wind angles varying wind incidence angles. results exhibit a huge difference in wind-induced pressures on windward as well as leeward faces as compared to a regular cubical model. Although the experimental study gives a fair picture of the field conditions and the results, some field studies have also been carried out for producing extreme conditions. Hangan et al, (2017), had analyzed new full-scale measurement techniques such as Doppler Radars and LiDARs to allow a better portrayal of events such as tornadoes and downbursts. Chuang and Spence (2017) had done a full-scale case study of a 40-story four-span plane steel frame and including parameters like wind hazard analysis, aerodynamic analysis, structural analysis, damage analysis, non-collapse loss assessment, collapse assessment, dynamic shakedown and collapse of wind excited system and collapse loss assessment.

Solari (2017) studied the topography effects, atmospheric turbulence and aerodynamic wind actions; found that the dynamic wind in nature as stated by Hu et al. (2017), causes huge damages that frequently may lead to collapse of the buildings. In order to reduce the induced wind loads, dynamic responses and the adverse effects, we need a broad study over other parameters such as size, shape, edge and or corner modifications of a building. The formation of wind loads on high-rise structures is known to be significantly influenced by the external shapes of tall buildings along their height. The optimized shape of a building can be chosen by altering the flow pattern around a building by modifying the building shape (Ahmed et al. (2017) and Alminhana (2018)). Zheng et al. (2018) have experimentally investigated the aerodynamic performance of tall building models with modified corners (chamfered and recessed). Stathopoulos and Zhou (1993) pictured the wind pressures on surfaces of various buildings with sharp corners by adopting numerical simulation methods. Through the studies it has been verified that the recessed type corners are more efficient in the reduction of the lift forces and also, chamfered type corners prove to be more efficient in the reduction of the drag force. Kim and Kanda (2013) investigated the spatial-temporal characteristics of pressure fluctuations on tapered and set-back tall buildings. Silva et al, (2018) studied conventional roof and roof edge shapes for building roof shape optimization for the wind energy exploitation for both turbulence intensity and wind velocity.

Most of the buildings are constructed in clusters with different arrangements among themselves as well as with the upstream wind. Due to the close proximity of another building, the wind pressure coefficients of such structures vary from that of the isolated standing structure. The interference effect between two or more buildings in close proximity is important in the field of building aerodynamics (Khanduri et al. 1997). Wind pressure on the main structure may grow or fall as a result of the adjacent buildings' obstruction, depending on a number of factors (Chitra et al. 2017). Tse et al, (2017) have experimentally investigated the surrounding wind conditions of building arrays in twisted wind flows, Xu et al (2017) has performed a comparative study between 400m and 200m tall buildings experimentally and investigated the pedestrian level winds around 40 different configurations super tall building models through wind tunnel tests, Amin and Ahuja (2012) has calculated the mean interference effects between two rectangular buildings (‘L’and ‘T’ plan shape) located in close proximity by wind tunnel test and Ming (2010) carried out wind tunnel tests on 27 typical tall building models and analysed the characteristics of wind-induced pressures and forces on these buildings. Through these studies, as concluding remarks, it was said that the building height and passage width are the most influential parameters in determining acceptable wind conditions near building arrays. Many other analytical, numerical, and or experimental studies has been carried out to evaluate wind loads on buildings in interference conditions for various indifferent structure with multiple arrangements among themselves (Kheyari and Dalui (2015), Kar and Dalui (2016), Bairagi and Dalui (2014), Mukherjee and Bairagi (2018), Gurjar and Amin (2017)). Li et al. (2017) concluded that there is no analytical formula available for evaluation of the wind effects on irregularly shaped tall buildings with or without interfering with buildings in close vicinity.

Although, a number of studies have been done to check the induced wind pressure on the faces of indifferent plan shape buildings, to date, no comparative study between two complex plan-shaped structures has been indexed. In this paper, a number of parameters (such as complex shape and change in shape) are taken into account for the experimental study through BLWT. A thorough

study of two complex structures, Model-1 (M-1)-Figure. 2(a) and Model-2 (M-2) Figure. 2(b) has been carried out. The results obtained from the pressure distribution on Face-A only in isolation and interference have been explained in detail due to the limited space of the paper. Further, a comparative study has been done for a better understanding of the effects of minor change the in plan of building towards the associated pressure.

2. Methodology

2.1 Experimental Configuration Aspects

The experiment has been carried out in a BLWT (Boundary Layer Wind Tunnel) with a cross sectional area of 4 x 10^6 mm^2 and a total length of 15 x 10^3 mm. The fluid motion is lined by establishing a square shape honey comb at the tunnel's inlet, which also generates the required vortex flow. Terrain has been developed for the experimental study by placing the physical barriers at the upstream of the wind tunnel. With the assistance of suction from blower fan, the wind continually travels through the tunnel at a constant speed of 10 m/sec.

On each surface of the building model, the flow separation-induced pressure variation is evaluated. A pressure tapping built of 1 mm steel tubing is used to detect pressure. This resulting pressure is gauged and connected to a Baron instrument via a pressure transducer that is connected to each pressure taping. On a one-meter-long probe, the "TESTO - 480" Baratron Pressure Transducer can detect relatively modest differential head Wind speeds in the tunnel at various heights. The variation in mean wind profile velocity and turbulence intensity recorded above the turn table at the downstream end of the wind tunnel is shown in Figure 1. The mean wind speed profile inside the wind tunnel follows the Power Law with an Index, $\alpha = 0.22$ for the present study. The turbulent intensity of the flow is found 12% near the floor of the tunnel.

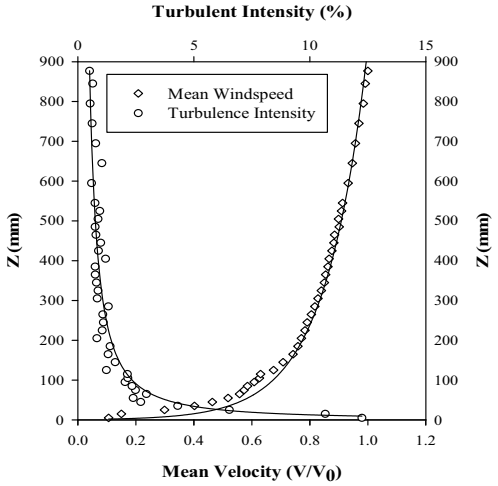

Figure 1. Mean wind speed and turbulence intensity profile

2.2 Details of models

The building models are scaled at 1:300 length scale. For the purposes of comparison, the plan area and height of the two models were maintained the same at 40,000 mm^2 and 600 mm, respectively. Figures 2(a) and 2(b) for M-1 and M-2, respectively, show all the specifications for the plan and elevation views as well as the spots of the pressure measurements of the models. Despite the fact that the area has remained the same, it is easy to see how the plan has altered.

Both the models are instrumented with similar positions of pressure taping points uniformly in order to check for the complete distribution as well for relating the results among both the models for pressure distribution at each face separately. However, in this paper the pressure values in the

form of pressure coefficients are pinpointed for Face-A only for both the models for the wind incident angles (0^0, 30^0, 60^0, 90^0, 120^0, 150^0 and 180^0) for isolated conditions, Figure. 3(a) and Figure. 3 (b) for M-1 and M-2 respectively.

Cp for four interference conditions for both the models have been experimentally calculated. For each location of pressure measurements, the pressure coefficient is established as: IS: 875 (Part 3), 2015.

$$C_p = \frac{\text{Pressure at any point } (P_a)}{0.6\ V_z^2}$$

Where, Vz is the design wind speed in m/s (10 m/s for this experiment).

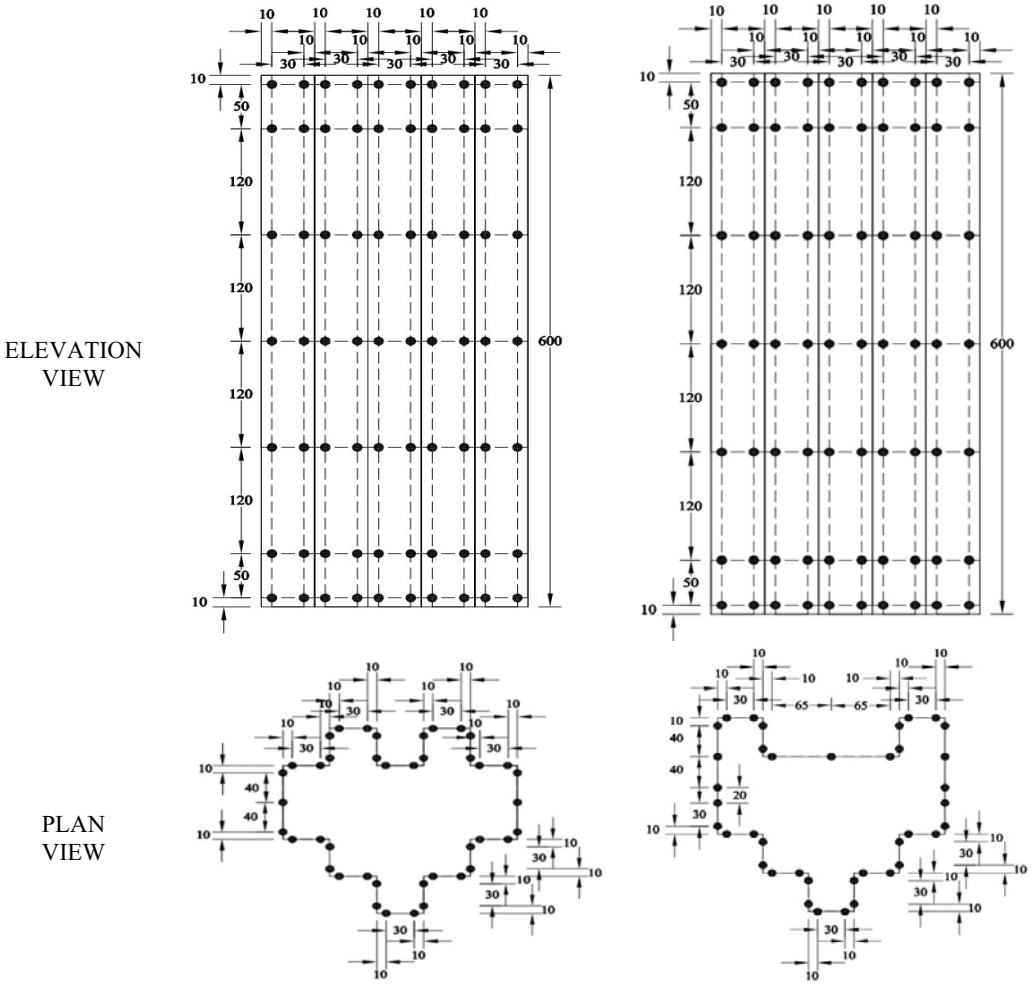

Figure 2. Pressure taping layout of building models

Both the models have more than 270 pressure taps at seven different height levels of 10mm, 60mm, 180mm, 300mm, 420mm, 540mm and 590mm from the bottom up to get a better image of the pressure distribution on all sides and faces of the models.

The objective of the study is to discover how the building's external shape's slight alterations affect the flow streamlines. For both the models of isolated and interferential situations, a thorough study of Face-A has been demonstrated. Additionally, average Cp magnitudes for each face for both models are performed, and a full discussion is conducted. Interference Factors are used to study the impact of having a building model nearby, and the results are then thoroughly described.

Figure. 3 Various wind incidences (Isolated Condition)

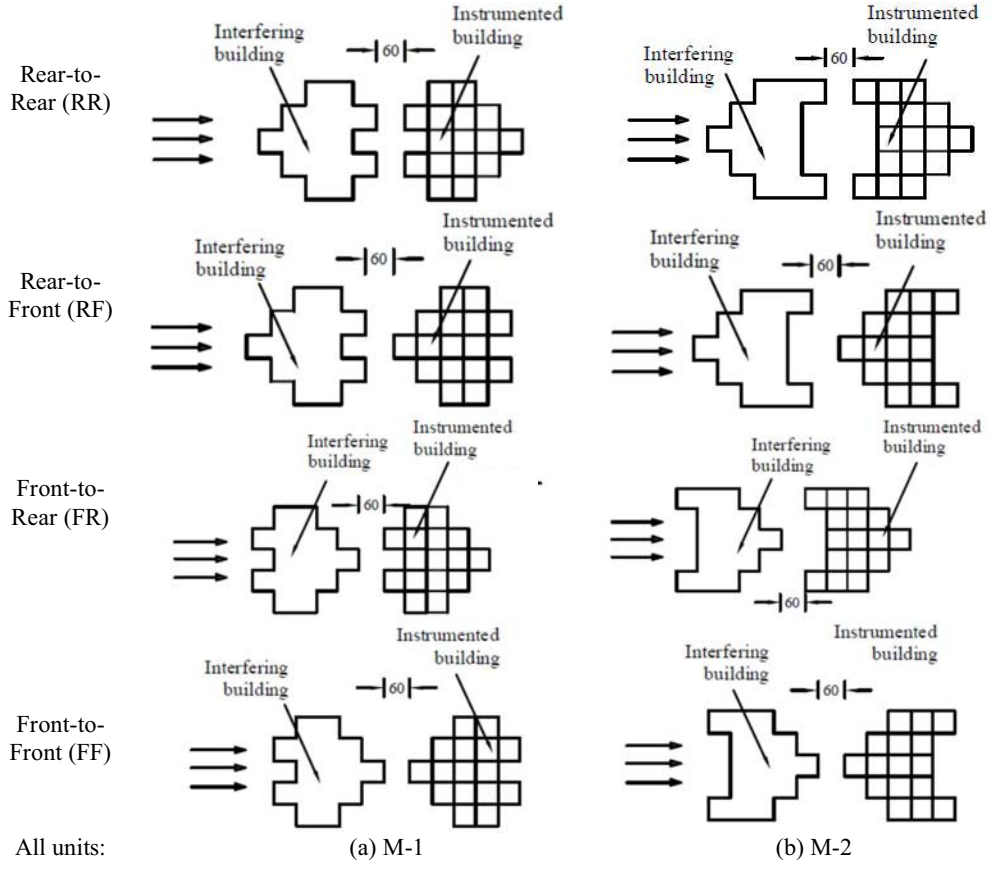

Figure. 4 Various Interference Conditions (Unit: mm)

3. Analysis Of Results: Isolated Condition

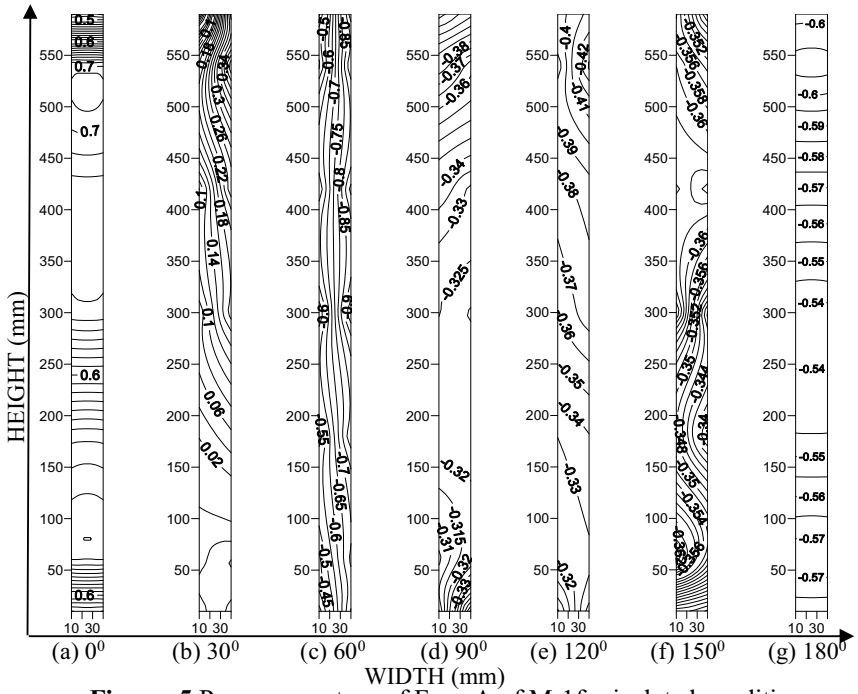

Figure. 5 Pressure contour of Face-A of M-1for isolated condition

The distribution of mean pressure coefficients is shown in Figure. 5 for isolated conditions with wind incidence angle from 0° to 180° at an interval of 30°. For 0° wind incidence the pressure is uniformly distributed from 0.51 to 0.67 on the 1/3rd to 1/2nd height of the building model due to direct undeviating wind force. At 30° wind incidence condition the wind is getting twisted along the horizontal centerline and Face-A is now not in the direction of undeviating wind force, due to this condition the magnitudes of C_p are seen to have lower magnitudes as compared to 0^0 wind incidence condition. Further, at 60° angle of incidence suction is generated throughout the face with a magnitude ranging between -0.50 to -0.85. Suction is created because of the skewed angle of wind incidence along with the interference of nearby faces thus flow separation is taking place at Face-A. At 90°, the downstream wind direction is further getting away from Face-A and disturbances can be observed to form at the upper ½ and bottom 1/3rd region only, at 1/2nd to 1/3rd distance form half height of model no pressure effect is seen. At 120° the wind is twisting but the direction of it is just opposite that of at 90° as well the fluctuation is also not too high as compared to other wind incidences. At 150° huge fluctuation of wind pressure and large twisting of the wind can be seen as the Face-A falling into the wake region. At 180° wind incidence, the distribution of Cp is observed to get uniformly distributed over the height of the model due to the symmetrical plan shape as wind is getting equally distributed at both sides after it is incident at Face-K and gathering at Face-A from both sides. The maximum C_p of 0.71 is found at 1/4th height of the model from top for 0° wind incidence and the minimum C_p of -0.31 is found at 1/6th of the height of the model from the bottom at 90° wind incidence.

Figure. 6 shows mean pressure distribution of M-2 for isolated conditions at wind incidence angles 0° to 180° at an interval of 30°. The flow as well as the plan of M-1 is symmetrical in 0° and 180°. The magnitude of C_p is varying from 0.40 to 0.69 at 0° whereas, the variation of C_p at 180° is from -0.47 to -0.59, both the magnitudes show large similarities to Cp of M-1 at 0° and 180° respectively. At 0° Face-A is at direct incident of wind flow and at 180° the face is at the leeward side and falls into wake region. The maximum and minimum Cp's also falls at 0° and 180° with, 0.68 and -0.47 magnitudes of Cp respectively. However, no influence of wind is observed at height 400mm to 520mm and 150mm to 320mm respectively for 0° and 180° wind incidences. At 30° of

wind incidence for bottom 1/6th height no effect of induced pressure is observed. Above this height the pressure is rising from 0 to 0.30 where the wind can be observed to twist at upper 1/6th height of the model with fewer fluctuations.

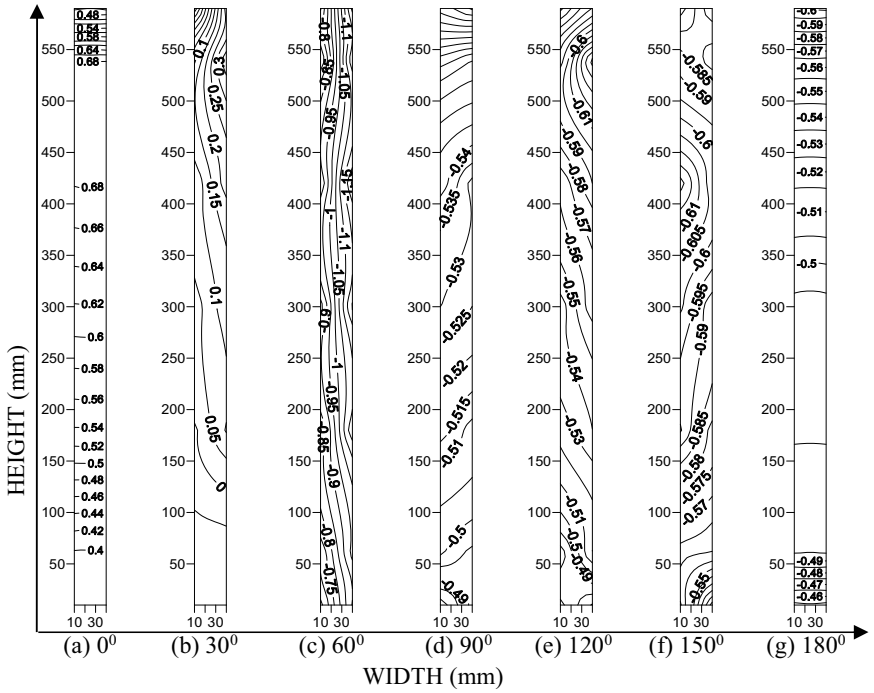

Figure. 6 Pressure contour of Face-A of M-2 for isolated condition

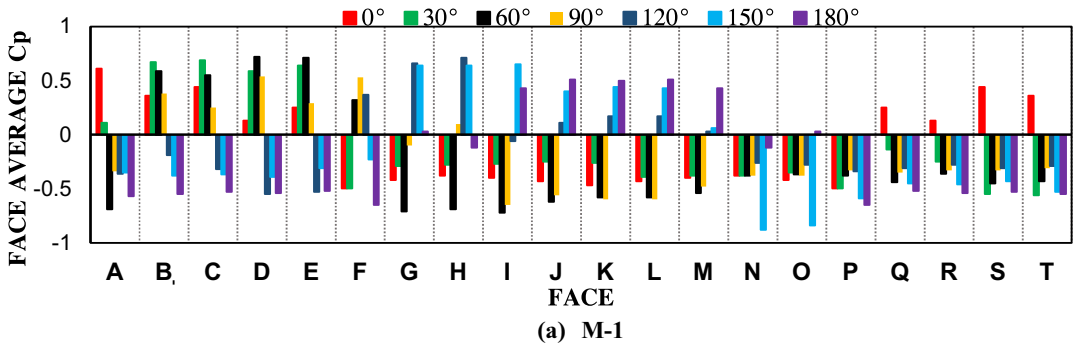
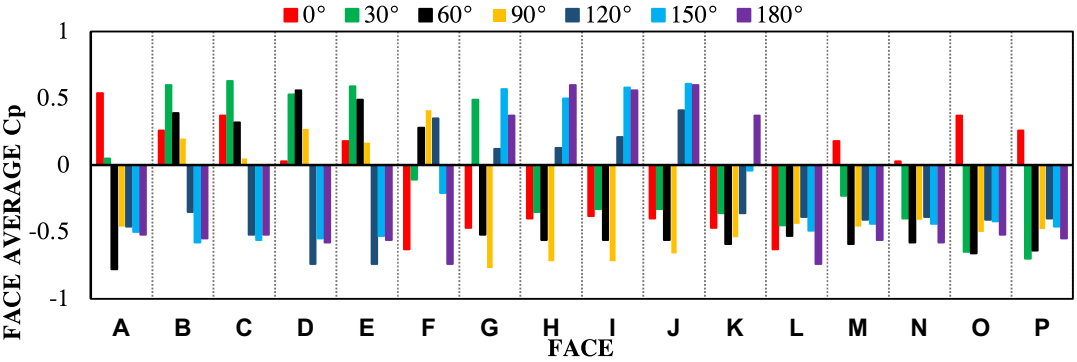


(a) M-1



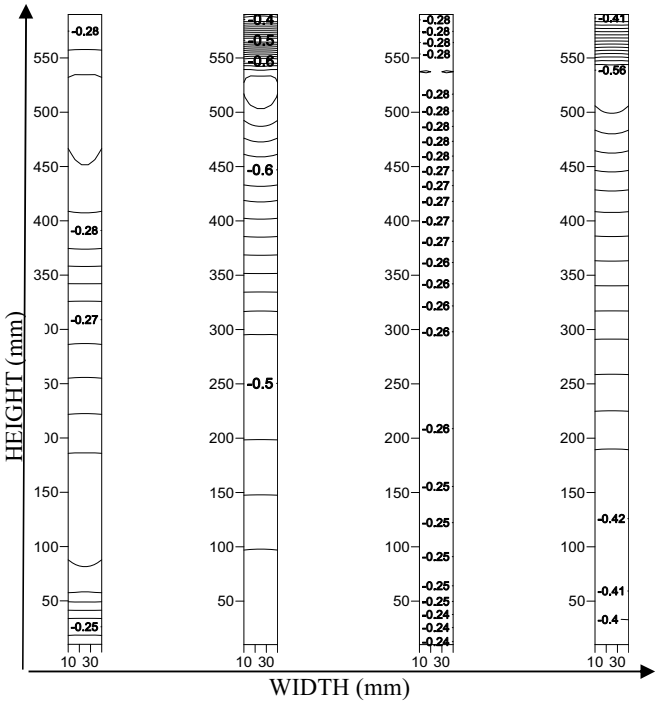
(b) **M-2**

Figure. 7 Face Average Cp distribution al the periphery (Isolated condition) (a) Model-1; (b) Model-2

At 60° wind incidence (Figure 6), large fluctuations at the Face-A along the width can be observed which is distributed throughout the height of the model. The least magnitude of suction -0.75 can be observed at bottom height of the model which is constantly rising till -1.15 magnitudes at 3/4th height of model. The Cp continues to fall until it reaches the lowest magnitude of -0.75 at the model's highest point. While suction is still produced at 90°, the change in Cp throughout the height is reduced (0.48 to 0.54), with the least magnitude at the bottom and top and the greatest magnitude of 0.54 at 420 mm. From a height of 420mm to 600mm the fluctuations are rapid which shows upwash phenomena of the wind flow. Although, the direction of twisting wind at 90° is opposite from that at 30° but the magnitude and variation at the Face-A is similar to that at 120°, with the magnitude varying from -0.49 to -0.61. At 7/8th height of the model a large fluctuation and thus rotation of wind can be seen with 0.62 at the center of the rotation.

Maximum face value of M-1(Figure. 7(a)) is about 0.71 at isolated condition is observed at 60^0 (Face-E) and 120^0 (Face-H) direction of wind incidences simultaneously both due to the depressed positioning of the faces and the wind is getting trapped at between the depressed edges at both the faces. From cladding design point of view isolated building orientations at 30^0, 60^0 and 120^0 angles of wind incidences should be given extra care while designing whereas the building orientation at 0^0 wind incidence is best suited as of generates average magnitudes of face values among all.

At M-2 (Figure. 7(b)) maximum negative face value of -0.78 is observed at Face-A at 60^0 of wind incidence. High negative face value (-0.77) is observed at Face-G at 90^0 wind incidences followed by Face-F and Face-L with decrement of about 4% at 180^0 wind incidence both due to flow separation from the faces at wide angles due to the orientation of faces to the direction of wind incidence. Face-E and Face-E are also experiencing high negative face values at 120^0 wind incidence angle due to the depressed orientation of faces. Highest face value is observed at Face-C (0.63) of 30^0 wind incidence angle closely followed by 150^0 and 180^0 of wind incidence with magnitudes of 0.57 (Face-G) and 0.60 (Face-H and Face-J) respectively mainly due to trapping of wind between the inner edges of the faces.



(a) RR (b) RF (c) FR (d) FF

Figure. 8 Pressure contour of Face-A of M-1 for interference condition at (a) RR, (b) RF, (c) FR and (d) FF

Interference Condition

Both the models have been studied for four interference conditions as, RR, RF, FR and FF orientation (as shown in Figure. 4) of the building with respect to twin their buildings located at the downstream of the wind stream. For all setups, the spacing between obstructing building models is fixed at 10% of the instrumented building model's height (60 mm).

The distribution of mean pressure coefficients is shown in Figure. 8 for four interference conditions. For RR condition it can be observed that the suction is generated for the entire Face-A of principal building with maximum suction of -0.29 at 1/3rd height of the model and minimum suction of -0.25 at 1/6th height of the model. From height 1/3rd to full height of model the pressure is very uniformly distributed, no influence of the interfering building model is observed from 1/6th to 1/3rd height of model. Uniform distribution can also be seen for FF interference condition throughout the height of the model with maximum suction of 0.56 at 1/6th height of the model from top and minimum suction of -0.40 at top and bottom of the model. However, from height 50mm to 200mm very less fluctuation can be observed. The uniformity of the pressure distribution along the height is due to the symmetrical plan shape as well as symmetrical orientation of both the models with respect to wind incidence. For three interference conditions except RR condition upwash is seen at 1/6th height of the model from top. The variation in the Cp for RF and FF conditions are high and ranges from -0.40 to -0.64 and -0.40 to -0.56 respectively. In both of RR and FF conditions due to the orientation of both the models, at Face-A of principal model wind is getting trapped between both the models and a shielding effect is created due the presence of interfering model with less variation of Cp (-0.24 to -0.28 for both the conditions). For interference conditions of RF, FR and FF least to no influence of interfering model is observed at 0mm to 100mm, 200mm to 300mm and 50mm to 200mm respectively.

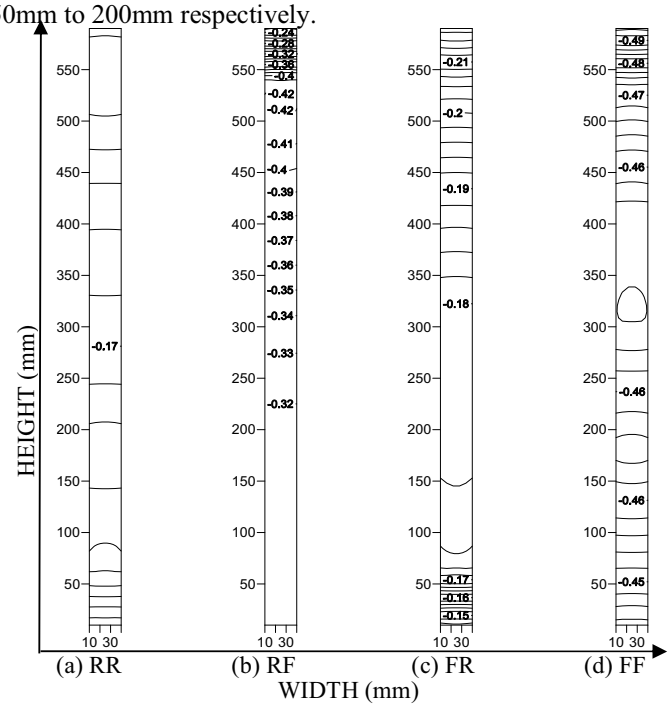


Figure. 9 Pressure contour of Face-A of M-2 for interference condition at (a) RR, (b) RF, (c) FR and (d) FF

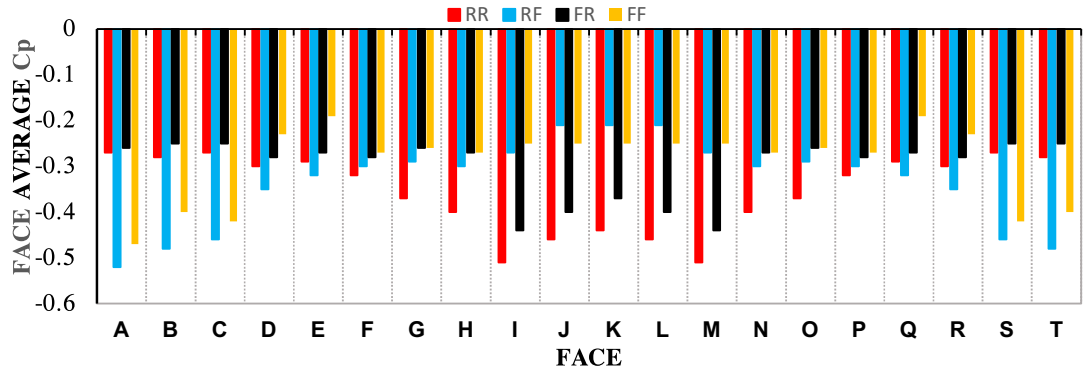
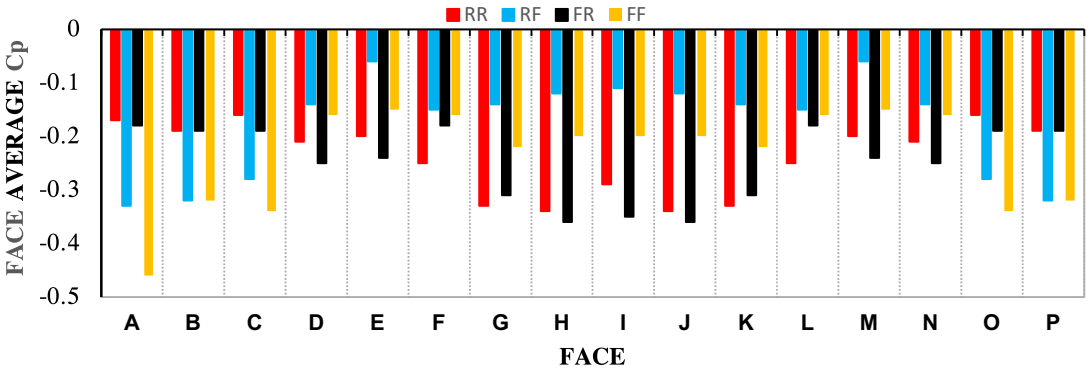
Figure. 9 shows the distribution of mean wind pressure for four interference conditions. Face-A is least affected at RR because to the building's orientation, where the wind deviates symmetrically at greater angles on both sides after incidence on the obstructing model. Thus, very less suction is created at Face-A throughout the height. The maximum Cp (-0.185) is at the top and minimum Cp (-0.155) at the bottom of the model. From bottom to 1/10th height the wind is trapped thus rapid

fluctuation of the values can be observed. At RF and FR conditions influence of incident wind doesn't show any effect between bottom to 1/3rd and 1/6th to 1/2nd height of the model respectively. For RF condition the magnitude of pressure is varying from -0.32 to -0.42 and further reducing from -0.42 to -0.28 at 1/3rd to 7/6th and 7/6th to full height of the model respectively. A huge fluctuation at 7/6th to full height is observed due to the upwash phenomenon of the building as a result of presence of hindering building. In FR condition although the fluctuations are rapid but have very less change in the magnitude and thus, varying from -0.18 to -0.218 from 1/2nd to full height of the model. At bottom 1/10th of the height of model rapid change in the Cp can be observed as a result of entrapped wind at such height between both the models. However, no influence of interference of neighboring building model is observed from1/3rd to 1/2nd height of model in such condition. At FF orientation due to the symmetry of the stream of wind flow as well as the arrangement of the buildings the distribution of the Cp is also observed to be symmetrical horizontally as well as vertically. The magnitude of Cp is seen to increase from -0.44 to -0.48, fall from -0.48 to -0.45 at the model's bottom to 1/4, and climb from 1/4 to 1/2 height. Although a minor vortex can be seen at half the model's height, a similar distribution is shown at the upper half of the model. All interference cases exhibit upwash, with the exception of the RR orientation, which resembles M-1.



(a) Model-1



(b) Model-2

Figure. 10 Face Average Cp distribution al the periphery (Interference condition)

at (a) Model-1; (b) Model-2

At M-1 (Figure 10 (a)) the minimum magnitude of face value (-0.19) is observed at Face-E and Face-Q of FF condition whereas maximum magnitude of negative face value (-0.52) is observed at Face-A of BF condition. Due to the front orientation of the principal model, huge fluctuation is seen between the face values along the faces of the model. Due to maximum shielding of principal model of M-2 (Figure 10(b)) at BB condition least fluctuation between the face values among the

faces is seen. Whereas at BF condition maximum least magnitude of negative face value (-0.06) is seen at Face-E and Face-M. Whereas maximum magnitude of negative face value of -0.46 is observed Face-A of FF condition.

The blockage effect happens when one or more objects block the fluid flow's path from reaching the principal object. The existence and impact of an intruding structure are indicated by the interference factor on the original structure. This factor is being used to assess the fluctuation in pressure at a surface on the instrumented tall building. The interference factor is evaluated by, Kar and Dalui (2016), Zu and Lam (2018).

$$\text{Interference Factor} = \frac{\text{Pressure for selected point in interfering condition}}{\text{Pressure for selected point in isolated condition}}$$

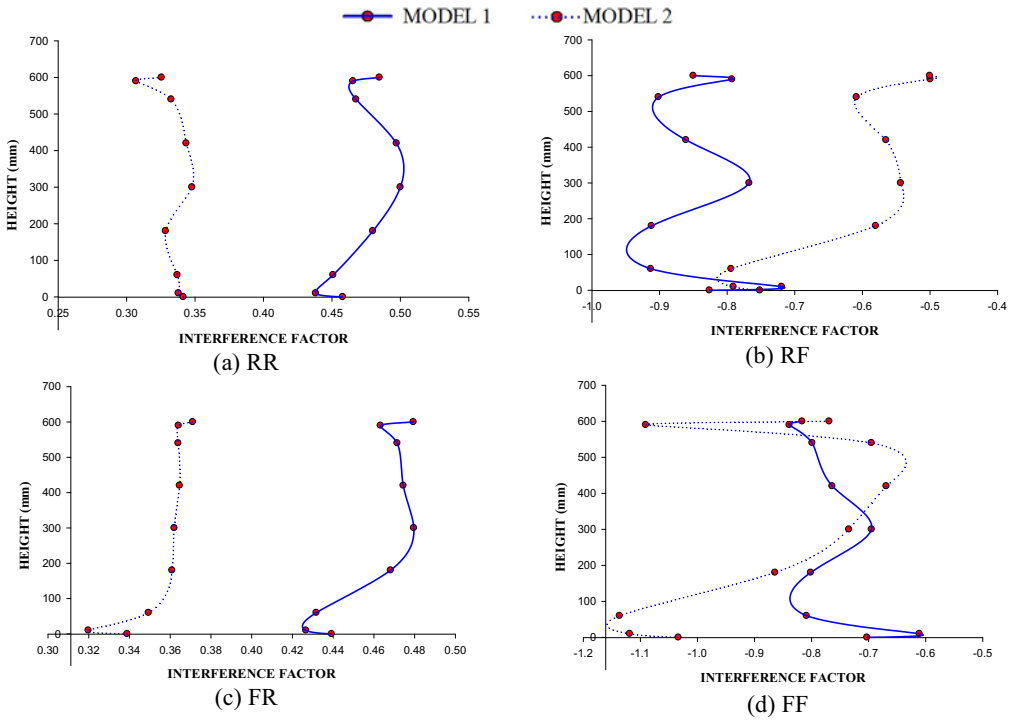


Figure.11 Interference Factor of Face-A along centerline (M-1 and M-2)

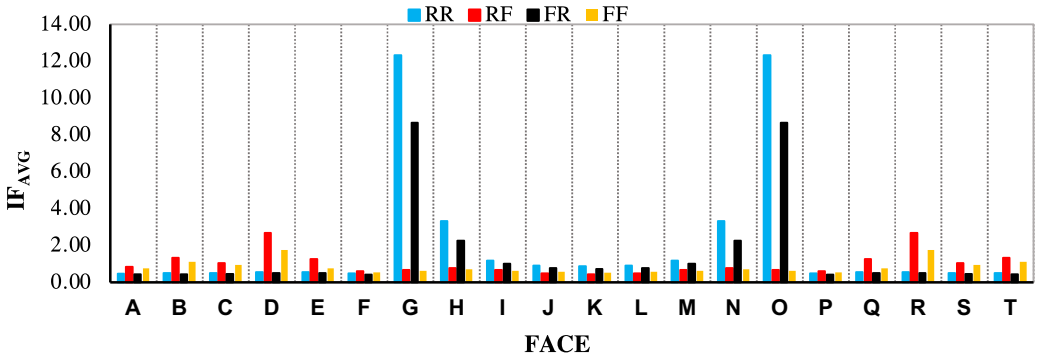
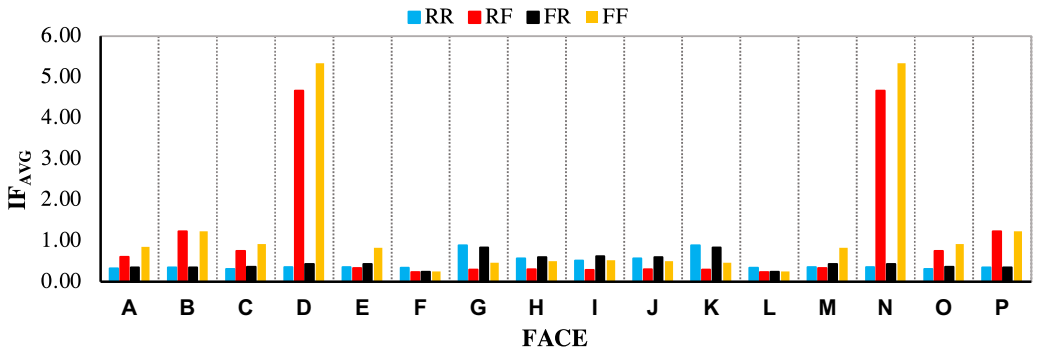
Figure. 11 shows comparison between the IF of M-1 to M-2 for similar interference conditions. For RR and FR interference condition variation of IF's along vertical centerline is almost similar for both the models with appreciable change in the magnitude. For RR condition the magnitude of IF for M-1 (maximum 0.50) is higher as compared to M-2 (maximum 0.35) which shows large reduction in IF for M-2 as compared to M-1. For FR a similar variation can be observed between magnitudes of IF's for M-1 (maximum 0.48) as compared to M-2 (maximum 0.37). At RF and FF interference condition a noticeable decrease to the Cp (IF<1) on the principal building is observed due to interference effect created by the presence and orientation of interfering building. In RF interference condition magnitude of IF M-1 (maximum -0.72) is higher as compared to M-2 (maximum -0.51) which shows large reduction in Cp for M-1 as compared to M-2. However, the variation of IF's for M-1 and M-2 at FF blockage condition have no similarity with large variation of Cp along the centerline of Face-A. The orientation of the interfering and the principal building models are playing vital role in the magnitudes of IF. The height between ½ to ⅔ of the height at the centreline of Face-A exhibits the largest influence of the obstructing model under all obstructing conditions; however, this height may vary depending on the topography.

The impact of the interfering building model is demonstrated in the following section by calculating the absolute magnitudes of Face Average Interference factors. The magnitudes of IF_{avg} are significantly more important than the magnitudes along the signs since the signs fail to accurately represent the IF and are entirely reliant on the pressure and/or suction magnitudes of C_p at isolated and interference building models.

$$\text{Face Average Interference Factor } (IF_{AVG}) = \frac{\text{Face Average } C_p \text{ for selected face in interfering condition}}{\text{Face Average } C_p \text{ for selected face in isolated condition}}$$



(a) M-1



(b) M-2

Figure 12. IF_{AVG} distribution along the periphery of (a) M-1 and (b) M-2

The wind is blowing at either 0^0 or 180^0 at both models under the interference condition, causing the models to behave symmetrically along the front Face-A. Figure 12. The highest magnitude (12.33) of IF_{AVG} is observed at symmetrical Faces G and O under the RR and FR interference circumstances of M-1. These high magnitudes are caused by the faces' depressed placements (refer to Figure 3) at the isolated wind situation at 180^0, which causes enormous oscillations to be noticed along the height of the faces. As a result, the faces' G and O face values abruptly change to 0.03 when compared to the surrounding faces. The neighboring symmetrical Faces H and N behave similarly to Faces G and O, respectively, for comparable causes. At RF and FF condition of M-2 model high the wind is flowing at 0^0 as similar to is to isolated wind condition. The symmetrical face pairs Face- D and N shows high magnitudes (4.67) of IF_{AVG} due to its depressed positions and large disturbances at isolated condition to 0^0 wind incidence and thus making the Face values very abrupt as compared to nearby face. In all the interference conditions the face value magnitudes doesn't show abrupt changes and are under wake region throughout.

4. Conclusions

This study emphasizes to find correlation between the effects of wind incidence on two distinct plan shape tall building models. The experiment has been carried out by creating Terrain Category

2 (IS: 875- Part-3 (2015), under a constant flow with the wind velocity of 10 m/sec. The plan area for Model-1 and Model-2 is kept same, as 40000mm². The effects of various wind incidences and also various blockage conditions between twin buildings has been studied separately at the nib Model-1 and Model-2 of i.e., Face-A through experimental setup within BLWT. A comparison study of mean pressure coefficients and interference factor along the vertical centreline between Model-1 and Model-2 has been carried out. For isolated conditions, wind angle is varied from 0° to 180° (at an interval of 30°) and for interference conditions, four different orientations between the twin buildings were used as RR, RF, FR, and FF. The conclusions drawn from the experimental results are as follows.

1. Experimental results of wind pressure coefficients of Model-1 and Model-2 shows good agreement with various wind incidence conditions with minute difference in the magnitudes of Cp. However, large difference is observed between both the models for 60° wind incidence condition where, the nature of pressure is changing throughout the vertical centerline of the models.
2. For both the model negative pressure is observed for all interference conditions due to presence of interfering model.
3. In Model-1 and Model-2, when the principal models are faced front irrespective of the orientation of interfering models, high suction is developed between both the twin models as compared to rear-facing principal models where, flow separation is taking place.
4. Among all the interference conditions the /Cp variation is seen between ½ to ⅔ of the height at the centerline of Face-A
5. At the interference condition the face average magnitudes at Model-1 is dominated by the orientation of interfering models; whereas that in Model-2 is dominated by the orientation of the principal model.
6. At all the conditions it is observed that the wind is getting trapped between ground and 10mm height of the model whereas, upwash is seen at 590mm height of the model.
7. On the basis of wind tunnel studies, it can be distinguished that the performance of Model-2 is better than Model-1 in both isolated as well as interference conditions for all wind incidences and orientations respectively.

CDME-GAT: Context-Aware Depression Detection Using Multiembedding and Graph Attention Networks in Social Media Text

Minni Jain, *Member, IEEE*, Siddh Jain, Amita Jain, and Bhavuk Garg

***Abstract*—Depression, a prevalent mental health concern, requires timely identification and intervention. Automating the early stage identification of depression cues within social media text has become critically important. Existing methods for depression identification through text obtained from social media have shown promising results; however, these methods do not address the graphlike nature of social media data. To date, there has been little work addressing this problem by appropriately modeling social media data. This article aims to effectively harness the power of multiembedding techniques and graph attention networks (GATs) for depression identification. To overcome these limitations, the current study presents a novel methodology that combines multiple token-level embeddings, including BERT, RoBERTa, and DeBERTa, with GATs to leverage the graphlike nature of social media data and detect depression cues from such text. A dataset comprising 100 000 tweets has been curated using data from publicly available annotated tweet datasets. This dataset maintains a balanced distribution between depressive and nondepressive text samples. This was followed by a rigorous cleaning and preprocessing pipeline. Next, these data were transformed into a numeric feature matrix using multiple-word embeddings, which enabled the treatment of tweets as nodes in a graphlike structure. This graph was used for training a GAT model with multiple self-attentional layers, culminating in a linear layer for mapping traits to binary classes. The model presented in the current study achieves a precision of 97.2%, a recall of 96.4%, and an F1 score of 96.7% on a benchmark dataset.**

***Index Terms*—Depression detection, graph attention network (GAT), graph inference, mental health assessment, multiembedding.**

I. Introduction

DEPRESSION is a common mental disorder marked by loss of pleasure or interest in activities for long periods. As reported by the World Health Organization (WHO), an estimated 3.8% of the population experiences depression, including 5% of adults (4% among men and 6% among women), and 5.7% of adults older than 60 years; approximately 280 million people in the world have depression[1]; life events such as loss, childhood adversity, and unemployment contribute to the development of depression; and this has yielded repercussions spanning the social, economic, and health domains.

Depression among women is about 50% more common than among men. Worldwide, more than 10% of pregnant women and those who have just given birth experience depression [1]. Although there are known, effective treatments for mental disorders, more than 75% of people in low and middle-income countries receive no treatment [2]. Access to quality mental health care faces obstacles globally, including a lack of funding, a shortage of adequately trained healthcare professionals, and the social stigma attached to mental disorders. Current circumstances have raised the urgency of early depression identification and preemptive measures to extend support to those affected. In today's world of social media, people resort to sharing their lives on digital platforms. This data can be analyzed to find precious insights into the mental state of individuals. Thus, analyzing text available on social media has emerged as a promising approach for early depression detection and proactive mental health care.

The current study presents a comprehensive investigation into depression detection through textual analysis of social media data using graph attention networks (GATs). GATs, a class of neural networks, have showcased remarkable prowess in capturing dependencies intrinsic to graphlike structures [3]. They accurately encapsulate interactions among neighboring nodes, thus presenting an enriched contextual comprehension of the data. Contrasted against conventional models such as LSTM [4] and CNNs [5], proven to excel in sequential and gridlike formations, GATs wield a distinctive edge in handling the graphlike nature of social media data. By leveraging masked self-attentional layers, GATs can incorporate graph topology and capture relational information efficiently. This is particularly valuable for text classification tasks that require an adept understanding of the context and semantics of a given text.

Beyond the model architecture, this article addresses critical aspects such as selecting an optimization algorithm and using multiple-word embeddings instead of just one for feature extraction. The current study proposes an ensemble method for the embeddings generated by pretrained language models (PLMs) such as BERT [6], RoBERTa [7], and DeBERTa [8] for formulating a feature matrix, which helps capture various aspects of the textual data.

Furthermore, the article presents a comprehensive text preprocessing pipeline to ensure dataset quality and enhance model performance. This pipeline spans data collection, text cleaning, stemming, and length-based filtering among other methods, collectively weaving a balanced and refined dataset. Thus, the biases and noise in the data are mitigated, ensuring the model's robustness and generalization capabilities.

Contributions:

1) The current study leverages an extensive dataset of around 100 000 social media posts, which helps broaden the scope of the research.
2) Introducing an efficient method for constructing feature matrix-based graphs, valuable for modeling complex textual relationships.
3) Using GATs for precise depression detection in social media text, capitalizing on attention mechanisms and graph-based representations to focus on important words.
4) The proposed approach represents an advancement over the current state-of-the-art methods in depression detection through textual sequences.

Further sections are as follows. Section II casts a spotlight on related work in the fields of depression detection and social media analysis. Section III details the proposed methodology, covering the dataset, preprocessing techniques, model architecture, and model training. Section IV includes experimental setup and evaluation of time complexity and outcomes, with result analysis and comparison with baselines following in Section V. Finally, Section VI concludes the study, highlighting the contributions, limitations, and pathways for forthcoming research works in this area.

II. Related Works

The increased use of social media in the last decade has paved the way for new opportunities to access and analyze user-generated content. However, the vast amount of data generated online and the sensitivity of mental-health conditions calls for leveraging natural language processing (NLP) to automate mental health analysis for early detection and prevention of depression and stress.

In the initial phases of research, statistical attributes were used, which were then integrated into established machine learning methods, as demonstrated by Castillo-Sánchez et al. [9], involved the adoption of well-known techniques such as SVM, random forest, and logistic regression, and employed to detect conditions pertinent to mental health.

Recent advancements in mental-health-related tasks have demonstrated notable progress by utilizing deep-learning models to capture semantic information [11], [12], [13], [14].

Furthermore, the integration of attention mechanisms underscores how they effectively make models to focus on the most significant part of the input [13], [15], [16], [17], [18].

PLMs such as BERT, detailed by Haque et al. [19], and RoBERTa, exemplified by Murarka et al. [20], play a pivotal role in identifying various mental health concerns. These models harness their adept contextual modeling capabilities to provide substantial insights. In a noteworthy study, Ji et al. [22] curated a comprehensive dataset from social media platforms and utilized pretrained BERT to post-train a domain-specific model called MentalBERT, which demonstrated improved performance across multiple depression detection datasets.

Graph-based neural networks, such as graph convolutional networks (GCNs) [23] and GATs [3], excel in social media text analysis due to their capacity to capture relationships, context, and interactions within interconnected data [24].

Ensemble learning, a technique combining multiple models, enhances predictive performance while reducing variance, bias, and noise in data analysis [25], [26], [27].

Table I summarizes the contributions of some notable studies in this field.

Previous studies have predominantly focused on detecting depression in social media text using individual PLMs or deep-learning methods such as LSTMs and GCNs [23]. However, these studies have often been constrained by small datasets, limiting their applicability considering the vast volume of data generated online every second. In contrast, the current study leverages a comprehensive dataset of 100 000 tweets, significantly broadening the research scope. Additionally, we employ an ensemble of multiple PLMs to construct the feature matrix for the texts, facilitating the incorporation of richer semantic information and enhancing model performance. The current study introduces an innovative and effective approach for graph construction from the feature matrix, enabling accurate modeling of the inherent graphlike nature of social media data. By utilizing GATs [3] for data modeling and depression detection, our study surpasses the limitations of existing methods and offers a more robust solution.

III. Proposed Methodology

The primary objective of the proposed research work is to detect depression, from public posts collected from social media, particularly Twitter. We have a sample set $\{U_i, V_i\}$ in which $i \in [1,N]$, where each of the posts U_i is labeled with a label $V_i \in \{0, 1\}$, and N is the size of the dataset. The goal is to search for potential indicators of depression in every post U_i and accordingly label it as depressive (indicated by "1") or nondepressive (indicated by "0"). Therefore, the challenge at hand can be defined as a binary text classification problem. Here, a function (P) with model parameters γ is developed

to classify each post (text sample) U_i into the correct label V_i, shown as follows:

$$\text{argmax } \gamma \prod_{i=1}^{N} P(V_i \mid U_i, \gamma).$$

Prior to delving into the subsequent sections, it is important to address some preliminary topics pertinent to the subject matter of this research article.

A. Preliminary

NLP involves using computers to perform various tasks related to understanding and analyzing human language. There are several state-of-the-art models capable of processing natural language text. These models can analyze large volumes of complex textual data to extract valuable insights.

1) Context-Aware Word Embeddings: The development of context-aware word embeddings has significantly advanced the field of NLP. This evolution is exemplified by the progression from BERT [6] to RoBERTa [7] and ultimately to DeBERTa [8], each introducing novel techniques to enhance language understanding and performance across various NLP tasks.

Introduced by Google AI researchers in 2018, bidirectional encoder representations from transformers (BERTs) revolutionized NLP by capturing contextual information from both left and right contexts. Trained on extensive corpora such as the Toronto Book Corpus and Wikipedia, BERT employs bidirectional transformers and pretraining objectives such as masked language modeling and next-sentence prediction. Its ability to capture nuanced relationships between words has led to remarkable performance in tasks such as text classification and question answering.

Following BERT's success, Facebook AI introduced RoBERTa in 2019 with a focus on refining pretraining methodologies. By increasing model size, utilizing dynamic masking, and removing the next-sentence prediction task, RoBERTa achieves improved representations and better generalization in downstream tasks. Furthermore, RoBERTa adopts a larger byte pair encoding (BPE) vocabulary, enabling it to handle a broader range of subword units and rare words more effectively.

In 2020, Microsoft Research introduced DeBERTa, which builds upon RoBERTa's advancements and further refines word order modeling and sentence coherence. By incorporating disentangled attention and an enhanced mask decoder, DeBERTa allows for more granular analysis of token relationships, capturing complex linguistic structures more accurately. Additionally, DeBERTa incorporates relative position bias in self-attention and parameter sharing across layers, resulting in superior performance, particularly in scenarios with limited training data or resource constraints.

2) GATs: GATs, a subset of graph neural networks (GNNs), have garnered attention for their adeptness in generating robust representations for NLP tasks. Introduced by Veličković et al. [3], GATs employ masked self-attentional layers to effectively weigh information from neighboring nodes in a graph. This enables GATs to learn intricate patterns and relationships within graph-structured data, proving valuable for tasks involving graphlike data, such as social media networks. Unlike traditional neural networks, which assume fixed-size vector inputs and struggle with graph-structured data, GNNs excel in differentiating, identifying, and establishing relationships between words and phrases.

An overview of the proposed methodology has been provided in Fig. 1. The method begins with (a) data collection and dataset structuring followed by (b) data preprocessing. Then, (c) the input text is subjected to multiple text encoders, which facilitate

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 01,2024 at 04:51:56 UTC from IEEE Xplore. Restrictions apply.

This article has been accepted for inclusion in a future issue of this journal. Content is final as presented, with the exception of pagination.

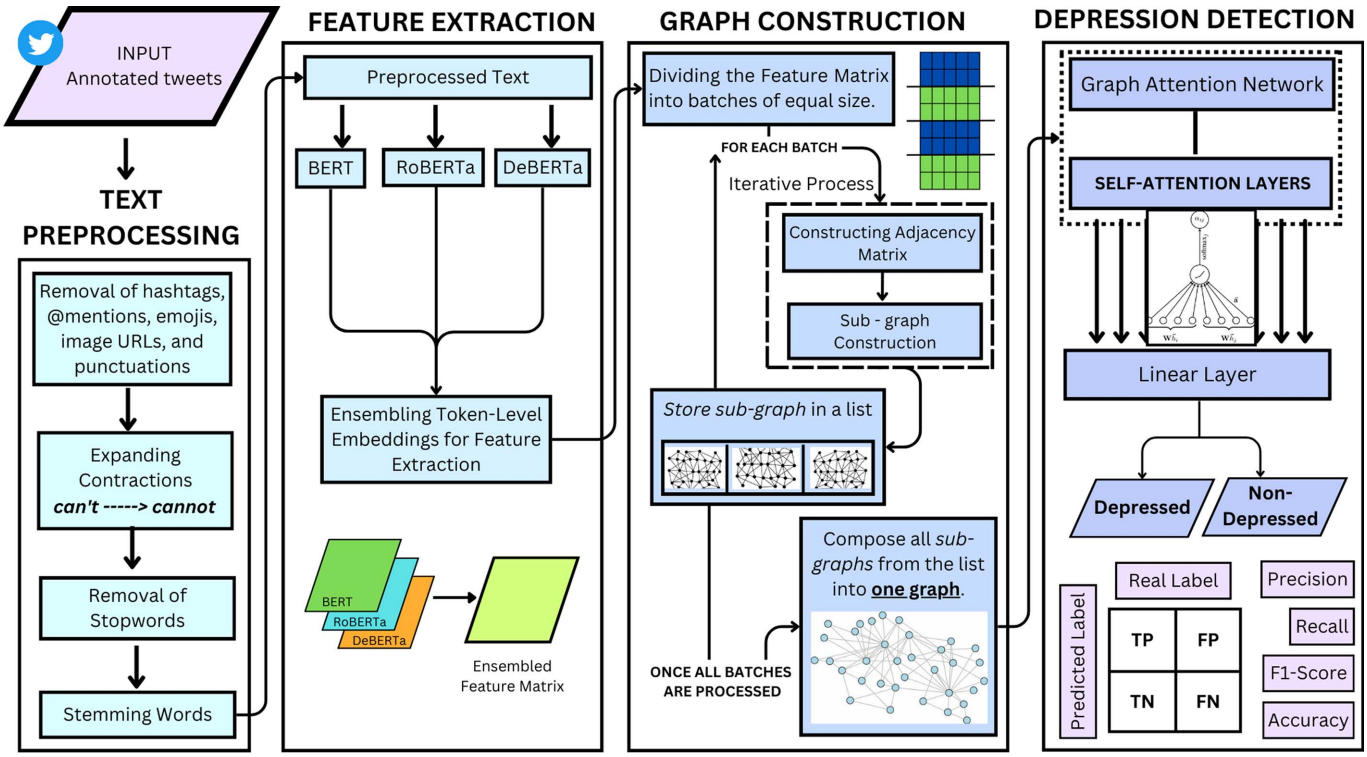

Fig. 1. Overall architecture of proposed methodology.

the generation of word embeddings for deeper language comprehension. The (d) embeddings thus obtained are stacked to create a 3-D feature representation which is then (e) adjusted back to 2-D by fusion along the z-axis. Further, (f) the feature matrix is transformed into a graph, (g) which is then used to train the classification model. Further sections discuss these steps in detail.

A. Dataset Preparation

1) Data Collection: The data largely include Twitter posts. Additionally, some open-source datasets such as Sentiment 140, which contains tweets classified as positive, negative, and neutral, have also been incorporated. While it is always intended to ensure the credibility and quality of the data sources, it is important to note that the verification process mainly pertains to the dataset itself rather than individual posts or statements within the dataset. Table II provides a comprehensive overview of the datasets that contribute to the final dataset utilized in this study, along with detailed descriptions of their contents.

2) Dataset Structuring: For constructing the dataset, following steps were taken. First, it was ensured that the resulting dataset has equal number of posts of both labels, i.e., for a dataset of size N, $N/2$ posts should be the ones labeled as "depressive" and $N/2$ posts should be labeled as "nondepressive."

Consider the set of depressed posts $X = \{X_1, X_2, X_3, \ldots, X_n\}$ and the set of nondepressed posts $Y = \{Y_1, Y_2, Y_3, \ldots, Y_n\}$, where $n = N/2$. Afterwards, these N posts are arranged alternatively to construct the final dataset. This approach ensures an equal number of posts of each class belonging to training, testing, and validation sets cutout from this dataset, thus avoiding

TABLE II
DATASET DESCRIPTION

Dataset Name	Source Datasets	Dataset Size	Content Details
Depressive Tweets Mega Dataset	I am diagnosed with depression [38]	58	Tweets with the theme that the author has been diagnosed with depression.
	I am fighting depression [38]	80	Tweets with the theme that the author is fighting depression.
	I suffer from depression [38]	554	Tweets with the theme that the author is suffering from depression.
	Tweetdata.txt [39]	160 454	Text file containing a large repository of tweets that sound depressed.
	Depressive_ tweets_ processed [40]	2323	Comprises tweets that have been labeled as depressed.
Random Tweets Dataset	Sentiment140 [41]	200 000	1 600 000 annotated tweets extracted using the twitter API. 200 000 tweets were randomly selected from this dataset.
Final Dataset	Depressive Tweets Mega Dataset	50 000	50 000 tweets selected at random from this dataset containing 163 469 tweets labeled as depressed.
	Random Tweets Dataset	50 000	50 000 tweets which did not suggest depression, were selected at random from this dataset

any kind of class imbalance at any point in the dataset. Hence, the final dataset of posts $U = \{U_1, U_2, U_3, \ldots, U_N\}$, is constructed such that

$$U = \{X_1, \quad Y_1, \quad X_2, \quad Y_2, \quad X_3, \quad Y_3, \quad \ldots, X_n, \quad Y_n\}.$$

B. Text Preprocessing

The dataset comprises text collected from social media posts, which often contain noise in the form of slang words, emojis, hashtags, and incorrect punctuation. To address this, the text undergoes cleaning through several steps. Initially, hashtags, URLs, image URLs, emojis, and @mentions to other user accounts are removed. Subsequently, punctuation marks are eliminated to further reduce noise. Contractions are then expanded to their original base form words, enhancing understanding of sentiments by the encoder and model. Finally, each post is tokenized into words using NLTK's word tokenizer. Thus, the ith post in the data $U^i = \{U^i_1, U^i_2, \ldots, U^i_{Ni}\}$, where U^i_j is the jth token of the ith post, and N_i denotes the number of tokens in U^i. Now, all the *stop words* are removed from ith post, thus, reducing the ith post to $\hat{U}^i = \{\hat{U}^i_1, \hat{U}^i_2, \ldots, \hat{U}^i_{Ki}\}$, where $\hat{U}^i_j$ is the jth token and K_i denotes the number of tokens in $\hat{U}^i$, such that $K_i \leq N_i$.

After this, each of the tokens in the post $\hat{U}^i$ is reduced to its base form using PorterStemmer. For example, the words "running" and "ran" are both reduced to "run," and the words "depression" and "depressing" are both reduced to "*depress*." Finally, all elements in the processed ith post, U^i, are rejoined, such that the final input is of the form $U^i = \{U^i_1; U^i_2; \ldots; U^i_{Ni}\}$, where ";" denotes concatenation and N_i denotes the number of tokens in the ith post. This concludes the text-cleaning process and M cleaned posts are obtained.

C. Context-Aware Text Encoder

PLMs have transformed NLP by excelling in comprehending and generating humanlike text, leveraging extensive training on diverse textual data. They offer numerous advantages in text modeling, including contextual understanding facilitating interactions across lengthy sequences. Additionally, PLMs integrate semantic information and pretraining knowledge, enhancing sentence-level representations. Their adaptability and efficiency in handling language nuances, along with the ability to capture intricate linguistic structures, further improve the modeling process. However, for more fine-grained representations, it is better to consider not one but multiple such sentence encoders, each with its specific properties, to capture the semantics of the text from various viewpoints. Hence, the current study follows this approach of using multiple context-aware text encoders, BERT [6], RoBERTa [7], and DeBERTa [8] to obtain token-level embeddings.

The input representations are obtained through each encoder using E layers of the transformer with the preprocessed input U_i. This process can be denoted as $X_i = \text{encoder}_k(U_i, E)$ where $X_i \in R^N \times D_h$ denotes the outputs of the Eth layer of the kth text encoder, encoder_k. Here, R is the set of real numbers, N denotes the length of the sequence, and D_h is the hidden dimension of the kth text encoder.

D. Ensemble of Token-Level Embeddings for Feature Extraction

The embeddings for every encoder are obtained as a matrix of dimensions $M \times D_h$ where M is the number of posts in the dataset and D_h is the hidden dimension of the encoder. For uniformity, the value of D_h for all three encoders is ensured as equal. For k encoders, we obtain k matrices of dimensions $M \times D_h$ and stack them along a third axis to obtain a new 3-D matrix of size $M \times D_h \times k$. This matrix is then flattened by compressing the values across the newly introduced dimension by average pooling, as shown in Fig. 2. This process yields a matrix of context-aware token-level embeddings of dimensions $M \times D_h$, where M is the number of posts in the dataset and D_h is the hidden dimension of the encoders. The matrix thus obtained is the feature matrix.

E. Graphical Modeling of Textual Data through Batch Processing

This section emphasizes the creation of a graph from extracted features. The primary goal is to depict relationships between data points (posts) as edges in a graph, with nodes representing the data points. To construct the graph, the first step involves creating the adjacency matrix, a square matrix used to represent a finite graph. Each element within the matrix indicates whether pairs of vertices in the graph are adjacent.

For constructing the adjacency matrix, we obtain a dot product of the feature matrix with its transpose. Thus, for a dataset having M posts, the dimensions of the adjacency matrix will be $M \times M$. In the resulting adjacency matrix, a row is in the format $X^i = \{W^i_1, W^i_2, W^i_3, \ldots, W^i_M\}$, where X^i denotes ith post and W^i_j denotes the weight of the edge between X^i and X^j. The weight indicates the strength or significance of the relationship between the posts. Due to the potentially large size of the dataset, directly constructing a graph from the adjacency matrix may not be feasible due to space and time constraints. Hence, the current study adopts a novel approach to overcome this obstacle and construct graphs efficiently. Algorithm 1 guides the processing of the feature matrix in batches, with each batch containing C posts. For each batch, an adjacency matrix is constructed, leading to the formation of a distinct graph known as a "*subgraph*."

A detailed explanation of the construction of subgraphs has been provided as follows. Consider a feature matrix of dimensions $M \times D_h$, where M is the number of posts and D_h is the hidden dimension of the encoder. Every batch of the feature matrix of dimensions $C \times D_h$ is processed to construct a subgraph. So, for every batch of C posts, the batch adjacency matrix is obtained as the dot product of the batch feature matrix and its transpose, thus resulting in a batch adjacency matrix of dimensions $C \times C$. Each row of this matrix is of the form, $X^i = \{W^i_1, W^i_2, W^i_3, \ldots, W^i_C\}$, where X^i denotes ith post of that batch and W^i_j represents the weight of the edge between X^i and X^j. A graph constructed from this batch adjacency matrix using the *NetworkX* library is the subgraph. We iterate over the feature matrix

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 01,2024 at 04:51:56 UTC from IEEE Xplore. Restrictions apply.

This article has been accepted for inclusion in a future issue of this journal. Content is final as presented, with the exception of pagination.

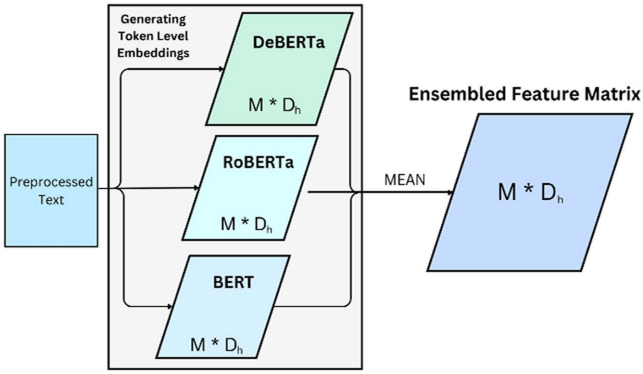

Fig. 2. Ensemble of token-level embeddings.

in batches, constructing subgraphs for each batch. This process continues until all data points have been processed, resulting in *M/C* subgraphs. Each subgraph obtained after processing a batch is stored in a listlike data structure for future access. This allows for efficient memory management and access to individual subgraphs as needed.

In the concluding step, all subgraphs are combined into a unified graph. The composition involves a straightforward union of both node sets and edge sets. It is worth noting that the node sets of the input graphs do not necessarily have to be disjoint. Additionally, attributes of the graph, its edges, and nodes are propagated to this union graph. Hence, we obtain a graph of M vertices and $M \times M$ edges.

F. Attention-Based Supervised Learning Model for Depression Detection

After constructing the graph, the "*edge index*," which is a tensor detailing the edge connectivity information of the graph, is obtained. It is usually a tensor of shape *(2, num edges)*, where each column contains a pair of node indices (source and target) that define an edge in the graph. Here, "*num edges*" stands for the number of edges in the graph. This tensor specifies how nodes are connected.

Next, the dataset splits into training, validation, and testing datasets. To create these sets, "masks" are used, which are binary arrays that specify which data points belong to each set. These masks help to ensure control over how data split and prevent data leakage (i.e., ensuring that data used for validation and testing are not inadvertently included in the training set). Also, separate tensors are used for the node feature matrix and the target labels, which are used to create the "data" object for representing graph data.

1) Model Overview: GATs [3] are employed for training due to their robust representations and learning capabilities, particularly notable in applications such as recommendation systems, NLP, and healthcare. Given the graph-natured data from social media, these models are particularly well suited for such datasets. In GCNs [23], every neighboring node has the same importance. This should not be the case since some nodes are more essential than others. GATs offer a solution to this problem by leveraging masked self-attentional layers. To consider the importance of each neighbor, an attention mechanism assigns a weighting factor to every connection. In this way, the model addresses several key challenges of spectral-based graph neural networks simultaneously.

The current study uses multiple self-attentional layers instead of just one which helps the increase model capacity to capture intricate graph patterns and relationships, enabling the GAT to learn hierarchical representations of the graph and promote better modeling of extracted features. As proposed by Veličković et al. [3], through their article, GATs [3], the model working is detailed as follows. Each attention layer in the graph has an input set of node features $v = \{v_1, v_2, \ldots, v_N\}$ where $v_i \varepsilon R^G$, where N denotes the number of nodes and G is the number of features in each node. The output is a new set of node features $v' = \{v'_1, v'_2, \ldots, v'_N\}$, $v'_i \varepsilon R^{G'}$, where G' is the updated cardinality value.

The process is initialized with each node undergoing a linear transformation, enhancing its expressive capabilities to elevate input features into higher level representations. Subsequently, the model engages in self-attention across nodes, employing a shared attentional mechanism denoted as a: $R^{F'} \times R^{F'} \rightarrow R$ to calculate attention coefficients, $c_{ij} = a\,(Wh_i, Wh_j)$, that indicate the importance of node j's features to node i. Hence, the model "allows every node to attend on every other node, dropping all the structural information." Notably, the computation of c_{ij} is confined to all the nodes j within the neighborhood of node i, achieved through the implementation of masked attention to incorporate the graph structure into the mechanism.

2) Model Training: The training process starts by initializing the GAT [3] model class. The model is initialized with the number of nodes in the input graph, which is determined by the shape of the feature matrix, and the number of classes, which is set to *2* for binary classification tasks. The Adam [32] optimizer is used as the optimization algorithm. We define the cross-entropy loss [34] as the loss function to measure the difference between predicted and true class labels.

The model is trained by iterating through multiple epochs, as described in Algorithm 1. In every epoch, the model is first set to training mode to enable dropout and batch normalization layers to operate differently compared to the evaluation phase. Then, the gradients of the optimizer are reset to zero before computing gradients in each iteration. Next, the input features and graph edge indices are passed to the GAT [3] model to obtain node embeddings (h) and class predictions (z). The loss in each iteration is computed by comparing the predicted class labels (z) with the true labels *(data.y)* only for the training nodes, as indicated by the "train_mask." The training and validation accuracies are calculated by comparing the model's predictions with the ground truth labels, considering only the respective subsets of nodes ("train_mask" and "val_mask").

Finally, the loss gradients are computed with respect to the model's parameters, and these weights are updated using the optimizer's update rule. Upon completing all epochs, the trained GAT model is returned for prediction on new data or further analysis. Model performance is assessed on the test data to analyze the effects of hyperparameters such as learning rate, number of epochs, and self-attentional layers on the results.

Algorithm 1 CDME-GAT

Input: Tweets (posts from twitter)
Output: Classification of the tweet (depressive or nondepressive)

1. Read the dataset and perform text-preprocessing.
2. Obtain token-level word embeddings using BERT, RoBERTa, and DeBERTa.
   $X_i = encoder_k(U_i, E),\ X_i \in R^N \times D_h$
3. Ensemble the word embeddings to form the feature matrix. (F_m)
4. Divide the feature matrix into batches and create a list.
5. For each batch B_i of dimensions $C \times D_h$, where C is the number of posts per batch and D_h is the hidden dimension of the encoders:
   I. Construct the adjacency matrix (A_m) of dimensions $C \times C$:
   $A_m = (F_m).(F_m{}^T)$
   II. Construct a subgraph (G_{sub}) and store it in the graph list (L_G)
   $G_{sub} = Graph(A_m)$
   $L_G.append(G_{sub})$
6. Compose all the *subgraphs* in the list to form a single graph (G) representing token-level relationships.
   $G = compose_all(L_G)$
7. Obtain the edge index (E_{ix}) of the graph.
8. Split the dataset into train, validation, and test datasets.
9. Create train, validation, and test masks as *"train_mask,"* *"val_mask,"* and *"test_mask,"* respectively.
10. Create separate tensors x and y for storing the features associated with each node in the graph and labels associated with each node.
    $x = tensor(F_m, dtype = float)$
    $y = tensor(df['label'], dtype = long)$
11. Create a "Data" object for representing the graph data.
    $data = Data(x = x, edge_index = E_{ix}, y = y)$
12. Define a custom accuracy function which calculates accuracy as a percentage of the correctly predicted instances.
13. Initialize the GAT model class.
    $model = GAT(num_nodes = F_m.shape[1], num_classes = 2)$
14. Initialize the optimizer (O) and the loss function (L_F).
    $O = Adam(model.parameters(), lr = 0.01)$
    $L_F = CrossEntropyLoss()$
15. For each training epoch
    I. Set the model in training mode.
    II. Zero out the gradients of the optimizer.
    III. Compute node embeddings (h) and predictions (z) using the GAT model.
    IV. Calculate the loss using specified criterion, considering only the training nodes:
    V. Calculate the training and validation accuracies using the custom accuracy function defined in step 11:
    VI. Backpropagate the gradients through the GAT model.
    VII. Update the model's parameters using the optimizer
16. Return the trained GAT model.

IV. Experimentation Setup, Time Complexity and Results

This section details the experimental setup for the presented work. Various metrics such as test accuracy, precision, recall and F1 score are considered to evaluate the model performance. These metrics help to get a deeper idea of how well the model performs under different experimental settings. The current study considers the macroaverage F1 score for the ablation study and performance comparison with other baselines, which calculates metrics for each label and finds their unweighted mean. Since there is no class imbalance in the dataset considered, the macroaverage and weighted average F1 scores would be equal here.

A. Experimental Configurations

In this section, we have discussed the experimentation performed to observe the effect of various hyperparameters on model performance. The text-preprocessing methods, as detailed in Section III-B, involved several essential steps to ensure dataset quality and enhance the performance of our text classification model. A balanced, cleaned dataset of 100 000 texts was prepared through this preprocessing pipeline, focusing on relevant content and equal representation of depressed and nondepressed samples. 60% of the dataset was used for training the model, and the remainder was equally split for validation and testing of the model performance.

Experiments with different embeddings and ensembles, listed in Tables III and IV, informed the feature matrix selection. For the proposed model, an ensemble of the matrices obtained from BERT [6], RoBERTa [7], and DeBERTa [8] was used. We have experimented with two models, GCNs [23] and GATs [3].

For optimization of the GCN [23] model, adaptive moment estimation with weight decay (AdamW) [33] was used, which is an optimization algorithm that builds upon the Adam [32] optimizer. It helps stabilize the optimization process and can lead to better generalization of performance. However, for the GAT [3] model, which uses self-attentional layers, Adam proved to be better at optimization than AdamW. Hence, it was concluded, that the effectiveness of the optimization algorithm depends on the specific dataset, problem, and architecture. Final model configuration, detailed in Section IV-C, includes a single GAT layer with multiple masked self-attentional layers and a Linear layer projecting outcomes into depressive and nondepressive categories.

B. Time Complexity

This section elaborates on the assessment of the asymptotic time complexity of the proposed approach. The approach is segmented into five phases, and the time complexity of each phase is determined based on Algorithm 1.

1) Text Preprocessing: The time complexity for text preprocessing is determined as $O(N * (n * (1 + 8 * k) + m))$, where N is the total number of tweets, n is the average length of tweets, k is the average word length, and m is the average number of words per tweet.

2) Feature Extraction: The feature extraction phase is characterized by a time complexity of $O(N * (n + D_h))$, where N is

TABLE III
CDME-GCN—EXPERIMENTAL AND ABLATION STUDY RESULTS

Exp. No.	Embeddings and Experimental Settings	Test Acc.	P	R	F1
1	Word2Vec + Glove + FastText (AdamW lr = 0.01, weight decay = 0.04, 800 epochs)	91.95	93.38	90.29	91.80
2	Glove + FastText (AdamW lr = 0.01, weight decay = 0.04, 800 epochs)	92.17	94.30	89.77	91.98
3	**BERT + RoBERTa +DeBERTa (AdamW lr = 0.01, weight decay = 0.04, 500 epochs)**	**93.99**	**95.05**	**92.97**	**94.01**
4	BERT + RoBERTa +DeBERTa (AdamW lr = 0.01, weight decay = 0.04, 800 epochs)	93.84	94.79	92.84	93.89

Note: Exp. No.: experiment number, Test Acc.: test accuracy, P: precision, R: recall, F1: F1 score, lr: learning rate. The bold entries correspond to the experimental configurations delivering superior results for the models CDME-GCN and CDME-GAT, respectively.

the total number of tweets, n is the average length of tweets, and D_h is the hidden dimension of the encoders.

3) Graph Construction: The time complexity of the graph construction phase is expressed as $O(N * c^2)$, where N is the total number of tweets and c is the size of the submatrix or batch size.

4) Calculation of Edge-Indices: The time complexity for calculating edge indices is $O(E)$, where E is the number of edges in the graph.

5) Model Training: Model training exhibits a time complexity of $O(E * D_h)$, where E is the number of edges in the graph and D_h is the hidden dimension of the encoder which is also the number of features representing each node of the graph.

Combining the individual time complexities of all phases of the proposed approach, we get the final asymptotic time complexity as

$$O(E * D_h + N * (n * (1+8 * k) + m + c^2)).$$

C. Experimental Results Analysis and Ablation Study

Details of our extensive work and results across various experimental configurations are presented in Tables III and IV. We first trained a GCN [23] model with Word2Vec [35], Glove [36], and FastText [37] embeddings, all of which have $D_h = 512$. The model achieved satisfactory results on the concerned evaluation metrics. The optimizer used here is AdamW [33], and the number of training epochs is 800. The experimentation was done over a range of hyperparameter values. Despite excluding Word2Vec due to poor performance, negligible improvement was observed. With GCN [23] based model architectures, it was found that training required a higher number of epochs (in the range of 500–1000) to achieve good results on the given data. Later, we changed the embedding set and used BERT [6], RoBERTa [7], and DeBERTa [8], each of which has $D_h = 768$. It was found that the results improved for every metric by 2%–3% as we experimented with different learning rates and weight decay values. The experimental configuration yielding the best overall performance for the CDME-GCN model is highlighted in Table III.

The CDME-GCN model configuration utilized the AdamW optimizer with a weight decay of 0.04. For feature representation, BERT, RoBERTa, and DeBERTa were employed. The learning rate was set to 0.01, and the model was trained for 500 epochs. This configuration achieved an accuracy of 93.99%, precision of 95.05%, recall of 92.97%, and an F1 score of 94.01% on the test dataset.

As detailed in Table IV, extensive experimentation was conducted on the GAT [3] model, with different embedding sets across a varied range of the number of self-attentional layers. During the experimentation phase, a few points became clear. First, the GAT model outperformed the GCN model, requiring fewer training epochs for optimal results. Second, BERT, RoBERTa, and DeBERTa embeddings exhibited superior performance in representing textual data compared to Word2Vec, Glove, and FastText.

Adam proved more effective in optimizing the CDME-GAT model than AdamW, which performed well with CDME-GCN. Increasing the number of attention heads initially improved results, but eventually plateaued or declined. The optimal configuration, highlighted in Table IV, utilized 64 self-attentional layers. It employed BERT, RoBERTa, and DeBERTa embeddings, with a learning rate of 0.01 and 250 epochs. This configuration achieved an accuracy of 94.58%, precision of 96.67%, recall of 93.29%, and an F1 score of 94.36% on the test dataset. Figs. 3 and 4 illustrate the visualizations of the results obtained from the ablation study.

D. Validation of Proposed Approach Through Statistical Significance

Model validation ensures the fulfillment of the study's objectives by comparing the model's output to the output of the data-generation process. The model performance is validated through a z-test conducted on two random samples extracted from the dataset employed in the present study. In sample 1, 5120 posts were considered (N_1), of which 4655 (X_1) were correctly classified. The proportion of correctly classified tweets here is $p_1 = 0.9092$. Sample 2 comprised 4000 posts (N_2), of which 3635 (X_2) were correctly classified. So, the proportion of correctly classified tweets is $p_2 = 0.90875$.

The following set of null (H_0) and alternate (H_a) hypotheses was developed to test the model's validity.

(H_0): proportion of correctly classified tweets in both samples is the same, $p_1 = p_2$.

(H_a): proportion of correctly classified tweets differs in both samples, $p_1 \neq p_2$.

The value of the pooled proportion is calculated as

$$P = \frac{X_1 + X_2}{N_1 + N_2} = \frac{4655 + 3635}{5120 + 4000} = 0.909.$$

The z-statistic for a two-tailed test can be calculated as

$$z = \frac{p_1 - p_2}{\sqrt{P(1-P)\left(\frac{1}{N_1} + \frac{1}{N_2}\right)}} = \frac{0.9092 - 0.90875}{\sqrt{0.909 \times (0.091)\left(\frac{1}{5120} + \frac{1}{4000}\right)}} = 0.074.$$

As $|z| = 0.074 \leq z_c = 1.96$, we fail to reject the null hypothesis. Therefore, at the $\alpha = 0.05$ significance level, there is

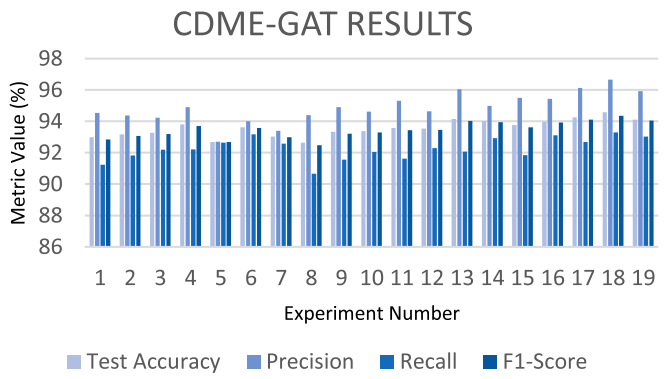

Fig. 4. Visualizing results of CDME-GAT model.

inadequate evidence to suggest a difference in the population proportions p_1 and p_2. Hence, the accuracy of the proposed model remains consistent across various sample sizes of the same dataset. Consequently, the findings of the CDME-GAT model for depression detection are deemed reliable.

V. PERFORMANCE COMPARISON

In this section, we delve into the comprehensive experimental performance of the baseline models and the proposed methods on the Depression_Mixed dataset [31]. This dataset, focused on weakly supervised depression detection, encompasses subreddits from Reddit. Each post within the dataset is categorized as either indicative of depression or not, providing a collection of monologues that detail the speaker's mental state. The evaluation is conducted across precision, recall, and F1 score metrics for a thorough comparison.

A. Overall Results

The overall experiment results of our model and the baselines are listed in Table V. An overview of this table shows that PLM-based models such as BERT [6] and RoBERTa [7] perform better than others with over 90% score across all metrics. MentalRoBERTa [22], which has implicitly infused domain-specific knowledge in this case, performs better than both BERT [6] and RoBERTa [7] but cannot match up to the performance of the proposed model. This shows the advantage of capturing the text semantics through various viewpoints by employing multiple PLMs.

The outcomes obtained from other baselines, such as logistic regression combined with features [29], and deep-learning methods such as CNN [28] and GRU [30], fall short of satisfaction. Notably, BiLSTM_Att [17], which incorporates attention mechanisms alongside Bidirectional LSTM, demonstrates superior performance, underscoring the effectiveness of attention mechanisms in addressing these challenges. KC-NET [18], leveraging mental state knowledge extracted from COMET and infusing it via GRUs, delivers robust results with an impressive 95.5% precision, 95.3% recall, and 95.4% F1 score. A more recent method introduced an ensemble model combining the Gaussian Naïve Bayes classifier and Bi-LSTM to extract contextual semantics from text using POS tagging and Word2Vec [27]. However, the results of this approach fell short of expectations.

TABLE V
MODEL PERFORMANCE COMPARISON

Methods	Description	P	R	F
BiLSTM + Naïve Bayes [27]	Ensemble model using Naïve Bayes and BiLSTM along with POS tagging and Word2Vec	75.0	70.2	68.2
GRU [30]	GRU-based model with stacked layers for binary classification. The hidden states of the final time-step are used for decoding.	84.4	84.4	84.4
CNN [28]	A three-channel convolution as the encoder. Post-level embeddings are obtained using max-pooling and features of optimized word embeddings are concatenated for decoding.	85.2	85.1	85.1
LR+Features [29]	Logistic Regression (LR) combining selected linguistic features	89.0	92.0	89.0
BERT [6]	Initialized by the pre-trained weights of BERT-base.	91.4	91.4	91.4
BiLSTM_ Att [17]	Attention mechanism is used on the output of a bidirectional LSTM network. The attended hidden states are used for decoding.	90.4	95.0	92.6
RoBERTa [7]	Initialized with the pre-trained weights of RoBERTa-base.	93.2	92.4	92.9
MentalRoBERTa [22]	Initialized from the pre-trained weights of MentalRoBERTa.	93.4	93.0	93.3
KC-Net [18]	Extracted mental state knowledge from COMET and infused it using GRUs to explicitly model the mental states of the speaker.	95.5	95.3	95.4
CDME-GCN	Ensembles multiple word embeddings and models the features on a Graph Convolutional Network.	95.3	94.3	94.8
CDME-GAT	Ensembles multiple word embeddings and models the features on a GAT.	**97.2**	**96.4**	**96.7**

Note: P: precision, R: recall, F1: F1 score.

CDME-GCN attains a noteworthy performance on the Depression_Mixed [31] dataset with 95.3% precision, 94.3% recall, and 94.8% F1 score. However, the proposed method, CDME-GAT, establishes new state-of-the-art results by surpassing the baseline PLM-based methods with a remarkable 3%–4% improvement and outperforming current state-of-the-art methods by 1%–2% across all metrics. The proposed CDME-GAT model achieves outstanding metrics of 97.2% precision, 96.4% recall, and 96.7% F1 score on this dataset, underscoring its effectiveness in handling longer sequences and intricate textual content.

VI. CONCLUSION

The current study presents CDME-GAT, a multiembedding GAT for identifying texts that suggest depression. First, the feature matrix is extracted from the token-level embeddings representing the preprocessed tweets. Then, a graph constructed from these features is used to train a GAT with multiple masked self-attentional layers. After extensive experimentation, it is concluded that the model performs best with 64 self-attentional layers, beyond which the results tend to either saturate or drop depending upon other hyperparameters such as the learning rate and optimization algorithm. The obtained traits are mapped to a binary classification by a linear layer.

Our model demonstrates improved results over current state-of-the-art methods for depression detection on a benchmark dataset. Despite this success, there remains room for enhancing model performance. The ensemble of multiple embeddings, a critical aspect of our method, could benefit from further refinement by using different pooling techniques and studying their impact on the model performance. Additionally, advancements in the model architecture specifically tailored for depression detection could yield improvements. A more comprehensive approach to model social media data with improved representations can provide superior classification results. As the field of NLP continues to evolve, we anticipate the emergence of more domain-specific PLMs that could further elevate the quality of results.

While the present study focuses on detecting depression through textual content sourced from social media, it is crucial to acknowledge that online data exists in various forms, including images, videos, audio, and more. Efforts must be made, to develop methods capable of processing multimodal data to extract valuable information and model it effectively for depression detection. Additionally, it is essential to explore methods to classify the intents or causes of depression, moving beyond mere identification for a more in-depth analysis of a patient's situation and improved treatment strategies. Notably, mental health care often lacks the attention it deserves in many places globally. We aspire that the findings of this study contribute to early stage depression detection, potentially benefiting as many individuals as possible.

Concentration of betanin from model beetroot extracts by using nanofiltration: parameter estimation and sensitivity analysis

Ashwani Kumar Tiwari and Manish Jain*

Abstract

BACKGROUND: Nowadays, research focusing on natural compounds is getting more importance across the globe. Recently, natural bioactive compounds have gained the attention of researchers as a consequence of their exemplary physicochemical properties and exceptional utility in the food and pharma industries. However, separating and concentrating these bioactive compounds from their origin sources still poses a considerable challenge to their profitable commercial usage. The current study focuses on the application of a facile nanofiltration method for recovering betanin from model beetroot extract solutions using a polyamide nanofiltration membrane. Furthermore, the three-parameter Spiegler–Kedem model was used to determine the transport parameters of the membrane and theoretically predict the performance of the membrane. Additionally, variance-based sensitivity analysis methods were deployed to study the sensitivity of different operating and membrane transport parameters.

RESULT: The results indicate that the membrane exhibited the highest rejection of 99% and permeate flux of 3.14 10^{-5} m^3 m^{-2} s^{-1} at 0.6 MPa pressure and 600 mL min^{-1} flow rate. The data obtained through the Spiegler–Kedem model were coherent with the experimental observations. Simulations on sensitivity analysis revealed that specific hydraulic permeability and cross-membrane pressure majorly influence permeate flux and rejection.

CONCLUSION: This study showed that nanofiltration with 150 Da cut-off membranes effectively concentrated betanin with 99% rejection. Higher cross-membrane pressure and higher feed flow rates were preferable operating conditions for higher rejections. Variance-based sensitivity analysis showed that cross-membrane pressure and hydraulic permeability are the most influential parameters affecting permeate flux and rejection.

Keywords: Betanin; nanofiltration; phenolic compound; NF process modeling; sensitivity analysis

INTRODUCTION

Phenolic compounds are one of the most abundant subsidiary metabolites in plants and are identified by single or more aromatic rings that contain single or multiple hydroxyl groups.[1-3] These compounds offer many human-health-related functional benefits. Phenolics exhibit physiological benefits such as anti-aging, anti-infective, anti-inflammatory and antiproliferative properties.[4-7] Betanin is one such phenolic compound. It is a water-soluble vacuolar chromo-alkaloid found in *Beta vulgaris* L, also known as beetroot and chukandar.[8] Betanin finds applications in various industries, including the food industry as a colorant and the pharmaceutical industry as an active ingredient in medicines. It is also used for coloring meat substitutes, gelatine, desserts, sausages and dairy products.

The recovery of phenolic bioactive compounds such as betanin from their natural sources is tedious owing to the high enzyme activity in most foods and plants. Therefore, the choice of extraction method must be made with the greatest caution to prevent the chemical change of the target molecules.[9] The standard method for separating and concentrating phenolic compounds is liquid–liquid extraction followed by evaporation or crystallization. Liquid–liquid extraction requires organic solvents such as chloroform, *n*-hexane, ethanol, propanol, ethyl acetate, and acetone.[10,11] These solvent-based processes are very costly, and the phenolic extracts may contain residual solvents, making them unfit or undesirable for food applications.[1]

Nanofiltration (NF) seems to be a promising technology for concentrating phenolic compounds owing to certain benefits, such as no involvement of phase transition, low energy consumption, no use of organic solvents and low waste disposal. Moreover, other biological molecules such as sugars and proteins can be easily separated from phenolic solutions, and concentration and purification steps can be combined in one step, reducing operational costs and time. Membrane-based processes can run continuously

Department of Applied Chemistry, Delhi Technological University, New Delhi, India

and are easy to scale up to the commercial level.[12] The application of NF to concentrate phenolic compounds is a relatively new concept and is still being investigated. However, only a few studies are available on using NF for the concentration of bioactive compounds.[13-20]

Arboleda Mejia *et al*.[13] investigated the rejection percentage for total phenolic content (TPC) and proanthocyanidins and found 73% and 92% rejection using four NF membranes (CA series: laboratory-prepared by phase inversion and one commercial NF90). Tonova *et al*.[14] also separated the phenolic compounds from Eurasian water milfoil hydrolysate using NP030 (MWCO of 500 Da). Giordana *et al*.[15] have concentrated the bioactive compounds from strawberry juice using a polyvinylidene difluoride NF membrane with a molar mass cut-off ranging between 150 and 300 Da. They found that the NF of natura juice has retention values >95% for the TPC. In another similar work, Carmela Conidi *et al*.[17] concentrated the phenolic compounds from orange press liquor using four different membranes: NF-70 (polyamide+polysulfone), NF-200 (poly-piperazine amide), N30F (polyethersulfone) and NFPES10 (polyethersulfone) having MWCO of 180, 300, 400 and 1000 Da, respectively. The investigations revealed that all of these NF membranes showed a high average rejection percentage towards anthocyanins (89.2–95.9%) and flavonoids (70–95.4%). In other similar works, Mello *et al*.[20] concentrated the flavonoids and phenolic compounds in aqueous and ethanolic propolis extract using NF90 membrane (polyamide and polysulfone). They found that the aqueous solution of propolis retained almost 99% flavonoids and 84% phenolic compounds. However, the retention values were reduced to 90% for flavonoids and 53% for phenolic compounds during the filtration of ethanolic solutions.

In previous studies,[13-19,21,22] the authors have only concentrated the phenolic compounds, and a detailed investigation of the membrane transport phenomenon using mathematical models was not reported. Besides this, no literature has been found on the concentration of betanin using the NF membrane. The objective of the present study is to investigate the performance of the NF membrane for the concentration of betanin and predict the transport parameters. Accurate estimation of these parameters is crucial to optimize the NF process, design the scale-up setups and predict the viability of the process in commercial-scale operations. The Spiegler–Kedem model was used to describe the transport phenomenon and validate the data. Rigorous research was also conducted to analyze the effects of various operating conditions and transport parameters through sensitivity analysis.

MATERIALS AND METHODS

Materials

Laboratory-grade betanin (molecular weight 550.47 g mol^{-1}) was bought from TCI Chemicals, Adambakkam, India. The reverse osmosis (RO) water was collected from the RO water purification machine available at Delhi Technological University, Delhi. Flat sheet NF membranes (HFT-NF 150 and HFT-NF 300) were supplied by Permionics Pvt. Ltd, Gorwa Vadodara, India.

Experimental setup and procedure

A schematic diagram depicting the laboratory-scale experimental setup prepared for NF is presented in Fig. 1. The setup contained a test cell of stainless steel for mounting the NF membrane with an active membrane area of 0.007856 m^2. The other specifications of the membrane test cell were supplied by the manufacturer and

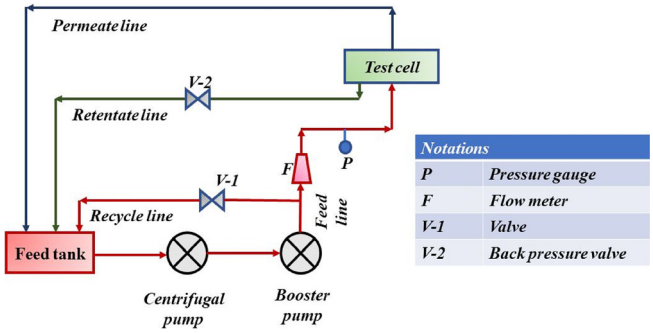

Figure 1. Block diagram of the prepared NF setup.

are mentioned in Table 1. A ¼ horsepower centrifugal pump followed by a booster pump (flow rate 100 GPD, maximum pressure 1.2 MPa) was employed for transporting the feed solution from the feed tank (capacity 10 L) to the membrane test cell. The setup also comprised a needle valve and a back pressure valve at the bypass and feed lines, which can be adjusted to control the feed stream flow rate and cross-membrane pressure. A flowmeter (rotameter of flow rate ranging from 100 to 1200 mL min^{-1}) and pressure gauge (glycerine filled 0 to 1.6 MPa) were employed to measure the feed flow rate and to maintain the hydraulic pressure, respectively. After filtration, separate tanks were used to collect the retentate and the permeate stream from the membrane test cell setup. The permeate flow rates and fluxes were determined by measuring the collected volume of permeate in the tank after a constant interval. The permeate and retentate streams were then reprocessed into the feed tank for a single constituent experiment with betanin.

Experiments were conducted at five different feed concentrations (0.1, 0.2, 0.3, 0.4, 0.5 g L^{-1}), cross-membrane pressures (0.2, 0.3, 0.4, 0.5, 0.6 MPa) and tangential flow rates (200, 300, 400, 500, 600 mL min^{-1}). The range of cross-membrane pressure was selected based on the magnitude of pure water flux and the limitations of the experimental setup. The experimental run for every dataset was performed thrice to check the accuracy of every datum. The betanin concentration in the feed and permeate solutions was determined using a UV spectrophotometer (UV-1800; Shimadzu, Kyoto, Japan) at a wavelength of 534 nm. The standard calibration curve was made using different concentration solutions ranging from 10 to 500 mg L^{-1}.

Initially, the rejection values were checked for two different membranes: HTF-NF 150 and HTF-NF 300, having molecular cut-offs of 150, and 300 Da, respectively (purchased from Permionics Pvt. Ltd). Both membranes showed significantly higher rejection values (>90%). However, the overall flux from the HTF-NF 300 membrane was considerably lower than the HTF-NF 150-membrane. Therefore, the HTF-NF 150 membrane was selected for this particular study. A comparison of the performance of HTF-NF 150 and HTF-NF 300 membranes is reported in the Supporting information (Appendix S1).

Theory

Membrane transport equations

The model given by Spiegler–Kedem can report the equations for the mass transport of permeating species inside the membrane.[23] It is a three-parameter model based on irreversible thermodynamics, which states that all forces acting on permeating species

Table 1. Specification of the test cell

Parameter	Value
Total active membrane area	0.007856 m^2
Membrane diameter	0.1 m
Channel thickness	1 mm
Feed spacer porosity	0.75
Permeate spacer porosity	0.65

are linearly correlated with all fluxes.[24] Equation (1) describes the permeate volumetric flux (J_p) across the membrane.

$$J_p = \frac{L_p}{\rho}(\Delta P - \sigma \Delta \pi) \quad (1)$$

where L_p is the hydraulic permeability, σ is the reflection coefficient, ΔP is the difference in pressure across the membrane and $\Delta\pi$ is the difference in osmotic pressure across the membrane. The linear relationship between osmotic pressure and concentration is given by Eqn (2) as

$$\pi = \alpha c = \frac{\upsilon RT}{M_w} c \quad (2)$$

where α is the constant of proportionality and c is the concentration.

The rejection defines the measure of the separation efficiency of the membrane. The actual rejection (R_j) inside the membrane at a particular point is described in Eqn (3).

$$R_j = \frac{(1-F)\sigma}{1-\sigma F} = 1 - \frac{C_p}{C_m} \quad (3)$$

where C_m and C_p are the concentrations at the membrane's surface on the feed and permeate sides, respectively. Equation (4) gives the flow parameter used in Eqn (3).

$$F = \exp\left(-J_p \frac{1-\sigma}{B_m}\right) \quad (4)$$

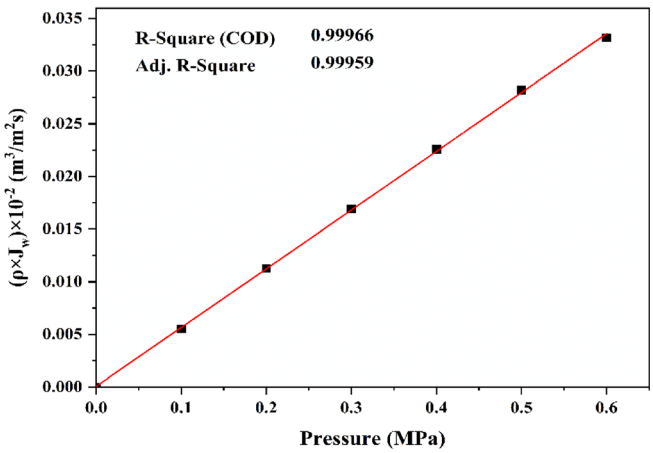

Figure 2. Pure water '$\rho \times J_w$' *versus* ΔP at a constant flow rate of 500 mL min^{-1}.

where B_m is the local solute permeability coefficient of the membrane. Now, the mathematical expression for J_p can be revised in terms of permeate and bulk variables and is given by Eqn (5).

$$J_p = \frac{L_p}{\rho}\left[\Delta P - \sigma \frac{\upsilon RT}{M_w}\phi c_b \left(\frac{(1-F)/\phi}{(1-F)/\phi + (1-\sigma)/\sigma}\right)\right] \quad (5)$$

where ϕ is the concentration polarization and is defined mathematically in Eqn (6).[25-30]

$$\phi = \frac{c_m - c_p}{c_b - c_p} = \exp\left(\frac{J_p}{k}\right) \quad (6)$$

Here, C_b is the bulk solution's solute concentration, and k defines the mass transfer coefficient and is calculated using Eqn (7).

$$k = a \times Q_f^b \quad (7)$$

where Q_f is the volumetric feed flow rate, and a and b are constant coefficients for a given system.

Parameter estimation technique

The above model contains five unknown parameters: the specific hydraulic permeability (L_p), local solute permeability coefficient (B_m), the reflection coefficient (σ) and two mass transfer coefficients (a and b). The actual values of these unknown parameters are required for theoretically evaluating the membrane performance. Values of these parameters were determined by deploying a parameter estimation method and fitting the experimental data in the transport model.[31,32] Appendix S2 represents the general algorithm for the parameter estimation.

Variance-based sensitivity analysis

It is essential to identify the most influential operating and transport parameters to identify the suitability of membranes and optimize the process by controlling the operating parameters. Global sensitivity analysis (Sobol sensitivity analysis) can be used for this purpose, which provides a detailed analysis of which parameter is more sensitive and how the interaction of different input parameters affects the output parameters.[33-35] First-order sensitivity (S) represents the sensitivity of a particular input parameter, and total sensitivity (S_T) represents the sensitivity of that parameter, including the effects of interactions with other parameters.[33-35] Thus, ($S_T - S$) represents the sensitivity effects of interactions of a particular input parameter with other input parameters. The details of the variance-based sensitivity analysis are given in Appendix S3.

RESULTS AND DISCUSSION

All of the experiments and simulations were performed using betanin model solutions with varied feed concentrations at different operating conditions. The cross-membrane pressure was changed from 0.2 to 0.6 MPa, and feed flow rates were changed from 200 to 600 mL min^{-1} at ambient temperature.

Unknown parameter estimation and model validation

Estimation of specific hydraulic permeability (L_p)

The value of L_p does not vary with the solute concentration in the feed.[23,24] Thus, L_p was determined by measuring the pure water flux values at different pressures with a fixed flow rate. Figure 2 represents the graph between the experimental value of pure

Method 2	L_p, B_m, σ, a and b optimization	26.40	2.68	7.03	1.02

Abbreviations: J_P, permeate flux; mAPE, maximum absolute percentage error; MAPE, mean absolute percentage error; R%, rejection percentage.

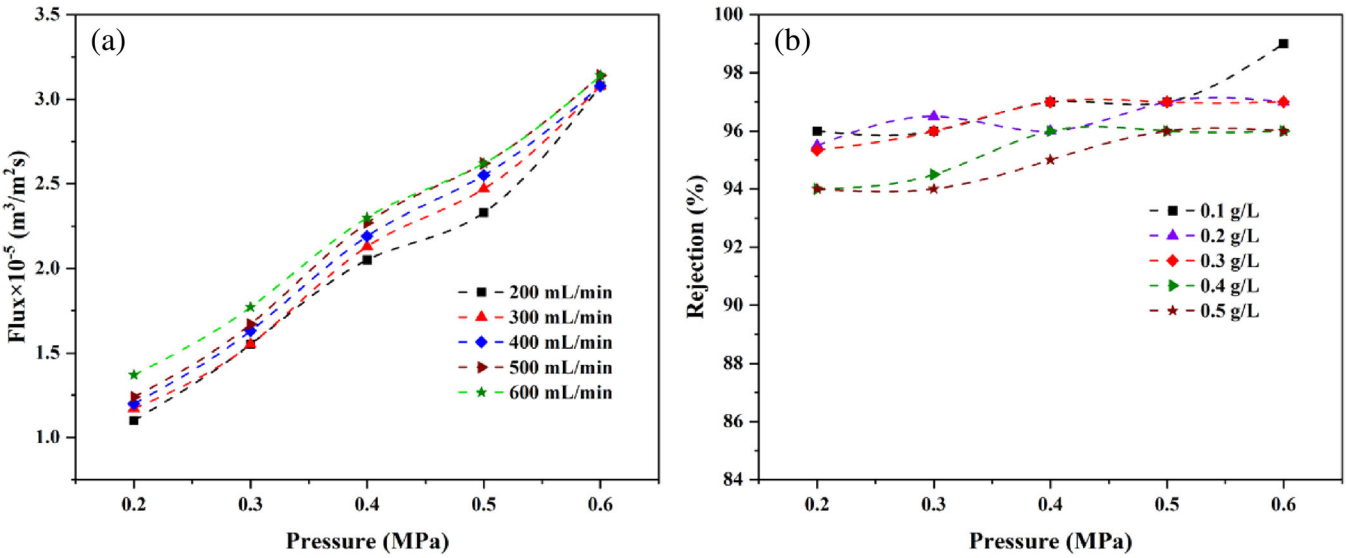

Figure 3. Influence of pressure on (a) permeate flux at a constant feed concentration of 0.1 g L^{-1} and (b) percentage rejection at a constant feed flow rate of 600 mL min^{-1}.

water 'ρ × Jw' *versus* ΔP at a constant flow rate of 500 mL min^{-1}. Experimental results were fitted in the linear equation, and the slope of the curve represents the value of L_p [Eqn (1)]. Experimentally, the value of hydraulic permeability was obtained as 5.52 × 10^{-8} kg m^{-2} s^{-1} Pa^{-1}. The above set of equations now has only four unknown parameters: B_m, σ, a and b.

Estimation of solute permeability (B_m), reflection coefficient (σ) and mass transfer coefficients (a and b)

The values of B_m, σ, and a and b were estimated using different experimental runs at various operating conditions. The cross-membrane pressure was varied from 0.2 to 0.6 MPa, and the feed concentration from 0.1 to 0.5 g L^{-1}. The temperature was maintained at 22 ± 1 °C for the experiment. Feed flow rates of 200, 300, 400, 500 and 600 mL min^{-1} were used for all sets of experimental runs.

The values of different membrane transport parameters (B_m, σ, a and b) were estimated by minimizing the overall error between the theoretical and experimental data. In this experimental work, two optimization methods have been used to analyze the variation of different model parameters on permeate flux and rejection. In the first optimization method, the value of L_p was calculated using the slope of pure water flux *versus* pressure graph. This value was then fixed for optimizing B_m, σ, a and b. The complete data points used for optimization and their model validation data are shown in Appendix S4. For this case, the mean absolute percentage errors for permeate flux and rejection were 11.06% and 1.05%, respectively. All five parameters were optimized in the second optimization method to minimize overall error between theoretical and experimental data points. The mean absolute errors for permeate flux and rejection were 7.03% and 1.02%, respectively. The data for this case is provided in Appendix S5.

Table 2 clearly shows that the optimization of all five parameters (L_p, B_m, σ, a and b) using theoretical and experimental data points (Method 2) showed the lowest mean absolute percentage error for permeate flux and rejection than other optimization methods. Thus, the same values were considered the actual values of these parameters.

Effects of various operating conditions

Various operating conditions, such as feed concentration, cross-membrane pressure and feed flow rates, can influence the performance of the membrane test cell. The roles of these operating conditions were investigated using the same experimental results used for parameter estimation reported in the previous section [Estimation of solute permeability (B_m), reflection coefficient (σ), and mass transfer coefficients (a and b)].

Effect of cross-membrane pressure

Figure 3(a) shows that permeate flux increased with increasing cross-membrane pressure. The results obtained showed that at a constant flow rate of 600 mL min^{-1}, the value of permeate flux

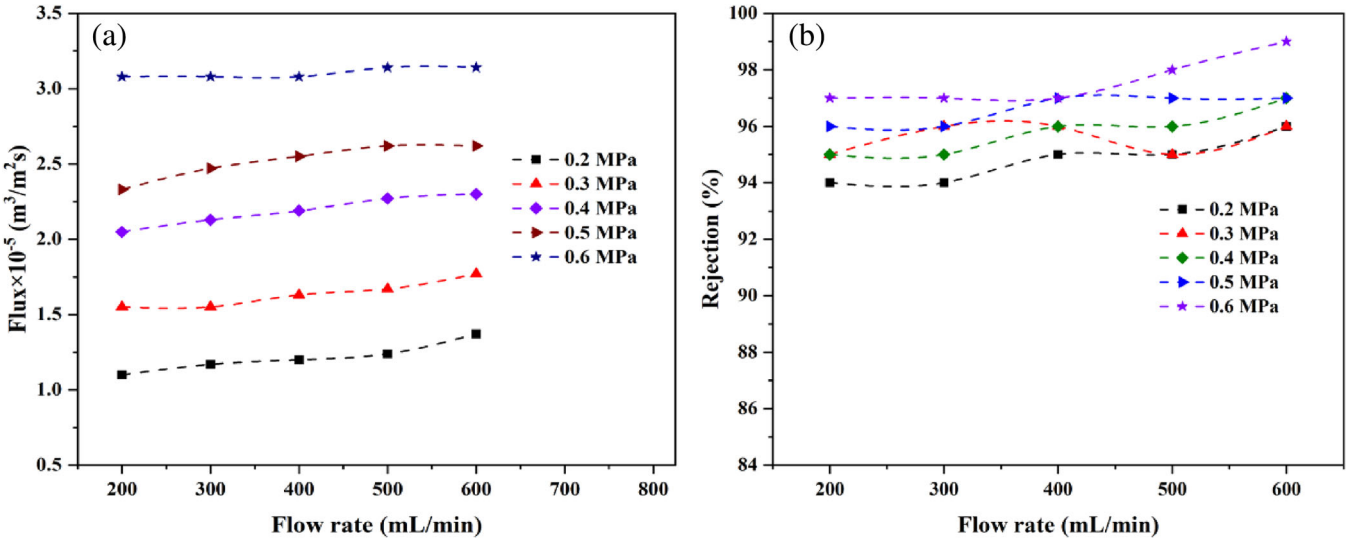

Figure 4. Influence of feed flow rate on (a) permeate flux and (b) percentage rejection, both at a constant feed concentration of 0.1 g L^{-1}.

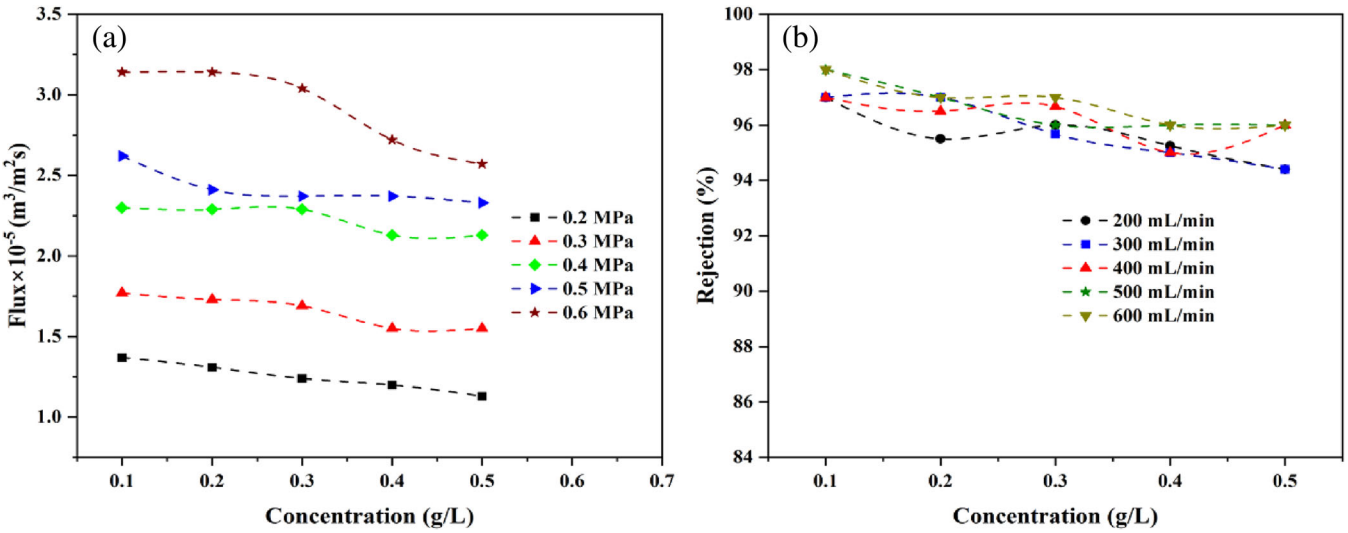

Figure 5. Influence of feed concentration on (a) permeate flux at a constant feed flow rate of 600 mL min^{-1} and (b) percentage rejection at a constant pressure of 0.6 MPa.

increased from 1.37 × 10^{-5} to 3.14 × 10^{-5} m^3 m^{-2} s^{-1} for a feed concentration of 0.1 g L^{-1}, and from 1.13 × 10^{-5} to 2.57 × 10^{-5} m^3 m^{-2} s^{-1} for a feed concentration of 0.5 g L^{-1}. This is likely to have resulted from the increase in the force for permeation, as cross-membrane pressure acts as the main driving force for the mass transfer across the membrane. The rejection percentage increased slightly from 96% to 99% as the cross membrane pressure increased from 0.2 to 0.6 MPa for a feed concentration of 0.1 g L^{-1}, and from 94% to 96% for a 0.5 g L^{-1} feed concentration at a fixed flow rate of 600 mL min^{-1}, as depicted in Fig. 3(b). This may be because an increase in cross-membrane pressure results in the increment of hydraulic flux. However, solute flux does not vary much with varying cross-membrane pressure, as diffusive mass transport dominated over convective mass transport (σ = 0.969), hence resulting in an overall decline in permeate concentration and a slight increase in rejection values.

Effect of feed flow rates

Figure 4(a) depicts the variation of permeate flux as a function of feed flow rates ranging from 200 mL min^{-1} to 600 mL min^{-1} at different pressure variations of 0.2 to 0.6 MPa. It can be seen from the graph that the permeate flux increased from 1.10 × 10^{-5} to 1.37 × 10^{-5} m^3 m^{-2} s^{-1} at a constant pressure of 0.2 MPa and a constant concentration of 0.1 g L^{-1}. The same trend was found for other values of pressure and concentrations. This is because a high feed flow rate reduces the concentration polarization and thus leads to low osmotic pressure differences across the membrane. The values of solute rejection percentage increased from 97% to 99% as the feed flow rate was increased from 200 to 600 mL min^{-1} at a constant pressure of 0.6 MPa and constant concentration of 0.1 g L^{-1} [Fig. 4(b)]. As discussed earlier, a higher flow rate reduces the concentration polarization owing to higher mixing in the feed section, which reduces the osmotic

Table 3. Ranges of different parameters for sensitivity analysis

Parameters	Range
Trans-membrane pressure, MPa	0.2–0.6
Feed concentration, kg m^{-3}	0.1–0.5
Feed flow rate, m^3 s^{-1}	3.3×10^{-6} to 10×10^{-6}
Specific hydraulic permeability coefficient, kg m^{-2} s^{-1} Pa^{-1}	5.5×10^{-9} to 5.5×10^{-7}
Solute permeability, m s^{-1}	4.03×10^{-6} to 4.03×10^{-8}
Reflection coefficient	0.8–1

pressure across the membrane. Osmotic pressure is the driving force for solute transport. Thus, lower osmotic pressure leads to lower solute transport across the membrane and enhances solute rejection. A similar trend was seen for other values of concentration and pressure.

Effects of feed concentration

The values of permeate flux and permeate flow rate reduced with an increase in feed concentration of betanin as higher concentration caused higher osmotic pressure, which decreased the driving force for mass transfer. Figure 5(a) represents the decline in permeate flux value from 3.14×10^{-5} to 2.57×10^{-5} m^3 m^{-2} s^{-1} as the feed concentration increased from 0.1 to 0.5 g L^{-1} at a feed flow rate of 600 mL min^{-1} and a constant pressure of 0.6 MPa. A similar trend was also seen for other values of feed flow rates and pressure. Also, Fig. 5(b) showed the decrease in the rejection percentage from 97% to 94.4% as the feed concentration was increased from 0.1 to 0.5 g L^{-1} at 0.6 MPa pressure and 200 mL min^{-1} feed flow rate. This is a consequence of the lower water and higher solute flux at higher solute concentrations in the feed.

Sensitivity analysis

In order to understand the impact and interdependence of various input variables (C_b, ΔP, Q, L_p, B_m and σ) on output variables (J_p and R_j), the sensitivities of input parameters were analyzed using a suitable range as reported in Table 3. As already discussed in theory (Theory section), variance-based sensitivity analysis requires the formulation of two independent matrices (P and Q) containing equal numbers of input parameter sets. All of the model evaluations were performed in Google Colab. All data were stored in a CSV file for further processing.

The sample size selection was based on the consistency of the first-order and total sensitivity index of various membrane parameters and input variables on output variables. Normalized sensitivities (first-order and total) of different operating conditions and membrane test cell parameters for permeate flux and rejection percentage with variation of sample sizes are represented in SM 6 and SM 7, respectively. As S_i and S_{Ti} were computed after every batch (containing 100 random samples) selected from the whole dataset, convergence occurred slowly after a certain number of samples. The results show that first-order sensitivity and total order sensitivity index fluctuated initially up to 5000 samples, and then varied marginally. By performing different runs, it was found that the sensitivities of all input parameters remained constant after a 50000 sample size, which provides confidence for evaluating the values of sensitivities at a 50000 sample size.

Sensitivity of operating and transport parameters for permeate volumetric flux

Values for S, S_T and their differences ($S_T - S$) were calculated by performing model evaluations in Google Colab (Fig. 6). It was seen that the normalized sensitivities (S and S_T) of specific hydraulic permeability were found to be highest, followed by cross membrane pressure, and sensitivities of all other operating parameters like feed flow rate, feed concentration, solute permeability and reflection coefficient were comparatively negligible. Thus, it can be concluded that hydraulic permeability and cross-membrane pressure are the most influential parameters for total volumetric permeate flux. Results further show that $S_T - S$ is negligible compared to their original total and first-order sensitivity values, indicating that interactions of L_p and ΔP with other input parameters have insignificant effects on the permeate flux. Operating and transport parameters can be sorted in decreasing order as $L_p > \Delta P > C_b > \sigma > B_m > Q$ (Fig. 6(a)).

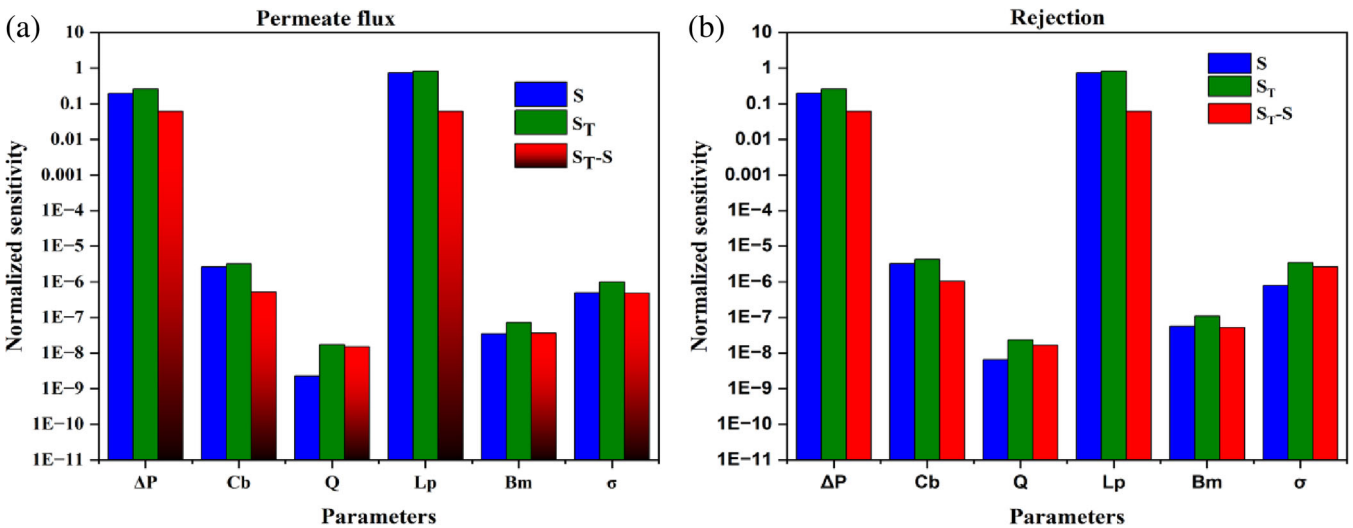

Figure 6. Sensitivity of different operating and membrane module parameters for (a) permeate flux and (b) rejection.

Sensitivity of operating and transport parameters for rejection

Figure 6(b) reports the S, S_T and $S_T - S$ of operating and membrane test cell parameters for rejection. Similar to the case for permeate flux, ΔP and L_p are the most influential parameters. Also, interactions of ΔP and L_p with other transport and operating parameters have negligible effects on the rejection, as shown in Fig. 6(b).

CONCLUSIONS

In this work, the membrane test cell performance of HFT-NF 150 was investigated experimentally and theoretically for the separation of model betanin feed solutions of different concentrations. The predictions for output characteristics obtained theoretically from the Spiegler–Kedem model are well-matched with the experimental results. Low mean absolute percentage error (MAPE) values for output characteristics such as permeate flux and rejection percentage provide confidence for integrating the HFT-NF 150 membrane test cell to design a commercial scale NF unit. Also, the effects of various operating parameters were analyzed in this work. The value of permeate flux increased with the increase in cross-membrane pressure and flow rate but decreased with an increase in concentration. The maximum permeate flux of 3.14×10^{-5} m^3 m^{-2} s^{-1} and a percentage rejection of 99% were obtained at a high flow rate of 600 mL min^{-1} and high pressure of 0.6 MPa, but at a low feed concentration of 0.1 g L^{-1}.

Variance-based sensitivity analysis was also used to analyze the influence and interdependence of operating and membrane test cell parameters on permeate flux and rejection values. The indices began to converge after 5000 and were found to be almost stable at a sample size of 50000. Specific hydraulic permeability and cross-membrane pressure were the most influential parameters for permeate flux and rejection compared to others.

Plant extracts may also contain other bioactive molecules, including proteins, lipids, sugars and minerals, with different molecular sizes. These molecules can also be separated by applying a series of membrane-based processes, such as MF for >100000 Da size particles, UF for micro-size particles, and different cut-off NF membranes for sugars and minerals. A study is required to investigate the separation of these compounds from real plant extracts using membrane-based processes.

Symbols

L_p	Specific hydraulic permeability, kg m^{-2} s^{-1} Pa^{-1}
B_m	Membrane solute permeability coefficient, m s^{-1}
F	Flow parameter
J_p	Permeate flux through membrane, m^3 m^{-2} s^{-1}
c	Solute concentration, kg m^{-3}
k	Mass transfer coefficient, m s^{-1}
a	Coefficient in mass transfer correlation
b	Exponent of Reynolds number in mass transfer equation
d	Membrane test cell diameter, m
P	Pressure, Pa
Q	Flow rate, m^3 s^{-1}
R_j	Rejection
S_c	Schmidt number
S_h	Sherwood number
R_e	Reynolds number
M_w	Molecular weight of solute, kg mol^{-1}
R	Universal gas constant
T	Temperature, K

Greek letters

ϕ	Concentration polarization
υ	Vant Hoff factor
α	Proportionality constant for osmotic pressure
π	Osmotic pressure, Pa
σ	Reflection coefficient
ρ	Density, kg m^{-3}

Subscript

p	Permeate side
b	Bulk side
m	Membrane–feed interface

ACKNOWLEDGEMENT

Abstract. We explore the variable generalized Chaplygin gas (VGCG) model in the theory of matter creation cosmology within the framework of a spatially homogeneous and isotropic flat Friedmann - Lemaître - Robertson - Walker space-time. Matter creation cosmology is based on reinterpretation of energy-momentum tensor in Einstein's field equations. This creation corresponds to an irreversible energy flow from the gravitational field to the created matter constituents. The variable Chaplygin gas (VCG) is also studied as a particular solution. We use the Markov Chain Monte Carlo method to constrain the free parameters of three models, namely, ΛCDM, VGCG and VCG models with and without matter creation from the latest observational data from baryon acoustic oscillations, cosmic chronometer, type Ia supernovae (Pantheon) including gamma-ray burst, quasars, and the local measurement of H_0 from R21 data. Two different combinations of dataset provide a fairly tight constraint on the parameters of the ΛCDM, VGCG and VCG models. The present values of various cosmological parameters are obtained which give very close to ΛCDM model. Furthermore, we perform the stability analysis, Bayesian evidence analysis and information criteria analysis for these models through studying the sound speed, Bayes factor, and AIC and BIC selection criterion. The values of sound speed for VGCG and VCG models shows that both the models are stable. According to AIC, it is observed that VGCG and VCG models with matter creation are supported considerably less by current observations whereas BIC shows that these models are not favoured by observational data.

Keywords:Cosmological model, Matter creation, Chaplygin gas model, Dark energy.

1. Introduction

The discovery of the late-time accelerated expansion of the Universe has become one of the most important theoretical challenge in modern cosmology. One of the

‡ Corresponding author

Accepted Manuscript
For Review Only

first observational evidence of this late-time acceleration was shown through the measurement of type Ia supernovae [1–3]. Subsequently, more observations such as Sloan Digital Sky Survey (SDSS) and WMAP [4], baryonic acoustic oscillations (BAO) [5], and cosmic microwave background (CMB) anisotropies [6–10] have confirmed that the Universe is spatially flat and two-thirds of the energy content is dominated by an exotic component with large negative pressure, referred to as dark energy. The simplest candidate for dark energy is the cosmological constant with its equation of state $w = p_\Lambda/\rho_\Lambda = -1$. This model is known as Lambda-Cold dark matter (ΛCDM) model which has three major components: a cosmological constant associated with dark energy, cold dark matter and ordinary matter. This model emerged in the late 1990s as a concordance model. Despite its observational success, ΛCDM model suffers at least from two problems: the cosmological constant problem (CCP) and the cosmic coincidence problem [11, 12]. Many alternative theories have been proposed beyond the ΛCDM model to solve these conundrums. Generally, these alternative theories have been divided into two main classes: First, and possibly the most is the dark energy model in which a new cosmic fluid or matter field is introduced within the framework of general relativity [13]. The other is the modified theories of gravity in which the standard general relativity Lagrangian is modified based on some concrete physical mechanism [14].

We are concerned here with the first kind of dark energy proposal where the dark energy component might be explained by a background fluid with an exotic equation of state, so-called the Chaplygin gas (CG) model [15]. The Chaplygin gas [16] had an origin that was not cosmological. It was used to explain the lifting force on an airplane wing. As the equation of state has negative pressure, it has recently attracted new interest in cosmology. It is used as perfect fluid to describe the accelerating expansion of the Universe with equation of state $p_{Ch} = -A/\rho_{Ch}$, where A is a positive constant, and p_{Ch} and ρ_{Ch} are the energy density and pressure, respectively. The striking feature of CG model is its ability to unify two of the Universe's unknown dark sections: dark matter (DM) and dark energy (DE) [17, 18]. Since the CG model has been ruled out by the observations, this model was extended to the so-called generalized Chaplygin gas (GCG) with the equation of state [19] $p_{Ch} = -A/\rho_{Ch}^\alpha$, where $0 \leq \alpha \leq 1$. This GCG model is also regarded as a unification of DE and DM [20–23]. Gou and Zhang [24] have proposed a variable Chaplygin gas (VCG) model, which explains the evolution from dust to quintessence or phantom. In such model the equation of state is characterized by $p_{Ch} = -A(a)/\rho_{Ch}$, where A is the function of the scale factor a. Yang et al [25], and later on, Lu [26] generalised the VCG model with the equation of state $p_{Ch} = -A(a)/\rho_{Ch}^\alpha$, which is known as variable generalized Chaplygin gas (VGCG) model which also explains the evolution from dust to quintessence or phantom. Some more works on VCG and VGCG models can be found in Refs. [27–32]

Nevertheless, even in the context general relativity, there are other theories to explain the current accelerated expansion of the Universe. As stated above, the presence of negative pressure is the main factor required to accelerate the expansion

For Review Only

of the Universe. This may also occur, for instance, when the physical system departs from a thermodynamic equilibrium state [33]. In this connection, Zeldovich [34] first stated that the process of cosmological particle creation at the expenses of the gravitational field can be phenomenologically described by a negative pressure. In cosmology, gravitationally induced particle production has a long history. Using the non-equilibrium thermodynamics of open systems, Prigogine et al. [35, 36] proposed the first self-consistent macroscopic formulation of the matter creation process into the Einstein field equations. Later on, Calvâo et al [37] clarified the process through covariant formulation. It has been stated that matter creation can be explained in the realm of the relativistic non-equilibrium thermodynamics. According to several studies [38–47], matter creation cosmology may explain the accelerating expansion of the Universe. The late-time evolution of the Universe has been explained by many authors [48–57]. Since many significant observations have been examined in recent years and the current accelerated expansion of the Universe is satisfactorily explained, the matter creation cosmology is an extremely intriguing topic. The crucial aspect of this model is to take into account the option for the particle production rate, which is still unknown. However, it is assumed to be the function of the Hubble parameter H.

In our previous work [58], we mainly concentrated on the generalized Chaplygin gas inspired by matter creation cosmology and derived the best-fit values of model free parameters. In this paper, to make more complete discussion on contribution of matter creation in CG models, we are interested in discussing the consequences of a variable generalized Chaplygin gas (VGVG) model incorporating the background of matter creation cosmology within the framework of a homogeneous and isotropic flat Friedmann-Lemaître-Robertson-Walker space-time. We also consider a special model of CG, namely, variable Chaplygin gas (VCG). We focus on the analytical solutions and observational analysis of the proposed models to explore the contribution of matter creation. To make our discussion more complete, we use a Bayesian analysis to constrain the parameter space of these models using baryon acoustic oscillations, Cosmic Chronometers data, the Pantheon type Ia supernova including the Gamma Ray Bursts, Quasars and local measurement of H_0 from R21. It is worthy reviewing that the VGCG and VCG models with matter creation can alleviate H_0 tension. We also discuss the stability, Bayesian evidence analysis and selection criterion to distinguish our models with the existing dark energy models such as ΛCDM model.

The paper is organized as follows: In Section 2, for the sake of clarity, we give a brief introduction of matter creation in cosmology. Section 3 is devoted for the background dynamics of the VGCG model in the presence of matter creation. The analytical solutions of VGCG and VCG models are presented in Sections 4 and 5, respectively. Recent observational data and posterior analysis are explored in Section 6. Section 7 is devoted to results and discussion on the consistency of VGCG and VCG models with the observations. Further, Subsections 7.1-7.4 present the evolutions of cosmological parameters, stability, information selection criteria and Bayesian evidence analysis, respectively, and finally, in Section 8, we present the summary of the results.

2. Basic formalism of matter creation

The thermodynamics of matter creation were first applied to cosmology in the late 1980s by Prigogine and collaborators [35, 36]. They included matter creation explicitly in the matter stress-energy tensor in the Einstein field equations. Later on, Calvão et al [37] discussed and generalized this phenomenological approach through a covariant formulation allowing specific entropy variation. Nowadays, it has been applied in many gravitational theories. In this paper we follow the approach of Prigogine et al [35, 36], which presumes that matter creation takes place at the expense of gravitational energy. The basic formalism of matter creation in theory of general relativity is as follows.

Let us consider an open thermodynamical system where the particle numbers are not conserved. The particle flux vector is assumed to have the form $N^\mu = nu^\mu$, where N is number of particles, n is the particle number density, given by $n = N/V$ and u^μ is the usual particle four velocity. For open systems, the non-conservation of the particle number satisfies the balance equation

$$\nabla_\mu N^\mu \equiv n_{,\mu}u^\mu + 3Hn = n\Gamma, \tag{1}$$

where Γ stands for the rate of change of the particle number in a physical volume $V = V_0a^3$ (where V_0 is the co-moving volume) and $u^\mu_{;\mu} = 3H$ denotes the fluid expansion for FLRW Universe and by notation $\dot{n} = n_{,\mu}u^\mu$. The overdot denotes derivative with respect to the cosmic time. Clearly, $\Gamma > 0$ indicates the creation of particle while $\Gamma < 0$ stands for particle annihilation and $\Gamma = 0$ means there is no creation of matter, i.e., particle number is conserved. The entropy flux vector is given by $s^\mu = n\sigma u^\mu$ [37], where σ is the specific (per particle) entropy. It is to be noted that the entropy must satisfy the second law of thermodynamics $s^\mu_{;\mu} \geq 0$. The incorporation of variable N into the cosmological scenario modifies the first law of thermodynamics as [36, 37]

$$d(\rho V) + pdV - (h/n)d(nV) = 0, \tag{2}$$

where $h = (\rho + p)$ is the enthalpy (per unit volume), and ρ and p are the energy density and thermodynamic pressure, respectively. It is assumed that the Universe evolution continues to be adiabatic, in the sense that the entropy per particle remains unchanged ($\dot{\sigma} = 0$). Equation (2) can be rewritten as

$$d(\rho V) + (p + p_c)dV = 0, \tag{3}$$

where the extra contribution p_c in (3) can be interpreted as a non-thermal pressure, known as creation pressure, defined as

$$p_c = -\frac{h}{n}\frac{d(nV)}{dV}. \tag{4}$$

Using (1) into (4), we get the following form of creation pressure [37]

$$p_c = -\frac{(\rho + p)}{3H}\Gamma. \tag{5}$$

Hence, the creation pressure p_c can be identified with the particle production rate Γ. The simplest possible case, and probably the most physically choice would be one

Accepted Manuscript
For Review Only

for which the characteristic time scale for matter creation is the Hubble time itself. Phenomenologically, this is equivalent to [59, 60]

$$\Gamma = 3\beta H, \tag{6}$$

where β is a positive constant. Using (6) into (5), the creation pressure gives

$$p_c = -\beta(\rho + p). \tag{7}$$

Hereafter, we refer ρ as ρ_{Ch} and p as p_{Ch} for energy density and pressure of Chaplygin gas perfect fluid.

3. Basic field equations

Let us consider the following geometry of the Universe which is very well described by the homogeneous and isotropic flat Friedmann-Lemaître-Robertson-Walker (FLRW) spacetime

$$ds^2 = -dt^2 + a^2(t)\left(dr^2 + r^2 d\theta^2 + r^2 sin^2\theta d\phi^2\right), \tag{8}$$

where $a(t)$ is the scale factor of the Universe. Throughout we use the units such that the speed of light $c = 1$. For comoving observer, $u^\mu = \delta^\mu_\nu$, in which $u^\mu u_\mu = -1$.

The Einstein field equations are written as

$$R_{\mu\nu} - \frac{1}{2} g_{\mu\nu} R = 8\pi G T_{\mu\nu}, \tag{9}$$

where the symbols have their usual meaning. In a general relativistic framework the basic macroscopic variables which describe the thermodynamic states of a relativistic simple fluid are the energy-momentum tensor $T_{\mu\nu}$, the particle flux vector N^μ, and the entropy flux vector s^μ. In this work we shall consider a Universe with matter contents as baryons and Chaplyin gas endowed with matter creation (Chaplygin gas means a perfect fluid having exotic equation of state). Thus, we write the energy density and the pressure of the mixture as a sum of two terms that describe the baryon matter component and Chaplygin gas fluid with matter creation. By taking into account matter creation the effective energy-momentum tensor for the mixture can be given by [37]

$$T_{\mu\nu} = (\rho_{Ch} + \rho_b + p_{Ch} + p_c) u_\mu u_\nu + (p_{Ch} + p_c) g_{\mu\nu}. \tag{10}$$

where ρ_{Ch} and ρ_b are the energy density of Chaplygin gas fluid and baryons, and p_{Ch} and p_c the pressures of Chaplygin gas fluid and particle creation, respectively. The Einstein field equations (9) for line element (8) and energy-momentum tensor (10) yield

$$H^2 = \frac{8\pi G}{3}(\rho_{Ch} + \rho_b), \tag{11}$$

$$\dot{H} + H^2 = -\frac{4\pi G}{3}\left(\rho_{Ch} + \rho_b + 3p_{Ch} + 3p_c\right). \tag{12}$$

where $H = \dot{a}/a$ is the Hubble parameter. In a comoving frame the dot denotes derivative with respect to cosmic time t.

Assuming that baryons are self-conserved, namely the baryon density evolves in

the normal way, $\rho_b = \rho_{b,0}a^{-3}$, where subscript 0 denotes the value of a quantity at the present time. Thus, the energy densities of the baryon and matter decouple so that the conservation equation $T^{\mu\nu}_{;\nu} = 0$ gives

$$\dot{\rho_{Ch}} + 3H(\rho_{Ch} + p_{Ch} + p_c) = 0. \tag{13}$$

In recent years, it has been suggested that the change of behavior of the missing energy density might be regulated by the change in the equation of state of the background fluid. In this respect Chaplygin gas was introduced as an exotic background fluid with the equation of state described by $p_{Ch} = -A/\rho_{Ch}$, where A is a positive constant [15]. It gives a unified picture of dark matter and dark energy. However, it was ruled out due to inconsistent with the observational data. Subsequently, a more generalized model of the Chaplygin gas is characterized by an equation of state $p_{Ch} = -A/\rho^{\alpha}_{Ch}$ $(0 \leq \alpha < 1)$, which is known as generalized Chaplygin gas (GCG) [17]. It has been shown that this model can be accommodated within the standard structure formation scenarios [17,18]. Therefore, Chaplygin gas models look to be good alternative to explain the accelerated expansion of the Universe.

Guo and Zhang [24] proposed a new Chaplygin gas model, known as variable Chaplygin gas (VCG) model with equation of state $p_{Ch} = -A(a)/\rho_{Ch}$, where $A(a)$ is a function of the scale factor a. In this scenario, the variable Chaplygin gas can drive the Universe from dust to quiescence or phantom. Later on, Yang et al [25] presented a variable generalized Chaplygin gas (VGCG) model whose equation of state is given by [25, 26]

$$p_{Ch} = -\frac{A_0 a^{-n}}{\rho^{\alpha}_{Ch}}, \tag{14}$$

where A_0, n and α are parameters in the model.

In this work, we are interested to study the VGCG model with the cosmology of matter creation along with VCG as particular model.

4. VGCG model with matter creation

Using (7) and (14), Eq. (13) reduces to

$$\rho'_{Ch} + 3(1-\beta)\left(\rho_{Ch} - \frac{A_0 a^{-n}}{\rho^{\alpha}_{Ch}}\right) = 0, \tag{15}$$

where prime denotes derivative with respect to $x = ln(a)$. By taking explicitly the integral of (15), one finds the solution of energy density for VGCG as

$$\rho_{Ch} = \rho_{Ch,0}\left[A_s(1+z)^n + (1-A_s)(1+z)^{3(1-\beta)(1+\alpha)}\right]^{\frac{1}{1+\alpha}}, \tag{16}$$

where $\rho_{Ch,0}$ is the present energy density and $z = (1/a) - 1$ is the redshift and $A_s = \frac{3(1-\beta)(1+\alpha)}{3(1-\beta)(1+\alpha)-n}\frac{A_0}{\rho^{(1+\alpha)}_{Ch,0}}$. For an expanding Universe, we must have $n > 0$ and $(1-\beta)(1+\alpha) > 0$.

Let us investigate the cosmological parameters, specifically the Hubble parameter,

Accepted Manuscript For Review Only

deceleration parameter, equation of state parameter and jerk parameter in order to compare these models with ΛCDM.

Using (16) into (11), the Friedmann equation can also be expressed as

$$H(z) = H_0 E(z), \tag{17}$$

where

$$E(z) = \Big[(1-\Omega_{b,0})\left\{A_s(1+z)^n + (1-A_s)(1+z)^{3(1-\beta)(1+\alpha)}\right\}^{\frac{1}{(1+\alpha)}} + \Omega_{b,0}(1+z)^3\Big]^{1/2}. \tag{18}$$

The acceleration of the Universe is measured by the deceleration parameter which is defined in terms of redshift as

$$q(z) = -1 + (1+z)E(z)^{-1}\frac{dE(z)}{dz}. \tag{19}$$

Using (18) into (19), we obtain

$$q(z) = -1 + \frac{1}{2E^2(z)}\Bigg[3\Omega_{b,0}(1+z)^3 + \frac{(1-\Omega_{b,0})nA_s(1+z)^n + 3(1-A_s)(1-\beta)(1+\alpha)(1+z)^{3(1-\beta)(1+\alpha)}}{\left(A_s(1+z)^n + (1-A_s)(1+z)^{3(1-\beta)(1+\alpha)}\right)^{\frac{\alpha}{1+\alpha}}}\Bigg]. \tag{20}$$

The equation of state (EoS) parameter for the VGCG model is given by

$$w(z) = \frac{-A_s\left(1-\frac{n}{3(1-\beta)(1+\alpha)}\right)(1+z)^n}{A_s(1+z)^n + (1-A_s)(1+z)^{3(1-\beta)(1+\alpha)}}. \tag{21}$$

Lastly, we present the another cosmographic parameter, namely, jerk parameter which is an important tool to distinguish between dynamical models even if they are equivalent kinematically. The degeneracy of the jerk parameter comes from its definition as a third order differential of the scale factor. Its value for the ΛCDM model is 1 (constant), independent of the redshift. In terms of q, it is defined as [8]

$$j(z) = q(2q+1) + (1+z)\frac{dq}{dz}. \tag{22}$$

In forthcoming section, we use the above expression to draw the trajectory of $j(z)$ using best-fit values of parameters and discuss the behavior accordingly.

5. Particular Solution

In this section, we discuss the particular solution of VGCG model. Assuming $n \neq 0$ and $\alpha = 1$ in Eq.(14), the VGCG model reduces to variable Chaplygin gas (VCG) whose EoS is given by $p_{Ch} = \frac{A_0 a^{-n}}{\rho_{Ch}}$. In this model, the energy density is

$$\rho_{Ch} = \rho_{Ch,0}\left[A_s(1+z)^n + (1-A_s)(1+z)^{6(1-\beta)}\right]^{1/2}, \tag{23}$$

Accepted Manuscript

For Review Only

where $A_s = \frac{6(1-\beta)A_0}{\{6(1-\beta)-n\}\rho^2_{Ch,0}}$. Using (23) into the Friedmann equation (11), we obtain

$$H^2(z) = H_0^2\Big[(1-\Omega_{b,0})\left(A_s(1+z)^n + (1-A_s)(1+z)^{6(1-\beta)}\right) + \Omega_{b,0}(1+z)^3\Big]. \quad (24)$$

The deceleration parameter and EoS parameter for this model can be respectively obtained as

$$q(z) = -1 + \frac{1}{2E^2(z)}\Bigg[3\Omega_{b,0}(1+z)^3 + \frac{(1-\Omega_{b,0})nA_s(1+z)^n + 6(1-A_s)(1-\beta)(1+z)^{6(1-\beta)}}{\{A_s(1+z)^n + (1-A_s)(1+z)^{6(1-\beta)}\}^{1/2}}\Bigg], \quad (25)$$

and

$$w(z) = -\frac{A_s\left(1-\frac{n}{6(1-\beta)}\right)(1+z)^n}{A_s(1+z)^n + (1-A_s)(1+z)^{6(1-\beta)}}. \quad (26)$$

6. Observational data

This section addresses the datasets and method to constrain the model parameters of VGCG and VCG models alongwith ΛCDM model. We use the recent observational data of Baryon Acoustic Oscillation, Cosmic Chronometer, Standard candles and Hubble data $R21$ to constrain the model parameters which are described below:

6.1. Baryon Acoustic Oscillations:

We use a set of 17 uncorrelated data points from different Baryon Acoustic Oscillations (BAO) measurements of Refs. [61–74]. The collection of these data points is summarized in Table 1 of Ref. [75]. In the context of BAO, a significant aspect is the computation of the sound horizon at the time of photon-baryon decoupling, r_d, which is defined as

$$r_d = \int_{z_d}^{\infty} \frac{c_s(z)}{H(z)}\, dz, \quad (27)$$

where $c_s(z)$ symbolizes the baryon-photon fluid's sound speed, calculated by $c_s(z) \approx c\left(3 + \frac{9\rho_b(z)}{4\rho_\gamma(z)}\right)^{-0.5}$. Here, $\rho_b(z)$ and $\rho_\gamma(z)$ stand for the densities of baryons and photons, respectively. In observational terms, BAO yields two key projected measures: $\Delta z = \frac{r_d H}{c}$ and $\Delta\theta = \frac{r_d}{(1+z)D_A(z)}$, where Δz is the redshift shift, $\Delta\theta$ is the angular displacement related to BAO and $D_A(z)$ is the angular diameter distance. These measures primarily inform about the product $r_d \times H$. To effectively separate these parameters, independent estimations of the Hubble parameter, specifically H_0, are essential.

Accepted Manuscript For Review Only

6.2. Cosmic Chronometers:

The Cosmic Chronometers (CC) approach provides a method for estimating the Hubble parameter $H(z)$ at different redshifts, leveraging the age difference between passive evolving galaxies. This method is based on the differential age approach, where the relative age of galaxies at different redshifts is related to the inverse of the Hubble parameter. We use a set of 30 uncorrelated CC measurement of $H(z)$, as discussed in Refs. [76–79]. The χ^2 function is defined

$$\chi^2_{CC} = \sum_{i=1}^{30} \frac{[H_{obs}(z_i) - H_{th}(z_i)]^2}{\sigma(z_i)^2}, \tag{28}$$

where $H_{th}(z_i)$ denotes the theoretical value of $H(z)$ at redshift z_i for a given set of cosmological parameters, $H_{obs}(z_i)$ denotes the observed values of $H(z)$ at redshift z_i, and $\sigma(z_i)$ is the uncertainty in the measurement of H_i.

6.3. Standard Candles:

For standard candles (SC), we use uncorrelated measurement of Pantheon type Ia supernovae (SNe) [80], the measurements from Quasars [81] and Gamma Ray Bursts [82]. The Pantheon dataset, follow the luminosity-distance relationship, which can be modeled by $d_L = (1+z)\int_0^z \frac{c}{H(z')}\, dz'$, where d_L is the luminosity distance, z the redshift, c the speed of light, and $H(z')$ is the Hubble parameter as a function of redshift. Gamma-Ray Bursts (GRBs) are utilized by correlating their observed properties, like peak luminosity or total emitted energy, with distance. Their relationship is given by $L_{GRB} = 4\pi d_L^2 F_{obs}$ where L_{GRB} is the intrinsic luminosity and F_{obs} the observed flux. Quasars are considered as the correlation between their luminosity and the size of their broad emission line region, estimated via reverberation mapping. Their distance approximation is $d_L \propto \sqrt{\frac{L_{quasar}}{F_{obs}}}$, with L_{quasar} representing the intrinsic luminosity.

6.4. R21 measurement:

We use $H_0 = 73.04 \pm 1.04\ kms^{-1}Mpc^{-1}$ [83] in our analysis which we denote as $R21$. This is obtained from the Cepheid-SNe sample including systemic uncertainties and lies near the median of all analysis variants which gives a result much closer to the observed in the supernovae sample [84].

We use two different combinations of above datasets. Combination of the first three set of data ($BAO + CC + SC$) is referred as **"BASE"** dataset in our subsequent analysis. The other set of data is termed as **"BASE+R21"**. We use the total likelihood function to derive the joint constraints from the previously mentioned observational data on the model parameter space ($H_0,\ \Omega_b,\ A_s, n,\ \alpha,\ \beta$). In our analysis, we perform a global fitting to determine the cosmological parameters using a Markov Chain Monte Carlo (MCMC). We follow a nested sampler as it is implemented within the open-source package *Polychord* [85] with the *GetDist* package [86] to generate MCMC for

7. Results and discussion

The constraints on different models with and without matter creation for two different combinations of data, namely BASE and $BASE + R21$, are listed in Tables 1 and 2, respectively. As one can see from these tables, the best-fit values of these parameters are nearly same for different dark energy models. It is to be noted that the inclusion of local measurement $H_0 = 73.04 \pm 1.04\ kms^{-1}Mpc^{-1}$ from $R21$ [83] with BASE data, i.e.,$BASE + R21$ always makes the H_0 value higher than BASE data for all the three models discussed above. For ΛCDM, we obtain $H_0 = 71.432^{+1.111}_{-1.038}\ kms^{-1}Mpc^{-1}$ for full datasets, $BASE + R21$ where as for VGCG and VCG, we get $H_0 = 72.674^{+0.355}_{-0.758}$ $kms^{-1}Mpc^{-1}$ and $H_0 = 72.680^{+0.399}_{-0.775}\ kms^{-1}Mpc^{-1}$, respectively. The residual tensions of these fitting results with $R21$ are 0.95σ, 0.36σ and 0.34σ, respectively. On the other hand, we find $H_0 = 69.791^{+1.008}_{-1.070}\ kms^{-1}Mpc^{-1}$, $H_0 = 69.649^{+1.265}_{-2.379}\ kms^{-1}Mpc^{-1}$ and $H_0 = 69.638^{+1.207}_{-2.491}\ kms^{-1}Mpc^{-1}$ with BASE data taken for ΛCDM, VGCG and VCG models, respectively. The $R21$ value of H_0 exhibits a strong tension with the Planck 2018 release $H_0 = 67.4 \pm 0.5$ [10] at 3.92σ CL. Using BASE dataset, we find that the current H_0 tension can be alleviated to 2.19σ in ΛCDM, 1.51σ in VGCG and 1.84σ in the VCG model. In Figures 1-3, we show the constrained contours at 68.3% and 95.4% confidence levels in various parameters plane using two different combinations of data for ΛCDM, VGCG and VGC models, respectively.

In what follows, we discuss the evolutions of different cosmological parameters, stability of the models, selection criteria and Bayesian evidence analysis to compare the proposed models with the existing dark energy models.

7.1. Evolution of cosmological parameters

The evolutions of $H(z)$ with respect to the redshift z for VGCG and VCG with and without matter creation are shown in Figs. 4-7, respectively. The figures also show a comparison of VGCG and VCG models with ΛCDM model. As observed, VCG model closely matches the observed data during the whole evolution whereas the VGCG model coincides during late time evolution of the Universe.

Using BASE and $BASE + R21$ datasets, we obtain the present values of $q(z)$, $w(z)$ and $j(z)$ for ΛCDM, VGCG and VCG models with and without matter creation, respectively which are summarized in Tables 3 and 4. The evolutions of $q(z)$ with redshift z of all the three models for BASE and $BASE + R21$ datasets are shown in Figs. 8 and 9, respectively. We observe that the models show a transition from deceleration ($q(z) > 0$) to acceleration ($q(z) < 0$). In figures, a dot represents the present value of $q(z)$. The present values of $q(z)$ at $z = 0$ from BASE and $BASE + R21$ datasets are $q_0 = -0.591^{+0.01}_{-0.01}$ and $q_0 = -0.590^{+0.02}_{-0.02}$ for ΛCDM, $q_0 = -0.541^{+0.02}_{-0.02}$ and $q_0 = -0.542^{+0.05}_{-0.05}$ for VGCG model and $q_0 = -0.553^{+0.03}_{-0.03}$ and $q_0 = -0.555^{+0.03}_{-0.03}$ for VCG model with matter creation, respectively, as given in Table 3. The values of q_0 show that the models undergo accelerated expansion at present-day. We obtain the transition value z_{tr} where the models transit from deceleration to acceleration at $z_{tr} = 0.610^{+0.030}_{-0.022}$

and $z_{tr} = 0.631^{+0.037}_{-0.023}$ for VGCG model, and $z_{tr} = 0.674^{+0.029}_{-0.016}$ and $z_{tr} = 0.687^{+0.036}_{-0.031}$ in case of VCG model, respectively. These transition values are very close to the ΛCDM transition values (cf. Table 3). We also present the values of z_{tr} and q_0 in Table 4 for these models without matter creation.

The evolutions of EoS parameter $w(z)$ with z of ΛCDM, VGCG and VCG models are shown in Figs. 10 and 11 with two datasets. For both datasets, EoS shows quintessence phase ($-1 < w < 0$) at present and ΛCDM behavior at late epoch. Figures 12 and 13 show the evolutions of the jerk parameter, $j(z)$ with respect to z for the discussed models using BASE and $BASE + R21$ datasets. Based on these two datasets, the present values of $j(z)$ for VGCG model are $j_0 = 0.933^{+0.21}_{-0.21}$ and $j_0 = 0.941^{+0.10}_{-0.10}$ where as for VCG model we get $j_o = 0.979^{+0.02}_{-0.02}$ and $j_0 = 0.966^{+0.02}_{-0.02}$, respectively which are very close to the value $j_0 = 1$ of ΛCDM model.

The ages of Universe for all the models are given in Table 3. The constrains on the age of the Universe for VGCG model are $t_0 = 13.91^{+0.03}_{-0.03}$ Gyr with BASE dataset and $t_0 = 13.94^{+0.07}_{-0.07}$ Gyr with $BASE + R21$ dataset whereas for VCG model we have $t_0 = 13.87^{+0.03}_{-0.03}$ Gyr and $t_0 = 13.89^{+0.01}_{-0.01}$ Gyr, respectively. The ages of the Universe for these Chaplygin gas models are very close to the age of the Universe of ΛCDM model. In Table 4, we list the present values of z_{tr}, q_0, w_0, j_0 and t_0 for the proposed models without matter creation to compare the deviation for constraint results on extended CG models that with matter creation.

7.2. Stability of the model

In order to determine the stability of the models, we analyze the squared sound speed of the VGCG and VCG fluids with and without matter creation. For any cosmic fluid model, the squared sound speed $\mathcal{C}_S^2$ can be estimated from the relation: $\mathcal{C}_S^2 = dp_{Ch}/d\rho_{Ch}$. It is noted that $\mathcal{C}_S^2 \geq 0$ corresponds to the stable behavior while $\mathcal{C}_S^2 < 0$ leads to unstable behavior of the model. Thus, the physical values of $\mathcal{C}_s^2$ for stable model must be in the range of (0, 1). Outside of this region, one encounters gradient/tachyonic instabilities and/or instabilities linked to superluminal propagation.

The squared sound speed for VGCG model is given by

$$\mathcal{C}_S^2 = \frac{\alpha A_s(1-\frac{n}{3(1-\beta)(1+\alpha)})(1+z)^n}{A_s(1+z)^n + (1-A_s)(1+z)^{3(1-\beta)(1+\alpha)}}. \tag{29}$$

and for VCG model we have

$$\mathcal{C}_S^2 = \frac{A_s(1-\frac{n}{6(1-\beta)})(1+z)^n}{A_s(1+z)^n + (1-A_s)(1+z)^{6(1-\beta)}}. \tag{30}$$

The sound speed should be positive in the stable model and hence this is justified by taking the constant $\alpha > 0$. Using the best-fit values of model's parameters of BASE and BASE+R21 datasets in above equations, we find the current values $\mathcal{C}_S^2 = 0.329$ and $\mathcal{C}_S^2 = 0.379$ for VGCG model while $\mathcal{C}_S^2 = 0.730$ and $\mathcal{C}_S^2 = 0.740$ for VCG model which are listed in Table 3. We plot the trajectories of $\mathcal{C}_S^2$ with z in Figs.14 and 15 using two combinations of datasets for VGCG and VCG models. The trajectories show that the squared sound speed is always positive through out the evolution lying in $(0, 1)$ and hence positive and less than unity in both the discussed models. This ensure that these

models do not surpass the velocity of light which confirm their stability. Table 4 shows the $\mathcal{C}_S^2$ for VGCG and VCG models without matter creation. The $\mathcal{C}_S^2$ are positive and less than unity that also confirm the stability.

7.3. Model selection

We calculate the values of χ^2_{min}/dof for ΛCDM, VGCG and VCG models with and without matter creation, which are placed in Tables 5 and 6, respectively. Here, the value of dof (degree of freedom) equals to the number of observational data points (N) minus the number of parameters (K). Here, the number of observational data points for BASE is $N = 273$ (Cosmic Chronometer =30, type Ia supernova(pantheon)=40 and Uncorrelated BAO=17, Hubble diagram for quasars = 24 and Gamma Ray Bursts=162), and $N = 274$ for BASE+R21, and number of parameters are $K = 3, 6$ and 5 for ΛCDM, VGCG and VCG models with matter creation, and $K = 5$ and 4 for VGCG and VCG models without matter creation, respectively. From Tables 5 and 6, we observe that both the models with and without matter creation have $\chi^2_{min}/dof < 1$ for both datasets. This shows that both the models are in good agreement with respect to the observational data as far as χ^2_{min}/dof is concerned.

Although the above analysis are in good agreement with one another, further differences arise due to the choice of cosmological model made.

In what follows, we use the information criteria (IC) which have a deep underpinning in the theory of statistical inference. There are two such IC, namely, Akaike information criteria (AIC) [87] and Bayesian information criteria (BIC) [88], which are respectively

defined as

$$AIC = \chi^2_{min} + \frac{2NK}{N-K-1}, \tag{31}$$

$$BIC = \chi^2_{min} + K \ln N. \tag{32}$$

where χ^2_{min} measures the quality of the model and K, the number of parameters, interpret model complexity. We calculate the relative values between different models. The one that minimizes the AIC (or BIC) is usually considered the best model. Using ΛCDM as the reference model, we define the AIC and BIC differences as follows: $\Delta AIC = AIC_x - AIC_{\Lambda CDM}$ and $\Delta BIC = BIC_x - BIC_{\Lambda CDM}$, where x represents either VGCG or VCG model. This gives the assessment of strength of the models. The criteria for judging the AIC model [89] are: when $0 \leq \Delta AIC < 2$, the model has almost same support from the data as the best model, for $2 < \Delta AIC \leq 4$, the model is considerably less supported, the range $4 < \Delta AIC < 10$ still supports the considered model. The observational data does not support the model at values of $\Delta AIC > 10$.

In the case of BIC, the range $\Delta BIC < 2$ is considered to support the model from observational data. There is slight evidence against the considered model if $2 < \Delta BIC < 6$. For a value in the range $6 < \Delta BIC < 10$, we obtain strong evidence against the considered model; if $\Delta BIC > 10$, we obtain even stronger evidence against the model [90].

The AIC (BIC) and $\Delta AIC(\Delta BIC)$ for VGCG and VCG models with and without matter creation against the ΛCDM model are listed in Tables 5 and 6, respectively. The ΔAIC values of VGCG and VCG models show that these models are still supported by current observational data. For BIC selection method, it seems that these models are not in favored by observational data. The reason is that AIC is always more general

towards extra parameters whereas BIC tends to penalize them. Hence, the AIC remains useful as it gives an upper limit to the number of parameters.

7.4. Bayesian evidence analysis

In this subsection, we first briefly review the basis of Bayesian inference and model comparison. We then present the computation of the Bayes factor of the two proposed models. The Bayesian evidence applies the same type of likelihood analysis familiar from parameter estimation, but at the level of models rather than parameters. It depends on goodness of fit across the entire model parameter space [91]. It comes from a full implementation of Bayesian inference at the model level, and is the probability of the data given model. It updates the prior model probability to the posterior model

probability using Bayes theorem. The Bayesian evidence is defined as [91–93]

$$E = \int \mathcal{L}(\theta) P(\theta)\, d\theta \tag{33}$$

where θ is the vector of parameters, $\mathcal{L}$ is the likelihood, and $P(\theta)$ is the prior distribution of those parameters before the data were obtained. The evidence of a model is thus the average likelihood of the model in the prior. The Bayesian evidence rewards model predictiveness. Hence the evidence will not penalize the extra parameter in this case, because it does not change the model parameters.

The ratio of the evidence of two models, say M_1 and M_2 is known as the Bayes

Accepted Manuscript
For Review Only

factor which is defined as [94]

$$B_{12} = \frac{E(M_1)}{E(M_2)}, \tag{34}$$

The Bayes factor provides a measure with which to discriminate between the models. It is usual to consider the logarithm of the Bayes factor, for which the so-called Jeffreys scale [95,96] gives empirically calibrated levels of significance for the strength of evidence. Many papers on Bayesian evidence have adopted the interpretive scale suggested by Jeffreys which is presented in Table 7. For each model and dataset we estimate the values of the logarithm of the Bayesian evidence ($\ln E$) and the Bayes factor ($\ln B$) which is the difference between the mean $\ln E$ of ΛCDM model and model concerned. These values are obtained by taking the priors and the dataset described in Sect. 6. We assumed the ΛCDM model as the reference one, say M_1 and therefore its entry is zero by definition.

Table 5 presents the Bayesian evidence and Bayes factor for VGCG and VCG models with matter creation. Looking at the "BASE" and "BASE+R21" datasets respectively, we find $\ln B_{12} = 2.114$ and $\ln B_{12} = 1.983$ for VGCG model, and $\ln B_{12} = 2.689$ and $\ln B_{12} = 2.581$ for VCG model which suggest that VGCG model has positive evidence where as the VCG model has moderate evidence.

Similarly, using the priors and the same datasets, we obtain the Bayes factor for VGCG and VCG models without matter creation which are provided in Table 6. By considering the "BASE" data, we find $\ln B_{12} = 2.271$ for VGCG model and $\ln B_{12} = 8.994$ for VCG model. BASE+R21 data gives $\ln B_{12} = 1.37$ for VGCG model and $\ln B_{12} = 8.318$ for VCG model. It suggests that VGCG model has positive evidence by both the datasets where as the VCG model has strong (decisive)) evidence.

8. Conclusion

In this paper, we have examined the variable generalized Chaplygin gas model inspired by matter creation mechanism in cosmology. Our motivation of this study was in effects of matter creation on the evolution of the Universe filled by variable generalized Chaplygin gas as a perfect fluid using the latest cosmological observations. Specially, we have proposed two Chaplygin gas models with matter creation, i.e., VGCG and VCG and have investigated their evolutionary behaviors via observational datasets. We have placed the constraints on them using two different data combinations: BASE (BAO+CC+SC) and BASE+R21. We have found that the VGCG, VCG and ΛCDM models give a similar χ^2_{min} and correspondingly χ^2_{min}/dof. In what follows, we summarize the results and evolutions of these models.

As stated above, the focus has been on exploring the cosmological models influenced by gravitational matter creation, specifically considering an extended version of the Chaplygin gas with EoS $p_{Ch} = -\frac{A(a)}{\rho^{\alpha}_{Ch}}$ where $0 < \alpha \leq 1$. This approach is utilized to examine the late-stage acceleration of the Universe within the context of a flat FLRW spacetime. Additionally, we have delved into a special scenario where $\alpha = 1$,

Accepted Manuscript
For Review Only

corresponding to the variable Chaplygin gas with EoS $p_{Ch} = -\frac{A(a)}{\rho_{Ch}}$, and incorporated the concept of matter creation. A parallel discussion on these models without matter creation has also been presented.

In the preliminary discussion, it has been explained that matter creation induced by gravity can be regarded as an irreversible scalar phenomenon, contributing an extra decay (or creation) pressure to the energy-momentum tensor in the cosmological fluid mixture. This supplementary creation pressure is characterized by the matter creation rate, denoted as Γ, along with other relevant physical parameters of the fluid. Studies have shown that viewing the Universe as an open system with ongoing matter creation aids in comprehending its current rapid expansion phase. As the nature of the matter creation rate, Γ is still unknown, we have adopted phenomenological approach, assuming Γ evolves as $\Gamma \propto H$. These models were found to be consistently either decelerating or accelerating, lacking a transition from a deceleration phase to an acceleration phase, contradicting the SNe observational data. Nevertheless, our findings indicate that by incorporating the VGCG and VCG equations of state in the matter creation model, a phase transition does occur, even with the aforementioned form of Γ.

The initial section of this manuscript details the analytical solutions derived for matter creation models applying both VGCG and VCG equations of state. Solutions for various cosmological parameters such as energy density, Hubble parameter, deceleration parameter, EoS parameter, and jerk parameter have been deduced as functions of redshift. In the manuscript's latter section, two different joint observational analysis have been performed to constrain the parameters of the model. Tables 1 and 2 present the best-fit values for these model parameters with and without matter creation. We observe that VGCG and VCG models with matter creation can alleviate the current H_0 tension from 3.92σ to 1.51σ and 1.84σ using BASE data. The current values for $q(z)$, $j(z)$, $w(z)$, $t(z)$ and $\mathcal{C}_S^2$ are listed in Tables 3 and 4 and their evolutions have been plotted in Figures 4-13. Our observations indicate a notable variance in the VGCG and VCG models with parameter β from the ΛCDM. These plots vividly illustrate the models' capability to generate late-stage cosmic acceleration while also reflecting a decelerated expansion in earlier times. The transition redshift values, q_0, w_0 and age of the Universe with respect to VGCG and VCG models with and without matter creation are found to be very close to ΛCDM and Planck 2018 release. The evolution trajectories of $j(z)$ reveal minimal deviation from the ΛCDM model for both VGCG and VCG models.

Our analysis employing both AIC and BIC methodologies indicates that models such as VGCG and VCG with and without matter creation exhibit in the range of $4 < \Delta AIC < 10$, suggesting to as much as the preferred model with the joint observational data. In terms of BIC values, the models VGCG and VCG with and without matter creation present $\Delta BIC > 10$, providing evidence against the data used for analysis. It is noteworthy that the squared sound speed for these models lies within the $0 < \mathcal{C}_S^2 < 1$ range, thereby not exceeding the speed of light, which signifies the stability of these models. Consequently, it is deduced that the models discussed in this paper yield cosmological parameters that are well-bounded by the combined observational da-

ta. Furthermore, these models closely resemble the ΛCDM model in their behavior.

In statistical sense a physical model may be thought as described by a set of parameters. The determination of these parameters may be carried out in many ways; the most commonly used framework to accomplish this is the Bayesian evidence analysis. We have calculated the Bayesian evidence and consequently the Bayes factor to measure the discrimination between the models. Assuming priors for different parameters and ΛCDM model as reference one, we have found that the VGCG model with and without matter creation has positive evidence on Jeffrey scales where as VCG model has moderate evidence with matter creation, and has decisive evidence without matter creation by both datasets.

Acknowledgement

We thank the anonymous referees for useful comments and suggestions that have helped us to improve our manuscript. One of the authors, Y.B. is thankful to Delhi Technological University, New Delhi for providing Research Fellowship to carry out this work.

***Abstract*— Automatic Image captioning is a computationally intensive and structurally complicated task that describes the contents of an image in the form of a natural language sentence. Methods developed in the recent past focused mainly on the description of factual content in images thereby ignoring the different emotions and styles (romantic, humorous, angry, etc.) associated with the image. To overcome this, few works incorporated style-based caption generation that captures the variability in the generated descriptions. This paper presents a Style Embedding-based Variational Autoencoder for Controlled Stylized Caption Generation Framework (RFCG+SE-VAE-CSCG). It generates controlled text-based stylized descriptions of images. It works in two phases i.e., (*i*) Refined Factual Caption Generation (RFCG), and (*ii*) SE-VAE-CSCG. The former defines an encoder-decoder model for the generation of refined factual captions. Whereas, the latter presents a style embedding-based variational autoencoder for controlled stylized caption generation. The overall proposed framework generates style-based descriptions of images by leveraging Bag-of-Captions (BoC). More so, with the use of a controlled text generation model, the proposed work efficiently learns disentangled representations and generates realistic stylized descriptions of images. Experiments on MSCOCO, Flickr30K, and FlickrStyle10K provide state-of-the-art results for both refined and style-based caption generation, supported with an ablation study.**

***Index Terms*— Bag-of-Captions (BoC), Computer Vision, Controlled Text Generation, Image Captioning, Natural Language Processing, SMU, Stylized Image Captioning, Variational Autoencoder.**

I. INTRODUCTION

IMAGE captioning comprises the description of different objects, their properties, and the interaction between objects in the form of natural language description [1]. With the advent and recent developments in deep-learning techniques, image caption generation has made astounding progress in recent years. Recent methods focus [2, 3, 4, 5] mainly on the factual description of the image, ignoring the inherent sentiments or style within the image. Style-based description of an image provides a way to imitate the language expressing the behavior of human beings. It learns about linguistic styles and utilizes this knowledge to generate style-based image descriptions. Fig. 1, distinguishes between the Factual (F) and style-based (romantic (R), and humorous (H)) caption generation. This example shows that style rich caption provides more reasonable and sentimental descriptions with different opinions or feelings. These artistic captions generated can be further used in numerous applications like storytelling, for visually impaired solutions, visual question answering, etc. and providing better understanding of human expressions. Also, image captions incorporating multiple styles will make visually impaired people perceive images from different perspectives.

Fig. 1: Difference between Factual Image Captions and Stylized Image Captions

In recent past, very few works [6, 7, 8] have explored the generation of the description of images with a specific style. It resulted in the generation of a few publicly available style datasets i.e., Flickrstyle10K [7] , SentiCap [9], and Personality caption dataset [10]. Stylized captioning observes the limitation in generating realistic stylized captions due to limited available paired data i.e. *{Image, factual captions, styled captions-Humorous, Romantic}*. The idea of stylized captioning can be made more generic and robust by developing frameworks independent of the paired set of inputs. To the best of our knowledge, only [10, 11] have attempted to design the frameworks independent of the paired set of inputs. Above mentioned works [6, 7, 8] integrated factual image content with style phrases and rely on paired factual and stylized caption data for training. Ideally, a stylized image captioning model should fulfill two conditions, (*i*) provide the correct description of images, and *(ii)* generates correct stylized words or phrases in correct positions of descriptions. However, the generated sentences do not incorporate sufficient style-related information which is important to describe the content of an image. This may happen due to small size of stylized dataset due to which it is difficult to preserve the correlations between images and captions. This makes the generation of stylized

This article has been accepted for publication in IEEE Transactions on Cognitive and Developmental Systems. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TCDS.2024.3405573

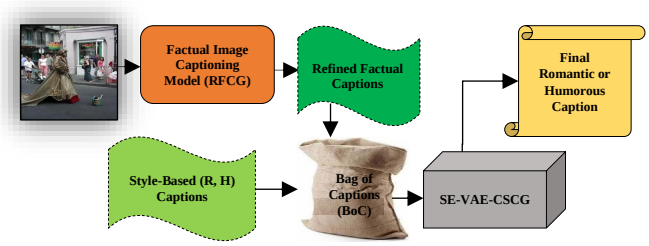

Fig. 2: Block Diagram Representation of the proposed framework

descriptions very difficult. To overcome this challenge and capture the variability in style rich captions, the frameworks should utilize the unpaired set of images and captions, i.e., image is not available with any styled caption. This makes the caption generation acceptable in wider range of applications by not being restricted with the availability of factual and styled captions. In this direction, the proposed work defines Style Embedding-based Variational Autoencoder for Controlled Stylized Caption Generation Framework (SE-VAE-CSCG). It works in two phases. Initially, it generates refined factual captions and forms a Bag-of-Captions by combining both paired and unpaired sets of samples. In the second phase, the BoC feeds the captions to SE-VAE Controlled Caption Generator. Fig. 2 represents a block diagram of the proposed method. The main contributions of this paper are as follows:

(1) An efficient encoder-decoder-based Refined Factual Caption Generation (RFCG) is proposed. It helps the framework to learn from multiple GTs wisely along with visual features, being independent of any personal perspective. RFCG leverages Smooth Maximum Unit (SMU) activated (Squeeze and Excitation Network) SENet at the encoder and soft attention, LSTM, and Bi-LSTM at the language decoder. This improves channel interdependencies at almost no computational cost.

(2) A novel Bag of Captions (BoC) is defined which is a collection of both paired and unpaired samples of caption set ∈ {refined factual, romantic, humorous} for every image sample. It enables the framework to learn and generate stylized captions even if the styles of the image are not highlighted in Ground Truths (GTs).

(3) The proposed SE-VAE-CSCG Framework works in two parts, a modified Variational Autoencoder with Style Embeddings (SE-VAE) and a Deep-LSTM-based generator and discriminator. It learns both unstructured (semantics) and structured (style) feature distributions jointly to generate controlled and plausible stylized captions by updating the style weights.

(4) Extensive experiments on MSCOCO [12], Flickr30K [13], and a subset of FlickrStyle10K [7] demonstrate the efficiency and efficacy of the proposed Refined Factual Image Captioning model and Controlled Style Caption Generation model.

The organization of the rest of the paper is as follows: Section II presents the different state-of-the-art for factual image captioning, stylized image captioning, and controlled text generation. Section III discusses the proposed methodology. Section IV presents the Dataset Used, Implementation details with the results obtained. Finally, Conclusions are drawn in Section V.

II. RELATED WORKS

When This section discusses the related works for factual image captioning, stylized image captioning, and controlled text generation.

A. Factual Image Captioning

Image captioning is a multidisciplinary task that aims to describe the contents of an image in the form of natural language. Traditional methods [14, 15] cannot generate variable-length captions and the descriptions generated from these methods are far from natural. To overcome these limitations deep-learning-based methods [3] [16, 17] are incorporated. Mao et al. [16] proposed a multimodal-RNN structure that utilized deep-CNN networks with m-RNN to generate novel sentence descriptions. Vinyals et al. [17] proposed an end-to-end framework that generated qualitative and quantitative results by generating sentences in plain English. Further, an extension to LSTM is presented in [18] coined as g-LSTM. This model inputted extra semantic information from the image and generated variable-length natural sentences for a particular image. Inspired by the recent development in attention mechanisms in deep learning, various models adopted different attention mechanisms [2, 3] etc. Further, few models [19, 20] paid more attention to salient objects for the generation of corresponding words. Lu et al. [21] proposed an adaptive attention-based captioning model with visual sentinel. This model decides whether to pay attention to the image or the visual sentinel. The work in [22] presented a modified beam search strategy for concept-augmented image captioning with fused YOLO9000 and ResNet features.

With the advancements in deep-learning, the transformer-based models [5] [23] are being widely used for image captioning task. These models captured relative spatial relationship between image regions and provided a better computational complexity. Also, Li et al. [24] proposed entangled transformer to extract more discriminative features by considering novel objects. Pan et al. [25] proposed X-linear attention network for image captioning that leveraged 2^{nd} and higher order interactions by exploiting low-rank bilinear pooling. In recent times, Large Language Models (LLMs) demonstrated outstanding zero and few-shot performance on a range of tasks like translation, text summarization, and common-sense reasoning. These models are able to learn the complex relationships between visual characteristics and language expressions because they have been trained on large datasets that contain corresponded with images and captions. Researchers utilized the concept of LLM in image captioning tasks to improve caption generation and to get enriched captions [26, 27]. LLM-based captioning models still require more finer visual details as the caption generated does not offer more detail. Also, the LLM-based captioning models sometimes fails

This article has been accepted for publication in IEEE Transactions on Cognitive and Developmental Systems. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TCDS.2024.3405573

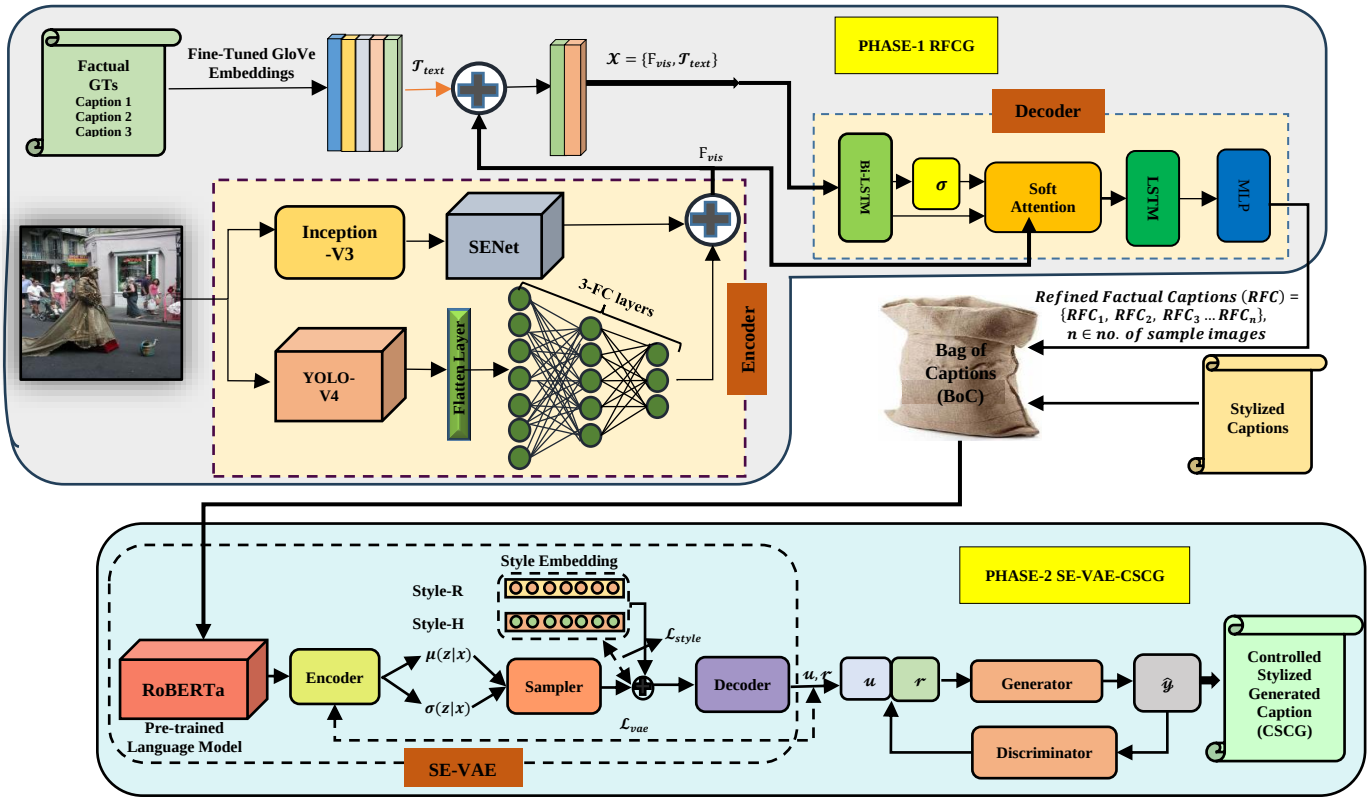

Fig. 3: Illustration of the proposed Control with style Framework: Phase-I RFCG Module, and Phase-II SE-VAE-CSCG Module. In Phase-I, RFCG module encoder generates visual embeddings as F_{vis} for the input image. Whereas RFCG module decoder receives combination of text embeddings $\mathcal{T}_{text}$ and the visual embeddings F_{vis} given by $\mathcal{X} = \{F_{vis}, \mathcal{T}_{text}\}$, generating refined captions as Refined Factual Captions (RFC) = $\{RFC_1, RFC_2, RFC_3 \ldots RFC_n\}$, n ∈ no. of sample images. From Phase I, a Bag of Captions (BoC) is defined that leverages Style Embedding based Variational Auto-Encoder-CSCG (SE-VAE-CSCG) in Phase-2 for generation of controlled stylized captions.

to elicit a judgment or rarely, generate malformed image descriptions. This may omit semantically important image details as LLM-based fusion process sometimes ignores inter-element dependencies. To overcome this issue in captioning model, this paper fuses the factual knowledge from images with the stylized knowledge to generate coherent and diverse image captions.

B. Stylized Image Captioning

Stylized image captioning aims to generate captions that incorporate different styles or sentiments in the captions. This technique focuses not only on the factual content but also on the linguistic style content in the image. Gan et al. [7] proposed a novel framework that addressed the generation of captions with styles for images and videos. This model incorporated style factored-LSTM modules and multi-task learning. Also, Chen et al. [6] presented a style-factual LSTM module that captured factual and style knowledge for the generation of style-based descriptions of images. Another work proposed an adversarial learning model named MSCap [28] for multi-style image captioning. Existing methods are based on styles trained captions aligned to images, generating captions with low relevance. To overcome this limitation Mathews et al. [29] proposed SemStyle to generate visually relevant styled captions from a large corpus of styled text without paired images. Sentimental Image Captioning [8] automatically incorporated sentiments within images using attention LSTM. Further, fluent and relevant descriptions are generated with inherent sentimental styles and language LSTM. Li et al. [11] proposed a novel data augmentation framework that extracted style phrases from small-scale stylized sentences and provides factual descriptions from them. Another work, [30] proposed two-step transformer-based method for style-based caption generation: first, separate style presentations from substantial corpora of stylized text; then, join the separated style representations to the image content. Wu et al. [31] generated stylized sentences in a multi-pass decoding process using reinforcement learning paradigm. Few researchers [32, 33] also focused on LLM model based stylized caption generation. Though these methods have shown promising results, they still require sufficient samples with desired style labels, and additional training. However, these methods are less flexible as they require paired prompts that represent the relations and differences between different styles. To address this concern, the paper uses paired style and factual descriptions for an image to multiple stylized descriptions with the use of unpaired data that also captures variability in the generated captions. With this the proposed model also provided an improvement in style accuracy as the proposed framework incorporates text-only data for stylized captioning. This enables the proposed framework to learn task-specific details and subtleties that are challenging for fully zero-shot methods.

C. Controlled Text Generation

Deep generative models have gained immense popularity in recent years. Hu et al. [34] proposed a formal connection

This article has been accepted for publication in IEEE Transactions on Cognitive and Developmental Systems. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TCDS.2024.3405573

between GANs and VAEs which provided a powerful tool to analyze a diverse set of existing model variants. Goodfellow et al. [35] introduced GAN that simultaneously learns the generator-discriminator model and provided improvements in the performance of the classification models for limited labeled data. Larsen et al. [36] combined GAN and VAE to learn feature representation in the discriminator module based on the VAE reconstruction objective for enhanced image generation. Due to the non-differentiability of discrete samples in text generation, discriminator-based modules are hard to implement. Few works [37] [38] focused on VAEs without discriminators for the controlled generation of text. These models provided good results when compared with LSTM language models but still, they lack disentangled latent representations. To overcome this limitation, Chen et al. [39] presented a GAN model that learned disentangled representation in an unsupervised manner. Further, Siddharth et al. [40] discussed VAEs-based semi-supervised learning for disentangled representation of images. In another work, Hu et al. [41] presented a controllable text generation model which generated plausible text sentences controlled by learning disentangled latent representations with designated semantics. Intending to generate sentences with semantic coherence Betti et al. [42] presented CTERM-GAN which assesses the coherence with the external conditioning. To provide improvements in interpretability this paper focused on the disentangled representation of text with consistent style or sentiments.

III. PROPOSED METHODOLOGY

This section discusses a proposed framework which is sub-divided into two sub-sections namely: (1) Refined Factual Caption Generation (RFCG), and (2) Stylized Image Captioning using SE-VAE, and modified controlled text generation module. The two-phase proposed framework is depicted in Fig. 3. To generate a style-based description of images first the factual descriptions are extracted and generated factual captions are fed to the SE-VAE-CSCG. This model is able to generate stylized descriptions with unpaired style transfer i.e., for a given image there is no need for corresponding factual and stylized captions. Also, this model does not require any image features for the generation of style-based descriptions. The detailed structure of the two models is discussed below:

A. Refined Factual Caption Generation

Refined Factual Image Caption Generation (RFCG) utilizes an encoder-decoder structure to generate refined factual captions of images using the available factual GTs per image. It helps the model to produce human-independent (unbiased) refined captions by merging both visual features (global features and object-level local features) with finetuned GloVe embeddings-based text encodings in the encoder. The decoder learns the combined visual and textual encodings to generate the most likely refined factual descriptions unbiased from human perception using Bi-LSTM and LSTM layers.

(i) RFCG- Encoder

In RFCG-Encoder, Inception-V3 [43] extracts global spatial features of images. Symmetric and asymmetric modules in 42 layered architecture of Inception V3 [43] provide low error rates with high efficiency when compared with its previous versions and its contemporaries. A feature vector of dimensions $(10 \times 10 \times 2048)$ extracted from the Inception-V3 is passed to the Smooth Maximum Unit (SMU) activated Squeeze and Excitation Network (SENet) [44] to improve the channel interdependencies with no added computational cost. It performs channel scaling with learned weighted features as f_{vec}. We have used SMU [45] activated features to map with original channels, that has the potential to provide performance improvements when compared with traditional activation functions i.e., ReLU. SMU can be realized using the smooth activation of the maximum function which can smoothly approximate the ReLU activation. The internal architecture is provided in Fig. 4. Mathematically, squeeze and excitation operations are represented by:

$$z_{se} = \mathbb{f}_{sq} = \frac{1}{H \times W} \sum_{i=1}^{H} \sum_{j=1}^{W} m_{se}(i,j) \quad (1)$$

$$s = \mathbb{f}_{ex}(z, W) = s_{ex} \quad (2)$$

The output is scaled and is given by:

$$\mathbb{f}_X = \mathbb{f}_{scale}(s_{ex}, m_{se}) \quad (3)$$

To incorporate local descriptions of the visual semantics, local objects in the scene are detected using YOLO-V4 [46]. DropBlock regularization in YOLO-V4 supports better detection speed, accuracy, and mean average precision. The detected object features are flattened and passed through 3-fully connected layers resulting in a feature vector of dimension $[1 \times 256]$. Now, both the global and local visual encodings are concatenated as $\mathrm{F}_{vis} = \{\mathbb{f}_1, \mathbb{f}_2, \ldots . \mathbb{f}_N\}, \mathbb{f}_i \in \mathcal{R}^{\mathcal{D}}, i \in (1, N)$ and are further merged with fine-tuned GloVe [47] embedding-based text encodings given by $\mathcal{T}_{text}$. Unlike Word2Vec [48], GloVe embeddings highlight word co-occurrences to obtain the word embeddings. Now, the text and visual encodings are given as $\mathcal{X} = \{\mathrm{F}_{vis}, \mathcal{T}_{text}\}$, are combined and passed to the RFCG decoder.

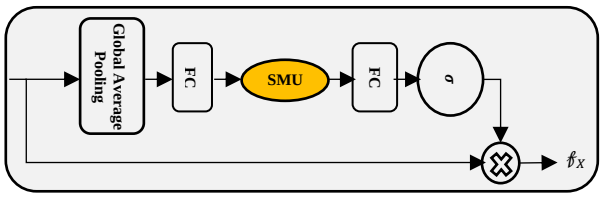

Fig. 4: SMU-activated SENet

(ii) RFCG-Decoder

This sub-section describes briefly the language generation process involved in the proposed RFCG. The language decoder is based on the Bi-LSTM network. The Bi-LSTM network solves well the problem of fixed sequence-to-sequence prediction. The combined text and visual embeddings $\mathcal{X} = \{\mathrm{F}_{vis}, \mathcal{T}_{text}\}$ are fed to the Bi-LSTM layer. The output generated from the Bi-LSTM network is activated with sigmoid activation. Also, the sigmoid-activated (σ) output is attended to using a soft attention mechanism. The soft attended features obtained are learned with the help of F_{vis}. By multiplying the related segmentation map with low weight, soft attention discredits unimportant parts. Therefore, high attention zones retain their original worth, whereas low attention areas approach zero. The process can be described mathematically as:

$$\mathbb{S}_i^t = \mathcal{W}_{\mathbb{S}} \tanh(\mathcal{W}_{\mathcal{X}} \mathcal{X}_i + \mathcal{W}_h h_{t-1} + \mathscr{b}_s) + \mathcal{W}_f \mathbb{f}_i \quad (4)$$

Where, are the $\mathcal{W}_{\mathbb{S}}$, $\mathcal{W}_{\mathcal{X}}$, $\mathcal{W}_{\mathbb{f}}$ $\mathcal{W}_h$ are the weights and $\mathscr{b}_s$ is the

This article has been accepted for publication in IEEE Transactions on Cognitive and Developmental Systems. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TCDS.2024.3405573

bias factor. Also, $\mathbb{S}_i^t$ is the importance score and

$$\mathbb{S}_i^t = (\mathbb{S}_1^t, \mathbb{S}_2^t \ldots . \mathbb{S}_n^t)^T \quad (5)$$

Furthermore, the attention at time t is given by:

$$a_i^t = \frac{\exp(\mathbb{S}_i^t)}{\sum_{i=1}^{n} \exp(\mathbb{S}_i^t)} \quad (6)$$

For improved feature learning, the soft-attended and sigmoid-activated features are learned using LSTM layers. Further, the resulting output generates a word on the next time node using the MLP function that incorporates backpropagation through a time algorithm to update the parameters of the LSTM network. The objective function defined for the optimization of the proposed RFCG is given by:

$$\vartheta = arg \max_{\vartheta} \sum_{m,y} \sum_{t=0}^{N} \log p(y_t | m, \vartheta, y_1, y_2 \ldots y_{t-1}) \quad (7)$$

ϑ is the learnable parameter with m feature maps whose weight is $m \in \{m_1, m_2 \ldots m_t\}$. y is the sentence that describes the image well. Further, the cross-entropy loss is incorporated to minimize the loss function to maximize the probability of each correct word appearing. The cross entropy-loss function is given by:

$$\mathcal{L}(\vartheta) = -\sum_{t=1}^{N} \log\left(p_\theta(w_t^* | \mathbb{G}_{1:t-1}^*)\right) \quad (8)$$

where N is the number of words in a sentence; ϑ denotes all the parameters in the model; $\mathbb{G}_{1:t-1}^*$ is the Ground Truth (GT).

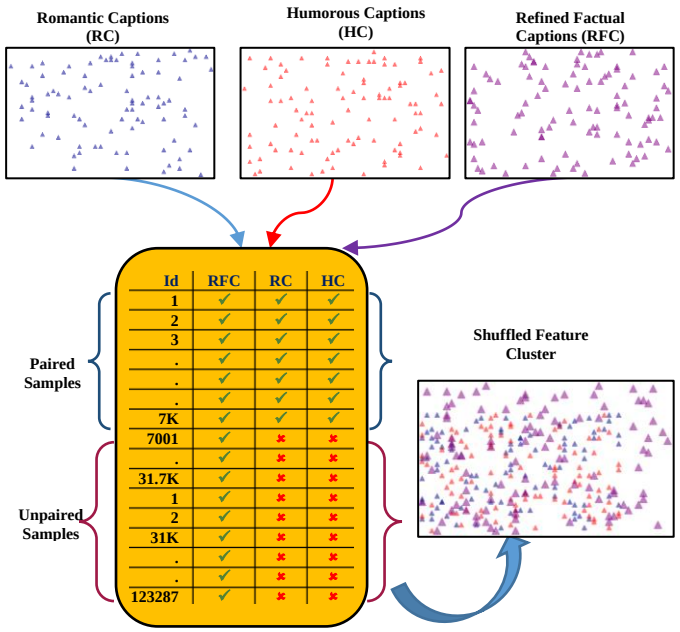

Fig. 5: Structure of Bag-of-Captions (BoC)

(iii) Bag-of-Captions (BoC)

The Refined Factual Captions (RFC) generated from the factual image captioning model, given as $RFC = \{RFC_1, RFC_2, RFC_3 \ldots RFC_n\}, n \in no.of\ sample\ images$ and the stylized captions- Romantic captions (RC) and Humorous captions (HC) combinedly define BoC, as shown in Fig. 5. It consists of 7K paired sample set as $\{RFC, RC, HC\}$ while the remaining samples include only RFC obtained from Flickr30K and MSCOCO datasets. Therefore, the BoC contains a set of paired captions and unpaired captions. All the samples are combined and shuffled and the shuffled feature cluster of captions is further split into training, validation, and test sets. Table I presents the details of training, testing, and validation splits. The contents of BoC are fed to SE-VAE-CSCG which are utilized for the generation of diverse and stylized descriptions of an image without directly depending on image features.

TABLE I
TEST, TRAIN & VALIDATION SPLITS FOR BOC

Datasets	Captions in BoC	Training Samples	Testing Samples	Validation Samples
Flickr30K FlickrStyle10K	RFC- 31,783 RC-7000 HC- 7000	32,048	6868	6867
MSCOCO FlickrStyle10K	RFC-1,23,287	1,15,287	11,000	11,000

B. SE-VAE-CSCG Model

It presents the Phase 2 of the proposed framework which is defined in two parts: (i) SE-VAE, and (ii) CSCG Module. The proposed modules generate stylized captions of an image using stylized embeddings based on variational autoencoder (SE-VAE) and controlled stylized caption generation. The architecture of the proposed method is depicted in Fig. 3.

(i) SE-VAE Module

The recent controlled text generation-based works [49] [50] [51] have explored the controlled text learning ability of Variational Auto-Encoder (VAE). In view of these works, the proposed work, attempts to introduce style-based caption representation for controlled text generations by defining modified Style-Embedding based Variational Autoencoder (SE-VAE), as depicted in Fig. 3. It receives paired and unpaired sample sets from BoC in the form of contextualized vector representation, derived from RoBERTa [52] by inferencing from both sentence and word embeddings. The VAE encoder constructs a latent distribution $\mathbb{N}(\mu, \sigma)$ using a mean and a variance vector. The latent distribution z is assumed to be a normal distribution whose loss function is defined as:

$$\mathcal{L}_{vae} = -\mathbb{E}_{q(z|x)}[\log p(x|z)] + \varphi.\mathbb{KL}(q(z|x)||p(z)) \quad (9)$$

Where the first term in the above equation represents the likelihood of the reconstruction of the original text x, while the second term is the KL-divergence between the latent distribution and standard normal distribution. Further, $p(z)$ is the prior for standard normal distribution, and $q(z|x)$ is the posterior distribution. Also, φ is the balancing parameter that learns the capacity between self-reconstruction and style features.

Previous works [41] [42] incorporated disentangling style attributes whereas the proposed method utilizes the style learnt from structured samples to generate target style representations for both unstructured and structured representations. It adjusts the style strength by simply adjusting the style weights. The embeddings are differentiated for different styles (romantic, humorous) using one hot vector encodings as Style-R and Style-H. It enhances the latent feature representations for both structures and unstructured latent vectors. Further, the style embeddings are represented by: $\mathbb{S} = \{s_1, s_2, \ldots, s_k\}, s_i \in \mathbb{R}^{k \times d}$, where $k = 2$ is the number of styles (Style-R and Style-H). These embeddings are randomly initialized and updated by minimizing the similarity between the style embeddings and latent fusion. The structure representation is depicted in Fig. 6, where the similarity is minimized using the

This article has been accepted for publication in IEEE Transactions on Cognitive and Developmental Systems. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/TCDS.2024.3405573

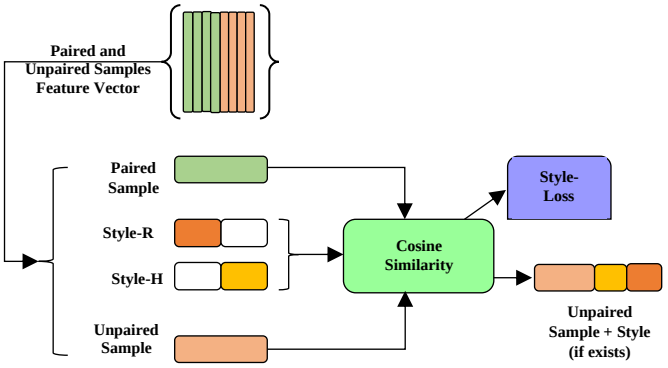

Fig. 6: Style-loss Calculation and Representation

cosine similarity with the assumption that style embedding is highly related to the latent features. The style loss for the same is defined as:

$$\mathcal{L}_{style} = -\sum_{i=1}^{k} \mathscr{b}_i \log\left(sigmoid\left(\cos\left(s_i, \mathcal{d}(z)\right)\right)\right) \quad (10)$$

In equation 7, the sigmoid function ensures the range of cosine similarity. $\mathscr{b}_i$=1 if the style given represents the style of the input sentence, otherwise $\mathscr{b}_i$=0. $\mathcal{d}(z)$ represents the stop gradient which is used to compute the style loss. Therefore, equation (9) is modified as:

$$\mathcal{L}_{\grave{vae}} = -\mathbb{E}_{q_{(Z|X)}}[\log p(x|z) + \mathcal{d}(\mathcal{s}_x)\,] + \varphi.\,\mathbb{KL}(q(z|x)||p(z)) \quad (11)$$

For sentence x, $\mathcal{s}_x$ represents its style embedding which is used as a constant vector. Hence, the total loss function defined for the proposed SE-VAE is:

$$\mathcal{L}'_{SE-VAE} = \delta_{vae}\mathcal{L}_{\grave{vae}} + \delta_{style}\mathcal{L}_{style} \quad (12)$$

Where, δ_{vae} and δ_{style} are the hyperparameters that balance the weights between VAE-loss and style loss.

(ii) CSCG Module

Controlled Stylized Caption Generation (CSCG) module, as shown in Fig. 3, leverages a generator and a discriminator structure. The output generated from the SE-VAE is represented in the form of unstructured representation $\mathcal{u}$ and structured representation $\mathcal{r}$. It trains the generator $\mathcal{G}$ that reconstructs the captions for generating plausible text. Further, the discriminator $\mathcal{D}$ enforces the generator to produce coherent attributes. The generator and the discriminator form a pair of collaborative learners and provide feedback signals to each other. Also, the collaborative optimization represents the wake-sleep algorithm [53].

The generator $\mathcal{G}$ is a Deep LSTM-RNN architecture that generates the final caption sequence in the form of tokens $\hat{x} = \{\hat{x}_1, \ldots, \hat{x}_T\}$ conditioned on $(\mathcal{u}, \mathcal{r})$, mathematically represented as:

$$\hat{x} \sim \mathcal{G}(\mathcal{u}, \mathcal{r}) = p_{\mathcal{G}}(\hat{x}|\mathcal{u}, \mathcal{r}) = \prod_t p(\hat{x}|\hat{x}^{<t}, \mathcal{u}, \mathcal{r}) \quad (13)$$

Where, $\widehat{x^{<t}}$ are the tokens preceding $\hat{x}$. Also, $\hat{x}$ is parametrized using the softmax function for time step t.

$$\hat{x} \sim softmax(o_t/\mathcal{T}) \quad (14)$$

$\mathcal{T} > 0$ is the temperature normally set to 1 and o_t is the logit vector.

The unstructured part incorporates standard Gaussian prior modeling for continuous variables whereas, the structured representation contains both continuous and discrete variables that encode different styles efficiently. Further, the SE-VAE is modified by combining the parameters of the encoder and generator. This modified SE-VAE loss is minimized to optimize the reconstructed captions, which is represented mathematically as:

$$\mathcal{L}_{SE-VAE} = -\mathbb{E}_{q_E(\mathcal{u}|X)q_{\mathcal{D}}(\mathcal{r}|X)}\left[\log p_{\mathcal{G}}(x|\mathcal{u}, \mathcal{r}) + \mathcal{d}(\mathcal{s}_x)\,\right] + \varphi.\,\mathbb{KL}(q_E(\mathcal{u}|x)||p(\mathcal{u})) \quad (15)$$

The distribution defined over $\mathcal{u}$ and $\mathcal{r}$ for the encoder and discriminator is mathematically given as:

$$\mathcal{u} \sim E(x) = q_E(\mathcal{u}|x) \quad (16)$$

$$\mathcal{D}(x) = q_{\mathcal{D}}(\mathcal{r}|x) \quad (17)$$

Further, these distributions are utilized as the output at the current step and the input to the next step along the sequence of decision-making. The resulting caption denoted by $\widetilde{\mathcal{G}_{\mathcal{T}}}(\mathcal{u}, \mathcal{r})$, is given as input to the discriminator that measures the fitness to the target attributes for structured and unstructured representation. The loss for the same is calculated as:

$$\mathcal{L}_{attr,\mathcal{r}} = \mathbb{E}_{p(\mathcal{u})p(\mathcal{r})}\left[\log q_{\mathcal{D}}(\mathcal{r}|\,\widetilde{\mathcal{G}_{\mathcal{T}}}(\mathcal{u}, \mathcal{r}))\right] \quad (18)$$

$$\mathcal{L}_{attr,\mathcal{u}} = \mathbb{E}_{p(\mathcal{u})p(\mathcal{r})}\left[\log q_E(\mathcal{u}|\,\widetilde{\mathcal{G}_{\mathcal{T}}}(\mathcal{u}, \mathcal{r}))\right] \quad (19)$$

Combining the equations, the final generator objective function is given as:

$$min(\mathcal{L}_{\mathcal{G}}) = \mathcal{L}_{SE-VAE} + \alpha\mathcal{L}_{attr,\mathcal{u}} + \beta\mathcal{L}_{attr,\mathcal{r}} \quad (20)$$

Where α and β are balancing parameters.

The discriminator is also a Deep-LSTM-based architecture that learned differently as compared to the SE-VAE encoder. The unstructured representation $\mathcal{u}$ is learned in an unsupervised manner while the structured representation $\mathcal{r}$ used labeled examples to entail a designated style (romantic or humorous). Therefore, efficient semi-supervised learning is defined for the discriminator. To learn the specified semantic meaning and style, a set of labeled examples $(\mathcal{X}_L = \{(x_L, \mathcal{r}_L)\})$ is used represented by:

$$\mathcal{L}_{disc} = \mathbb{E}_{\mathcal{X}_L}[\acute{\log}\, q_D(\mathcal{r}_L|x_L)] \quad (21)$$

Besides the conditional generator, $\mathcal{G}$ synthesizes noisy style-attribute pairs which used semi-supervised learning. To alleviate this issue minimum entropy regularization [54] is incorporated to provide robust model optimization. The resulting objective is given by:

$$\mathcal{L}_{\mathcal{D}-\mathcal{O}} = \mathbb{E}_{p_{\mathcal{G}}(\hat{x}|\mathcal{u}, \mathcal{r})p(\mathcal{u})p(\mathcal{r})}[log q_{\mathcal{D}}(\mathcal{r}|\hat{x}) + \rho\mathcal{H}\left(q_{\mathcal{D}}(\mathcal{r}'|\hat{x})\right)] \quad (22)$$

Where, $\mathcal{H}\left(q_{\mathcal{D}}(\mathcal{r}'|\hat{x})\right)$ is the empirical Shannon entropy of the distribution $q_{\mathcal{D}}$ and ρ is the balancing parameter. The final training discriminator objective is given by the following equation:

$$\min\left(\mathcal{L}_{\mathcal{D}}\right) = \mathcal{L}_{disc} + \theta\mathcal{L}_{\mathcal{D}-\mathcal{O}} \quad (23)$$

IV. RESULTS AND DISCUSSIONS

To evaluate the performance of the proposed framework MSCOCO, Flickr30K, and FlickrStyle10K datasets are used in the experimentations. The Flickr30K and MSOCOCO datasets are used for refined Factual Caption generation. To generate text-controlled stylized captions for any given image, style annotations for two different styles namely romantic and humorous styles are utilized from FlickrStyle10K [7]. For this dataset, only 7K style annotations are publicly available. This results in the collection of 7K paired samples and 24,783 from Flickr30K and 1,23,287 MSCOCO which are used for Phase II experiments.

A. Implementation Details

In phase-1, the Refined Factual Caption Generation (RFCG) is trained with Adam [55] optimizer with a learning rate of $1e^{-5}$ for the encoder module whereas for the language decoder, the learning rate is set as $4e^{-4}$. Further, the batch size is set as 64 and RFCG is trained for 60 epochs. Also, to extract the text features, fine-tuned GloVe embeddings are utilized with dimensions for embeddings as 300. To evaluate the performance of the proposed RFCG, BLEU@N [56] and METEOR (M) [57] scores are used.

For the generation of stylized captions, in Phase-2, using the proposed SE-VAE-based controlled text generation, the Adam optimizer is utilized with a learning rate of 0.0005. The input to the SE-VAE is the embeddings extracted from RoBERTa with a batch size of 512 tokens. The dimensions for the latent features and style embeddings are $[1 \times 768]$. The model can generate sentences with a sentence length limit of ≤ 25. To evaluate the performance of generated stylized captions, Style Transfer Accuracy (cls) and Perplexity (ppl) of the proposed model is evaluated. Also, the relevancy of the captions generated is evaluated in terms of BLEU@N (B-1, B-3) [56] and METEOR (M) [57].

B. Experimental Results

This section discusses the results of the experiments conducted for two phases: (i) RFCG and, (ii) CSCG

This section summarizes the performance of the proposed RFCG architecture on the Flickr30K and MSCOCO Karapathy split datasets. Table II and Table III presents the comparison of the proposed RFCG based generated refined captions with other state-of-the-art on Flickr30K and MSCOCO datasets. Compared with the other state-of-the-art in Table II, the proposed method provides a significant improvement in terms of B-1, B-2, B-3, B-4, and METEOR. The key reason for consistently improved performance of the proposed RFCG model is that it leverages the benefit of rich Yolo-V4 based region specific local features and Inception-V3 based global visual features while merging with GloVe embeddings-based text features in comparison to raw VGG 16 based encoders [4], and CNN based encoders [2] visual features. In addition to this the proposed RFCG module incorporates Bi-LSTM and rich visual features enabled soft attention-based language decoder which provides further enhancements in the generating refined captions when compared with hard and soft attention [3]. Also, From Table-III it is evident that the our proposed RFCG module provided significant results when compared with many recent state-of-the-art [20] [25] [58, 59, 60]. Also, [26] LLM-based fusion reports very low scores as fusion of captions collapse into a caption that does not offer more detail. To overcome this the proposed framework generates more detailed factual captions which are further fused with style-based captions for the generation of stylized image captions.

Further, when compared with [23] the model provides improvements in terms of B-2, B-3, B-4, and M only. Fig. 7(a) and Fig. 7(b) present the validation and test accuracy and loss curves for the proposed RFCG model. From this, it is evident that with the increase in the number of epochs, the accuracy of the proposed RFCG model increases while the losses decrease. It is evident from the figures that after 60 epochs the performance of the proposed RFCG module does not provide significant improvements in the results. Hence, early stopping criteria is used to stop the training after receiving consistent results for next 10 epochs. Fig. 8 presents the qualitative results of the proposed RFCG. It is observed that the proposed RFCG expresses the relationships between objects, attributes, and scenes with more refined syntactic and semantic descriptions, over base LSTM and other models [3, 4, 25].

Fig. 8: Refined Captions Generated by Proposed RFCG Model on Flickr30K and MSCOCO datasets.

Fig. 9: Stylized Romantic and Humorous Captions Generated Using Controlled Stylized Caption Generation (CSCG) (a) With Flicr30K unpaired samples (24,783) and (b) With MSCOCO unpaired samples (1,23,287 samples)

unpaired samples from Flickr 30K whereas Test Case 2 utilizes 1,23,287 unpaired samples from MSCOCO. Also, both the test cases contain 7K paired samples. Table IV presents the comparison of the proposed SE-VAE CSCG model for both the test cases with other state-of-the-art in terms of BLEU-1, BLEU-3, and METEOR (M) scores with style accuracy (cls) and perplexity (ppl). StyleNet [6] and SF-LSTM [7] incorporate factored LSTM and style-factual LSTM decoders for end-to-end learning of stylized romantic and humorous captions. The works [11] [28] [30] [31] attempted multi-style-based caption learning using unpaired data but the proposed SE-VAE-CSCG captures the unstructured and stylized disentangled representations better than [11] [28], using the concept of controlled styled SE-VAE, with the significant rise of B-1 score value by an amount of 3.9, 15.8, 8.5 and 7.4 respectively. From Table IV we can infer that Test Case 2 provides significant results for all the evaluation metrics. Hence, increasing the number of unpaired samples confirms efficient learning of linguistic styles in the final encodings Furthermore, it can be observed from the qualitative results of the proposed SE-VAE-CSCG, as reported in Fig. 9, that the image content is described with the usage of the correct style i.e., romantic and humorous with more realism, fluency, grammatical correctness and diversity.

A. Ablation Studies

An ablation study is carried out to exhibit the influence of (i) RFCG module and (ii) SE-VAE-CSCG module (iii) number of unpaired captions fed to the BoC from MSCOCO dataset on the performance of the proposed framework.

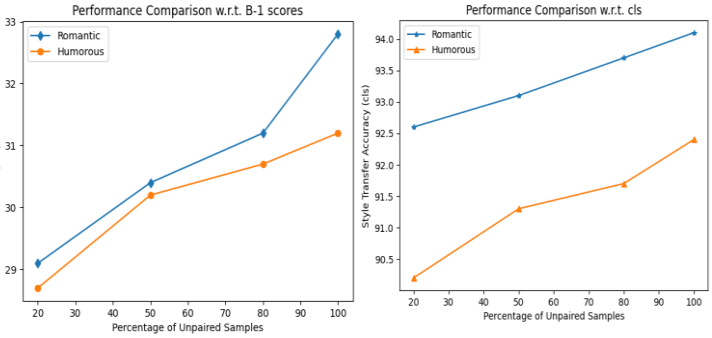

Fig. 10: Ablation study comparison results for percentage of number of samples utilized for generation of romantic and humorous captions

TABLE V
Ablation Study Results for Proposed RFCG Module for Flickr30K Dataset

Encoder Feature Representation	B-1	B-2	B-3	B-4	M
VGG-16	62.0	43.4	26.1	19.2	17.8
Inception-V3	64.7	45.2	26.2	19.5	18.9
R-CNN	65.8	45.7	27.3	20.1	19.2
Yolo-V4	65.9	45.7	28.1	20.7	19.3
Inception-V3 + Yolo-V4	**69.6**	**49.4**	**32.1**	**23.3**	**21.6**

i) In RFCG module the encoder utilizes efficient Inception-V3 + Yolo-V4 visual features. The key reason to use Inception-V3 + Yolo-V4 based features, is highlighted in the ablation study reported in Table V, for Flickr30K dataset. It confirms that RFCG module performs superior for Inception-V3 + Yolo-V4 based visual features over VGG-16, Inception V3, R-CNN, Yolo-V4, with a prominent rise in B-1, B-2, B-3, B-4 and M scores.

TABLE VI
Ablation Study Results for Proposed SE-VAE-CSCG Module

Style	Case	Basic-VAE	VAE	SE	CSCG	B-1	B-3	M	cls	ppl
Romantic	Test Case 1	✓	×	×	✓	18.7	5.4	6.2	66.7	6.5
		×	✓	×	✓	27.2	8.2	10.5	86.4	7.9
		×	✓	✓	✓	**30.2**	**9.4**	**12.5**	**91.6**	**9.7**
	Test Case 2	✓	×	×	✓	18.9	6.1	6.4	68.3	6.8
		×	✓	×	✓	28.1	8.6	10.8	87.9	7.9
		×	✓	✓	✓	**31.7**	**11.1**	**14.2**	**93.7**	**11.3**
Humorous	Test Case 1	✓	×	×	✓	18.2	5.1	6.1	62.1	6.2
		×	✓	×	✓	26.9	8.1	10.2	85.7	7.2
		×	✓	✓	✓	**29.7**	**9.0**	**11.6**	**89.7**	**9.3**
	Test Case 2	✓	×	×	✓	18.8	5.4	6.3	67.1	7.1
		×	✓	×	✓	27.4	8.7	10.9	87.0	7.5
		×	✓	✓	✓	**30.3**	**10.1**	**11.9**	**91.4**	**10.6**

ii) The ablation study results for proposed SE-VAE-CSCG module are shown in Table VI. Where it can be observed that the style-based captions are generated using three different models Basic-VAE + CSCG, VAE + CSCG, and SE-VAE + CSCG respectively. It is observed that there is a significant increase in the B-1, B-2, M, cls, and ppl scores for the proposed SE-VAE-CSCG module. The scores obtained for both Test Case 1 and 2 makes it evident that the proposed SE-VAE-CSCG module generates stylized descriptions with favorable accuracy, and perplexity trade-offs by efficiently lifting the word-level knowledge to sentence-level knowledge and learning disentangled representations.

iii) Further, ablation is also carried out to study the influence of number of unpaired captions fed to the BoC from MSCOCO dataset to exhibit the generalizability and independence of the proposed framework over limited no of structured captions. Initially, for MSCOCO and FlickrStyle10K dataset we utilized 7K paired samples and 20% unpaired samples from MSCOCO. With increase in the number of samples from 20% to 50%, 80%, and 100% samples a prominent increase in values of B-1 and cls is observed in Fig. 10.

V. Conclusion

This paper presents a novel style-based caption generation framework that generates style-controlled descriptions of images in two phases: (i) Refined Factual Caption Generation (RFCG), and (ii) Controlled Style Caption Generation, SE-VAE-CSCG. The proposed framework generates realistic and stylized descriptions of images with controlled text generation. The proposed RFCG generates meaningful human-independent (unbiased) refined captions by merging both visual features (global features and object-level local features) and textual features. The presented SE-VAE-CSCG module exhibits independence on the number of structured samples, as it delivers refined stylized captions even for majority of unstructured samples projected in terms of improved style accuracy.

We also present a novel Bag of Captions (BoC) concept which is a collection of both paired and unpaired samples of captions. This helps to learn disentangled representations by lifting the word-level knowledge to sentence-level knowledge. Further, an ablation study is also conducted to support the experiments. In future work, the focus can be extended to large-scale stylized datasets incorporating different styles.

Abstract: As wireless signals are broadcast in nature, which implies that, a broadcast communication purposive to a predetermined destination may be received by a non-intended intermediate station. Cooperative transference, which employ interposed stations to pass on the eavesdropped data to attain the contrast gains, has a substantial capability to revamp the channeling effectiveness in wireless systems. In this it is evident that having cooperation amid stations in a wireless system can accomplish higher throughput with enhanced network lifetime. Proffered work bestows a model for medium access layer called Cooperative MAC protocol based on optimal Data Rate (CMAC-DR). In the proffered work, stations with more data rate aid stations having lesser data rate in their communication by redirecting their congestion. In CMAC-DR model, utilizing the conveyance of eavesdropped information, potential helper stations with more data rate Send out Helper Ready to Send (HRTS), the stations with less data rate maintains a table, called Co-op table of potential helper stations, that can aid in its transmissions. During communication, the source station with low data rate chooses either transmitting by the way of a helper station, so that it lowers the end to end transference delay and increases the throughput or opt only direct transmission, if no potential helper is found or if CMAC-DR becomes an overhead. By analyzing varied simulated scenarios, CMAC-DR evaluates the elevation in the overall network lifetime, throughput and minimization of delay. The CMAC-DR protocol is unambiguous and in accordant with legacy 802.11 also when compared to this, we find improved performance in terms of delay throughput and network lifetime since data rate is considered as relay selection condition.

1. Introduction

In contemporary time, wireless systems are advancing into a versatile devices beside immense data executions done by them [1]. Aforesaid accomplishments need fast connectedness and sturdy fault preventiveness [2,3]. Those necessities, besides enormous growth of wireless networks with constrained spectrum availability has evolved into momentous complications like extent crisis and more interventions. This circumstance necessitates an advance in the direction of origination of a modish wireless strategy that can facilitate a more methodical use of the accessible spectrum. While

unfolding strategies like "Multiple-Input-Multiple-Output" (MIMO) system, commences to advance the spectrum capability, but its utilization is constricted as its dimensions, price and the power for the compact wireless systems poses certain restrictions [4].

An auxiliary technique called cooperative transference guarantees to furnish some merits of the MIMO with certain restraints. The major objective was to introduce a best relay selection scheme for a multi hop communication between source and destination, there by improvising network performance. Cooperative transference cites in to the synergetic refining and relaying of an eavesdropped data by the stations which are encompassing source station. The perception of cooperative transference is to fully leverage the disseminating complexion of the wireless channel and to create a geographical diversification, specifically transfer variance, thereby attaining immense boost in system robustness, capability, delay, notable depletion in interventions, and extension of coverage scale [5]. The preliminaries of cooperative transference are found at the physical layer, although, the conception of cooperative transference is obtainable in varied dispositions at higher layer protocols. To be able to retrieve the physical layer data and to have swift flexibleness to sustained potency, it is legitimate to instigate the concept of cooperative transference in the layer which is immediate aloft the physical layer, viz. the medium access control (MAC) sublayer.

In cooperative transmission, numerous stations in wireless adhoc system function in adjoint to behave as an effective antenna assembly. Cooperative transference at the physical layer utilizes the broadcast character of the wireless system and eavesdropped information to enhance the effectiveness [6]. The stereotypical MAC models have long-drawn treated this attribute as a complication, preferably considering it as an alternative to overcome many bottlenecks. The methodology of cooperation employs this feature, and fabricate a state-of-the-art MAC model in wireless adhoc systems. The Cooperative MAC protocol based on optimal Data Rate (CMAC-DR) model for IEEE 802.11 wireless adhoc networks avail oneself of both the transfer characteristic of the wireless channel and cooperative distinctiveness. Contemporary 802.11 MAC models are primarily focused on throughput and capability under overloaded circumstances, particularly when every station contains a frame in standby condition, all the time [7]. The studies on "saturated environments" are required to obtain understanding on functioning of the protocol. Moreover, the overloaded consideration is inappropriate for present-day utilizations viz. audio and video streaming.

In CMAC-DR model, we proffer the implementation of cooperation at MAC sublayer by considering a wireless adhoc systems, in which there are potential helper/ Relay stations (RS) through which the data frame from the source station might also get forwarded to the destination station and create a cooperative scenario. We study the performance, by carrying out a broad lay of simulations rooted on the scheme features as these are enumerated below:

- Throughput performance under heavy load.
- Network lifetime.
- Energy consumption.
- Delay performance.

The balance of the paper is systemized as follow: In section-II, analogous studies is chronicled. Section-III deals with the working of the proffered CMAC-DR model. Section-IV deals with the simulation results. The analysis of the performance parameter of proffered model is established in section-V, Section VI provides the interpretation of the proffered model and the possible subsequent considerations.

2. Related Works

According to "IEEE-802.11-Distributed Coordination" Function (DCF)[1], in the wake of a source station recognizing a channel as inactive for a span of Distributed Inter-Frame Space(DIFS), source station will back down from sensing the channel for a duration chosen between 0 and it's "Contention Window"(CW) [8-9]. Subsequently as the timer finishes, the frame exchanging procedure is initiated. Any intermediate stations eavesdropping any of the control frames (RTS/CTS) obtains the duration info from the frame header, and places its Network allocation vector(NAV). Now this is referred as an exposed station problem in the IEEE 802.11 systems in which all the intermediate stations which are receiving the control frames which are not intending to them [10], will be silenced for the duration specified in the frames. Though certain stations communication of other stations will not be interfered with the current transference, it will not be allowed to do so. Thereby overall network efficiency, throughput, and other Quality of Service(QoS) parameters are degraded.

CoopMAC[2], Cooperative MAC protocol for adhoc wireless systems. This protocol is formed on an aim of involving an intermediate station in an ongoing transmission of the source and destination stations. The intermediate station retransmits the information eavesdropped from the source to the destination [11]. Consequently, lessening the transmission duration for the congestion being managed. In CoopMAC, the relay selection function is done by the source station, it chooses the best intermediate station which dispenses the least transference delay to destination. Substantial simulations depict that CoopMAC enhances the throughput and delay efficiently. For each simulation, stations were arbitrarily localized in an area of radius 350 m. Increasing the network size, coverage range, throughput, reducing source to destination delay and including mobility in accordance with real time scenario was considered as a subsequent study.

DELCMAC[12], The intent of the diversified energy location based cooperative MAC(DEL-CMAC) model is to

better the efficiency of mobile adhoc networks MANETs with respect to overall network lifespan and energy. The energy utilization model considers the energy utilization of transceiver circuits along with the transmit amplifier [13]. A diversified utilization-focused optimum relay selection strategy is used to select relay on the basis of locale data and energy remnant. Also, for the purpose of enhancing the structural reuse, a resourceful NAV setting is considered to deal with the varying transference power of the source and intermediate stations. In this paper, considering hidden terminal issue, increased network capacity with more mobility, minimizing the throughput and delay degradation is kept as a future work.

The rDCF model presented in [14] chooses an agile process by publicizing the capability of each intermediate station to help through Hello frames. Nonetheless in both CoopMAC and rDCF, the helper node forwards the frame to the destination, immediately after the reception from source station. But the relay station in [15] transmits the frame only if there is no reception of an ACK from destination indicating that it is unable to decipher the frame of the direct transference. Persistent RCSMA reported in [14] utilizes the function of a diversified and cooperation through automatic retransmission request (ARQ) model. In this model, if the destination station deciphers a data frame containing errors through direct transference from the source station, it requests a transference from any of the intermediate stations which has eavesdropped the original transference.

In Coop MACA protocol [15], it considers packet aggregation and distributed contention based relay selection algorithm to furnish a robust alterations instantaneously for any changes in the network architecture specially for a general mobile situations. The author of the EMR model proposes the consideration of a priority-mapping scheme of existing throughput and unify the information into the control frames in order to choose the optimum relay node.

3. Proffered CMAC-DR Model

For cooperative transference, we mainly focus on a wireless adhoc system, where the stations can enhance their effective quality of service(QoS) by cooperation [16]. In which, every wireless station is presumed to act as a source station as well as a cooperative agent for another station as shown in figure 1. In cooperative wireless system, source station initially transfers their frames to the intermediate helper station, then the helper station proceeds onto forwarding its received data information to the destination station.

The CMAC-DR model is built upon the IEEE-802.11-Distributed-Coordination Function(DCF [17]. The transference powers for all the stations are assumed to be unvaried. Request to send(RTS) and clear to send(CTS) frames can be eavesdropped by other intermediate stations besides the source and destination stations. If source node has a MAC protocol data unit (MPDU) to transmit, it has an option to transfer straight to the destination, or to employ an intermediate helper station for transference [4]. Therefore, in CMAC-DR model, initially as in legacy mode of 802.11, RTS frame will be broadcasted but in which the RTS frame is modified in such a way that it also contains data rate of source station as shown in figure.2. Further including destination even all other stations overhear the RTS frame and gets the data rate of source station. Subsequently modified CTS frame as shown in figure.3. will be sent by destination station by including its data rate.

The potential helper station which has eavesdropped both RTS and CTS frames compares the data rate of the source with its own. If it is of higher data rate than that of the source station, then it enables its cooperation mode and broadcasts HRTS(Helper ready to send) frame in which the data rate of potential helper station will be incorporated in the frame structure (Figure.4.) [18]. Here potential helper station refers to the station which is in the coverage region of both source and destination stations with more data rate than that of the source and also not involving itself with any of communications with any other stations and also not being allocated with NAV from any nearby transmissions [19]. Thereby source station receives the HRTS frames of all the probable helper stations and maintains a Coop table in its cache memory. Further it compares and chooses the best relay station which has the highest data rate to transmit the data frame. As a consequence, increase in the channel efficiency with higher throughput and less delay is achieved [7]. If the source station does not receive an HRTS within its timeout, it will then initiate a straight transference to the destination. An acknowledgement(ACK) is sent to for a correct acceptance, regardless of the event of frame forwarded by an intermediate helper station, or is directly transferred from the source.

It is important to take into account that each station gathers and revises the information about the potential helper station at one's disposal and their respective data rates only when it is required [3]. The CMAC-DR model transacts this issue through cooperation(Co-op) table. The Co-op table will be formed by source node (Table1), for keeping the entry of an information with regards to a potential helper station address viz., 48-bit MAC address and its data rate of direct transference between the potential helper station and destination.

By the virtue of broadcast property of a wireless channel, the destination station will obtain the data frame by both source station and relay station [10]. In the event of destination correlating these two copies to decipher the original information efficiently, then cooperative diversity is completely leveraged. Similar modification is done on the Data packet (Figure.5), so that it get forwarded through the potential relay as per the proffered CMAC-DR model. The Data frame is transmitted by source (SRC) station and from the other direction via a helper station by a process of address exchange mechanism at the helper station i.e., Address1 field in the data frame is replenished with the destination station address and broadcasted with its data rate [20]. The destination node or the station which has sent clear to send (CTS) frame, after successfully decoding the same data frames which have arrived in two subsequent time slots, replies with an

ACK frame so that it acknowledges the affluent acceptance of the data frame either by direct transmission from source side or through the CMAC-DR model. Figure.6. represents the complete action flow of the CMAC-DR model.

3.1. Helper Node Control Plane

Determining the helper station among the intermittent capable relay stations is very important and also a bottleneck process in the co-operative transference [21]. The cooperative table is formed by the source station and it will select a helper station depending on the data rate. Once the potential helper selection is completed, it will act as a relay node. The data rate ensures the functionality of the CMAC-DR model, which indicates that how effectively the frame is received at the next station. The Helper control flow of the potential relay station initially will be in an idle mode. When the request to send (RTS) frame with data rate information is transferred by the source station and once the CTS frame is transmitted by the destination containing the data rate information, the potential helper overhearing both the frames, CMAC-DRs the RTS frame header extracts and compares the data rate of the source station with its data rate [22]. If it is more than that of the source, it will enter into the cooperation mode and prepares the Helper Ready to Send (HRTS) frame by adding its data rate information in the frame format and broadcasts it to the source station. Similarly, multiple HRTS frames will be sent to the source station from different capable relay stations.

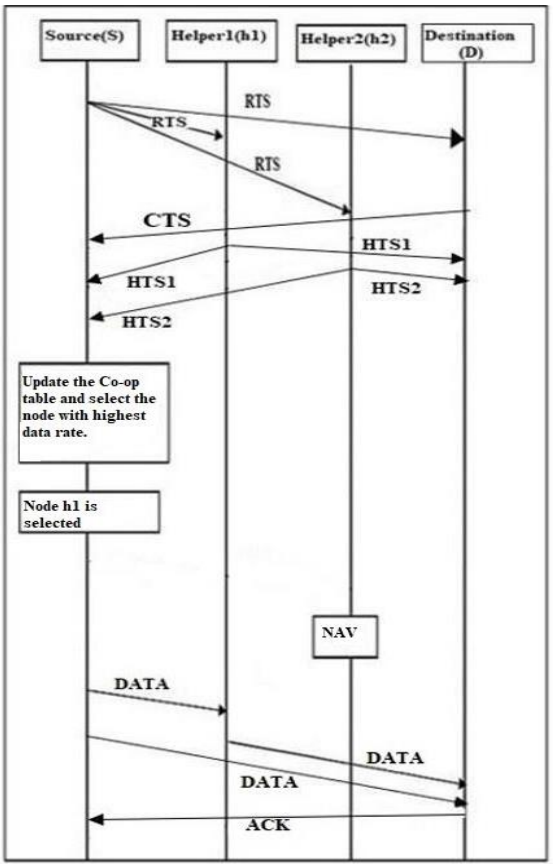

Fig.6. Action flow of CMAC-DR model

3.2. Helper Node Data Plane

Forwarding the data through the selected potential helper station after the exchanging of control frames is a challenging function in the cooperative transference [23]. CMAC-DR model suggests a most appropriate and ideal approach for data forwarding in cooperative transference [24]. The data frame forwarded by the source station is addressed to the selected helper node in which the address of the potential helper is in address field-1 of the data frame. Potential relay/helper station receives the data frame and verifies it whether it is addressed to it, if so, it checks for whether it is in cooperation mode or not. If the potential relay station is in coop mode, it replaces the address of the intended destination in the address field-1 of the data frame and transfers the frame to destination station with its data speed.

3.3. Co-operative Mode Selection

Choosing the transference mode is established by considering three conditions. firstly the intermittent helper nodes checks if it is having any RTS from any of the neighboring node for itself, secondly it is not allocated with Network allocation vector (NAV) from any other station in the network and, thirdly its data rate is more than that of the source station, only if all the above three case are satisfied then cooperative mode will be enabled and broadcasts helper ready to send (HRTS) frame[25].

Algorithm for mode selection by helper nodes

- Initialization.
- Check if it is having any RTS for itself.
- Check if is allocated with NAV from neighboring nodes.
- Check if helper node data rate > source node data rate.
- Transmit helper ready to send (HRTS).
- Else: Be in idle state.

3.4. Actions Performed by Source Node

Initially, source station will be in indolent mode until it has a MPDU to be transferred to the destination [26]. Once the buffer is full and wants to send a frame with body length of l bytes, it first verifies whether the channel is in standby for a DIFS, subsequently the source also waits for its CW to timeout and then it transfers a request to send (RTS) frame in which the data rate information is incorporated to withhold the channel, else it holds back for a random back-off time [27]. If destination side is free for communication it sends a clear to send(CTS) frame with its data rate. If the source station does not obtain a CTS inside “tRTS +tCTS +SIFS”, RTS is re-broadcasted. Next the intermediate potential helper

stations broadcast the helper ready to send (HRTS) frames by keeping their data rate information in the control frame. Now the source station waits for another $t_{Back-off}^{max}$+tHRTS+ SIFS, where $t_{Back-off}^{max}$ is the maximum back-off time for a helper node [20]. If it receives a HRTS within the waiting time, based on the information obtained from the HRTS control frames its cooperation table is updated and the station with maximum data rate is chosen as the helper station and MPDU is transferred through it, else direct transmission is done. The acknowledgment(ACK) has to be obtained within "tACK+16(l+ lh)/2R+2SIFS," where lh denotes length of the header in bytes, else source station would carry out an arbitrary back-off procedure [28]. The l and lh are represented in bytes and data rate(R) with bits per second, thereby the overall transference span for a data frame is given by "8(l+ lh)/2R." Figure.6. indicates the timing diagram of the CMAC-DR model. It considers two intermittent helper stations and a destination. TX and RX represents the transmission and reception line of the respective stations. Here tRTS, tCTS, tHRTS, tACK indicates transmission time for RTS, CTS, HRTS, ACK.

Relay selection algorithm by source node

- Obtaining data rate of the potential helper nodes through HRTS frames sent by them.
- Analyzing different data rate information of all the potential intermittent helper stations to get the relay station with highest data rate.
- If a helper station is chosen, transfer the MPDU through it.
- End

3.5. Enactments of Destination Station

The destination station will be in idle condition until it receives a RTS from the source station. Once the RTS is obtained and if it is self-addressed to itself [29], it will transfer a CTS succeeding a short inter-frame space (SIFS). It will then check for any HRTS frames by any intermediate potential helper stations. If yes, the destination station expects data frame from helper station and also from the source by direct transference. Next if the data frame is successfully obtained from the source station, a positive acknowledgement will be sent to the source indicating a successful transference. Similar optimal relay selection with time slot allocation can be viewed in other works [30].

4. Result Analysis

The stations are located spatially in diverse locale; thus, the fading attribute is also considered for all the stations along with channel fading for the network scenario as shown in Figure.7. The various network attributes that are set for the considered simulation scenario is given by Table.2.

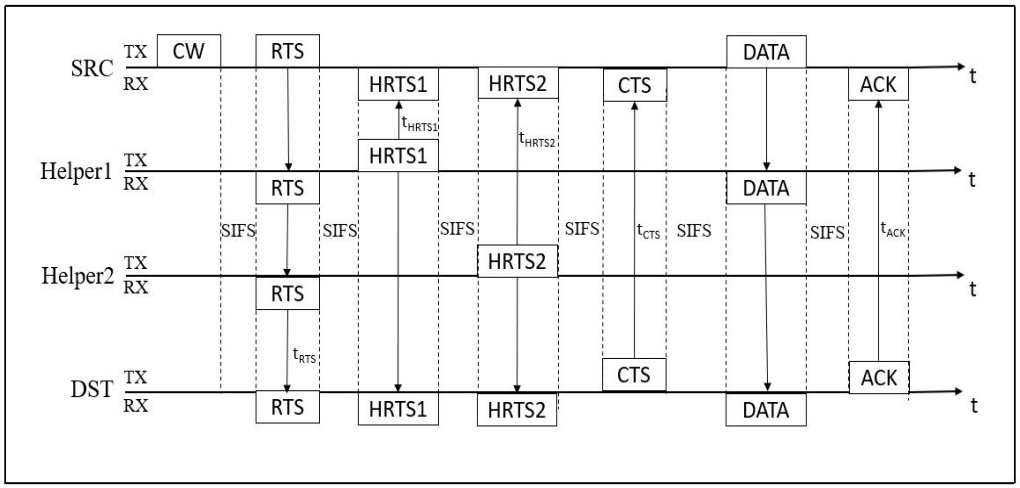

Fig.7. Timing diagram for CMAC-DR model

Simulation results of CMAC-DR model along with legacy 802.11b is evaluated using Qualnet. CMAC-DR model transmits the data frame from source to destination through a helper station based on the data rates. Node number is diversified between 10 to 100 and are located in random in a 600x600 m^2 terrain. The source station transfers packets in the range, 500 to 2313 of size 1024 bytes each with transference rate of 10 packet per second. The simulation time for the scenario considered is 100 seconds. All the stations are enabled with random mobility model. Throughput received, average unicast source to destination delays and total broadcast messages received clearly by the destination station.

Figure.9a. shows that with CMAC-DR model, the throughput given by bits/sec is more as MPDU is transferred cleverly by switching between direct transference and CMAC-DR model.

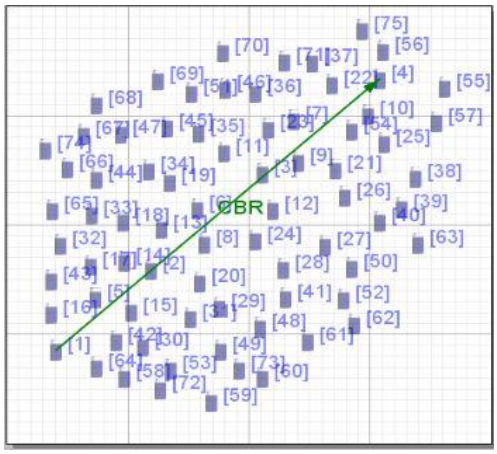

Fig.8. Wireless adhoc system simulation in Qualnet 7.1

Table 2. Simulation parameter

Attributes	Specifications
Node number	10-100
Simulation area (meter sq.)	600x600
Simulation time (seconds)	100
Traffic type	Constant bit rate (CBR)
MAC protocol (wireless)	802.11b
Data rate(MHz)	1, 2, 5.5, 11
Total packets sent	500-2312
Size of each packet	1024

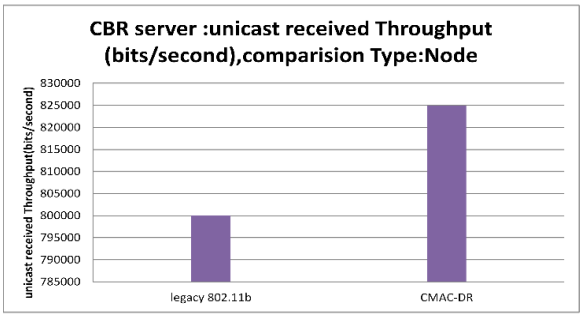

Fig.9a. Throughput of legacy 802.11b vs CMAC-DR model

The received throughput in CMAC-DR model shows increase of 604 metric value in comparison with the IEEE 802.11 protocol for 50 nodes adhoc network. The network lifetime in CMAC-DR model is more, due to the better transference of the MPDU and also because of the availability of stations for long duration.

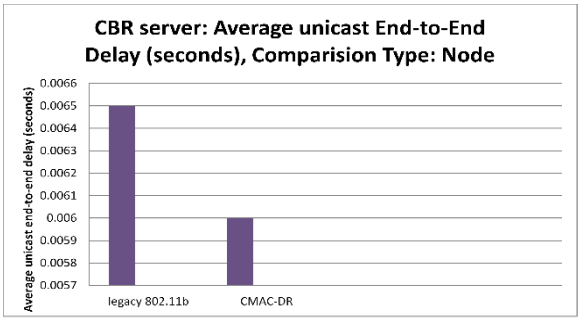

Fig.9b. Delay of legacy 802.11b vs CMAC-DR model

Figure.9b. shows the variation in source to destination delay. In CMAC-DR model frames are transmitted along the best path by choosing best relay node based on the best data rate, as a result delay is reduced in CMAC-DR model. The transmission of frames in legacy 802.11b MAC protocol is only on single-hop communication, whose data rate might be

slow due to channel fading and other parameters, so delay is more.

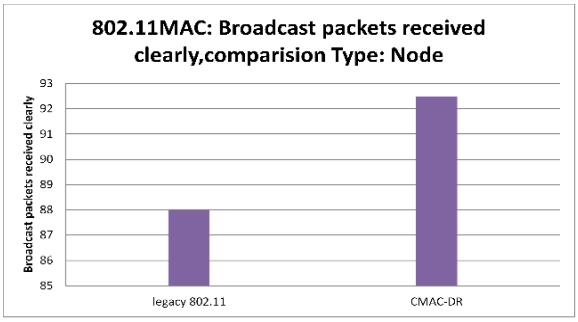

Fig.9c. Broadcast packets received clearly of legacy 802.11b vs CMAC-DR model

Figure.9c. indicates the Broadcast packets received clearly of legacy 802.11b vs CMAC-DR model, Broadcast packets received clearly is more in case of CMAC-DR model because of the employment of both direct transmission mode and also through a potential capable helper station with highest data rate i.e., CMAC-DR model.

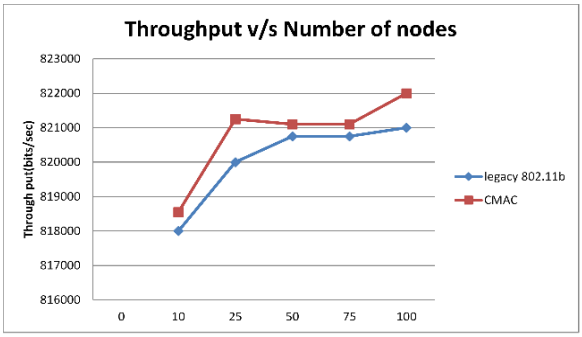

Fig.10a. Contrast in throughput vs number of node

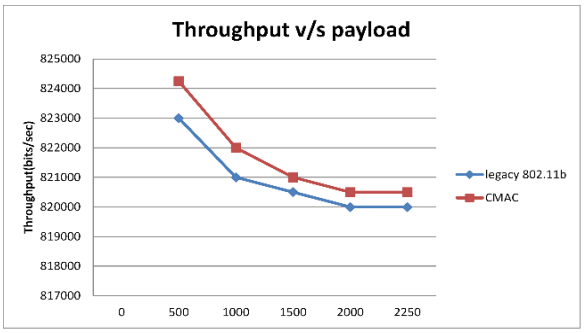

Fig.10b. Contrast in throughput vs payload

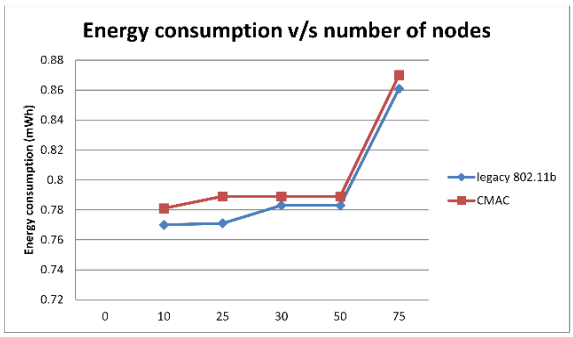

Fig.10c. Contrast in average transmission delay vs number of nodes

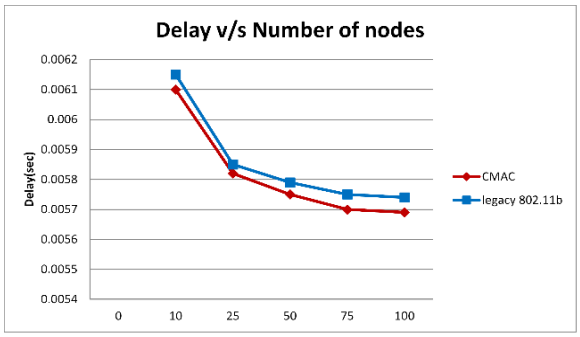

Fig.10d. Contrast in average delay vs number of nodes

The source station transfers 1000 packets to the destination through a wireless channel with various simulation attributes as mentioned in table 2. The simulation is performed for varied set of stations. Figure.10. represents the divergence in QoS, when the of nodes and payloads are varied. Figure. 10(a) & 10(b) indicates the contrast of throughput with node number and payload respectively. Our CMAC-DR model outperforms legacy 802.11b in terms of throughput. The refurbishment is attributed to the inclusion of the data rate as key feature for choosing the capable helper station. The node performance is enhanced, as the source station chooses the intermittent helper station with highest data rate during runtime, which also in turn increases the network lifetime. Average transmission delay provides the information of average latency in successful reception of a data frame. Figure.9c. shows that our CMAC-DR model has less transmission delay than legacy 802.11b, since our model employs a helper station with highest data rate. Also, average delay performance (Figure.10d.) is being enhanced by our CMAC-DR model in comparison with legacy 802.11b protocol. We know that as the number of retransmission limit increases, the delay in successful transmission also increases, we can observe that our CMAC-DR has better delay performance than the legacy 802.11b protocol when the re transmission limit is increased. Our CMAC-DR model is designed and proffered, so as to increase the throughput performance and utilize the channel efficiently for different number of nodes and for variation in payloads with reduced transmission delay. We can infer that CMAC-DR model is finer than IEEE 802.11 protocol by analysing the results obtained from the simulations.

5. Conclusions

The paper proffers CMAC-DR model to enhance the life span of an adhoc network, throughput and delay conduction of the wireless system. The proffered model ensures efficient channel utilization by a station and cleverly selects the capable station with highest data rate for MPDU transference. In a throughput scenario of our CMAC-DR, for a small number of nodes considered, we can see there is 69.2 % increase when compared to Legacy 802.11b and for large number of nodes we can observe 81.2% increase when compared to Legacy 802.11b. When delay of CMAC-DR is compared, for a smaller number of nodes, we can see there is 12.7 % decrease when compared to Legacy 802.11b and for larger number of nodes we can observe 17.3% decrease when compared to Legacy 802.11b.

The CMAC-DR model, precisely selects the mode of data transmission, thus it completely leverages the objective of the cooperative transference i.e., to aid the physical layer to receive the data frame from diverge locale and intelligently extract and combine the data frame so that the quality of transference is enhanced. The aimed objective performance of CMAC-DR model is achieved and it is analysed through numerous simulations and results obtained indicating the enhancement of the system performance. Including different channel fading model, mobility, reducing energy consumption and improving the delay performance is considered as a subsequent study.

Authors' Profiles

Nagesh. R. is currently working as Associate Professor Electronics and Communication Engineering Department at Government SKSJ Technological Institute, Bangalore.

He is pursuing his Ph.D. (Engg.) from Visvesvaraya Technological University, Belgaum in the area of Cooperative Computer Networks. He obtained his Master's Degree in VLSI and Embedded Systems from Visvesvaraya Technological University, Belgaum in 2007. He holds Bachelor's degree in Electronics and Communication Engineering from RV College of Engineering, Bangalore in 2002. He has more than 16 years of experience in Teaching and Industry. He was with Wipro Technologies, and TATA Elxsi Ltd. as Senior Chip Design Engineer. His major interest areas of research include Cooperative Computer Networks, MANETS, Vehicular Networks and Embedded Systems.

Dr. M. N. SreeRangaraju received BE Degree in 1985 from Bangalore University and MTech in 1991 from University of Mysore both in Electronics Engineering, and PhD (Telecommunication Engg) from VMU, Salem, TN, India in 2011.Professor of Electronics and Communication Engineering at Bangalore Institute of Technology (BIT), Bengaluru, India has been in Teaching UG and PG Students of Electronics and Telecommunication Engineering students for nearly Thirty Years. He has organized several National level conferences and workshops in this tenure. He has published his Research papers in Prestigious IEEE Conferences held in USA, China, Malaysia and Egypt. He also has served has Session Chair for several National and International Conferences held in India and aboard. He also has served as editor of several journals and Magazine. He holds life member of ISTE, MVLSI, and IMAPS and also member of IEEE. His research interests include mobile and wireless communications and networks, personnel communication services and high-speed communication routing protocols and wireless channel modeling.

N. R. Kushar Gowda completed his Bachelor's degree in Electronics and communication Engineering from Government SKSJ Technological Institute, Bengaluru in 2020. He has worked as a research intern at Nihon Communications limited, Bengaluru on a project to establish a cooperative scheme at MAC sublayer in wireless Adhoc networks. He has also presented a technical research paper at 3rd International conference on advanced production and Industrial engineering organized by Delhi technological university. He has also participated in Global hack the crisis hackathon to combat Novel corona widespread by designing a "Portable and Affordable Ventilator with Assist control for Novel corona virus- PAVAN" and secured second place in crisis response track of the hackathon. The project was one among the best top-30 ideas in Hack the crisis, India hackathon organized by Ministry of Electronics and Information Technology, Government of India. His major areas of interest include wireless communication and networks, Artificial Intelligence and Machine Learning.

Vinayak Shekharappa Antin completed his Bachelor's degree in Electronics and communication Engineering from Government SKSJ Technological Institute, Bengaluru in 2016. He Has worked with Volvo group as Lead ESW application engineer with skills AUTOSAR, Model Based, Agile, Embedded Linux. He was senior software engineer at HCL Technologies working on Configuration of AUTOSAR RTE (Design of Software Components (SWC's) and Integrate SWC's into the ECU architecture (Service, Data and Task mapping). Functional Development with Embedded C and MATLAB (SIMULINK, State flow). Writing Software Requirement specification for End to End functionality. He is presently working as a project engineer at FEV Creltech GmbH, Germany.

Abstract This study explores the application of Deep Learning in combating neglected vector-borne Diseases, a significant global health concern, particularly in resource-limited areas. It examines areas where Deep Learning has proven effective, compares popular Deep Learning techniques, focuses on interdisciplinary approaches with translational impact, and finds untapped potential for deep learning application. Thorough searches across multiple databases yielded 64 pertinent studies, from which 16 were selected based on inclusion criteria and quality assessment. Deep Learning applications in disease transmission risk prediction, vector detection, parasite classification, and treatment procedure optimization were investigated and focused on diseases such as Schistosomiasis, Chagas disease, Leishmaniasis, Echinococcosis, and Trachoma. Convolutional neural networks, artificial neural networks, multilayer perceptrons, and AutoML algorithms surpassed traditional methods for disease prediction, species identification, and diagnosis. The interdisciplinary integration of Deep Learning with public health, entomology, and epidemiology provides prospects for improved disease control and understanding. Deep Learning models automate disease surveillance, simplify epidemiological data processing, and enable early detection, particularly in resource-constrained settings. Smartphone apps driven by deep learning allow for rapid disease diagnosis and identification, boosting healthcare accessibility and global health outcomes. Improved algorithms, broadening the scope of applications to areas such as one health approach, and community engagement, and expanding deep learning applications to diseases such as lymphatic filariasis, hydatidosis, and onchocerciasis hold promise for improving global health outcomes.

1 Introduction

In the field of medical diagnostics, Deep Learning (DL) techniques have become increasingly potent instruments with the potential to transform decision-making processes completely. DL models have been applied to predict transmission risks and outcomes of neglected Vector-Borne Diseases (VBDs) in recent years. VBDs continue to be a major global health challenge, especially in settings with limited resources.

For example, studies on schistosomiasis mansoni and schistosomiasis japonica have demonstrated the significance of variables like water contact, geographic variances, and the history of infection in predicting the spread of the disease (Xu et al. 2013; Hammad et al. 1996). These studies have demonstrated that DL algorithms can predict disease outcomes with high efficacy and accuracy, sometimes even outperforming conventional logistic regression models. Similarly, research on cutaneous leishmaniasis by Bamorovat et al. (2021) has shown that DL has the potential to predict disease outcomes by using machine learning (ML) techniques to predict cases that will not respond.

Additionally, DL has been used to identify Chagas disease vectors automatically, with high accuracy rates that can

Published online: 10 June 2024

greatly enhance surveillance and control operations (Khalighifar et al. 2019; Parsons and Banitaan 2021). Strong correlations between predicted and true values have also been observed when using DL models to predict the Leishmania infantum load in dogs, which may help with disease surveillance and control (Torrecilha et al. 2017).

Other studies have demonstrated high accuracy rates in classifying complex image datasets related to VBDs, with a focus on the identification of snails and parasites of medical importance for schistosomiasis (Tallam et al. 2021; Liu et al. 2019). To improve diagnostic efficiency and accuracy, DL models have also been used to automatically classify various hepatic cystic echinococcosis subtypes from ultrasound images by Wu et al. (2022).

Furthermore, DL has been used to model optimization of benznidazole chitosan microparticles, demonstrating its potential for drug formulation optimization and key property prediction for disease treatment by Leonardi et al. (2009). Similarly, supervised artificial neural networks (ANNs) has been used to predict the pharmacological properties of compounds in drug discovery and treatment prediction for tropical diseases such as Chagas disease by Bamorovat et al. (2021).

This organized methodology enabled a thorough examination of DL's impact on neglected VBD research and its possible implications for global health outcomes.

1.1 Organisation of the study

The study begins with Sect. 1, which introduces the topic of this study. Section 2 contains findings of related published work, and explores the popular applications of DL in neglected VBDs. Section 3 represents Material and Methods explaining the article selection process and PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) framework for this study, including search strategy, inclusion criteria, quality assessment (QA) and final selection of the studies. The results and discussion Sect. 4 summarises the findings from the selected studies for the RQs of this study. Finally, Sect. 5 concludes the review by summarising the findings of the study and highlighting important avenues for future research.

2 Related work

DL techniques have been applied in several neglected VBDs to enhance disease diagnosis, control, and prediction. For example, studies on the application of DL for identifying and categorising parasites and vectors have been carried out. DL models have been used to identify snails and parasites of medical significance, which aids in the early diagnosis and treatment of schistosomiasis. Similarly, by categorizing and segmenting parasites, DL has been utilized to increase the accuracy of Chagas disease diagnosis.

Furthermore, DL has been used to create risk assessment tools and models to predict disease propagation. For example, research has employed DL algorithms to examine environmental variables that influence the spread of visceral leishmaniasis, offering valuable insights into the disease's dynamics and guiding focused intervention approaches. Additionally, DL has been applied to analyze satellite imagery and geographical data to predict the prevalence and distribution of VBDs, such as malaria and dengue, aiding in the development of early warning systems and effective disease control measures.

Moreover, DL has been applied to improve monitoring and surveillance programs for diseases. Large-scale epidemiological data can be analyzed using DL models to find patterns and trends in the spread of disease. This information helps health authorities allocate resources more wisely and launch interventions on time. These studies show how DL methods can help us better understand and treat neglected vector-borne illnesses, opening new avenues for enhanced disease prevention and control tactics.

Recent surveys have shown that ML and DL have substantial potential applications in diagnosing and treating VBDs. Ghosh and Dasgupta (2022) address the economic and health consequences of neglected tropical diseases, including VBDs, and highlight how ML techniques are being used to screen possible therapeutic compounds, assisting in the hunt for new drug targets. This paper emphasizes the importance of novel ML applications in solving the ongoing difficulties of neglected tropical diseases. Similarly, Yu et al. (2023) present an overview of common DL algorithms, such as ANNs, Convolutional Neural Networks (CNN), and Recurrent Neural Networks (RNN), focused on their use in disease prediction. They highlight DL's exceptional accuracy in medical applications, which frequently outperforms existing approaches, supporting its usage in disease prediction and diagnosis, including VBDs.

Further exploring the area, Sharma et al. (2022) investigate several DL architectures and their considerable impact on medical diagnoses. Their work emphasizes the benefits of DL, such as increased accuracy and efficiency, while also emphasizing the hurdles that must be overcome before widespread implementation. Shaikh et al. (2023) investigate different supervised ML algorithms for detecting diseases such as malaria, chikungunya, and dengue fever, with a specific focus on VBDs. They discovered that the modified Support Vector Machine (mSVM) had the highest accuracy, suggesting the promise of ML techniques to improve VBD diagnosis and management. Kaur et al. (2021) also critically analyze ML and DL methods for identifying and forecasting fatal disease outbreaks to limit the risk of disease spread. Collectively, these surveys demonstrate the impact of ML

and DL in the medical sciences, notably in improving the diagnosis and treatment of VBDs, and have the potential to be applied to neglected VBDs.

2.1 Research gaps and motivation for the study

In the current literature, an important gap in research addressed by our review is the lack of holistic analysis in DL approaches applied to neglected VBDs. Recent research tends to focus on individual applications rather than broad appraisals of DL's capabilities across all facets of disease management and control. Furthermore, primary VBDs, such as Dengue and Malaria, receive far more attention than other neglected VBDs, which are comprehensively discussed in this review.

While existing research focuses mostly on ANNs and CNNs, it overlooks some important topics and techniques within the DL paradigm. For example, the use of techniques such as Gated Recurrent Units (GRUs) for sequential analysis of data, generative adversarial networks (GANs) for synthetic data generation, and Reinforcement Learning (RL) for tailored treatment planning remains unexplored. Additionally, Graph Neural Networks (GNNs) and Explainable AI (XAI) approaches are notably absent from current research discourse. By highlighting these research gaps, this review provides a more comprehensive knowledge of the potential of DL in managing neglected VBDs.

Studies may demonstrate the efficacy of DL models in specific circumstances, but there is at times a dearth of discussion about the obstacles encountered and potential areas for development. This study fills these gaps by critically examining methodology, identifying strengths and limits, and recommending future research areas to improve the efficacy of DL strategies in neglected VBD control and management.

3 Material and methods

Following a comprehensive analysis of 64 papers from a variety of databases, including IEEE Xplore, Google Scholar, and PubMed, 16 studies that used DL to diagnose neglected VBDs, namely, Cutaneous Leishmaniasis, Hepatic Echinococcosis, Trachoma, Schistosomiasis, and Chagas Disease, were chosen for inclusion. These studies met the requirements for inclusion such as relevance, research thoroughness, peer review status, English language publication, and a focus on neglected VBDs.

3.1 Overview

Figure 1 contains the PRISMA flow diagram of this study, explaining the process by which 64 publications about neglected VBDs were found after a thorough search of IEEE Xplore, Google Scholar, and PubMed. In the first instance, we found 11 duplicates in the dataset, which were eliminated. Thereafter, we carefully went through 53 studies and excluded 16 that did not fit our predetermined inclusion requirements.

After the screening procedure, we identified 37 studies for retrieval. After retrieval, we thoroughly evaluated these studies to determine their eligibility and eliminated 21 studies for failing to meet the quality standards. 16 papers that satisfied all requirements made it to the final selection and were reviewed.

3.2 Research questions

Examining the current state of DL applications in neglected VBD research is the goal of this review. Of special interest is how these applications impact disease diagnosis, prognosis, and treatment. Additionally, the study attempts to comprehend the underlying reasons for the adoption of DL approaches for different VBDs in different geographical regions. According to our research goal, the following RQs have been developed:

(1) RQ1: What are the distinct sub-areas within neglected VBDs where DL techniques have been applied?
(2) RQ2: What is the scope of DL applications within each neglected VBD, and how do different DL models perform in disease-specific analysis?
(3) RQ3: How can interdisciplinary integration of DL with fields such as epidemiology, entomology, and public health improve understanding and control of neglected VBDs?
(4) RQ4: What emerging areas within neglected VBDs research present potential for DL applications, and how might leveraging DL in these areas lead to innovative solutions and advancements in global health outcomes?

3.3 Article selection

We intended to ensure a comprehensive and diverse selection of relevant literature about the study's topic by utilizing referred databases. An iterative and systematic process was employed to generate the search phrases. After creating a list of terms, the process was repeated until no more significant publications could be located. The studies published from July 1996 to November 2023 were considered for our review.

Logical operators such as AND and OR were used to create links between search terms and their synonyms. OR was used inside a group of synonyms and AND was used across groups to lessen the possibility of missing relevant research. To ensure thoroughness, references from the

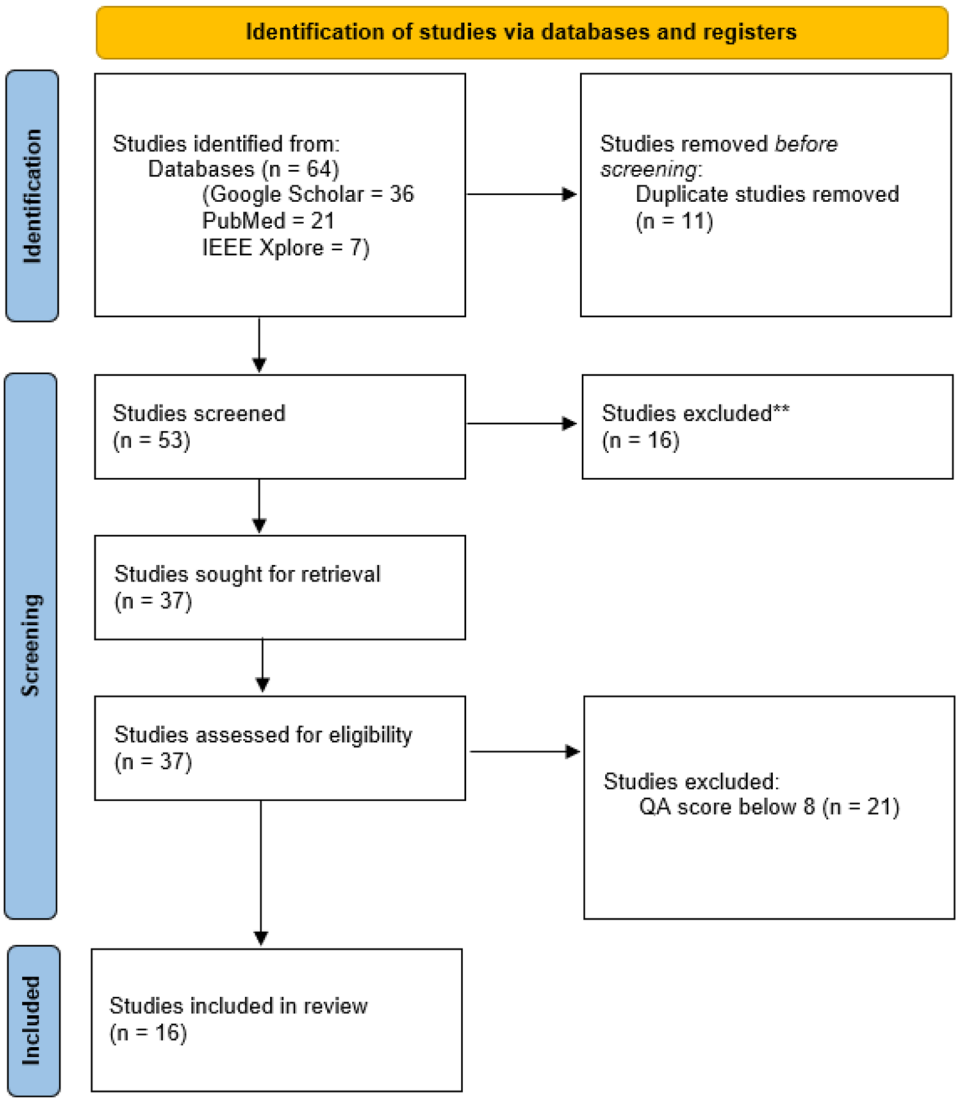

Fig. 1 PRISMA Flow Diagram of the Review. ** - did not meet the inclusion criteria, QA - Quality Assessment

collected research were manually cross-checked before being included.

Table 1 contains the search strategy for the study which combines the key concepts of our search question which in turn helps us to retrieve the required results.

3.4 Inclusion and exclusion criteria

When conducting this literature review, the following criteria were considered for inclusion:

(1) Studies that were published between July 1996 and November 2023.
(2) Studies that are cited by other researchers.
(3) Studies that are relevant to the application of DL in neglected VBDs.

Included studies were restricted to those published in English with citations and that were electronically accessible. If a conference study had a more recent journal version, only those published later were included. The suitability of each study for use in the diagnosis of tropical diseases was carefully assessed. Every search started with the title and keywords.

Table 1 Search strategy

("Trachoma" OR "Fascioliasis" OR "Leishmaniasis" OR "Lymphatic Filariasis" OR "Schistosomiasis" OR "Hydatidosis" OR "Echinococcosis" OR "Chagas" OR "Taeniasis" OR "Cysticercosis" OR "Onchocerciasis" OR "Mycetoma") AND ("Deep Learning" OR "Neural Network" OR "Neural Networks")

We also reviewed the introduction for publications where the information could not be inferred from the relevant sections. Following analysis, the entire text was downloaded for further reading and data extraction if these items satisfied our requirements.

During the literature review phase of this investigation, the following exclusion criteria were taken into account:

(1) Studies that are not addressing the RQs.
(2) Studies whose manuscript is not available in English.
(3) Studies on the neglected VBDs, where the focus is not on DL.

3.5 Quality assessment

Investigators independently assessed the quality of the included studies, which were all discussed, based on the QA of Diagnostic Accuracy Studies. The risk of bias was also studied in which data source, sample size, coherency of results, etc were analyzed. There were 10 criteria for QA of the collected studies based on applicability to our research problem, clarity in objectives and methodologies, availability of data information, declaration of comprehensive results and conclusions, and addressing limitations. These 10 criteria are comprehensively stated in Table 2 under the QA Questionnaire. The questions were rated: Yes (Y): 1 score, Partial (P): 0.5 score, and No (N): 0 score. Upon completion of the assessment, studies with a total score of 8 or above were selected. Table 3 showcases the QA scores calculated for the selected studies.

3.6 Final articles

The final selection included 16 papers that demonstrated the potential of DL and ML to address issues in neglected VBDs' control and management by emphasizing their roles in disease prediction, diagnostics, and treatment strategies.

4 Results and discussion

4.1 Research question 1

DL models have been investigated in many studies to predict the risks of schistosomiasis mansoni and japonica transmission (Xu et al. 2013; Hammad et al. 1996). In predicting the spread of disease, these studies highlight the importance of factors like prior infection history, contact with water, and regional variations. Furthermore, the application of DL is useful to forecast the course of diseases, as compared to conventional logistic regression models. ML techniques were applied in the cutaneous leishmaniasis study by Bamorovat et al. (2021) to predict unresponsive cases, demonstrating the potential of ML in disease outcome prediction.

The use of DL methods for the automated identification of Chagas disease vectors has been the focus of research by Khalighifar et al. (2019) and Parsons and Banitaan (2021). These studies show that identifying vector species with high accuracy rates can greatly enhance surveillance and control efforts. More investigation to integrate multimodal data sources, including genetic, clinical, and environmental data, could lead to comprehensive diagnostic tools that account for the complex interplay between factors that influence the course of a disease and the efficacy of a treatment strategy.

DL models have been used in studies to identify medically significant parasites and snails that cause schistosomiasis by Tallam et al. (2021) and Liu et al. (2019). These studies show that complex image datasets linked to VBDs can be classified with high accuracy rates, sometimes even surpassing the performance of highly skilled human parasitologists. DL models were used in the hepatic cystic echinococcosis

Table 2 Quality assessment questionnaire

QNo.	Quality assessment question
QA1	Are the objectives of the research clearly stated?
QA2	Is the research pertinent to the illnesses included in this review?
QA3	Does the study clarify the source of data for the chosen VBDs analysis?
QA4	Are the techniques for gathering data adequately described and supported by the goals of the study?
QA5	Does the study design and methodology provide a clear description of the DL techniques used in the investigation?
QA6	Are the conclusions and results expressed clearly?
QA7	Do the findings corroborate the conclusions?
QA8	Are the study's limitations stated clearly?
QA9	Does the study add value to the body of literature?
QA10	Does the study answer the research questions of the review?

study to automatically classify various subtypes from ultrasound images, improving the efficiency and accuracy of the disease's diagnosis (Wu et al. 2022). Research has employed ANNs for chitosan microparticles by Leonardi et al. (2009), showcasing the potential of DL in optimizing drug formulations and predicting key properties for treating Chagas' disease. To predict the pharmacological characteristics of compounds, the Chagas disease study by Guerra et al. (2013) used supervised ANN. This highlights the potential of DL in the process of finding new drugs and treating VBDs.

Using a Radial Basis ANN, the study on Leishmania infantum load prediction in dogs by Torrecilha et al. (2017) demonstrated a strong correlation between predicted and true values. In areas with limited resources, this may be helpful for Leishmania infantum surveillance. The success of DL for diagnostic purposes, especially in automating the classification of disease-related images and predicting treatment outcomes, like the development of smartphone applications for diagnosing trachoma and the classification of ultrasound pictures for hepatic cystic echinococcosis, shows how technology can democratize access to healthcare. Enhancing the interpretability and applicability of DL models should be the main goal of research, particularly in situations where data availability is inconsistent or limited.

Table 4 provides a comprehensive overview of the performance metrics for various models used in detecting Schistosomiasis Japonica, Schistosoma mansoni infection rates, and Schistosomiasis in the Senegal River Basin, highlighting their effectiveness and aiding in selecting the most suitable model for diagnosis.

Table 5 gives an overview of the performance metrics of Chagas disease vectors. The table helps depict the superiority of a few models in identifying vectors of different species.

Table 6 outlines the performance metrics for another neglected VBD, Leishmaniasis, where the Multilayer Perceptron (MLP) and Radial Basis ANN models show notable performance with a sensitivity of 90.3% and an area under the curve (AUC) of 0.88. These values are indicative of their reliability in diagnosing the leishmaniasis disease.

Table 7 details the performance metrics for echinococcosis disease, highlighting the high AUC values of the Deep Convolutional Neural Networks (DCNN) models (ResNet-50, ResNext-50, and VGG-16 (Visual Geometry Group 16-layer model)) for cystic (0.974) and alveolar echinococcosis (0.981), underscoring their effectiveness in detecting these conditions.

Table 8 summarizes performance metrics for Trachoma. The Automated Machine Learning (AutoML) models achieved impressive Area under the Precision-Recall curve (AuPRC) values. The AuPRC values of 0.945 and 0.975 for trachomatous inflammation-follicular (TF) and trachomatous inflammation-intense (TI) models, respectively were found.

This showcases their precision in diagnosing trachomatous inflammation. These models can also be applied to other VBDs where current research is scarce to improve disease control.

The boxplot of model accuracies for various Schistosomiasis models in Fig. 2 highlights the exceptional performance of the CNNs used for snail classification in the Senegal River Basin. This model, showing an accuracy of 99.64%, marks it as an outlier, with very high success in snail classification. This outlier status is evident, as it significantly outperforms

Table 4 Performance metrics for schistosomiasis japonica, schistosoma mansoni infection rates, and schistosomiasis in the senegal river basin

Disease	Model	Performance metric

other accuracies of the other models whose accuracy can be found between 83% and 99.6%.

Additionally, the high mean accuracy shown in the boxplot is indicative of the fact that the nominal models are reliable and potentially applicable to other diseases. This also suggests that the robust modeling approach, particularly for the CNN models, is effective and can be adapted for the detection and classification tasks of other neglected VBDs.

Similarly, the boxplot of model accuracies for Chagas disease in Fig. 3 reveals the outstanding performance of Principal Component Analysis (PCA) combined with

Table 7 Performance metrics for echinococcosis

Decision Tree (DT) and Random Forest (RF), which achieved a perfect accuracy of 100%, making it a clear outlier.

This is notable as it surpasses other models, which have identification rates between 83.0% and 98.9% for the TensorFlow + Deep Neural Network (DNN) model in Mexican and Brazilian species of the Chagas disease vector. The high mean accuracy displayed in the boxplot further suggests that these models are reliable and versatile enough to be applied to other diseases.

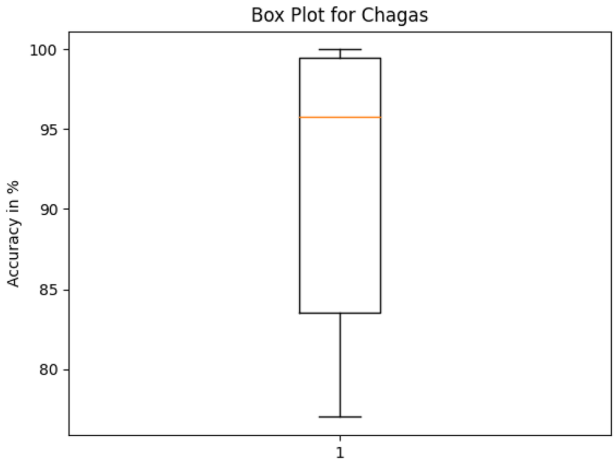

Fig. 3 Box Plot of model accuracy for Chagas

This highlights the robustness of the PCA + DT and PCA + RF models, indicating their potential effectiveness for a wider range of disease detection and classification.

Research has employed supervised ANNs to forecast the pharmacological characteristics of substances related to neglected VBDs such as in the study by Guerra et al. (2013). In the trachoma study, Milad et al. (2023) demonstrated how image processing applications can democratize access to artificial intelligence in healthcare by creating an AutoML smartphone application for trachoma diagnosis.

The research studies highlight a comprehensive exploration of the application of DL techniques in addressing various challenges related to VBDs. One notable aspect is the utilization of these advanced algorithms in disease prediction, where factors such as prior infection history, environmental conditions, and regional variations play crucial roles.

These studies underscore the importance of leveraging ML for accurate forecasting while demonstrating its superiority over traditional logistic regression models in most cases. Moreover, the automated identification of disease

vectors and medically significant parasites showcases the potential of DL in enhancing surveillance and control efforts, particularly in resource-constrained regions. However, while these studies provide valuable insights, further research could delve deeper into developing more robust models that consider additional variables such as climate change patterns, human mobility, housing conditions, and socioeconomic factors, which can significantly influence the dynamics of VBDs. Additionally, exploring interdisciplinary approaches by integrating epidemiological data with satellite imagery and mobile health technologies could offer new avenues for real-time monitoring and early warning systems.

To ensure fair access and patient safety in the age of artificial intelligence-driven diagnostics and treatment algorithms, it is also imperative to investigate the ethical implications and potential biases associated with algorithmic decision-making in healthcare settings.

4.2 Research question 2

Applications of DL have demonstrated a great deal of promise in treating neglected VBDs, with each illness offering its own set of opportunities and challenges. DL models, such as CNNs and back-propagation artificial neural networks (BP ANN), have been used for classification and predictive modeling in the case of schistosomiasis. BP ANN, for example, performed well in predicting transmission risks, as evidenced by significant metrics such as correlation coefficient and mean squared error (MSE) as depicted by Xu et al. (2013). Furthermore, CNNs demonstrated exceptional accuracy in the classification of schistosomiasis-related snails and parasites, with classification accuracy for snails reaching as high as 99.64% and for parasites as high as 88.14% by Liu et al. (2019).

DL applications have also helped with Chagas disease, especially with automating the identification of disease vectors. With accurate identification rates of over 80% for both Mexican and Brazilian species of Chagas disease vectors, DL algorithms greatly increased identification rates (Khalighifar et al. 2019). Furthermore, high accuracy rates in predicting Anti-Trypanosoma cruzi activity were obtained through the use of supervised ANNs, which is an important aspect of drug development for the treatment of Chagas disease (Guerra et al. 2013).

DL techniques have been used for prognostic and diagnostic purposes in leishmaniasis studies. For example, an MLP classifier with an AUC of 0.88 and an overall accuracy of 87.8% was able to predict unresponsive cases of cutaneous leishmaniasis by Bamorovat et al. (2021). Similarly, DL models such as radial basis ANNs have demonstrated potential in anticipating parasite load, which can help with disease management in Torrecilha et al. (2017).

Through DL applications, echinococcosis-another neglected VBD-has seen improvements in diagnosis and classification. DCNNs are among the models that have shown to perform better in identifying lesions associated with hepatic echinococcosis from imaging data; segmentation of these lesions achieved a Dice score of 89.89% by Xin et al. (2020). Moreover, DL models achieved accuracies ranging from 88.2 to 90.6% in the classification of hepatic cystic echinococcosis, outperforming conventional methods (Wu et al. 2022).

Novel DL applications for diagnosing Trachoma, an under-researched tropical disease affecting the eyes, have also been developed. High diagnostic properties were demonstrated by AutoML algorithms, which were able to identify TF and TI from conjunctival images with respective AuPRC values of 0.945 and 0.975 (Milad et al. 2023).

The analysis highlights how DL has the potential to revolutionize the treatment of neglected vector-borne illnesses such as trachoma, echinococcosis, leishmaniasis, schistosomiasis, and Chagas disease. Predictive modeling, species identification, and disease diagnosis have all shown impressive levels of accuracy when using DL models, such as CNNs and MLP classifiers.

More investigations are necessary to determine whether DL solutions can be scaled and applied to varied geographical locations and demographic groups. To take into account the complex nature of illness management and transmission, future research should concentrate on combining various data sources and creating hybrid DL models.

Research gaps still exist despite the advancements, such as the requirement for long-term studies to evaluate the effectiveness of DL-based therapies over the long run and initiatives to improve model interpretability.

Figure 4's histogram is essential as it compares the best models from various neglected VBDs, offering a concise overview for selecting effective models in our study. To summarize, DL applications have shown great promise for multiple neglected VBDs, encompassing diagnosis, prognosis, and predictive modeling and classification. In disease-specific analysis, models such as CNNs and MLP classifiers have demonstrated impressive accuracy, supporting risk assessment, species identification, and prognosis. More research is necessary to investigate the scalability and generalizability of DL models across various geographic locations and demographic groups impacted by these diseases.

Continuous research is necessary to modify DL approaches to new problems brought forth by urbanization and climate change. Research projects that include many disciplines can work together to create complete DL frameworks customized to the particular epidemiological conditions of neglected VBDs. This will help advance global disease surveillance, diagnosis, and control programs.

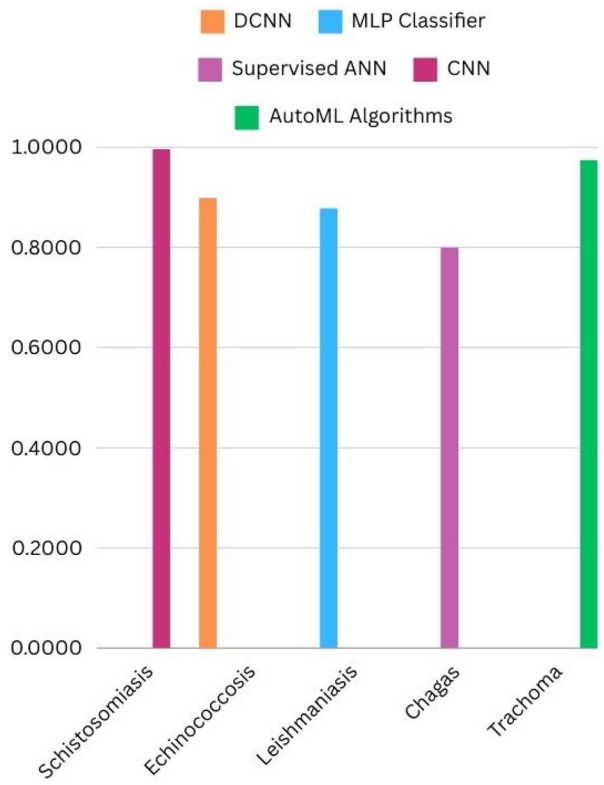

Fig. 4 Comparison of the accuracy of the best models of each neglected VBDs

4.3 Research question 3

DL's interdisciplinary integration with public health, entomology, and epidemiology offers a huge chance to improve our knowledge and ability to control neglected vector-borne illnesses. Advanced computer methods, such as DL models, can be used to understand the intricate dynamics of vector behavior and disease transmission.

DL models like CNNs and BP ANN have proven to be effective in evaluating epidemiological data to forecast disease transmission dynamics. These models can pinpoint important risk factors, such as environmental variables, socioeconomic position, and human behaviour, that contribute to the spread of disease (Xu et al. 2013; Parsons and Banitaan 2021). These findings are critical for improving public health initiatives and developing focused interventions to lessen the burden of neglected vector-borne illnesses.

DL algorithms also help in identifying disease vectors with high accuracy. These algorithms enable quick and accurate species identification by utilizing image processing techniques, which is essential for efficient vector surveillance and control strategies (Khalighifar et al. 2019).

Integrating DL methodologies with geographic information systems (GIS) amplifies our capacity to comprehend and address health crises. Researchers can pinpoint regions at high risk of transmission and prioritize interventions by evaluating geographical data and mapping disease hotspots. Public health officials can better distribute resources with this geographically informed strategy, increasing the effectiveness of control efforts and lowering the disease burden among vulnerable groups (Hammad et al. 1996).

Furthermore, DL-powered smartphone apps like AutoML present a viable way to quickly diagnose diseases in environments with limited resources (Milad et al. 2023). These apps allow frontline healthcare workers to use basic mobile devices to diagnose diseases like trachoma with high accuracy, democratizing access to artificial intelligence in healthcare. These technologies aid in the prevention and control of neglected VBDs, especially in underprivileged populations, by enabling early detection and timely treatment.

Utilizing DL in forecasting, diagnostics, epidemiology, entomology, drug discovery, and public health offers a rare chance to transform our knowledge and management of underappreciated vector-borne illnesses. This multidisciplinary strategy makes use of cutting-edge computer techniques to evaluate large, complicated data sets, pinpoint important risk factors, and create focused solutions. Though there are several possible advantages, there are still several areas that require detailed investigation and a well-planned study. Creating DL models that can handle increasing complexities and are well suited to the subtleties of vector-borne illness transmission is one such topic. Researchers can improve these models' accuracy and prediction power by adding other data sources, such as environmental sensor data or genetic sequencing data, which will ultimately result in more efficient management measures.

Additionally, interdisciplinary cooperation is required to address the particular difficulties brought about by neglected vector-borne illnesses in various geographical locations and socioeconomic circumstances. Collaborations between researchers, medical professionals, and community organizations may be necessary to gather and evaluate data, create culturally competent interventions, and put long-term control measures into place. Further research on the moral ramifications of applying DL technology in public health contexts is also possible, especially with regards to privacy, equity, and accountability concerns. By filling in these research gaps and utilizing interdisciplinary integration to its fullest, we may significantly improve public health outcomes worldwide and lessen the burden of neglected VBDs.

Table 9 provides a comprehensive overview of the interdisciplinary approaches reviewed, highlighting their significance in disease prediction, diagnostic techniques, entomology, epidemiological studies, drug discovery and treatment, and public health interventions, showcasing their potential relevance and application in our study. Even though there is a lot of potential for integrating DL with public health, entomology, and epidemiology, there are a few challenges that

Table 9 Interdisciplinary approaches reviewed

Theme	Details
Disease prediction and forecasting	Transmission risk modelling (Xu et al. 2013); Prediction of unresponsive cases (Bamorovat et al. 2021); Predictive modelling of parasite load (Torrecilha et al. 2017)
Diagnostic techniques	Raman spectroscopy-based diagnosis (Zheng et al. 2018); Classification of ultrasound images (Wu et al. 2022); Lesion segmentation (Xin et al. 2020); Ultrasound-based diagnosis (Yang et al. 2023); Computed Tomography-based detection (Wang et al. 2023); Smartphone-based diagnosis (Milad et al. 2023)
Entomology	Vector identification of snails and Schistosoma (Tallam et al. 2021); Vector identification of snails and parasites (Liu et al. 2019); Chagas vector identification (Khalighifar et al. 2019); Chagas vector identification (Parsons and Banitaan 2021)
Epidemiological Studies	Neural network-based epidemiology modelling (Hammad et al. 1996)
Drug Discovery and Treatment	Trypanocidal drug identification (Guerra et al. 2013); Development of chitosan microparticles (Leonardi et al. 2009)
Public Health Interventions	Epidemiology modelling (Hammad et al. 1996); Smartphone-based diagnosis (Milad et al. 2023)

need to be resolved. These include addressing regional differences in illness occurrence, making DL technology accessible in environments with limited resources, and requiring bigger and more varied datasets. Getting past these obstacles will be essential for achieving the maximum benefit of interdisciplinary integration in the fight against neglected vector-borne illnesses and improving public health outcomes worldwide.

4.4 Research question 4

Novel approaches and improvements in global health outcomes can be attained in neglected VBDs like cutaneous leishmaniasis, hepatic echinococcosis, trachoma, schistosomiasis, and Chagas disease. ANNs and CNNs are two examples of DL models that have demonstrated promise in forecasting various diseases and identifying critical risk variables that contribute to the spread of disease (Xu et al. 2013; Tallam et al. 2021; Liu et al. 2019). When it comes to identifying intricate image collections associated with VBDs, such as pictures of snails and parasites, these algorithms have proven to be highly accurate (Tallam et al. 2021; Liu et al. 2019). Furthermore, DL algorithms have surpassed conventional methods in the high accuracy rates with which they have automated the detection of disease vectors as shown by Khalighifar et al. (2019) and Parsons and Banitaan (2021).

Understanding local conditions and disease epidemiology is crucial since the application of DL in forecasting VBDs can vary depending on geographical changes, demographic trends, and regional disparities. DL can help us better understand the dynamics of disease transmission and boost disease surveillance and management by integrating varied data sources and creating more sophisticated predictive modeling algorithms, as shown by Xu et al. (2013), Tallam et al. (2021) and Khalighifar et al. (2019). Furthermore, DL has demonstrated potential for improving drug formulations and resolving issues with drug solubility and absorption in the context of drug development for ailments such as Chagas disease (Leonardi et al. 2009)

Research on neglected VBDs could potentially address important issues, including quick disease detection, precise diagnosis, and efficient treatment monitoring, by incorporating DL. DL makes it possible to create prediction models that are adapted to local variations and demographic trends by utilizing a variety of data sources and cutting-edge algorithms. This improves disease surveillance and management. Additionally, DL algorithms enable the automation of diagnostic processes, which promotes prompt interventions and resource allocation-particularly in situations with limited resources where access to healthcare professionals may be restricted.

In conclusion, by enhancing disease prediction, comprehending transmission dynamics, and maximizing therapeutic development, DL in neglected VBDs research offers creative solutions and advances in global health outcomes. These developments could improve disease prevention tactics and help public health initiatives in areas of the world where VBDs are prevalent.

The study covers several neglected VBDs, including leishmaniasis, echinococcosis, trachoma, schistosomiasis, and chagas disease. However, it excludes some important illnesses due to limited available DL research studies, such as lymphatic filariasis, hydatidosis, taeniasis, cysticercosis, onchocerciasis, and mycetoma. These diseases present significant health challenges in various regions but are not extensively addressed, although they have been targeted for elimination in recent times. DL can also be beneficial in a variety of research and disease management contexts. DL algorithms can be applied to improve treatment plans, anticipate disease transmission patterns, and automate diagnosis. A more thorough grasp of the possibilities of DL in neglected VBD research can be attained by bringing these diseases into conversation.

DL applications in neglected VBDs study fields such as cutaneous leishmaniasis, hepatic echinococcosis, trachoma, schistosomiasis, and chagas disease could result in creative solutions and improvements in global health outcomes. These diseases pose serious health concerns in different parts of the world. By evaluating enormous volumes of clinical data and finding trends that could enhance patient outcomes, DL algorithms, for instance, might be utilized to enhance treatment regimens (Xu et al. 2013; Tallam et al. 2021; Liu et al. 2019).

Furthermore, by combining several data sources, including demographic trends, environmental factors, and vector populations, DL models can be used to predict disease transmission patterns, leading to more efficient disease surveillance and control (Xu et al. 2013; Tallam et al. 2021; Khalighifar et al. 2019).

Additionally, it has been shown that DL algorithms may automate disease detection through image analysis; this could be especially helpful in places where access to medical personnel is limited (Wu et al. 2022; Xin et al. 2020; Wang et al. 2023; Milad et al. 2023). Researchers can improve disease surveillance and management by utilizing DL in these neglected VBDs to create advanced predictive models that are adapted to regional differences and demographic trends. Also, DL can help create novel medicine formulations by enhancing the prediction of the bioavailability of drugs, which will result in better therapies for Chagas disease (Leonardi et al. 2009).

Finally, neglected vector-borne illnesses that can be treated using DL applications include cutaneous leishmaniasis, hepatic echinococcosis, trachoma, schistosomiasis, and Chagas disease. DL can completely transform global health outcomes in several domains by improving disease prediction, comprehending transmission patterns, and optimizing treatment techniques. A more thorough grasp of the possible advantages and challenges of using DL in neglected VBD research will require concerted efforts for interdisciplinary approaches leading to disease elimination shortly.

5 Conclusion

This comprehensive review summarizes the significant advances made possible by DL approaches in combating neglected VBDs, emphasizing their potential to transform disease monitoring, diagnosis, and management tactics. This work sheds light on the adaptability and usefulness of DL models across a range of neglected VBDs, including schistosomiasis, Chagas disease, Leishmaniasis, Echinococcosis, Trachoma, and others, through a comprehensive investigation of a large body of literature.

The findings demonstrate the effectiveness of DL algorithms in predictive modeling, species identification, diagnosis precision, and therapy optimization for neglected VBDs. Specifically, CNNs and ANNs have emerged as superior alternatives to traditional methods in disease prediction, vector identification, and parasite classification, presenting novel solutions to persistent issues in disease control and management. Also, the interdisciplinary application of DL to subjects such as epidemiology, entomology, and public health has greatly improved our understanding of disease dynamics and permitted focused interventions. DL-powered systems have intriguing opportunities for automating disease surveillance and diagnosis, especially in resource-constrained regions where access to healthcare experts is limited. The development of DL-powered smartphone applications enhances disease detection and diagnosis, thereby increasing healthcare accessibility. The review also emphasizes DL's ability to forecast disease transmission risks, identify disease vectors, classify parasites, and optimize treatment techniques for a wide range of neglected VBDs.

While this study focuses on specific diseases, it is important to recognize that DL has the potential to treat a broader variety of neglected VBDs, including lymphatic filariasis, hydatidosis, taeniasis, cysticercosis, onchocerciasis, and mycetoma. There is a limitation on the application of DL to these diseases in this review due to the unavailability of research studies. Furthermore, the potential of DL should be expanded to include vector resistance prediction, health data integration, and community engagement, which could foresee the formation of drug and parasite resistance, integrate diverse data for a more thorough understanding, and provide appealing community education tools. Expanding DL's scope to include these areas will improve interventions for VBDs and public health. Advocating for a broad research agenda and discourse is critical for realizing the full potential of DL in eliminating neglected VBDs and improving global health outcomes.

The study highlights the potential of DL for transforming disease monitoring, diagnosis, and management. By enabling targeted and efficient techniques, DL can reduce the global burden of neglected VBDs, contributing significantly to the elimination of these diseases. Continued study and collaboration are required to fully harness the power of DL and expand its influence on neglected VBDs worldwide.

REGULAR PAPER

Deep learning-empowered intrusion detection framework for the Internet of Medical Things environment

Prashant Giridhar Shambharkar[1] · **Nikhil Sharma**[1]

Received: 5 February 2024 / Revised: 22 April 2024 / Accepted: 20 May 2024

Abstract
The fusion of Internet of Things (IoT) technology into healthcare, known as the Internet of Medical Things (IoMT), has significantly enhanced medical treatment and operational efficiency. Real-time patient monitoring (RPM) and remote diagnostics enabled by IoMT allow doctors to treat more patients effectively and save lives. However, healthcare devices' interconnected nature makes them vulnerable to cyber-attacks, threatening patient privacy and security. Ensuring the security and accuracy of patient health data is paramount, as any tampering could have life-threatening consequences, especially in emergency situations. To address these challenges, this research focuses on developing robust security models to secure patient data in IoMT networks while meeting the growing demand for efficient healthcare services. Artificial intelligence (AI)-based technologies such as machine learning (ML) and deep learning (DL) have the potential to be employed as the methodology for intrusion detection. The goal of this research is threefold: firstly, the linear support vector machine (LinSVM) model; secondly, the convolutional support vector machine (ConvSVM) model; and finally, the categorical embedding (CatEmb) model, which have been proposed to overcome the issue of security in a network. This article offers the CatEmb model as the first effort to use a DL-based embedding approach to recognize intrusion in the IoMT environment, utilizing patient biometric and network traffic flow data. Our experimental results show the efficacy of the proposed DL models, with the LinSVM achieving a training accuracy of 99.78%, ConvSVM reaching 99.98%, and CatEmb achieving 99.84%. These models outperform existing methodologies by 2.61% in detecting network intrusions, as demonstrated through metrics such as detection rate and F1-score. Furthermore, the proposed approaches are thoroughly compared with the existing state-of-the-art studies.

1 Introduction

The latest advancements and innovations in developing IoT systems have revolutionized the industry as internet-connected devices are increasing rapidly. According to Gartner, by 2025, there will be 27 billion IoT devices, which will be twice as many as the number of Internet-connected intelligent devices today [1]. It revolutionized the healthcare industry by integrating intelligence accomplishment into medical devices. Nowadays, healthcare monitoring systems have been designed using IoT as they have low-cost sensors and consume low power. Recently, these sensors have been used to expedite the patient's remote monitoring. It also lessens the requirement for doctors to be physically present every time. The fusion of IoT into medical devices is known as the Internet of Medical Things (IoMT). Nearly 30% of the IoT devices market has been covered by IoMT [2]. The modern developments and trends in wireless communication and IoT have widely supported an immense range of healthcare applications like patients' health monitoring, early detection and diagnosis of various diseases, remote healthcare services [3], and healthcare emergencies [4]. Adapting practical and secure techniques for life-threatening (critical) emergency cases can lessen the dependency and need on caregivers and cheapen medical service costs [5]. Developing intelligent decisiveness systems can facilitate early cures and possibly save people's lives. Wearable devices are employed to examine the patient health of the community continuously. So, the caregivers can impart communication regarding monitoring and diagnosis services to the people belonging to innovative societies [6]. It may create a severe problem if these systems are affected by any security threats because this gives rise to a contravention of patients' health data and medical and privacy issues, which may also result in the death of those patients in extreme cases [7].

According to the Cynerio report, most IoT-connected healthcare equipment may clasp critical susceptibility [8]. The unexpected disclosure of these gadgets in public may give rise to uncertainty risks and aid the attackers in accessing the patient's records. The adversaries may also use the known susceptibility and advanced persistent threats (APT) to deal with the victim device. This might endanger people's lives. Therefore, security must be considered a top concern in an IoMT-based healthcare monitoring system. Using different methodologies and techniques, the detection and prevention of attacks can be implemented. Other attacks, namely denial of services (DoS), malicious network traffic injection, and the man in the middle (MITM), are accomplished to compromise and attack the IoMT networks [9]. Various techniques like intrusion detection systems (IDS), vulnerability management, log monitoring, end device monitoring, prevention systems, and threat intelligence are used for detection and mitigation. IDS is a modern technology among these systems that recognizes various network attacks and security issues in IoMT.

In IDS, signature-based rules, security policies, or network traffic anomalies are executed to recognize security attacks in IoT-based networks. As the attackers used modern hacking methods and updated attacking strategies, these traditional policies were inadequate to secure the system. For example, the attacker can easily evade security policies by performing network reconnaissance and configuring firewalls and routers by reverse engineering the network devices. Researchers are investigating ML and DL approaches as they have become vital in offering solutions for developing efficacious attack detection systems. Exposure to processing and computing capabilities permits researchers to use ML and DL approaches as they give better results in precisely forecasting attack events. It is very important to secure IoMT systems as medical data are very sensitive and can be affected by cyber-attacks. The significance and challenges associated with these systems are explained as follows:

- *Patient privacy and confidentiality:* Healthcare data, such as treatment plans, patients' medical reports, documents, and diagnoses, are highly sensitive data and must be kept confidential. Security breaches may result in identity theft, privacy violation, or even blackmail.
- *Patient Safety:* IoMT devices, such as pacemakers and insulin pumps, frequently have a direct impact on patient treatment. Any unauthorized access or manipulation of these devices could endanger patient safety or even lead to loss of life.
- *Data integrity:* It is essential to maintain the integrity of medical records for proper diagnosis and treatment. Medical record tampering could lead to inaccurate treatment decisions and endangering patient health.
- *Trust in the healthcare system:* Trust plays a vital role in the healthcare system. Patients must trust that healthcare suppliers are protecting their data from different security issues. If patients no longer trust their healthcare providers, they may withhold information or even stop coming in for treatment completely.
- *Sensitive Medical Data:* IoMT devices gather an immense amount of personal health data, such as vital signs, diagnosis, and specifics of treatment. This private information might be made public through a security breach, which could result in identity theft, intolerance based on medical history, or even blackmail.

The challenges of securing IoMT systems by considering the sensitivity of medical data and cyber-attacks are explained as follows:

- *Complex environment:* It is inherently difficult to secure IoMT systems as they comprise a large number of interconnected devices, networks, and platforms. Each component may have its own vulnerabilities which requires comprehensive security measures.
- *Resource constraints:* Many healthcare companies struggle with a lack of funding, technical expertise, and cybersecurity experts. Ensuring the security of IoMT systems can be difficult because it requires advanced security technologies and training staff to address the increasing cyber threats.
- *Evolving cyber threat landscape:* The cyber threats that specifically target IoMT systems are continuously developing, as attackers are using more advanced methods to overcome security measures. Maintaining high security for IoMT (Internet of Medical Things) devices within healthcare environments presents a continuous challenge. Healthcare industries struggle to keep pace with the evolving landscape of cyber threats and vulnerabilities associated with these devices. This requires proactive security measures to mitigate potential risks and safeguard sensitive patient data.
- *Compromised Medical diagnosis:* Tampering IoMT data as a result of a cyber-attack could lead to severe consequences. Malicious individuals possess the ability to modify prescription dosages, manipulate vital signs, or interfere with device performance, thereby resulting in inaccurate diagnoses, unsuitable treatment strategies, or even life-threatening circumstances.
- *Disrupted healthcare operations:* The entire healthcare industry might be severely impacted by a successful cyber-attack on IoMT systems. Hospitals could become unable to deliver appropriate medical care if they lose access to essential patient data. Medical information and other linked devices could also be at risk if the attack spreads throughout the network.
- *Heterogeneity:* IoMT networks consist of a wide variety of devices made by different manufactures, each with a different level of security. This makes it difficult to implement a one-size-fits-all intrusion detection approach.

- *Real*-time data: Data streams are continuously produced by IoMT systems. Effective analysis of this real-time data is necessary for intrusion detection in order to identify abnormalities quickly and prevent potential harm.

1.1 Motivation

The research was mainly carried out on traditional network-based datasets containing network flow traffic samples only. In [10], an intelligent IDS framework has been developed using ML and DL techniques for identifying cyber-attacks in traditional networks. However, these approaches are inappropriate in the IoMT as, in today's scenario, different IoT-enabled health sensors are linked to the internet. Even for evaluating attack detection, the traditional network datasets are unsatisfactory in the IoMT environment. Most research emphasizes evaluating network traffic to recognize attacks in intelligent healthcare applications. In healthcare applications, patient biometric data are essential to understand their health conditions better. There is a connection between unexpected falls in the attack impacting the network and patients' sensing information, affecting healthcare records' availability, confidentiality, and integrity. Therefore, in this paper, a dataset [11] containing both patient biometrics and network traffic samples has been considered to forecast the attack incident and evaluate the two diverse data types when the attack incident takes place. The security violation in the network or IoMT devices may cause intervention in obstructed communication, loss of information related to patient's health, and disease diagnosis. As the attackers are so expert and skilled, the security risks to IoMT devices are increasing daily. To our knowledge, we contemplate this research as the first effort to use a DL-based embedding approach to recognize intrusion in the IoMT environment that has bypassed the current state-of-the-art performance.

1.2 Contribution

The significant contribution of this work is explained as follows:

- This study presents DL models, i.e., linear support vector machine (LinSVM), a collaborative model: ConvSVM (combination of convolutional neural network (CNN) and support vector machine), and categorical embedding (CatEmb) to identify network-based assaults in the Internet of Medical Things (IoMT). This research provides the CatEmb model as the first-ever method that employs a DL-based embedding approach to recognize intrusion in the IoMT environment using a WUSTL-EHMS-2020 real-time dataset.
- The model's performance evaluation is carried out using a binary classification method that distinguishes innocuous network traffic from man-in-the-middle assaults, which include spoofing and Internet of Things (IoT) data injection attacks.
- Various preprocessing and feature engineering techniques that include dropping irrelevant columns with the help of a covariance matrix have been demonstrated, as these features may not significantly affect the detecting process. This helps build an effective model that takes less memory utilization and inference time in detecting attacks in the network. The input dataset is balanced using a data augmentation approach to provide enough data availability for both the regular and attack samples. Segregate the dataset features into categorical and continuous columns and implement well-known feature engineering approaches like standard scaler, a power transformer for continuous columns, and ordinal encoders for categorical columns.

- The proposed models have been contrasted with the existing techniques explored on a similar real-time and benchmark dataset, showing that our models are superior with the highest accuracy, precision, recall, and F1-score for detecting attacks in minimum inference time.

The rest of the paper is systematically organized as follows: Sect. 2 highlights the literature review, which covers the capability of ML and DL models on different network flow datasets; Sect. 3 explains the architecture and workflow of the proposed methodology for intrusion detection in the IoMT ecosystem, along with in-depth discussion of data preprocessing, hyperparameter tuning of ML models, and proposed DL models; Sect. 4 illustrates about the experimental setup, testbed and dataset description, experimental work, and comprehensive performance evaluation of proposed models with the existing work followed by the conclusion in Sect. 5.

2 Literature review

This section provides a comprehensive study of different IDS frameworks proposed by researchers to identify the attacks in the IoT environment using ML and DL approaches and highlights the need for security. Intruders may harm the IoT network in the absence of IDS. Therefore, IDS infrastructure plays a vital role in eliminating such research gaps. Here, multiple frameworks have been explored, which are discussed as follows:

Clifton et al. [12] explained the ML technique's role in health monitoring systems. These techniques have been used for controlling and managing false alerts while revealing severe health issues. The data used in their experiment combine the patient's clinical observations to provide quick alerts in an envisaged emergency. This work has been conducted at Oxford University Hospital. Fotouhi et al. [13] developed a healthcare monitoring framework comprising three integrants, i.e., a gateway, an access point (AP), and a coordinator. The coordinator is the node attached to the patient's body for gathering information related to the patient's health using sensors. Static nodes, called access points, are located in the room's walls and by sensors that use communication protocols (like 6LoWPAN, BLE, or ZigBee). The information gathered by the APs gets forwarded to the gateway. Then, this information gets transferred to the cloud server using the internet. Without proper testing and explanation, some techniques have been proposed in this system for securing the data. Baburaj and Rani [14] introduced a cloud-based healthcare platform that uses an SVM (support vector machine) approach to forecast patients' situations and envisioned diseases. No unauthorized users are permitted in the system.

A blockchain-based healthcare system framework has been designed by Chakraborty et al. [15], which helps overcome the problems associated with the traditional healthcare system related to the security issues of the records created during patient treatment. The framework has been set up to supervise the treatment process from beginning to end. Alabdulatif et al. [16] developed a cloud-based smart prediction framework. This system was based on the fully homomorphic encryption (FHE) approach and comprises three blocks, i.e., the intelligent community resident, cloud storage, and smart prediction model. The data is gathered and dispatched to the cloud storage repository system in the first block. The encrypted data gets amassed in the second block. The third block has been used to detect abnormal changes like attacks without decrypting data. A secured anticipating approach based on Holt's linear trend method has been developed to predict bizarre changes in patient's vital signs, which helps

detect different chronic diseases. The author also introduced a novel parallel technique of Holt's method for improving the effectiveness of the FHE model.

The development of network intrusion detection systems (NIDS) has resulted in an increasing adoption of artificial intelligence (AI) techniques, particularly ML and DL, in recent years. Extensive research has been conducted on both ML and DL techniques, with a significant trend toward DL. The reason for this choice might be traced to the progress made in graphical processing units (GPUs), which have facilitated faster computations required for deep learning methods. As a result, scholars are progressively using deep learning algorithms to suggest more accurate security measures for Internet-of-Things (IoT) networks, which handle substantial amounts of unprocessed data. Deep learning algorithms possess a high level of proficiency in analyzing complex patterns due to their deep design, which enables them to effectively distinguish between regular and atypical network data.

2.1 ML-based IDS frameworks for attack detection

This subsection discussed different ML-based frameworks for solving security-related problems in IoT networks. A security system has been suggested by Zhang et al. [17] that applied the RF (random forest) technique to detect anomaly traffic on the KDD-1999 dataset. With a 1% false positive rate (FPR), this technique achieves 95% accuracy as an anomaly detector. This dataset is employed to test anomaly detection algorithms. It is a generic Knowledge discovery and data mining dataset. Since 1999, this dataset has been used in many competitions. Rao and Swathi [18] employed the Indexed Partial Distance Search k-nearest Neighbor (IPDS-KNN) technique to assess various attacks. It achieved 99.6% accuracy performance. Shapoorifard et al. [19] use the k-nearest neighbor (KNN) approach and mainly emphasize decreasing the false alarm rate (FAR) and achieving 85.2% accuracy. Tao et al. [20] introduced a SecureData scheme that delivers privacy and security to patients' private records. The FPGA (field programmable gate array) platform is used to optimize the KATAN secret algorithm, which is implemented for secure communication. To overcome the attack detection problem in IoMT, Yaacoub et al. [21] discussed different types of ML-based privacy and security solutions. But, according to the author, there is still a need to introduce an effective IDS system to detect attacks. To analyze attacks in the smart hospital, an ensemble classifier IDS has been developed by Saba [22]. The decision tree (DT) technique attained 93.2% accuracy performance in categorizing the cyber-attacks in the KDDcup-99 dataset. This dataset was created in the traditional network without adding IoT device traffic. A mobile agent-based IDS has been introduced by Thamilarasu et al. [23] to identify both network and device-based attacks in the IoMT environment. The simulation-generated datasets were tested using ML and regression techniques. Using the DT technique in the evaluation process, the device and network-level intrusion detection achieved an accuracy of 97.93% and 99.8%, respectively. Kumar et al. [24] experimented in three stages. The author introduced an RF, naïve Bayes (NB), and DT ensemble in the first stage. In the second stage, XGBoost was applied to categorize regular and attack network records. In the third stage, to classify the attacks in the IoMT environment, the developed model was applied to the ToN-IoT dataset, which attained 96.35% accuracy. The industrial IoT network setup has been used to create this dataset using Modbus weather sensors. In the IoMT environment, these sensors are not commonly employed. Therefore, the above data could not be appropriate for identifying network attacks.

Radoglou et al. [25] developed an Intrusion detection and prevention system (IDPS) to identify and prevent various cyber-attacks against communication protocols like Modbus/TCP and HTTP, broadly used by e-healthcare services. Here, EHR uses HTTP, whereas IoMT uses Modbus/TCP protocol. The proposed IDPS can retrain ML techniques and test itself using an active learning approach. The CIC-IDS2017 dataset was employed in this experiment to analyze the functioning of ML techniques on the HTTP network dataset. DT classifier achieved an accuracy of 96.44% in categorizing network attacks. In comparison, RF attained 94.45% of the accuracy on the Modbus dataset. Zachos et al. [26] introduced a systematic and potent anomaly-based IDS (AIDS) for the IoMT environment. The three features, i.e., gateways, IoT devices, and network traffic features, were combined to devise a unique feature set. Various ML techniques have been applied to identify deviations in the gathered malicious and data events in the network to enhance the functionality of attack detection. Memory consumption level attributes and CPU were considered for evaluation in IoT devices. The TON_IoT Telemetry dataset has been used in this experiment. According to the result reported by the author, KNN, RF, and DT are the most appropriate ML techniques that are employed for the central detection integrant of the introduced system.

Binbusayyis et al. [27] inspected and showed a detailed comparison of different methods like KNN, SVM, ANN (Artificial Neural Network), NB, and DT. The experiment used the Bot-IoT dataset to compare the working performance of ML methods. This dataset comprises various attack categories like denial of service (DoS), theft attacks, and distributed denial of service (DDoS) attacks. Spoofing and MITM attacks are IoMT attacks not covered in this dataset. On the tested dataset, DT attained an accuracy of 100%, and other ML techniques like SVM, NB, and KNN achieved an accuracy of 99%. Saif et al. [28] proposed a hybrid methodology known as DHOA-ANFIS, with the objective of identifying routing vulnerabilities in wireless body area networks (WBANs). The novelty of their approach involves the integration of the adaptive neuro-fuzzy inference system (ANFIS) and the distributed Hopfield neural network (DHOA) in order to improve the precision of routing attack detection. The primary aim of this research is to improve the security and dependability of wireless body area networks (WBANs) by effectively tackling unique obstacles.

As per the study, ML techniques are used to identify attacks in IoMT. However, most datasets were created without considering the IoMT environment and attacks. The results presented by the authors in their research were outstanding, as in many contributions, the ML techniques achieved an accuracy of 95%. The IoMT study considered many input features like IoT device memory, network traffic, CPU, and metric features. However, researchers did not use or mention features like patient biometric data to identify cyber-attacks in the IoMT. Many researchers explored DL techniques to classify or identify the attack in the IoMT ecosystem.

2.2 DL-based IDS frameworks for attack detection

This subsection presents the DL-based IDS framework for solving security issues in IoT networks. To forecast various attack simulations in deep brain stimulators (DBSs), Rathore et al. [29] developed a DL algorithm that efficiently identifies the pattern of attacks and alerts a patient regarding that. To identify network attacks in the IoT environment, Manimurugan et al. [30] introduced a DL-based deep belief network (DBN) algorithm that achieved an accuracy of 96%. The experiment was conducted using the proposed model on the CICIDS dataset. This dataset generation did not concentrate on IoMT network attacks. For feature

selection, Saheed and Arowol [31] used particle swarm optimization (PSO) and ML/DL-based techniques to identify cyber-attacks in the network. Researchers used the NSL-KDD dataset to analyze the functionality of the suggested approach. The introduced model attained 99.76% of the accuracy performance. This dataset was not created with the IoT environment in mind and should not be used to assess attack identification in IoMT. Awotunde et al. [32] developed a swarm neural network (SNN) method that detects intruders while transmitting the data and permits accurate and efficient assessment of medical data at the network edge. The author used the NF-ToN-IoT dataset for the experiment, which amalgamates network data, operating systems, and telemetry. The author used a deep autoencoder (DAE) to decrease the dimensions of features. The author used a deep feed-forward neural network (DFFNN) in the IoT environment to recognize the network attacks. The DAE-DFFNN model achieved an accuracy of 89%, which is superior to ML techniques such as DT and SVM, as claimed by the researcher. For identifying malware in the IoMT ecosystem, Khan and Akhunzada [33] introduced SDN (software-defined network) enabled CNN (convolutional neural network) and LSTM (long short-term memory) hybrid DL model, which attained an accuracy of 99%. However, this framework was not used as IDS to determine network attacks in the IoMT ecosystem. Nandy et al. [34] developed intelligent agent-based SNNs to detect IoMT intruders. The experiment was conducted using the proposed approach on the ToN-IoT dataset, which attained 99.5% accuracy.

The above study of DL approaches indicates that these techniques were not highly introduced to identify IoMT network attacks. Most authors only explored the network traffic dataset in their experimental work to identify the attacks in the network, as discussed in Table 1. None of the above-mentioned results contemplate the combined features of patients' biometrics with the network flow data.

3 Proposed architecture and methodology

The performance of attack identification utilizing patient biometrics and network flow dataset has been improved in this paper by introducing DL-based models to find attacks in the IoMT environment. Before explaining our proposed procedure, we first outline the architecture of IoMT IDS, as shown in Fig. 1. This architecture maintains security performance and predicts attacks using ML and DL methods. The IoMT IDS architecture combines IoT gateway, security operators, network traffic collector, IDS, patient sensor devices, and ML or DL data processing techniques, which are used to monitor different types of attacks. The patient's device sensor comprises ECG devices, a pulse rate detector, a respiration rate tracking machine, temperature sensors, and a heart rate tracking machine. The information gathered using these sensor devices gets transferred to the remote servers using IoT network protocols like Message Queuing Telemetry Transport (MQTT) and Advanced Message Queuing Protocol (AMQP). Using wired or wireless communication, the IoT gateways gathered the sensor's information and transferred that information to remote areas. The proposed techniques comprise analytical accomplishments and data processing to identify intrusion in the IoMT ecosystem. Continuous analysis and monitoring are needed at the IDS level to reduce false positives and alert the user regarding the attacker. The physical premises monitoring and remote monitoring of patients are the primary applications of the IoMT environment, which helps to cure and save patients' health in the hospitals.

Figure 2 depicts the operational structure of the IDS framework to identify attacks using ML and DL techniques in the IoMT ecosystem. Rather than analyzing network flow traffic

Table 1 ML and DL methods to identify an attack in the network

Year	Authors	Methodology	Dataset	Description	Result	Limitations
2018	Su et al. [35]	Lightweight CNN	IoTPOT	The proposed methodology was employed to recognize DDoS cyber-attacks in IoT networks	$A = 94\%$	This dataset is a combination of IoT threats. This dataset is not used to identify attacks in the IoMT environment
2018	Nguyen et al. [36]	CNN classifier	IoT Botnet	The author introduced the model that combines the CNN classifier and PSI graph for Linux IoT botnet identifications in this paper	$A = 92\%$, $P = 91\%$, $R = 97.6\%$, F1 = 94%	This dataset contained flow-based features and was only used for malware identification in IoT networks
2019	Rathore et al. [29]	Recurrent neural network (RNN)	Dataset obtained from Physionet	To forecast various attack simulations in Deep brain stimulators (DBSs), the author introduced a DL model that efficiently identifies the pattern of attacks and alerts a patient regarding that	Different low loss value, RMSE = 0.095	There was no discussion of accuracy in the paper, and the simulated attacks were not actual

Table 1 (continued)

Year	Authors	Methodology	Dataset	Description	Result	Limitations
2020	Hussain et al. [37]	LR (logistic regression), KNN, NB, RF	CICIDS2017, IoT-23, CTU-13	The authors presented the idea of a universal feature set. Different ML models were considered for classifying the attacks	$A = 100\%$, $P = 100\%$, $R = 100\%$, F1 = 100%	Low accuracy; No hyperparameter tuning was carried out during the experimental process; Techniques took high prediction time; For the Universal Classification Process, the dataset needed to be combined
2020	Farhan et al. [38]	DNN (deep neural network)	CSE-CIC-IDS 2018	To classify the attack in the network, the author proposed the DNN model	$A = 90.25\%$, $P = 65\%$, $R = 59\%$	The proposed method achieved low precision and recall values, i.e., 0.65 and 0.59, respectively. No other techniques were considered for classifying the attack. The dataset is not viewed for identifying attacks in the IoMT network

Table 1 (continued)

Year	Authors	Methodology	Dataset	Description	Result	Limitations
2020	Sarhan et al. [39]	Extra tree classifier	UNSW-BN 15, ToN-IoT, CSE-CIC-IDS2018, BoT-IoT,	In this paper, four datasets were considered to show NetFlow features. The n Probe Tool generalized the datasets into universal feature datasets. The proposed approach achieved a weighted average of 70.81%, a prediction time of 14.67 µs, and an F1-score of 0.79	$A = 90.28\%$, F1 = 94%	Prediction time is high; For classification, no other techniques have been used; High FAR rate
2021	Kumar et al. [24]	Ensemble classifiers like RF, NB, and DT	ToN-IoT dataset	The suggested models were applied to categorize the attacks in the IoMT environment	$A = 96.35\%$, DR = 99.98%	Modbus weather sensors are employed to create a dataset generally not used for the IoMT environment. It contains only network traffic data. Therefore, the dataset could not be appropriate for identifying network attacks in IoMT; The false acceptance rate (FAR) is high

Table 1 (continued)

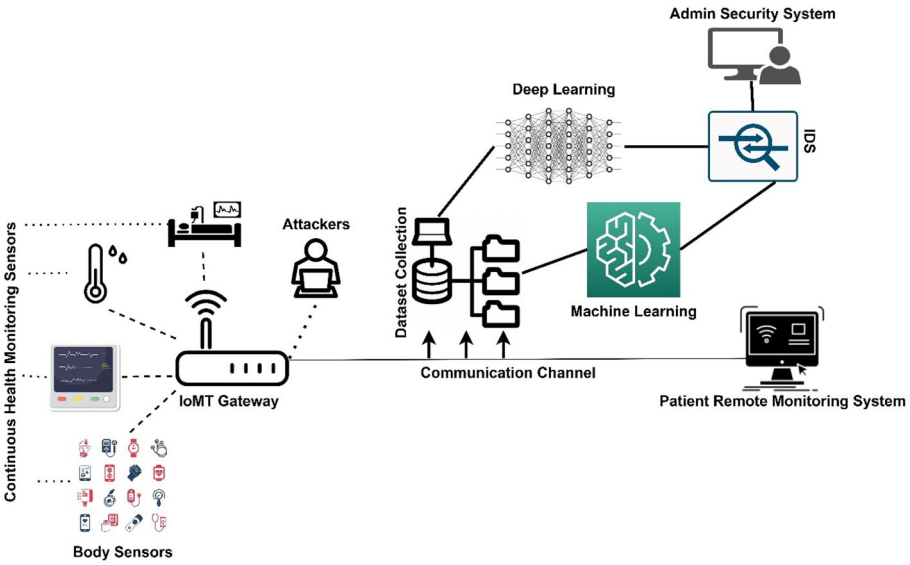

Fig. 1 ML and DL-based IDS Framework for IoMT environment

and identifying intrusion in the system, we used IoT sensing data that belongs to the patient's specific IoMT ecosystem. This IoT-based sensing data helps to detect patient biometrics anomalies and enhances the performance of attack identification whenever the intruder tries to attack the IoMT environment. With the help of both events' timestamps, i.e., patient biometric data events and network traffic events, the patient's biometric and network traffic data get combined. The final dataset presents a minority of features belonging to patient biometric data and the majority of the network traffic features.

In order to improve network-based attack detection in the Internet of Medical Things (IoMT), the framework as shown in Fig. 2 includes various DL models such as linear support vector machine (LinSVM), ConvSVM (a combination of convolutional neural network (CNN) and support vector machine), and categorical embedding (CatEmb). CatEmb is a novel embedding approach that employs deep learning techniques and leverages the WUSTL-EHMS-2020 real-time dataset for the purpose of intrusion detection. Moreover, the application of binary classification algorithms in a rigorous evaluation process allows for the differentiation between benign network traffic and potential attacks such as spoofing and IoT data injection attacks. This ensures the practical effectiveness of IoMT networks. The utilization of memory and inference time is optimized through the implementation of significant preprocessing and feature engineering approaches, such as systematic column reduction using covariance matrix analysis. Furthermore, data augmentation mechanisms are employed to achieve a balanced dataset, while feature segregation enables the utilization of conventional techniques such as standard scaler and power transformers for continuous columns and ordinal encoders for categorical columns. Finally, the optimal performance is achieved by seamlessly integrating with other components.

The computational demands of the proposed method are certainly significant, requiring substantial computational resources. To address this, we have chosen to implement the method on the centralized server of the IoMT system. By offloading the computational burden to a centralized server, we mitigate the impact of resource constraints within individual IoMT

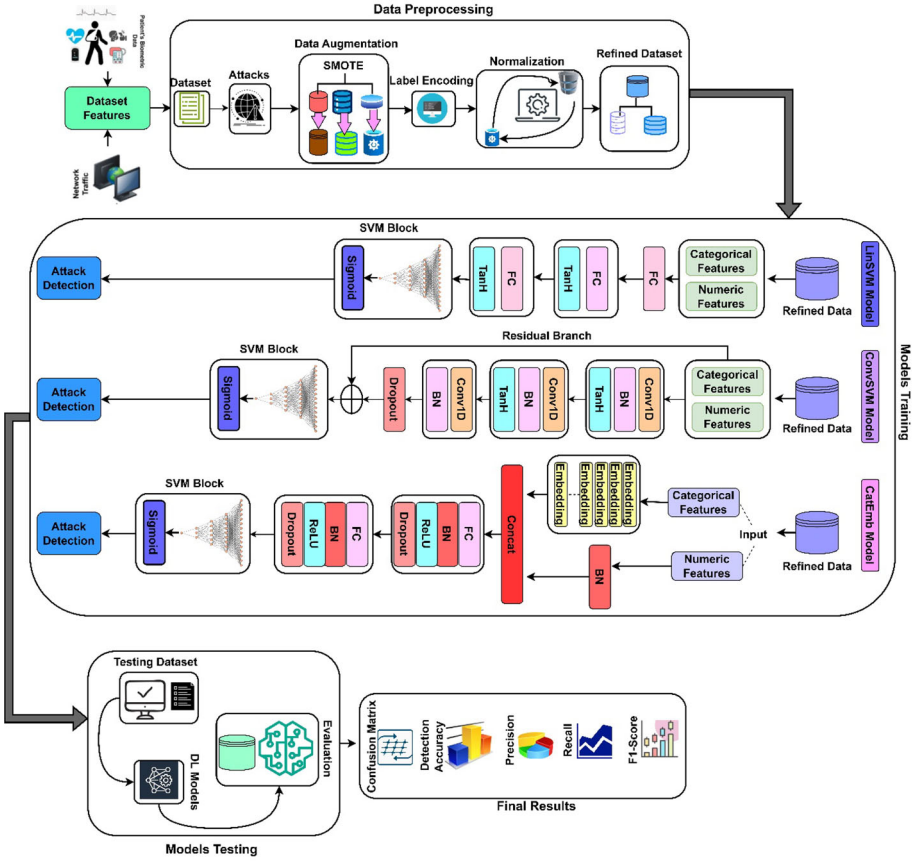

Fig. 2 Proposed work flowchart to detect IoMT attacks

devices. This design choice allows us to leverage the computational power and resources available on the server, which are typically more robust compared to those available on resource-constrained IoMT devices. Therefore, while acknowledging the high computational requirements of the method, our approach ensures that the resource constraints inherent in IoMT devices do not directly impede the implementation and functionality of the proposed method.

3.1 Data preprocessing

Data processing is a preliminary step before training and testing the ML or DL so that models can provide better results. This paper used popular techniques like standard scaler and simple imputer to preprocess the data. To begin with, standard scaler is a well-known method used for data standardization and primarily a preprocessing procedure performed before many ML or DL models to normalize the functional range of the input datasets. It is employed to scale the value distribution in such a matter that the observed value's mean is 0, and its standard

deviation is 1. Equation (1) shows the feature scaling with standard scaler [42].

$$X_{\text{FeatureScaled}} = \frac{X_{\text{FeatureCurrentValue}} - \text{mean}(X_{\text{Feature}})}{\text{StandardDeviation}(X_{\text{Feature}})} \tag{1}$$

where $X_{\text{FeatureScaled}}$ shows the scaled feature value after the successful execution of the scaling process; without any alterations, $X_{\text{FeatureCurrentValue}}$ displays the current feature value; X_{Feature} represents all of the dataset's feature columns; and the mean for each feature depicted by mean ().

In addition to the process, a dataset's missing values can be imputed using the Simple Imputer as expressed in Eq. (2). These values can be substituted with statistics like the mean, median, or most frequent value for the missing numbers, or it can use a provided constant. Here, y_{pq} represents the initial value; y'_{pq} denotes the imputed value for the elements located in the pth row and qth column; and strategy shows the imputation approaches like mean, median, most frequent value or a user-specified constant value.

$$y'_{pq} = \begin{cases} \text{strategy} & \text{if } y_{pq} = NaN \\ y_{pq} & \text{otherwise} \end{cases} \tag{2}$$

Furthermore, a power transformer [43] and a standard scaler are used to scale the data in the numeric columns. They are a family of monotonic and parametric transformations that convert skewed features into normal distributions using logarithmic transform to create data that is more Gaussian-like. It handles the modeling problem related to non-constant variance or any other type of condition where normality is required. Power Transformation is expressed by Eq. (3).

$$y(\lambda) = \begin{cases} \frac{((y+1)^{\lambda}-1)}{\lambda}, & \text{if } y \geq 0 \text{ and } \lambda \neq 0 \\ \log(y+1), & \text{if } y \geq 0 \text{ and } \lambda = 0 \\ -\frac{((-y+1)^{2-\lambda}-1)}{(2-\lambda)}, & \text{if } y < 0 \text{ and } \lambda \neq 2 \\ -\log(-y+1), & \text{if } y < 0 \text{ and } \lambda = 2 \end{cases} \tag{3}$$

Here, a parameter called λ is estimated in the fitting procedure, y indicated input data, and to make the data more Gaussian-like, the optimal value of λ is selected.

3.2 Feature engineering

It is an ML approach that uses data to develop new variables that aren't considered in the training set. It helps to modify datasets, including mutation, combination, addition, and deletion operations, to upgrade the training of the ML models and attain ameliorate accuracy and performance. Here, the feature selection approach has been applied to minimize the input variable by employing the pertinent features and eliminating the noise from the data [44]. In this paper, a co-variation matrix heatmap, which represents the linear correlations between the various variables in the dataset, has been used. It facilitates the identification of patterns and correlations between variables. The covariance between two variables, X and Y, can be determined using Eq. (4). Some columns were correlated throughout the dataset, so there is no need to consider those columns. Therefore, four columns, namely Dir, SrcAddr, DstAddr, and DtMac, were dropped by taking advice from the domain experts. After that, an ordinal encoder [45] encodes the categorical columns, i.e., Flgs and SrcMac. Each label is converted into an integer value through ordinal encoding, and the encoded data shows the order of

labels. Equation (5) is used to encode categorical column data using the ordinal encoder.

$$\mathrm{Cov}(X,\ Y) = \frac{1}{n-1}\sum_{i=1}^{n}\left(X_i - \overline{X}\right)\left(Y_i - \overline{Y}\right) \tag{4}$$

where the covariance between variables X and Y is denoted as Cov(X, Y); n represents the number of data points, X_i, Y_i; $\overline{X}$, and $\overline{Y}$ shows an average of X and Y.

$$x' = \mathrm{ord}(x) \tag{5}$$

where x' shows encoded value; ord indicates where category x is located in the given categories' parameter; x represents the original categorical value.

The dataset was portioned using distributions of 80% for the training and 20% for the testing datasets to accurately compute the ML and DL models' working performance. Further, the performance has also been evaluated for 70–30% dataset distribution and compared with 80:20% distribution output. The K-Fold cross-validation with ten folds has been used on the training dataset sample to demonstrate the range of working performance between the folds. Identifying the attacks using this model may be challenging as the dataset needed to be more balanced, with standard samples making up roughly 88% of the data. Hence, to balance the dataset in the training phase, an oversampling method, i.e., SMOTE (Synthetic Minority Oversampling Technique) [46], has been applied. The role of this technique is to balance the dataset by producing new synthetic samples for the minority class. In the SMOTE class, the fit_resample method is used from the imblearn library [47] that fits the SMOTE algorithm to the input data X and y, and returns the resampled data as expressed in Eq. (6). Here, X is a 2D array-like object representing the features of the input data, and y is a 1D array-like object, representing the target or label of the input data.

$$X_\mathrm{resampled},\ y_\mathrm{resampled} = \mathrm{smote.fit_resample}(X,\ y) \tag{6}$$

The amount of resampled data depends on the parameters passed to the SMOTE object. By default, it creates synthetic samples for the minority state class until the class distribution is balanced. Therefore, there will be equivalent data samples from the minority and majority classes. However, we can specify the amount of oversampling by setting the sampling_strategy parameter. For example, if sampling_strategy is set with a value of 0.5, then SMOTE will oversample the minority class by a factor of 0.5. Hence, there will be 50% more samples in the minority class than in the majority class. Table 2 represents the dataset before and after resampling.

Table 2 Dataset before and after resampling

IoMT dataset	Dataset before SMOTE Resampling		Dataset after SMOTE Resampling	
	Normal sample value	Attack sample value	Normal sample value	Attack sample value
WUSTL-EHMS-2020	14,272	2046	14,272	14,277

3.3 ML models & hyperparameters tuning

In this work, hyperparameter tuning to all the pre-trained ML models has been performed to improve the attack detection in the IoMT environment, which is explained as follows:

3.3.1 SVM

SVM is a linear classification and regression model that works well for real-world problems and can supervise related linear and nonlinear issues. This technique made a line or hyperplane that distinguished the data into classes [48]. To ensure that $y_i(w.x + b) \geq 1$ is always met, and the objective function must be reduced. Equation (7) represents the hyperplane function where w represents Weights, and b refers to bias.

$$H(x) = \begin{cases} +1, & \text{if } w.x + b \geq 1 \\ -1, & \text{if } w.x + b \leq 1 \end{cases} \tag{7}$$

3.3.2 DT

DT is a supervised ML technique that constantly divides the data based on a given parameter. The two entities may be used to explain the DT, viz. decision leaves and nodes. It is employed for addressing regression and classification issues [49]. The main objective of this algorithm is to develop a model that predicts the intent variable value by learning simple decision rules derived from the data attributes. In our analysis, we set the maximum depth value to 8.

3.3.3 LR

LR is a supervised ML approach for addressing classification and prediction issues. It is simple to elucidate and implement and well organized to train the data as it takes less time to classify unknown records [50]. It is used to forecast or compute the probability that the event occurs. It should be a binary target variable and provide probabilistic values ranging between 0 and 1. Equation (8) represents the LR model. In our analysis, we set the value of the random state and maximum iterations to 0 and 100, respectively.

$$q = \frac{\mathrm{e}(\mathrm{b0} + \ \mathrm{b1} * \mathrm{p})}{(1 + \ \mathrm{e}(\mathrm{b0} + \ \mathrm{b1} * \mathrm{p})} \tag{8}$$

where p is input values merged linearly using coefficient or weight values, *b0* is the intercept or bias value, *b1* represents a single input term *(p)*, and q is the predicted output.

3.3.4 KNN

It is a supervised ML approach for addressing classification and regression issues. It aims to forecast the proper class samples by measuring the distance amid all test data and training points. After that, it picks the K-Points, i.e., nearest to the test data. This technique computes the probability of the test data sample belonging to K training data classes and selects the class with the excessive probability [51, 52]. In our analysis, we choose two neighbors, set the leaf size to 100, and assign the average values from nearby neighbors as the final projected values. The closest neighbors are computed using the Euclidean distance (E), as

shown below in Eq. (9), where the number of neighbors denoted by k and the data points in the i^{th} dimension are a_i and b_i.

$$E = \sqrt{\sum_{i=1}^{k} (a_i - b_i)^2} \tag{9}$$

3.3.5 Gradient boosting classifier (Grad_Boost)

It is a collection of ML models that fuse multiple weak learning techniques, usually DT, to build a dedicated predictive model. It may be applied to address both regression and classification issues. Regularization techniques are employed to minimize the consequences of overfitting and to prevent deterioration by confirming that the fitting operation is limited [53]. It is a good technique that deals with unbalanced datasets. In our analysis, we set the value of the subsample, estimators, maximum depth, and maximum leaf nodes to 0.5, 1000, 8, and 1000 respectively. The result of H(x) for input x is defined in Eq. (10).

$$H(x) = \sum_{i=1}^{n} \alpha_i h_i(x) \tag{10}$$

where n shows number of leaves, and the value predicted for the region h_i is represented by a_i.

3.3.6 RF

A supervised ML approach is applied to address regression and classification analysis. It is based on the concept of ensemble learning, which integrates many classifiers to address challenging issues, upgrade model performance, and eliminate the problem of overfitting. With high dimensionality, this technique can manage big datasets [54]. Rather than depending on the DT, RF uses prediction from all the trees and forecasts the final result based on which predictions received the votes. In our analysis, we set the value of estimators, random state, and maximum leaf nodes to 1000, 1, and 1000, respectively.

3.3.7 XGBoost

It is a well-known supervised ML approach that is enforced to address classification and regression issues. It tries to forecast a target variable precisely by fusing multiple weak learning techniques. It is fundamentally similar to the Grad_Boost classifier, but the residual trees are constructed differently in XGBoost. The variables utilized as the roots and nodes of the residual trees are chosen by computing similarity scores between the previous nodes and the leaves [50]. In our analysis, we set the value of the estimators and maximum depth to 1000 and 8, respectively. Equation (11) represents the XGBoost model.

$$\text{ObjectiveFunction} = \text{Loss}(y_\text{true},\ y_\text{pred}) + \lambda \times \text{Complexity}(T) \tag{11}$$

where Loss (y_true, y_pred) represents the loss function that calculates the difference between the actual target values (y_true) and the expected target values (y_pred); A regularization term called complexity (T) penalizes the model's complexity; λ- referred to as the regularization parameter, determines how strong the regularization is.

Table 3 Hyperparameter tuning of ML models

ML models	Folds	Parameters optimized	Values
SVM	K-fold cross-validation = 10	Gamma	Auto
DT		Max_depth	8
LR		Random_state	0
		Max_iteration	100
KNN		N_neighbors	2
		Leaf_size	100
Grad_Boost		Subsample	0.5
		N_estimators	1000
		Max_depth	8
		Max_leaf_node	1000
RF		N_estimators	1000
		Random_state	1
		Max_leaf_node	1000
XGB		N_estimators	1000
		Max_depth	8

Table 3 depicts the hyperparameter tuning of the ML model. For the training process, all models are set with different parameter values and evaluated using 10K-fold cross-validation to lessen the variance in the findings over data partitioning and circumvent the model's overfitting.

3.4 Experimental configuration of DL models for IDS

This section discussed novel DL-based proposed models for recognizing attacks in the IoMT network. These models are trained using the different parameters, as shown in Table 4.

3.4.1 LinSVM (linear support vector machine)

In this model, we initialize the weight using Xavier Uniform [55] to ensure steady training. This helps prevent layer activation outputs from vanishing or exploding during the forward

Table 4 DL models parameters

Parameters	Values
Learning rate	0.0001
Embedding dimension	16
Epochs	200
Batch size	64
Optimizer	Adam
Activation function	ReLU, TanH

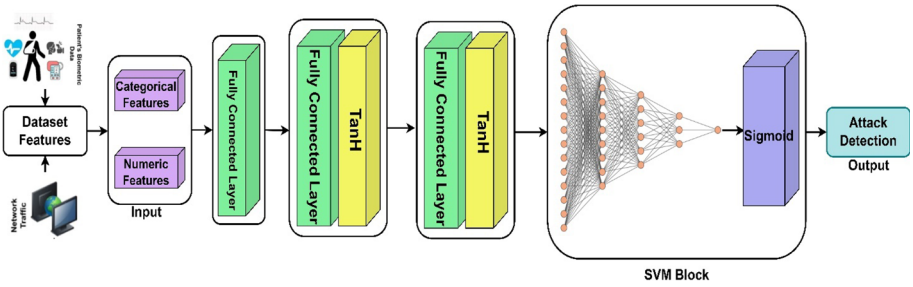

Fig. 3 Working flow of LinSVM for detecting IoMT attack

process through a DNN, and the bias terms are set to 0.01. Both categorical and numerical features were passed to block 1, containing fully connected layers (FC), in which the input gets augmented by a weight matrix in an FC, and a bias vector gets added to it. The output of block 1 is fed to block 2, containing the FC and Tanh (hyperbolic tangent) activation functions. A feed-forward neural network with several hidden layers is implemented in this class. Each hidden layer consists of a linear transformation followed by a TanH activation function. The classification between two classes is accomplished using the Tanh activation function. It has a range of between − 1 and 1. It makes learning more accessible for the next layer by centering the data and generating a mean near 0. The output of block 2 transferred to block 3, containing the same components. Then, the output from Block 3 is fed to the SVM block containing the FC layer and sigmoid activation function for the binary classification. Therefore, these modifications and nonlinear activation functions are applied in the forward technique to compute the final output. Figure 3 depicts the working flow of LinearSVM for detecting IoMT attacks.

3.4.2 ConvSVM (convolutional support vector machine)

ConvSVM is a combination of a convolutional layer and SVM. This model passed categorical and numerical features to block 1, containing a 1D convolutional layer followed by batch normalization (BN) and a Tanh activation function. Using this, hierarchical features are extracted from the input by the convolutional layers (conv1, conv2, conv3) and their related BN layers (BN1, BN2, BN3), which helps to enhance model generalization. This block applies sliding convolutional filters to 1-D input via a 1-D convolutional layer. Every value in the input vector gets multiplied by the kernel value in this operation. Using BN with a 1-D convolutional layer alleviates the model functionality by expediting the training process, employing more excellent learning rates, and eliminating internal covariate shifts. It also consumes less memory. Tanh activation function makes learning more accessible for the next layer by centering the data and generating a mean near 0. The output from Block 1 fed into Block 2, containing the same components as the earlier block. After that, the output of Block 2 was sent to Block 3, comprising a 1D convolutional layer and BN. Then, we used the dropout layer to drop noise or data value that is purposefully removed from a neural network to accelerate the processing of the model and prohibit it from overfitting. To save from vanishing gradient, we added a residual branch and concatenated it with an output of block 3. Finally, we pool the features using an adaptive average pooling layer, which was then passed to an SVM block containing an FC and the sigmoid activation function for the binary classification. Figure 4 depicts the working flow of ConvSVM for detecting IoMT attacks.

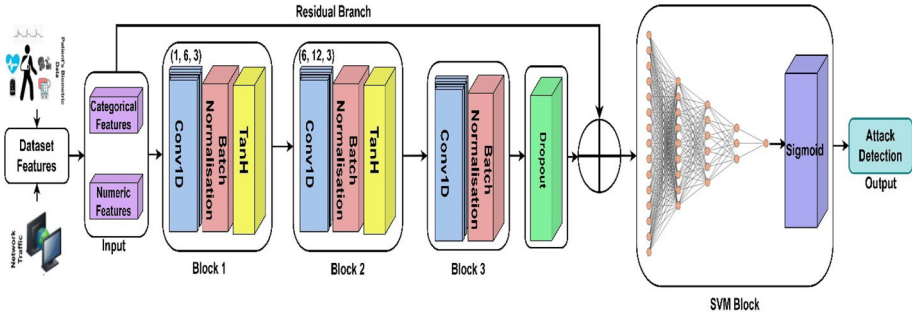

Fig. 4 Working flow of ConvSVM for detecting IoMT attack

3.4.3 CatEmb (categorical embedding)

Categorical entity embedding extracts the embedding layers of categorical variables from a neural network model and applies numeric vectors to represent the properties of the categorical values. It is usually used on categorical variables with high cardinalities. In this model, categorical features are separately handled by column embeddings. In contrast, the BN individually manages numerical features. Then, these features are concatenated together and fed to decider Block 1 containing the FC layer, BN, ReLU (Rectified Linear Unit) activation function, and dropout layer. In FC layers, the input gets multiplied by a weight matrix in an FC layer, and a bias vector gets added to it; BN helps to alleviate the model functionality by expediting the training process, employing more excellent learning rates, and eliminating internal covariate shifts; ReLU activation function fixes the vanishing gradients problem and does not allow activation of all the neurons at the same interval of time. Then, the dropout layer was used to drop noise or data value that was purposefully removed from a neural network to accelerate the processing of the model and restrain the model from overfitting. The output of block 1 is further sent to block 2, containing the same components. Then, the result of block 2 passed to the SVM block containing the FC layer and sigmoid activation function for the binary classification. Figure 5 depicts the working flow of categorical embedding for detecting IoMT attacks.

Table 5 shows the training parameters for all the proposed methods with learning rates

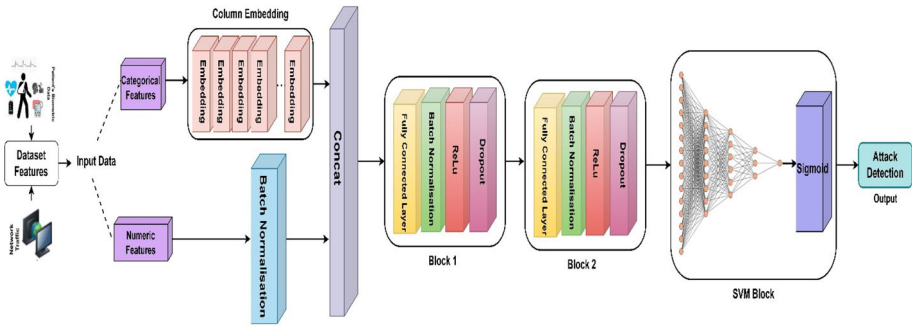

Fig. 5 Working flow of CatEmb for detecting IoMT attack

Table 5 Training parameters of the proposed models

Training parameters	DL models		
	LinSVM	ConvSVM	CatEmb
Initial state or attributes	in_features, hidden_size = 32, out_features = 1, n_hid_layer = 3	in_features = 40, out_features = 1	layers_dim = [64, 128] output_dim = 1 drop_prob = 0.5
Activation function	TanH	TanH	ReLU
Conv1D	–	Yes	–
BatchNorm1d	–	Yes	Yes
AdaptiveAvgPool1d	–	Yes	–
Batch size	64	64	64
Optimizer	Adam	Adam	Adam
Learning rate	0.0001	0.0001	0.0001

and batch sizes of 0.0001 and 64, respectively. In the further section, these models are also trained with different batch sizes like 128 and 256 to examine the methods' training loss and validation loss performance.

The CatEmb approach has superior performance compared to other DL models because of various factors inherent in its design which are explained as follows:

- Handling categorical variables: This model handles categorical variables with high cardinalities by using categorical entity embedding. This approach allows the model to present the properties of categorical values as numeric vectors and improves the model's ability to depict complex relationships within the data.
- Feature representation: This model employs column embeddings to manage categorical characteristics whereas BN handles numerical features individually. This distinct approach guarantees that the model accurately represents both categorical and numerical data.
- Neural network architecture: In this model, a neural network architecture consists of decider blocks (such as FC, BN, ReLU activation function, and dropout layers) and an SVM block. The decider blocks allow efficient feature extraction and learning. Furthermore, the model integrates dropout regularization to prevent overfitting and improve generalization.
- Efficient classification: The output from block 1 is further processed through block 2 before being transmitted to the SVM block for binary classification. This multi-layered approach allows the model to depict patterns and relationships in the data, which helps the model accurately classify the network intrusion.

These features help achieve superior results compared to other models and require less inference time to detect intrusion in the network.

4 Experimental setup and result discussion

This paper assesses ML and DL models using performance metrics, including accuracy, precision, recall, F1-score, specificity, and MCC. After that, this section highlights the working performance of the proposed model compared to the state of the art. Here, Fig. 6 repre-

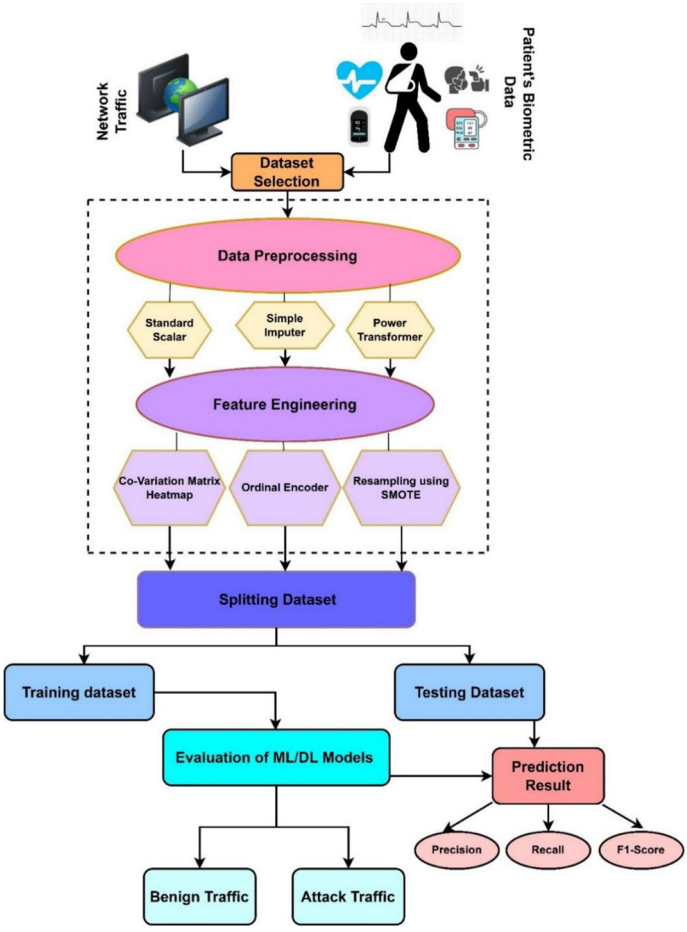

Fig. 6 Experiment outline to recognize IoMT attack

sents the experiment outline of this work. The WUSTL-EHMS-2020 dataset [11] has been selected as a network and patient biometric data combination. After that, data preprocessing techniques like standard scaler, simple imputer, and power transformer have been applied to clean and transform raw data into an appropriate format for the training process. Then, the feature engineering techniques, including co-variation matrix heatmap and ordinal encoder, were used to transform existing features or build new ones to enhance the performance of the models. The SMOTE function has been utilized for resampling the dataset to balance the classes. Further, the performance has been evaluated for 80–20% and 70–30% of dataset distributions for both ML and DL models to identify attacks in the IoMT environment.

To begin with, deep learning models, including LinSVM, ConvSVM, and CatEmb, are seamlessly integrated into the framework to enhance network-based attack detection in the IoMT). CatEmb is a novel embedding technique that employs DL techniques and recognizes intrusions using the WUSTL-EHMS-2020 real-time dataset. Additionally, the comprehensive evaluation using binary classification methods helps to separate benign network traffic from potential threats such as IoT data injection attacks and spoofing, guaranteeing useful

effectiveness in IoMT networks. Moreover, the memory consumption and inference time are optimized using extensive preprocessing and feature engineering techniques, such as systematic column reduction via covariance matrix analysis. The dataset is balanced through data augmentation methodologies, and feature segregation makes it easier to apply standard approaches such as ordinal encoders for categorical columns and standard scaler and power transformers for continuous columns. Finally, the optimal performance is achieved by seamlessly integrating with other components. This is confirmed by comprehensive evaluations on real-time benchmark dataset, which provide improved accuracy, precision, recall, and F1-score for attack detection. These results are achieved within a minimal inference time. The integration of DL models in IoMT environments highlights the effectiveness of these models in enhancing network security.

4.1 Hardware and software requirements

The experiment work has been implemented on Windows 10 (64-bit Operating System) with the configuration of 16 GB RAM, Intel(R) Core (TM) i5-7200U CPU @ 2.50 GHz. For training and testing the ML and DL models, python libraries like PyTorch (commonly utilized for developing deep neural networks) [56] and Scikit-learn [57] were used.

4.2 Healthcare testbed and dataset description

In [11], the author developed a testbed using a health monitoring sensor board. It gathered the information using various healthcare sensor devices affixed to the patient body. With a USB port's help, the panels connect to the window-based system, which uses C++ -based software for collecting the sensed data. The testbed combines components such as a sensor device that helps gather information related to patient health, an SDN controller, and the network gateway for envisaging the network flow traffic. The information generated using sensor and network traffic in the testbed gets utilized to identify the attacks and anomalies in the data. While developing the dataset, three attacks were considered, i.e., spoofing attacks, MITM attacks, and data injection. In the MITM attack, the intruder positioned himself as a router and received the message first. After altering or spoofing the message, reroute that file to the server. This results in an infringement of data integrity and confidentiality of the personal information in the network. In a spoofing attack, a program or a person pretends to be someone else to gain the victim's confidence so that the intruder can successfully enter the system, obtain information or money, and spread the virus. It results in an infringement of patient data protection and confidentiality. In a data alteration attack, the intruder manipulates or alters the information received at the intruder system from the gateway. The alteration could be made at random or following a rule. Then, the data is forwarded to the server. The modification by the intruder in the data causes a severe problem for the patient's health, as false diagnostics will be given to the individual depending on the alteration message.

The ARGUS Tool [58] creates this combined dataset of network traffic flow and biometric data features of patients. To attain the network traffic flow data, their traffic flow metrics and associated records were collected, along with the biometrics features containing diastolic blood pressure, temperature, respiration rate, systolic blood pressure, pulse rate, ECG ST segment information, heart rate, and peripheral oxygen saturation data. Table 6 shows different features of the dataset. All-inclusive, the dataset includes 44 features, out of which 35 features belong to the network traffic flow category. The dataset output is categorized as

Table 6 Description of ML features in the dataset

Metric	Type	Features description	Metric datatypes
Flgs	Flow Metric	Flags in the network	Int
SIntPkt	Flow Metric	Source inter-packet count	Float
DIntPkt	Flow Metric	Destination inter-packet count	Float
SrcBytes	Flow Metric	Source bytes	Float
DstBytes	Flow Metric	Destination bytes	Float
SrcLoad	Flow Metric	Source load	Float

regular traffic or attack traffic data. "0" represents the normal traffic, while "1" illustrates attack traffic data.

4.3 Performance evaluation metrics

The statistical parameters are applied to determine the working performance of the proposed models. To assess the performance of IoMT attack classification, we used four well-known metrics, which are explained as follows:

Using the above metrics shown in Table 7, the working performance of the ML and DL models gets assessed in terms of different standard metrics as discussed below:

Accuracy is elucidated as the ratio of the correct traffic categorization to the overall prediction of the test data for network traffic and is measured using Eq. (12). Precision is elucidated as the ratio of the correct categorization of attack traffic to the total of the correct and incorrect categorization of attack traffic samples in the dataset. The model functions well if the accuracy is high and is measured using Eq. (13). The recall/sensitivity is elucidated as the ratio of the correctly classified attack network traffic to the total of precisely classified attack network traffic and incorrectly classified attack network traffic in the dataset and is measured using Eq. (14). F1-score amalgamates the precision and recall of a classifier into a single statistic by calculating their harmonic mean as expressed in Eq. (15). Specificity is a performance evaluation standard that assesses a model's accuracy in detecting adverse events. It is especially crucial when accurately recognizing true negatives is essential, like in fraud detection or medical tests. It is measured using Eq. (16). MCC (Matthews correlation

Table 7 Components of confusion matrix

Components of confusion matrix	Description
True positive (TP)	In this case, both the forecasted and actual outcomes of the data point are valid. It is appropriately categorized as an attack sample
True negative (TN)	In this case, the data point's forecasted and actual outcomes are false. Therefore, it is appropriately categorized as a standard sample
False positive (FP)	In this case, the forecasted outcome of the data point is precise, and the actual result of the data point is false. It designated a standard data set as an attack sample
False negative (FN)	In this case, the forecasted outcome of the data point is false, whereas the actual result is valid. Therefore, it was restricted as a standard sample despite being an attack sample

coefficient) is a statistical tool is used to evaluate the model to measure the diversion of the actual values from the predicted values, similar to the chi-square measure in reference to a 2×2 contingency table. It is measured using Eq. (17). NVP (negative predictive value) is a statistical index used to analyze diagnostic accuracy evaluations and medical tests. It shows the likelihood that a person who tests negative on a diagnostic or screening test does not have the disorder or disease the examination intends to diagnose. The accuracy and significance of a negative test result are more likely to be determined by NPV. It is measured using Eq. (18). FPR (false positive rate) measure shows the module's outcomes that incorrectly predict the positive class as expressed in Eq. (19). FNR (false negative rate) measure shows those outcomes of the model which incorrectly predict the negative class as described in Eq. (20). FDR (false discovery rate) calculates the rate at which one mistakenly believes a null hypothesis is untrue. It is expressed using Eq. (21). FOR (false omission rate) is a statistical indicator called false omission rate (FOR), which is used in binary classification to evaluate the percentage of actual positive events that a model incorrectly predicts as negative. It is expressed using Eq. (22). ROC AUC (receiver operating characteristic area under the curve): The capacity of a model to discern between positive and negative classes across various classification thresholds is assessed using the ROC_AUC performance metric for binary classification models.

$$\text{Accuracy} = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{TN} + \text{FP} + \text{FN}} \tag{12}$$

$$\text{Precision} = \frac{\text{TP}}{\text{TP} + \text{FP}} \tag{13}$$

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}} \tag{14}$$

$$F1 - \text{Score} = \frac{2 \times \text{Recall} \times \text{Precision}}{\text{Recall} + \text{Precision}} \tag{15}$$

$$\text{Specificity} = \frac{\text{TN}}{\text{TN} + \text{FP}} \tag{16}$$

$$\text{MCC} = \frac{\text{TP} \times \text{TN} - \text{FP} \times \text{FN}}{\sqrt{(\text{TP} + \text{FP})(\text{TP} + \text{FN})(\text{TN} + \text{FP})(\text{TN} + \text{FN})}} \tag{17}$$

$$\text{NPV} = \frac{\text{TN}}{\text{TN} + \text{FN}} \tag{18}$$

$$\text{FPR} = \frac{\text{FP}}{\text{FP} + \text{TN}} \tag{19}$$

$$\text{FNR} = \frac{\text{FN}}{\text{FN} + \text{TP}} \tag{20}$$

$$\text{FDR} = \frac{\text{FP}}{\text{FP} + \text{TP}} \tag{21}$$

$$\text{FOR} = \frac{\text{FN}}{\text{FN} + \text{TN}} \tag{22}$$

4.4 Result analysis of ML models

This section highlights the evaluation performance of ML models like SVM, DT, LR, KNN, GradBoost, RF, and XGB using tenfold cross-validation on the WUSTL-EHMS-2020 dataset.

Table 8 Performance of ML models using tenfold cross-validation on the WUSTL-EHMS-2020 dataset

Average Score	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0	1.0

SVM and KNN achieved an average accuracy of 0.9998 and 0.9985, respectively, whereas other models attained 100% accuracy, as depicted in Table 8.

This section evaluates ML models by considering different performance metrics parameters like accuracy, precision, recall, F1-score, specificity, MCC, NPV, FPR, FNR, FDR, FOR, and ROC_AUC, as shown in Table 9. The inference time has also been considered here to check which model quickly recognizes attacks in the IoMT network with better accuracy. The performance has been evaluated for 70–30% and 80–20% dataset distribution. Here, SVM and KNN achieved 99.97% and 99.99% accuracy, respectively, whereas other trained models attained 100% accuracy. LR model takes less inference time, whereas RF takes the highest time among different models to identify an attack in the IoMT environment.

4.5 Result analysis of proposed DL models

This section evaluates DL models by considering different performance metrics parameters like accuracy, precision, recall, F1-score, specificity, MCC, NPV, FPR, FNR, and ROC_AUC, as shown in Table 10. The inference time has also been considered here to check which model quickly recognizes attacks in the IoMT network with better accuracy. The performance has been evaluated for 70–30% and 80–20% dataset distribution, as demonstrated in Fig. 7. Here, LinSVM achieved 99.96% accuracy, whereas other trained models like ConvSVM and CatEmb attained 100% accuracy. Among two models, i.e., LinSVM and ConvSVM, LinSVM model takes less Inference time, whereas ConvSVM takes the highest time to identify attacks in the IoMT environment, as depicted in Fig. 7 (i).

Based on the performance analysis, both LinSVM and ConvSVM models demonstrate optimal results on each metrics as depicted in Table 10. However, LinSVM model takes less time (0.1629 s) as compared to ConvSVM model (0.3116 s) for detecting intrusion in the network. In IoMT environment, timely detection of network intrusion is critical for ensuring safety and data security of patients. Therefore, based on the above-achieved results, LinSVM model appears to be the more suitable choice for deployment in resource-constrained IoMT environment.

4.6 Performance comparison of proposed models with existing ML and DL approaches

This section compares proposed ML and DL models with the existing methods, as shown in Table 11. Here, different existing methods have been proposed by the experts to identify attacks in the IoMT environment using IDS frameworks, which are discussed as follows: In [59], Dina et al. proposed feed-forward neural network model (FFNN) with the focal loss method to detect intrusion in the network and achieved 93.26% of accuracy. The author applied the focal loss function to remove the data imbalance challenge. In [60], Chaganti et al. developed a PSO-DNN (particle swarm optimization deep neural network) model to recognize intrusion in the network and achieved 96% accuracy. Furthermore, Wagan et al. [61] proposed a model combination of Bi-LSTM and fuzzy mean clustering to collect sensory medical data safely and recognize attack patterns in the IoMT environment. The proposed model attained an accuracy of 92.63%. In this work, the author mainly focuses on enhancing the performance of the IDs and improving the detection rate (DR), which is underutilized as the author hasn't analyzed both delay and DR simultaneously. The results achieved by the proposed models show that our models are superior to the existing approaches in terms of performance metrics like accuracy, precision, recall, F1-score, and MCC, as shown in Fig. 8.

Table 9 The working performance analysis of ML models

Metrics	ML Techniques

The proposed models took minimum intrusion detection time as compared to other ML and DL approaches.

4.7 Training and validation loss for DL models: *an ablation study*

The continuous monitoring of training and validation losses guarantees that the model is learning efficiently without overfitting and aids in the training process. Therefore, this section highlights these losses for different numbers of epochs that have been calculated along with training and testing accuracy and Inference time taken by the models to identify the attack in the network.

4.7.1 Training and validation loss for dl models after ($n \times 50$) Epochs

In this section, training and validation loss has been evaluated for LinSVM, ConvSVM, and CatEmb models after every ($n \times 50$) Epochs, where $n = 1,2 \ldots .., 4$ as shown in Table 12. To begin with model performance for 50 epochs, the CatEmb model performed better by attaining the highest accuracy among the other two models with 0.0285 training loss and 0.1562 validation loss. In addition to performance for 100 epochs, LinSVM has the lowest training and validation loss compared to the other models, with an accuracy of 99.98%. Furthermore, for 150 epochs, the ConvSVM model performed better by achieving the highest accuracy rate along with 0.0030 training loss and 0.0002 validation loss. In contrast, LinSVM models

Wagan et al. [58]	Fuzzy C-Means	92.63	92.05	96.14	96.9	–	–
Proposed methods	LinSVM	99.96	100	99.92	99.96	99.92	0.16297
	ConvSVM	100	100	100	100	100	0.31163
	CatEmb	100	100	100	100	100	0.0396

attained a training loss of 0.0001 and a validation loss of 0.0062, and CatEMB achieved the highest training and validation loss compared to other models. Finally, for 200 epochs, the ConvSVM model performed better by attaining a minimum training loss of 0.0013 and validation loss of 0.0004 with the highest training and testing accuracy compared to the other models.

In our research, we have noted improved scalability features within our proposed models by incorporating diverse and dependable data sources from various IoT devices into the training dataset. This integration ensures a high level of coherence and a wider range of data. Significantly, when the epoch count was increased from 50 to 200 ($(n \times 50)$ epochs, where $n = 1,2\ldots..,4$), the accuracy of our suggested model demonstrated minor fluctuations, highlighting its capacity to scale well. We used real-time dataset for conducting the training and testing of proposed model. Figure 9 shows the scalability analysis of our proposed models.

4.7.2 Training and validation plots for different batch sizes

This section demonstrates the training and validation loss plots on different batch sizes, including 64, 128, and 256. In Fig. 10a, c, and e, the training loss is measured on the vertical axis (Y), while the number of epochs is displayed on the horizontal axis (X). It is calculated for the number of epoch counts ranging from 1 to 200 for different batch sizes like 64, 128, and 256 using proposed DL models, namely LinSVM, ConvSVM, and CatEmb. It is observed from Fig. 10a, c, and e that LinSVM and ConvSVM converge to 0 after 50 epochs in all the batch sizes. Figure 10b, d, and f depicts the validation loss that is measured on the vertical axis (Y), while the number of epochs is displayed on the horizontal axis (X). The validation loss is calculated for the number of epoch counts ranging from 1 to 200 for different batch sizes using proposed DL models. It is observed from Fig. 10b, d, and f that after 50 epochs,

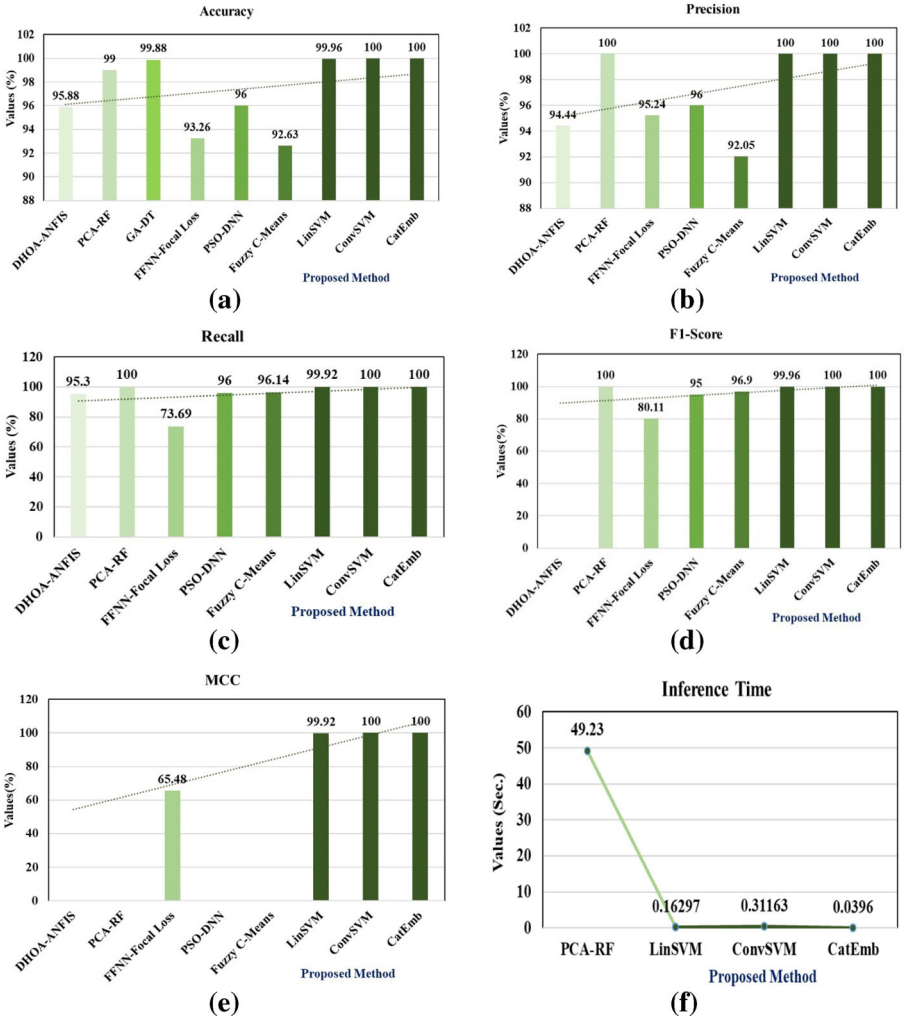

Fig. 8 Performance comparison of proposed models with DL-based existing methods **a** accuracy, **b** precision, **c** recall, **d** F1-score, **e** MCC, **f** inference time

ConvSVM converges to 0 rapidly as compared to the other two models for batch size 64. For 128 and 256 batch sizes, LinSVM and ConvSVM converge to 0 after 50 epochs.

In Table 13, the proposed DL models have been evaluated for different batch sizes like 64, 128, and 256 with a learning rate of 0.0001. To begin with, 64-batch size, LinSVM, ConvSVM, and CatEmb attained an accuracy of 99.96%, 100%, and 100%, respectively; in addition to performance evaluation for 128 batch size, all the proposed dl models achieved maximum accuracy. Furthermore, for 256-batch size, LinSVM attained an accuracy of 99.94%, whereas ConvSVM and CatEmb achieved 100% accuracy. Figure 11 depicts the performance of the proposed model for batch sizes 64, 128, and 256. For batch size 256, models take less inference time than batch sizes 64 and 128, as shown in Fig. 11d.

4.8 Performance evaluation of proposed approach with state-of-the-art

This section highlights the comparison of the proposed model with the state-of-the-art model. Our models achieved the highest performance compared to the other existing work, as shown in Table 14. Researchers have applied ML and DL approaches for designing an improved IDS, which are discussed and compared with the proposed models in this section. In [11], Hady et al. developed an upgraded healthcare testbed for monitoring the patients and used it to gather biometrics data of the patient along with network flow metrics. In this work, the author built a dataset that combines the feature of both biometric data of the patients and network flow metrics and then applied different ML approaches, including ANN, SVM, RF, and KNN, and attained an accuracy of 88.75%, 92.44%, 92.06%, and 92.27%, respectively. ANN achieved the lowest accuracy as compared to other models. In [62], Salman et al. recommend that any measure used to assess an ML model created for a security application

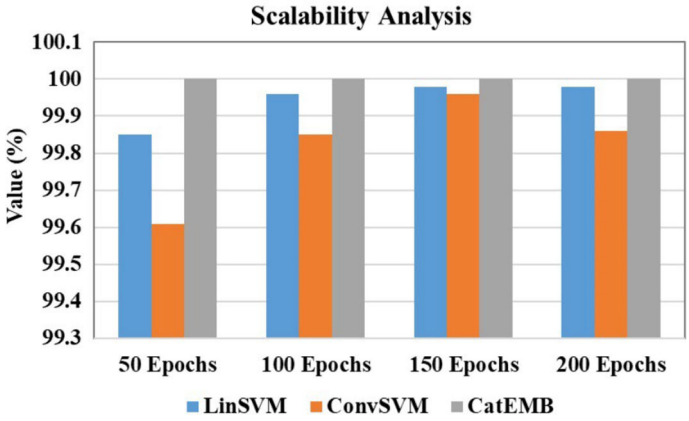

Fig. 9 Scalability analysis of proposed models

meet these two criteria: (1) the errors committed in incorrectly identifying attacks and benign activity shouldn't receive the same treatment, and (2) when a sample is accurately classified in a class, it shouldn't be mistakenly misclassified in the same class. Therefore, the authors suggested a safety score metric based on the cost related to the model results and fulfilling both criteria. Here, the author used three ml models, including LR, KNN, and RF, which achieved an accuracy of 87.3%, 88.5%, and 93%, respectively. In [63], Gupta et al. proposed a tree classifier to recognize intrusion in the network and attained an accuracy of 94.23%. In [64], Kilincer et al. proposed the XGB and LR model with tenfold cross-validation on four different datasets: the ICU dataset, ECU-IoHT, WUSTL-EHMS, and TON-IoT. For the WUSTL-EHMS dataset, the proposed model attained 96.2% of accuracy. For encoding IoMT data, Dhanya and Chitra et al. [65] proposed an autoencoder-based DL framework that fed the encoded features to the optimized XGB classifier to detect the malware in the network and achieved an accuracy of 98.98%. The XGB classifier was optimized using a genetic algorithm. In [66], Dhanya and Chitra proposed an optimized XGB to detect malware in the IoMT network. For XGB hyperparameter optimization, the differential evolution (DE) method was used by the author, who achieved an accuracy of 97.39%. Compared to the state of the art, our proposed models achieved 100% accuracy, which is superior to the existing work performance, as depicted in Fig. 12.

5 Conclusion and future scope

IoMT services are in more demand than ever before as the number of users has been increasing rapidly. This calls for a robust security model to thwart any unwanted activities. An attack detection method is also required in the security architecture for distributive networks to determine whether an intrusion has affected the network's data. The goal of this research is threefold: firstly, we suggest the linear support vector machine (LinSVM) model; secondly, the convolutional support vector machine (ConvSVM) model; and finally, the categorical embedding (CatEmb) model which have been proposed to overcome the issue of security in a network. This article offers the CatEmb model as the first effort to use a DL-based embedding approach to recognize intrusion in the IoMT environment. Compared to the other models,

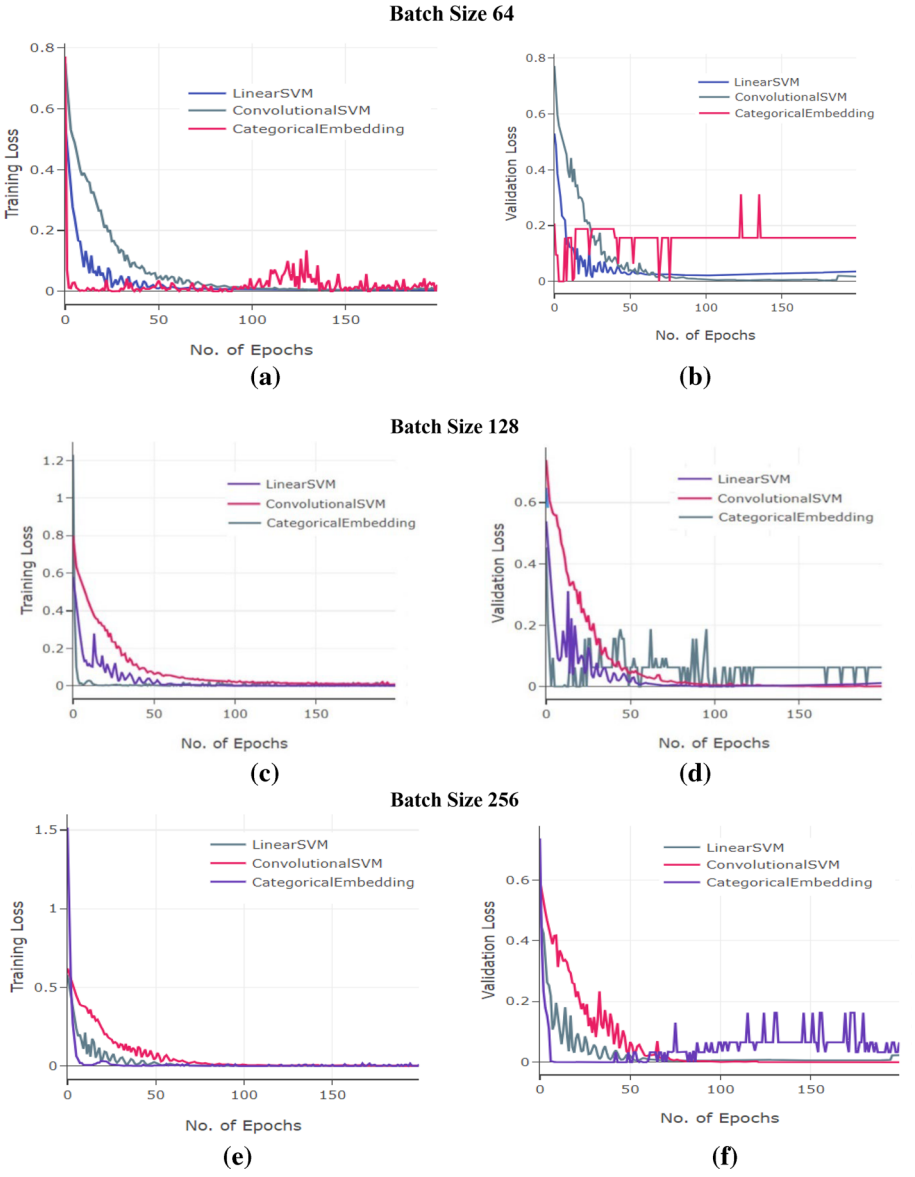

Fig. 10 Training and validation loss for DL models for batch sizes 64, 128, and 256. Batch size 64 **a** training loss for DL models, **b** validation loss for DL models, batch size 128 **c** Training Loss for DL models, **d** validation loss for DL models. Batch size 256 **e** training loss for DL models. **f** Validation loss for DL models

CatEmb takes less inference time in detecting attacks in the network. With a 100% accuracy, detection rate, and F1-score, our developed models exceed the state of the art in detecting network intrusions by utilizing the combined features of the network traffic flow metric and the patient's recent biometric dataset. In addition, an in-depth evaluation of different ML models, including SVM, LR, DT, KNN, GradBoost, RF, and XGBoost, has been explored

Table 13 Performance analysis of DL models for different batch sizes

Batch size	Model	TL	VL	TA	TA*	*P*	*R*	F1	IT (Sec.)

for intrusion detection in the IoMT ecosystem. Data preprocessing and feature engineering techniques play a vital role in achieving such an outstanding result by handling categorical data, imbalanced, noisy data, and dropping irrelevant columns, which may not significantly affect the detecting process. This helps build an effective model that takes less memory utilization and inference time to detect attacks in the network. Furthermore, the performance of DL models has been evaluated for the batch sizes 64, 128, and 256 to calculate the training

Table 14 Performance evaluation of proposed models with state of the art

Dataset	Year	Authors	Methodology	*A* (%)	*P* (%)	*R* (%)	F1 (%)	ROC_AUC (%)	Description	Observations
WUSTL-EHMS-2020	2020	Hady et al. [11]	SVM	92.4	–	–	–	82.37	The author merged the features of network flow traffic and patients' biometric features data	Needing to enhance the system's performance, and in experimental work, the author only considered accuracy and ROU_AUC metric in the position, which might not deliver a comprehensive grasp of the model's capabilities
			RF	92.13	–	–	–	91.45		
			ANN	90.04	–	–	–	93.42		
			KNN	92	–	–	–	87.48		
	2020	Salman et al. [62]	LR	87.3	–	–	50.9	–	The authors suggested a Safety score metric based on the cost related to the model results	Only certain dataset features were considered by the author in this work, and accuracy and F1-score were calculated, which may not have given readers a complete understanding of the model's potential
			KNN	88.5	–	–	65.5	–		
			RF	93	–	–	71.7	–		

Table 14 (continued)

Dataset	Year	Authors	Methodology	*A* (%)	*P* (%)	*R* (%)	F1 (%)	ROC_AUC (%)	Description	Observations
			CNN-Focal	93.08	94.23	73.38	79.63	–		
	2022	Gupta et al. [63]	Tree Classifier	94.23	93.8	93.72	93.8	90.68	The author proposed a tree classifier to recognize intrusion in the IoMT network and enhance the performance compared to [8, 50]	Unrealistic datasets were produced via data augmentation. The percentage of attack traffic in the network is relatively low
	2022	Chaganti et al. [60]	PSO-DNN	96	96	96	95	–	The author proposed a PSO-DNN-based framework for detecting intrusion in the network and enhanced the working performance of the models compared to [11, 56, 59, and 60]. For data preprocessing, standard scalers and simple imputers were used	Performance can be further enhanced using feature engineering techniques

Abstract
A hollow-core photonic crystal fiber based Refractive Index sensor in the terahertz frequency regime for bio-sensing application is proposed in this paper. Refractive index variation is used for the identification of different analytes with refractive indices ranging from n = 1.35 to 1.39. Zeonex is chosen as the fiber material. The proposed photonic crystal fiber (PCF) sensor features a solitary rectangular core enclosed by an arrangement of 16 rectangular air holes within the cladding area with different heights and widths. Simulation and numerical analysis are conducted using Finite Element Method-based based Comsol Multiphysics Software. The proposed PCF sensor exhibits relative sensitivity of 98.8%, an Effective Mode Area of 1.06×10^{-7} m^2 with a very low confinement loss of 7.751×10^{-14} dB/cm are achieved at a frequency of 1.4 THz for an analyte of refractive index 1.39 in X Polarization direction of electric field. Moreover, birefringence, non-linearity, effective refractive index and power fraction are also analyzed. Further simple PCF structure based on rectangle ensures that fabrication is feasible with current fabrication techniques.

Keywords Terahertz frequency regime · Rectangular core · Relative sensitivity · Biosensor

1 Introduction

Photonic crystal fibers are attracting attention in the terahertz (THz) range for their unique capabilities in guiding and manipulating electromagnetic waves. Moreover, high sensitivity, compact size, low cost, flexibility, and fast response make them ideal for a variety of sensing applications (Sultana et al. 2018). Particularly, bio-chemical sensing which includes detecting or sensing of various biological components such as different types of cancer cells, blood components, analysis of RNA, DNA, and proteins and malaria cells. Utilizing the low photon energy within the THz range, THz sensors offer exceptional penetration capability through porous samples while maintaining test layer integrity (Haddad et al. 2013). Furthermore, PCFs operating in the THz range offer

Published online: 02 June 2024

significant advantages in terms of sensing analyte due to their large filling area, as the diameter of air holes and fiber diameter is larger than PCFs that are being operated in the mid-infrared range (Ekhlasur Rahaman et al. 2020). Due to these properties, various THz sensors and detectors have been developed using PCF. The hexagonal, octagonal, elliptical, rectangular structure of photonic crystal fiber has already been introduced, with a hollow core or solid core. Hollow core fibers offer higher sensitivity than solid core fibers. Hollow-core fibers (HCFs) exhibit superior suitability for detecting distinct analytes having lower RI and also offer strong light-analyte interaction within the core (Hossain and Podder 2019). Compared to solid core or porous core PCF, HC-PCF has a larger core power fraction and a lower effective material loss since the core is only filled with the target analyte.

PCF is becoming an increasingly important component of contemporary biological and biomedical technology since it may be used to detect blood components and cancer cells in both invasive and non-invasive ways among other things. The traditional techniques, which are employed for various pathological examinations and imaging, take a very long time to perform and obtain findings. The terahertz radiation band has garnered significant attention from the scientific community in recent times as it is possible to transmit terahertz radiation using PCFs without any risk to human health (Ferdous et al. 2022). Numerous THz optical sensors have been documented for use in biological applications. The advantages of PCF enable researchers to test different models for the detection of different analytes. Arif et el. proposed a chemical sensor, having a hexagonal cladding with circular air holes for liquid sensing and attained a relative sensitivity value of 50%, 55.83%, and 59.07% for water, ethanol, and benzene, respectively (Arif et al. 2016). A PCF sensor based on terahertz regime suggested by Islam et al. achieved a relative sensitivity of 68.87% for Ethanol (Islam et al. 2018). A chemical sensor with rotated hexacore and heptagonal cladding design with circular holes proposed by Selim Hossain et al. exhibit a relative sensitivity of 68.48%, 69.20%, 66.78% for ethanol, benzene, and water analyte at 1 THz (Selim Hossain and Sen 2021). Rahaman et al. suggested a dumbbell shaped HC-PCF with rectangular air holes for chemical sensing using TOPAS as the fiber material and achieved a relative sensitivity of 96.25% for Ethanol (Rahaman et al. 2021). Hossain et al. investigated a rectangular core sensor for Bane chemical detection and achieved a relative sensitivity of 94.4% and a confinement loss of 1.71×10^{-14} cm^{-1} at frequency 1.8 THz (Hossain et al. 2020). Ahmed et al. proposed a blood component sensor for analytes such as RBCs, hemoglobin, WBCs, plasma, and water and achieved a sensitivity response of 80.93%, 80.56%, 80.13%, 79.91% and 79.39% at frequency 1.5 THz (Ahmed et al. 2019). Bulbul et al. investigated a general purpose biochemical sensor with rectangular air holes and obtained a relative sensitivity of 95.82% at 2.5 THz (Bulbul et al. 2021).

The proposed sensor is a refractive index sensor which means the difference in refractive index is used for the identification of different analytes with RI ranging from 1.35 to 1.39. Zeonex is used as the background material. Zeonex is a transparent thermoplastic. It is preferred due to its wide range of optical characteristics, including its consistent refractive index of 1.53 in the THz regime, low absorption loss of 0.2 cm^{-1}, high glass transition temperature, minimal water absorption, high biocompatibility, and exceptional chemical resistance even at high temperatures (Yadav et al. 2023). Rectangular air holes are introduced in the fiber with a rectangular hollow core in which analytes are filled. A full vector FEM is used for numerical analysis and COMSOL multiphysics software is used for simulation.

2 Sensor model design

Figure 1 displays the cross-sectional representation of the proposed PCF sensor. Zeonex is used as background materials with rectangular air holes and a rectangular core. The rectangular air holes of different widths and heights are arranged across PCF. The overall diameter of the proposed diameter is 3.3 mm. The Perfectly matched layer (PML) occupies the cladding area and serves as an artificial absorbing medium to absorb radiation energy at the outer surface in the computational area and the width of the PML is 165 µm. Within the domain, the complete mesh consists of 24,554 elements while along the boundary it comprises 2452 elements. The width W1 and height H1 of the core is 400 µm and 500 µm respectively. Width W2 is 200 µm and H2 is 1540 µm respectively. Parameters W3 and W4 are 1720 µm and 1520 µm respectively. Parameters H2, H3, H4 are 1540 µm, 1340 µm, 1240 µm respectively. The pitch (separation between two adjacent rectangles) is 20 µm. The core is infiltrated with analyte samples with refractive index ranges from 1.35 to 1.39 serving as a region where light analyte interaction takes place. To begin the study, firstly the core of the PCF sensor is injected with the liquid analyte. Figure 2 shows the light propagation through the core filled with analyte**.** Since very little light leaves the core region, there is very little loss. The red region exhibits the highest degree of light confinement, and as it approaches the core boundary, the light's intensity progressively drops which shows light well confined in core region. Furthermore, the direction of electric and magnetic field is shown by arrow. To measure the efficacy of the proposed sensor, vivid sensing properties such as relative senitivity, birefringence, effective mode area, and confinement loss are used as measures.

3 Fabrication feasibility

Various techniques like stack and draw (Bao et al. 2010), drilling, extrusion (Ghazanfari et al. 2017), sol–gel (Bise and Trevor 2005), capillary stacking, and 3D printing (Ebendorff-Heidepriem et al. 2014) are available for the fabrication of Photonic Crystal Fibers. The capillary stacking, stack and draw, and sol–gel fabrication techniques are ideal for circular-shaped air hole fabrication. Alternatively, asymmetrical PCF designs with

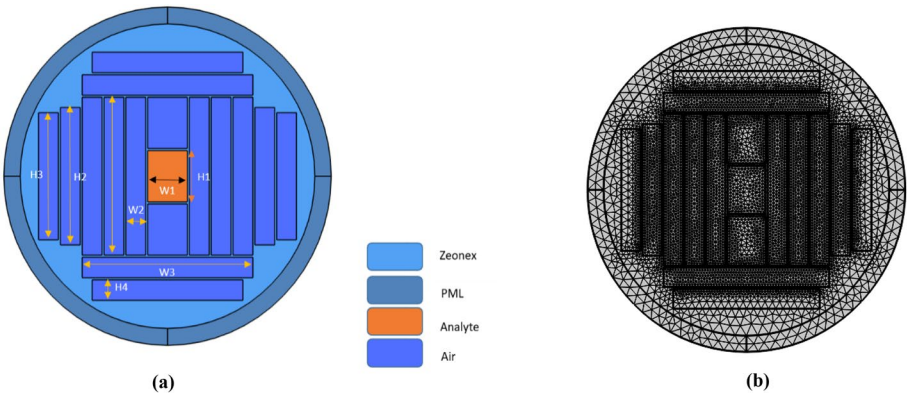

Fig. 1 **a** and **b** Sensor model design and meshing of proposed sensor

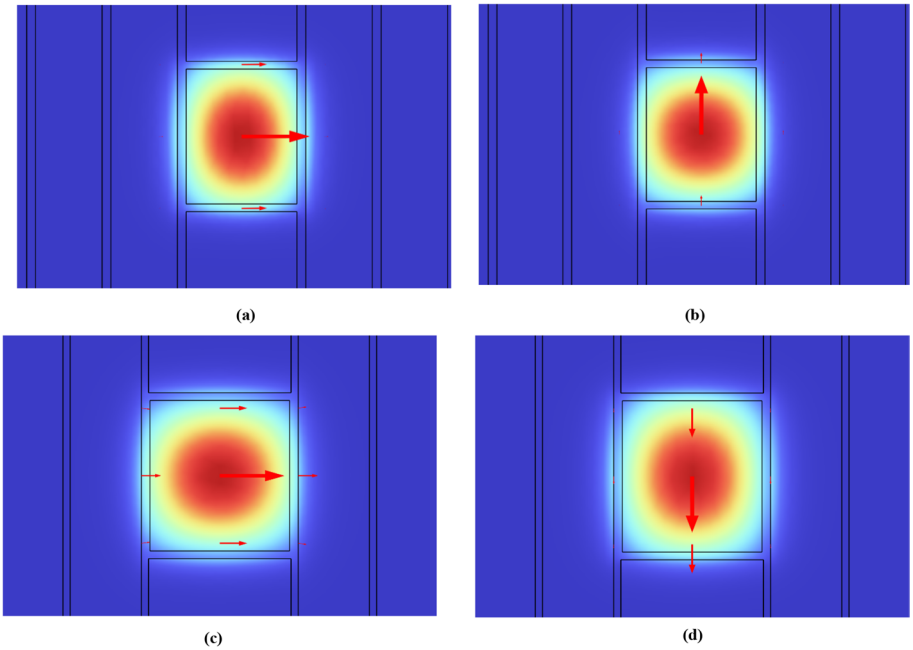

Fig. 2 **a**, **b** Mode electric field distribution and **c**, **d** Mode magnetic field distribution of the proposed fiber for analyte with refractive index 1.39 at 1.4 THz frequency in X and Y polarization direction respectively

rectangular, square, and elliptical air holes can be fabricated using 3D printing and extrusion technologies. Several asymmetrical PCF models have been fabricated by the Max Planck Institute, including elliptical and rectangular designs, demonstrating the successful fabrication of various PCF models (Bulbul et al. 2021). This ensures the feasibility of the fabrication of the suggested PCF fiber.

As the core of the proposed sensor is infiltrated with the analyte. Several infiltration techniques are available for the selective filing of PCF, which include selective filing by collapsing air holes (Xiao et al. 2004), by femtosecond laser micromachining (Wang et al. 2010), by splicing single-mode fiber etc.

4 Numerical analysis

The present study is done on three conditions Optimum (OPT), Optimum +2% (OPT +2%) and Optimum-2% (OPT −2%). To attain these conditions core width and height are altered by 2%. The width and height of the core are 400 µm and 500 µm for OPT condition. For OPT +2% condition the width and height of the core is 408 µm and 510 µm. Similarly, width and height have been set at 392 µm and 490 µm for condition OPT −2%. Different parameters are evaluated to analyze the performance of the proposed sensor for OPT, OPT +2%, OPT −2% conditions. These parameters include Relative sensitivity (RS), confinement loss (*CL*), power fraction (*P*), Non-linearity (γ), Effective mode area (EMA), and Birefringence. These parameters significantly impact the performance of the PCF sensors.

The RS is a crucial property that expresses the change in the optical response of the structure compared to the change in the external parameter. It measures the changes in the RI with the variation in the surroundings. It can be calculated using the following relation (Bulbul et al. 2022):

$$RS = \frac{n}{n_{eff}} \times P \tag{1}$$

Here, n is the RI of the sensing analyte and n_{eff} is the effective mode index (EMI). Here P represents the power fraction.

Power fraction (P) is the fraction of power located in the core of the fiber. It can be using the following equation (Habib et al. 2019),

$$P = \frac{sample \int R(E_x H_{y-} E_y H_x) dxdy}{whole \int R(E_x H_y - E_y H_x) dxdy} \times 100\% \tag{2}$$

Light traveling through the fiber experiences an average refractive index depending upon the design of the PCF. This average RI is called the effective mode index. EMI can be evaluated by Panda and Pukhrambam (2021):

$$n_{eff} = \frac{\beta}{k_o} \tag{3}$$

ere, β is the normalised propagation constant, k_o represents wave number in vacuum.

Birefringence is also one of the important parameter for designing the PCF sensor as high birefringence in PCF can be used to design sensors that are sensitive to the variation in RI. It describes the difference in refractive index between two perpendicular polarization directions (Yadav et al. 2023). It can be calculated to using,

$$B = |n_{eff}^x - n_{eff}^y| \tag{4}$$

The optimal region for analyte sensing and the cross-sectional area that interacts with the light is the effective mode area. We can evaluate the effective mode area by the relation:

$$EMA = \frac{\left(\iint |E|^2 dxdy \right)^2}{\iint |E|^4 dxdy} \tag{5}$$

Here, |E| denotes the electric field distribution of the proposed fiber sensor.

Confinement loss is an important factor in analyzing the efficiency of an optical device, particularly in photonic crystal fibers. It shows the amount of light leaked within an optical fiber or a waveguide due to inadequate light confinement within the core. Minimum the value of CL better would be the transmission of light within the waveguide.

$$CL\left(\frac{dB}{cm}\right) = 8.868 \times k_o \times l_m\left(n_{eff}\right) \times 10^{-2} \tag{6}$$

Here, k_o is the propagation constant, and $l_m(n_{eff})$ is the imaginary part of the effective refractive index of the propagating fundamental mode.

Non-linearity refers to the modifications in refractive index due to change in light intensity. By altering the parameters, a highly sensitive sensor can be designed to detect even subtle variations in the surrounding medium.

$$\Upsilon = \frac{2\pi}{\lambda}\left(\frac{n_2}{EMA}\right) \tag{7}$$

where n_2 is non-linear refractive index and EMA is effective mode area.

5 Result and discussion

To assess the guiding characteristics of the suggested rectangular core PCF, simulation and analysis are conducted using the FEM based COMSOL Multiphysics Software. Results for OPT, OPT − 2%, and OPT + 2% are evaluated and compared.

Figure 3 a, b shows OPT condition relative sensitivity variation with frequency for different analytes with RI ranging from n = 1.35 to 1.39. Relative sensitivity for analytes with higher refractive index is greater than for analytes with lower refractive index. We obtained relative sensitivity values 96.889%, 97.217%, 97.515%, 97.787%, 98.035% for RI of the analyte n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively in Y polarized direction at an operating frequency of 1.4 THz. Relative sensitivity values of 97.868%, 98.135%, 98.378%, 98.599%, 98.800% are achieved for analyte with RI n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively in X polarized direction at an operating frequency of 1.4 THz. These values indicate that there is an exceptionally high relative sensitivity obtained to all analyte samples.

Figure 4a, b shows relative sensitivity variation for OPT − 2% for different analytes. We obtained relative sensitivity values 94.997%, 95.481%, 95.921%, 96.321%, and 96.686% for RI of the analyte n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively in Y polarized direction at an operating frequency of 1.4 THz. Relative sensitivity values of 96.05%, 96.478%, 96.864%, 97.213%, 97.529% are achieved for analyte with RI, n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively in X polarized direction at an operating frequency of 1.4 THz. These values indicate that there is an exceptionally high relative sensitivity obtained to all analyte samples.

Figure 5a, b shows relative sensitivity variation for OPT + 2%. We obtained relative sensitivity values 98.312%, 98.528%, 98.726%, 98.906%, 99.07% for RI of the analyte n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively in Y polarized direction at an operating

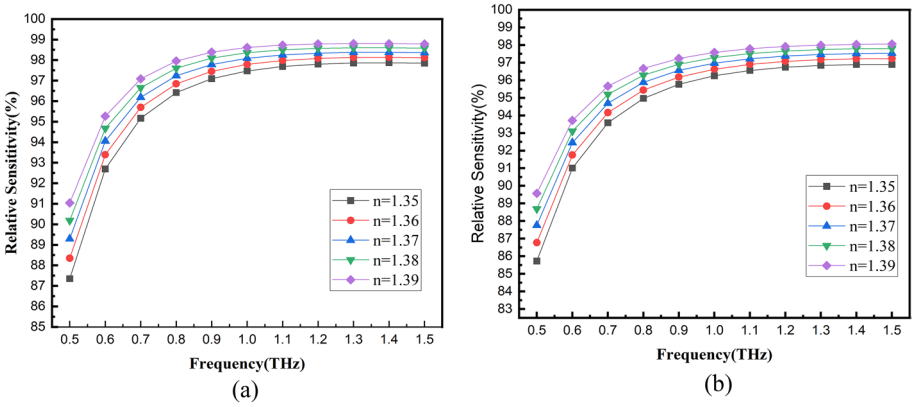

Fig. 3 **a** and **b** Relative sensitivity variation with frequency for OPT case in X and Y polarization directions respectively

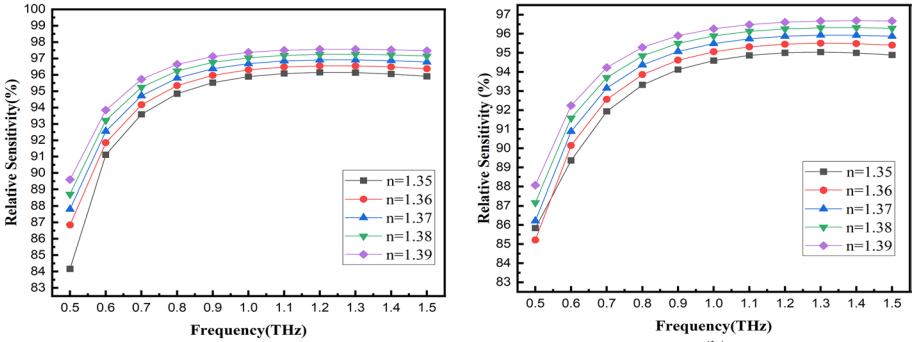

Fig. 4 **a** and **b** Relative sensitivity variation with frequency for OPT−2% case in X and Y polarization directions respectively

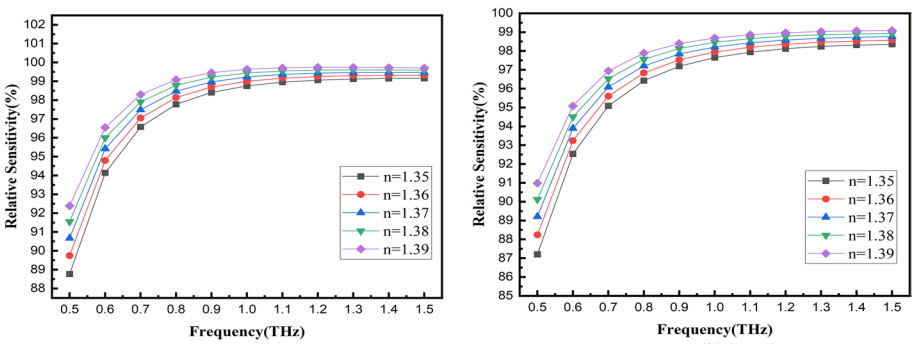

Fig. 5 **a** and **b** Relative sensitivity variation with frequency for OPT+2% case in X and Y polarization directions respectively

frequency of 1.4 THz. Relative sensitivity values of 99.149%, 99.315%, 99.466%, 99.604%, 99.730% are achieved for analyte with RI, n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively in X polarized direction at an operating frequency of 1.4 THz. These values indicate that there is an exceptionally high relative sensitivity obtained to all analyte samples.

Figure 6a–c shows birefringence of different analytes with RI, n = 1.35, 1.36, 1.37, 1.38, 1.39 for OPT, OPT +2%, OPT −2% condition. Birefringence decreases with increase in frequency. Birefringence values achieved for analytes with RI, n = 1.35, 1.36, 1.37, 1.38, 1.39 are 0.0015, 0.0015, 0.0014, 0.0014 and 0.0013 for OPT case; 0.0015, 0.0015, 0.0015, 0.0014, and 0.0013 for OPT −2% case; 0.0014, 0.0013, 0.0013, 0.0013, 0.0012 for OPT +2% case respectively at 1.4 THz operating frequency.

Figure 7a, b shows the EMA profile achieved for different analytes within the 1.35–1.39 RI range for X and Y polarization directions. With the increase in the frequency of light, there is a decrease in the EMA of the fiber. Higher frequencies mean shorter wavelengths and shorter wavelengths can be easily confined in the fiber. Furthermore, the fiber's waveguide dispersion becomes more prominent at higher frequencies, which leads to the tight confinement of light inside the fiber's core (Ferdous et al. 2022; Almawgani et al.

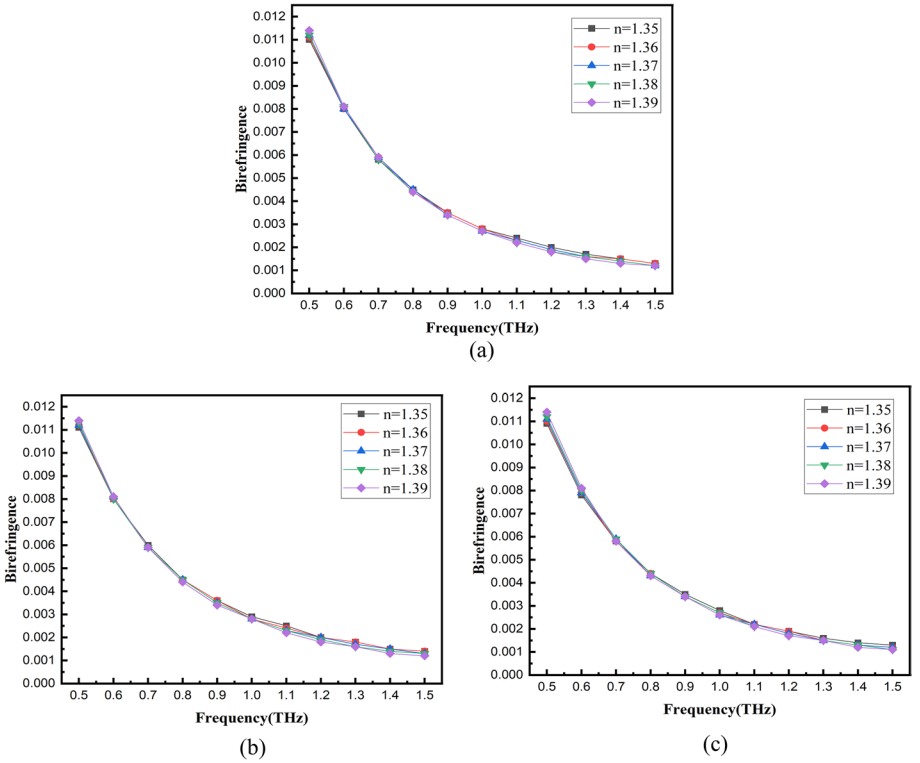

Fig.6 **a, b,** and **c** Birefringence variation with frequency for OPT, OPT−2%, OPT+2% respectively

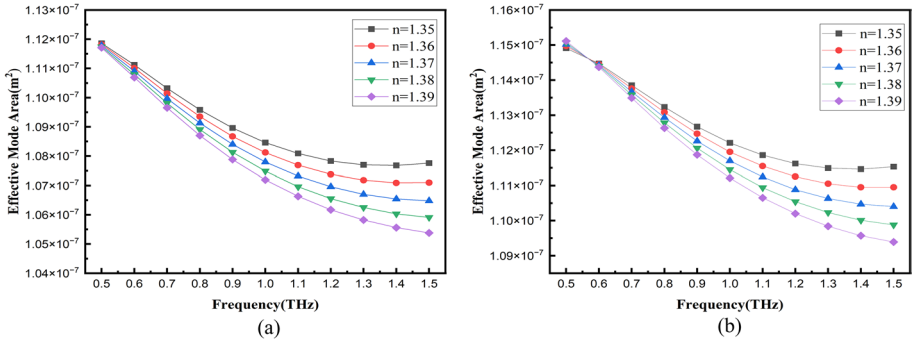

Fig. 7 **a** and **b** Effective mode area variation with frequency for OPT case in X and Y polarization directions respectively

2023). For OPT condition we achieved an average effective mode area of order 10^{-7} m^2. At 1.4 THz frequency effective mode area is 1.1146×10^{-7} m^2, 1.1095×10^{-7} m^2, 1.1047×10^{-7} m^2, 1.1001×10^{-7} m^2, 1.0957×10^{-7} m^2 for an analyte with RI, n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively with Y polarization of electric field. In X polarized direction we observed an effective mode area of 1.0768×10^{-7} m^2, 1.0709×10^{-7} m^2, 1.0654×10^{-7} m^2,

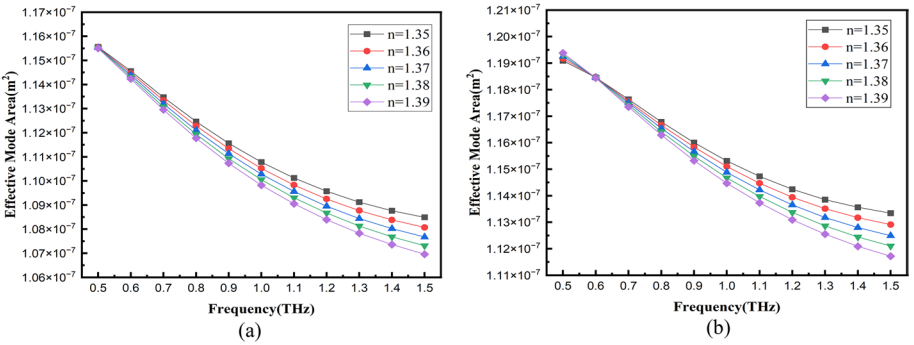

Fig. 8 **a** and **b** Effective mode area variation with frequency for OPT−2% case in X and Y polarization directions respectively

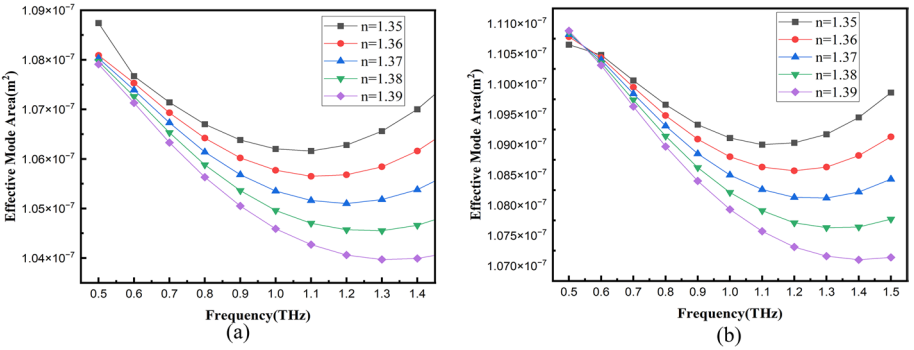

Fig. 9 **a** and **b** Effective mode area variation with frequency for OPT+2% case in X and Y polarization directions respectively

1.0603×10^{-7} m^2, 1.0556×10^{-7} m^2 for an analyte with RI, n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively.

Figure 8a, b represents EMA for OPT −2% condition. For 1.4 THz frequency effective mode area is 1.0945×10^{-7} m^2, 1.0882×10^{-7} m^2, 1.0822×10^{-7} m^2, 1.0764×10^{-7} m^2, 1.0710×10^{-7} m^2 for an analyte with RI, n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively with Y polarization of electric field. In X polarized direction we observed an effective mode area of 1.0700×10^{-7} m^2, 1.0616×10^{-7} m^2, 1.0538×10^{-7} m^2, 1.0466×10^{-7} m^2, 1.0399×10^{-7} m^2 for an analyte with RI, n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively.

Figure 9a, b shows variation of EMAfor OPT +2% condition for different analytes. At 1.4 THz frequency effective mode area is 1.1356×10^{-7} m^2, 1.1317×10^{-7} m^2, 1.1280×10^{-7} m^2, 1.1244×10^{-7} m^2, 1.204×10^{-7} m^2 for an analyte with RI, n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively with Y polarization of electric field. In X polarized direction we observed an effective mode area of 1.0876×10^{-7} m^2, 1.0838×10^{-7} m^2, 1.0802×10^{-7} m^2, 1.0768×10^{-7} m^2, 1.0736×10^{-7} m^2 for an analyte with RI, n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively.

Figure 10a, b shows the non-linearity variation for OPT condition for both X and Y polarization directions in frequency range of 0.5–1.5 THz. Non-linearity increases linearly with frequency. We achieved non-linearity values of 5.528×10^{-9} W^{-1} m^{-1},

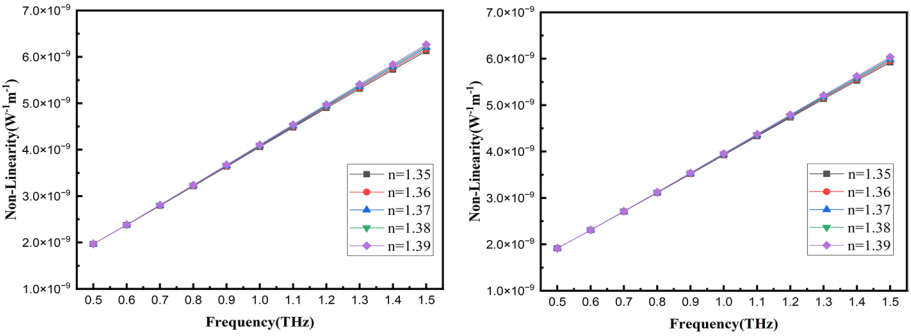

Fig. 10 **a** and **b** Non-Linearity variation with frequency for OPT case in X and Y polarization directions respectively

5.553×10^{-9} W^{-1} m^{-1}, 5.557×10^{-9} W^{-1} m^{-1}, 5.601×10^{-9} W^{-1} m^{-1}, 5.623×10^{-9} W^{-1} m^{-1} for RI of sensing analyte, n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively in Y polarized direction at 1.4 THz frequency. Non-linearity values of 5.72×10^{-9} W^{-1} m^{-1}, 5.753×10^{-9} W^{-1} m^{-1}, 5.783×10^{-9} W^{-1} m^{-1}, 5.811×10^{-9} W^{-1} m^{-1}, 5.837×10^{-9} W^{-1} m^{-1} were achieved for RI of sensing analyte n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively in X polarized direction at 1.4 THz operating frequency.

As shown in Fig. 11a, b which is OPT −2% condition we achieved non-linearity values of 5.6297×10^{-9} W^{-1} m^{-1}, 5.6624×10^{-9} W^{-1} m^{-1}, 5.6939×10^{-9} W^{-1} m^{-1}, 5.67242×10^{-9} W^{-1} m^{-1}, 5.7533×10^{-9} W^{-1} m^{-1} for RI of sensing analyte, n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively in Y polarized direction at 1.4THz frequency. Non-linearity values of 5.7587×10^{-9} W^{-1} m^{-1}, 5.8041×10^{-9} W^{-1} m^{-1}, 5.8470×10^{-9} W^{-1} m^{-1}, 5.8875×10^{-9} W^{-1} m^{-1}, 5.9255×10^{-9} W^{-1} m^{-1} were achieved for RI of sensing analyte n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively in X polarized direction at 1.4 THz operating frequency.

In Fig. 12a, b, for OPT +2% condition non-linear coefficient values of 5.4262×10^{-9} W^{-1} m^{-1}, 5.4448×10^{-9} W^{-1} m^{-1}, 5.4628×10^{-9} W^{-1} m^{-1},

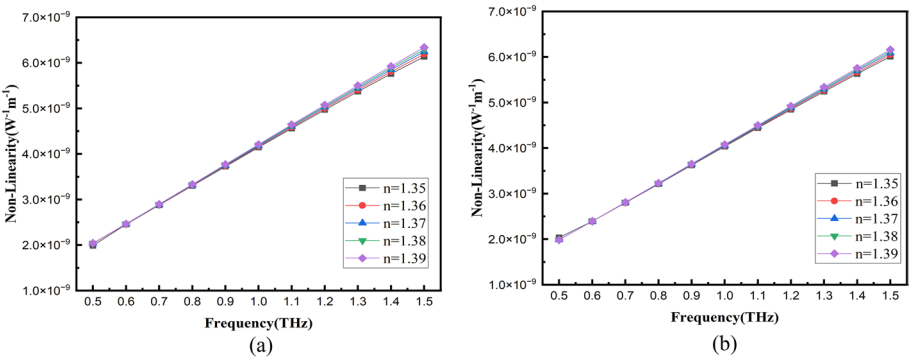

Fig. 11 **a** and **b** Non-Linearity variation with frequency for OPT−2% case in X and Y polarization directions respectively

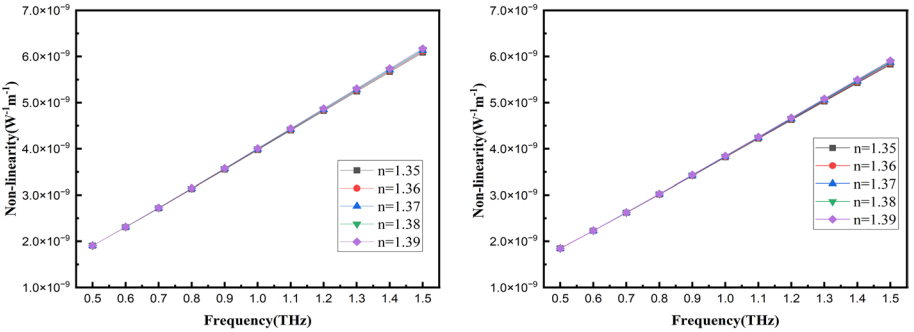

Fig. 12 **a** and **b** Non-Linearity variation with frequency for OPT +2% case in X and Y polarization directions respectively

5.4801×10^{-9} W^{-1} m^{-1}, 5.4970×10^{-9} W^{-1} m^{-1} for RI of sensing analyte, n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively in Y polarized direction at 1.4 THz frequency are achieved. Non-linear coefficient values of 5.6653×10^{-9} W^{-1} m^{-1}, 5.6854×10^{-9} W^{-1} m^{-1}, 5.7043×10^{-9} W^{-1} m^{-1}, 5.7223×10^{-9} W^{-1} m^{-1}, 5.7394×10^{-9} W^{-1} m^{-1} were achieved for RI of sensing analyte n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively in X polarized direction at 1.4 THz operating frequency.

Figure 13a, b shows OPT condition CL variation for both X and Y polarization directions in the 0.5–1.5 THz frequency range. The CL graph depicts that confinement loss decreases as frequency increases. The confinement of lights gets better with larger frequencies as larger frequencies correspond to shorter wavelengths and shorter wavelengths are easier to confine within the fiber's periodic structure, the CL decreases for larger frequencies. Further with increase in frequency, the waveguide dispersion within the fiber becomes increasingly significant, which results in a more pronounced confinement of light within the core (Yadav et al. 2023). We observed the CL of 8.409×10^{-15} dB/cm, 8.659×10^{-15} dB/cm, 3.559×10^{-14} dB/cm, 3.849×10^{-14} dB/cm, 5.639×10^{-14} dB/cm for RI of analyte, n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively in Y polarized direction at 1.4 THz frequency. In X polarized direction we observed CL

of 2.779×10^{-14} dB/cm, 2.489×10^{-16} dB/cm, 1.499×10^{-13} dB/cm, 7.479×10^{-14} dB/cm, 1.759×10^{-14} dB/cm for the RI of analyte, n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively at 1.4 THz frequency.

Figure 14a, b shows variation of CL for OPT −2% condition for which we achieved CL of 7.18×10^{-15} dB/cm, 1.51×10^{-14} dB/cm, 5.51×10^{-14} dB/cm, 9 .00× 10^{-14} dB/cm, 2.54×10^{-14} dB/cm for RI of analyte, n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively in Y polarized direction at 1.4 THz frequency. In X polarized direction we observed CL of 1.49×10^{-14} dB/cm, 9.56×10^{-13} dB/cm, 6.26×10^{-14} dB/cm, 6.55×10^{-14} dB/cm, 3.67×10^{-14} dB/cm for RI of analyte, n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively at 1.4 THz frequency.

Figure 15a, b represents confinement loss profile for OPT +2% condition for which we achieved confinement loss of 6.53×10^{-14} dB/cm, 7.58×10^{-14} dB/cm, 9.62×10^{-14} dB/cm, 9.74×10^{-15} dB/cm, 1.48×10^{-13} dB/cm for refractive index of analyte, n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively in Y polarized direction at 1.4 THz frequency. In X polarized direction we observed confinement loss of 4.71×10^{-14} dB/cm, 1.68×10^{-14} dB/cm, 8.51×10^{-14} dB/cm, 5.05×10^{-14} dB/cm, 2.97×10^{-15} dB/cm for refractive index of analyte, n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively at 1.4 THz frequency.

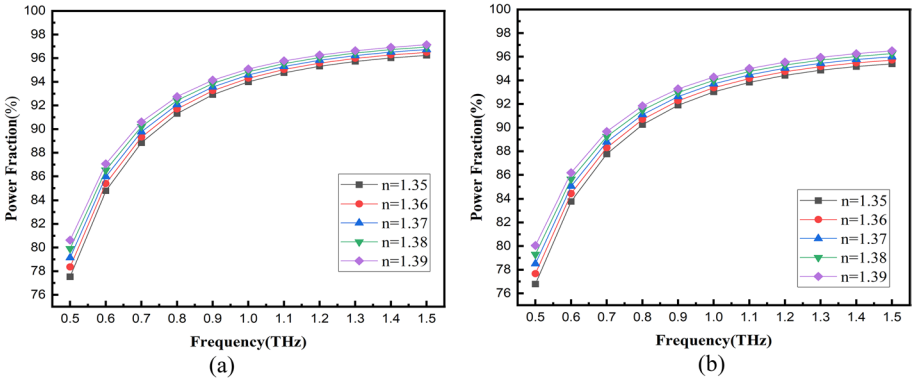

Fig. 16 **a** and **b** Power fraction variation with frequency for OPT case in X and Y polarization directions respectively

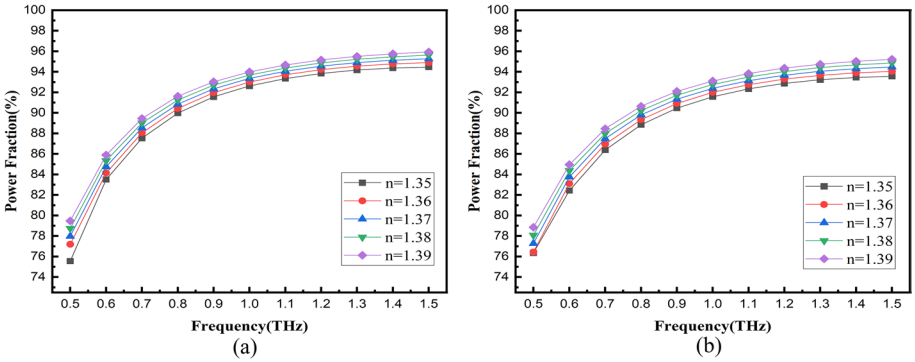

Fig. 17 **a** and **b** Power Fraction variation with frequency for OPT−2% case in X and Y polarization directions respectively

Figure 16a, b shows variation of power fraction of different analytes in X and Y polarized directions for OPT condition. One of the key factors influencing the sensor's performance is its sensitivity which is determined by Power fraction. The graph shows that core power fraction is generally more for analyte with higher refractive index. The values of power fraction have been achieved are 95.169%, 95.479%, 95.762%, 96.021%, 95.259% for RI of analyte n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively in Y polarized direction at 1.4 THz frequency. We also observed power fraction values as 96.023%, 96.277%, 96.509%, 96.722%, 96.917% for RI of analyte n = 1.35, 1.36, 137, 1.38, 1.39 respectively in X polarized direction at operating frequency of 1.4 THz.

Figure 17a, b represents power fraction values for the OPT −2% condition. Power fraction values have been achieved are 93.445%, 93.894%, 94.304%, 94.678%, 95.020% for RI of analyte n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively in Y polarized direction at 1.4THz frequency. We also observed power fraction values as 94.368%, 94.766%, 95.128%, 95.455%, 95.753% for RI of analyte n = 1.35, 1.36, 137, 1.38, 1.39 respectively in X polarized direction at operating frequency of 1.4 THz.

Figure 18a, b shows power fraction values for OPT +2% and we achieved power fraction values of 96.457%, 96.668%, 96.862%, 97.040%, 97.204% for RI of analyte n = 1.35, 1.36, 1.37, 1.38, 1.39 respectively in Y polarized direction at 1.4 THz frequency. We also observed power fraction values as 97.176%, 97.341%, 97.493%, 96.633%, 97.763% for RI of analyte n = 1.35, 1.36, 137, 1.38, 1.39 respectively in X polarized direction at operating frequency of 1.4 THz.

Table 1 shows the comparison between model suggested in this paper with previously suggested models in THz regime. The proposed design is a general-purpose sensor for bio sensing application which is capable of sensing different analytes with refractive index ranging from n = 1.35 to 1.39. Various analytes like Red blood cells, cancer cells have their refractive indices falling in RI range of 1.35–1.39, so the proposed detector is capable of detecting all these analytes. We have achieved better results than previously cited work with a design that is more sensitive to the RI change than many previously proposed designs.

6 Conclusion

In this paper, a rectangular core PCF sensor has been proposed for sensing different analyte with refractive index ranging from 1.35–1.39. The cladding is composed of rectangular shaped air holes. Zeonex is used as fiber material. The proposed refractive index fiber sensor can be utilized for detection of many biological components such as blood components (RBC, WBC, Plasma etc.), various cancer cells etc. The proposed sensor shows a very high relative sensitivity of 98.8% and 98.035% for an analyte of refractive index 1.39 at 1.4 THz operating frequency in X and Y polarized direction respectively. Besides CL is noticed only 7.75×10^{-14} dB/cm and 5.627×10^{-14} dB/cm in X and Y polarized direction respectively for an analyte of refractive index 1.39. Furthermore, other optical properties such as effective refractive index, EMA, and Non-linearity have been achieved. Table 2 shows values of different parameters for optimization conditions OPT, OPT −2%, OPT +2%. It is possible to build the suggested PCF using the current fabrication techniques. The proposed model has demonstrated a preference for being satisfactory in detecting various analytes.

ABSTRACT In this paper, a dual-band 4-port Multiple Input Multiple Output (MIMO) antenna with very small footprints of 16×12×0.25 mm^3 is proposed for mm-wave applications. The proposed antenna operates in dual frequency bands at 28 GHz and 41.69 GHz. The isolation of the MIMO antenna is achieved >20dB at both the operating frequency bands by etching the slot at optimized position in the ground plane. The calculated diversity parameters of the antenna are acceptable for MIMO applications. The realized peak gain, Envelope Correlation Coefficient (ECC) and Diversity Gain (DG) are found to be 6.05 dBi, ≤0.10, and 9.89 dB, respectively. Moreover, the Mean Effective Gain (MEG), Channel Capacity Loss (CCL) and Total Active Reflection Coefficient (TARC) are evaluated to verify the proposed antenna performance in MIMO technology. The channel capacity is evaluated to demonstrate the superiority of the MIMO antenna over singe port antenna. Bending analysis of the antenna is also done to check the feasibility of this antenna for high data rate mm-wave wearable applications. In addition to that, antenna S-parameter is measured on chest and hand of human body for wireless body area network. Finally, to ensure the electromagnetic radiation safety, the specific absorption ratio (SAR) is evaluated at 28/41.69 GHz for input power of 500mW and found within the acceptable range.

INDEX TERMS Dual-band antenna, MIMO antenna, flexible antenna, diversity parameters, channel capacity, SAR, link margin, mm-wave and 5G applications

I. INTRODUCTION

Fifth generation communication systems are being implemented worldwide due to the demand of high data rate in diversified digital platforms [1, 2]. To fulfil the demand of the excessive data consumption by multiple users, millimeter frequency band is being utilized in the most of the countries. An adequate bandwidth at 28 GHz for 5G communication is of great interest for the mobile communication purpose. The specified 28 GHz band is mostly used due to relatively less absorption loss and path loss [3]. In addition to that, the multiple input multiple output (MIMO) antenna is one of the most promising designs for the transmission/receiving of quality signals [4]. In the modern wireless technology, MIMO antenna is widely used due to its spatial multiplexing, improved channel capacity, minimum multiple paths fading [5, 6]. Therefore, the effort has been made in [7] to design a dual-band MIMO antenna which consists of inset fed patch and parasitically coupled patch to operate at 28/38 GHz. In [8], the patch antenna with triangular stub was designed to obtain dual frequency response in millimeter range radiating at 28 and 38 GHz. Linearly arranged four patch antenna structure is reported covering the millimeter frequency bands 24 - 34 GHz and 37.5 - 41.5 GHz [9]. However, the overall linear dimension of the MIMO design is 48×12×0.254 mm^3. A crescent-shaped radiating patch is used to design a dual-band MIMO antenna for 5G application in mm-wave. The defected ground plane is used to improve the isolation, but the ground plane is not connected in this MIMO design [10]. Metamaterial based dual-band MIMO antennas are presented for better

content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3412712

isolation in which decoupling structure is used between the two MIMO elements [11, 12]. In [13], 1×4 MIMO antenna is designed to operate at 38 GHz with self-isolated approach for 5G applications. A cross-shaped antenna is reported operating at 24.5 and 28.5 GHz [14]. This MIMO design consists of SSR as radiating element and demonstrates end-fire radiation. In [15], two antenna structures are designed on same ground plan to cover the sub 6 GHz band and mm-wave band simultaneously. A single element with multiple ports is also one of the approaches to design antenna for MIMO application as reported in [16]. This design operates at 28 GHz, but most of the diversity parameters of the MIMO antenna are not reported. The flexible MIMO antennas are another growing field of research in wireless industry and applicable in many contemporary fields of biotechnology, defense and sensors [17-19]. The various applications of the flexible antennas can be depicted in Fig. 1.

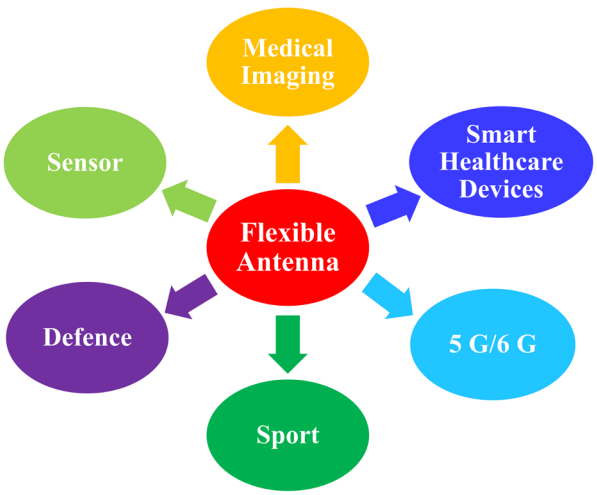

FIGURE 1. Flexible antenna applications.

In [20], two-port MIMO antenna is designed for sub-6 GHz ISM band applications. EBG structure is used to suppress the mutual coupling with overall gain of 9.50dBi. A 4×4 flexible MIMO antenna with size of 40×40×1.5 mm^3 is reported in [21]. The designed antenna demonstrates the dual-band response with UWB frequency range (from 3.18-12 GHz) by modifying the feedline. The antenna design for on-body application in the 28 GHz mm-wave band is reported in [22]. This design consists of a single radiating element with ground plane dimension of 29.06×11.42 mm^2. It is noticed that most of these flexible MIMO designs are operating in lower 5G bands.

Therefore, in this paper, a very small and flexible 4×4 MIMO antenna is reported for the millimeter frequency bands. The proposed antenna exhibits dual-band characteristics at 28/41.69 GHz. Various diversity parameters of the MIMO antenna are investigated using the CST Microwave Studio simulation software and measured results. In the existing literature, it is found that no one has reported bending analysis and analysed the channel capacity (CC) and SAR for the mm-wave 4-port MIMO antenna, which shows the significance of the proposed MIMO design.

The manuscript is organized in 10 sections including introduction as section 1. Sections 2 and 3 describe the antenna evolution and its implementation to design 4-port MIMO antenna. S-parameters and the important diversity parameters are evaluated and presented in sections 4 and 5, respectively. The CC and the bending analysis of the MIMO antenna are covered in sections 6 and 7, respectively. Moreover, to validate the use of proposed design for wearable electronics, the link margin is calculated in section 8, and on body measurement and SAR analysis are presented in section 9. Finally, the findings of the antenna design are concluded in section 10.

II. ANTENNA EVOLUTION AND S-PARAMETERS

The size miniaturization in the MIMO antenna is one of the important aspects for modern high speed communication systems. In this design, we have chosen the semi hexagonal microstrip patch (SHMP) because it occupies less area as compared to the semicircular patch, however, SHMP has current distribution similar to the semi disk patch.

The evolution stages of antenna design and the corresponding $|S_{11}|$ values are shown in Fig. 2 and Fig. 3, respectively. The SHMP was taken as the radiating patch along with a full ground plane for the initial antenna (Design-1). This antenna structure was fed using the microstrip line and resonates at 29.57 GHz. The resonance frequency of the design-1 is calculated by using certain approximations [23]:

(a) The SHMP is transformed to its equivalent rectangular patch of dimension $\mathcal{L} \times \mathcal{W}$.
(b) The rectangular patch is further transformed to its equivalent semicircular disk patch of effective radius ($\mathcal{A}_{eff}$).
(c) Now, using the value of $\mathcal{A}_{eff}$, the resonance frequency can be evaluated.

Thus, the design frequency of the proposed SHMP antenna can be given as:

$$\mathcal{F} = \frac{\xi_{mn} \times c}{2\pi \mathcal{A}_{eff} \sqrt{\varepsilon_{eff}}} \tag{1}$$

where,
$\xi_{11} = 1.84118$; for first dominant mode (TM_{11})
$\xi_{21} = 3.05424$; for second dominant mode (TM_{21})

$$\mathcal{A}_{eff} = \sqrt{\left\{2 \times \mathcal{L}_{eff} \times \left(\frac{\mathcal{W}_{eff}}{4}\right)\right\}} \tag{2}$$

Here, $\mathcal{L}_{eff}$, and $\mathcal{W}_{eff}$ are the effective length and width of the equivalent rectangular patch in which the fringing effect is taken into account [24]. ε_{eff} is the effective dielectric constant, and it can be calculated by taking the derived equivalent length and width of the rectangular patch as:

$$\mathcal{L} \approx 2 \times \mathcal{P} \tag{3}$$

$$\mathcal{W} \approx 3 \times \sqrt{3}\left(\frac{\mathcal{P}}{8}\right) \tag{4}$$

here,

$$\mathcal{P} \approx \sqrt{p_3 p_4}$$

Theoretically calculated values of lower and higher resonance frequencies are 29.44 and 48.84 GHz, respectively. When a narrow slot of dimension 2.62×0.31 mm^2 was etched in the ground plane (Design-2), the higher resonance is shifted towards lower side and the antenna radiates at two resonant frequencies of 25.55 and 41.69 GHz. Further, to obtain the lower resonance at 28 GHz, an additional stub was added on the top of SHMP (Design-3), while the higher resonance was stable at 41.69 GHz.

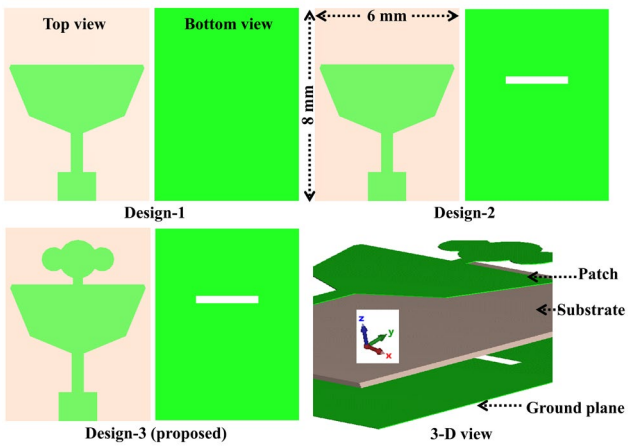

FIGURE 2. Antenna design stages.

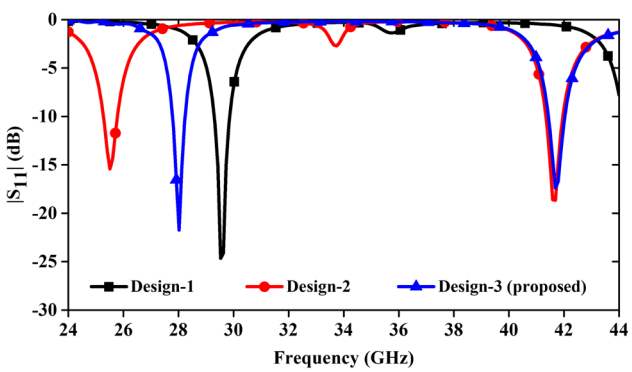

FIGURE 3. |S$_{11}$| graphs for different antenna designs.

III. 4-PORT MIMO ANTENNA DESIGN

The antenna design-3 is converted into a 4×4 MIMO antenna and demonstrated in Fig. 4. In this design, a flexible dielectric substrate (Rogers RO3003) with ε_r = 3.0, loss tangent 0.001, and thickness 0.25 mm is used. The overall dimension of the design is 16×12×0.25 mm^3. The optimized antenna dimensions are (in mm): L_s = 16, W_s = 12, p_1= 1.2, p_2 = 1.6, p_3 = 1.87, p_4 = 2.14, p_5 = 2.54, p_6 = 0.4, p_7 = 0.28, p_8 = 1.1, p_9 = 0.16, p_{10} = 0.5, p_{11} = 1.6, r_1 = 0.8, r_2 = 0.5, d = 0.52, r_2 = 1.2, L_g = 16, W_g = 12, g_1 = 2.62, g_2 = 0.31, g_3 = 5.6, g_4 = 3.38, g_5 = 4.89.

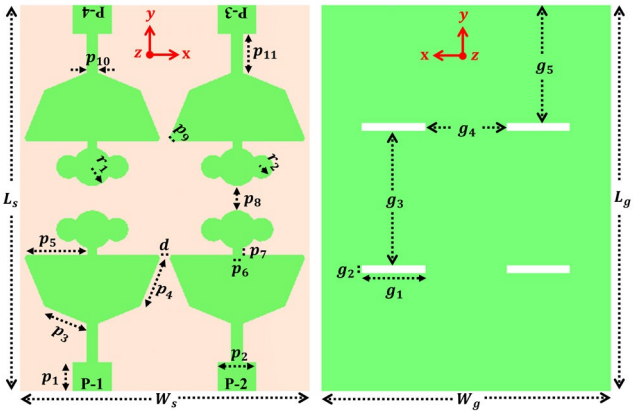

FIGURE 4. Structure of 4-port MIMO antenna.

IV. ANTENNA RESULTS AND DISCUSSION

The proposed MIMO antenna is fabricated and the prototype is shown in Fig. 5. The experimental setup for S-parameter measurement is depicted in Fig. 6. Vector Network Analyzer (VNA) with model no. N5247A is used to measure the scattering parameters of the MIMO antenna. The corresponding graph is shown in Fig. 7, in which the antenna shows the dual frequency bands at 27.6 and 40.0 GHz.

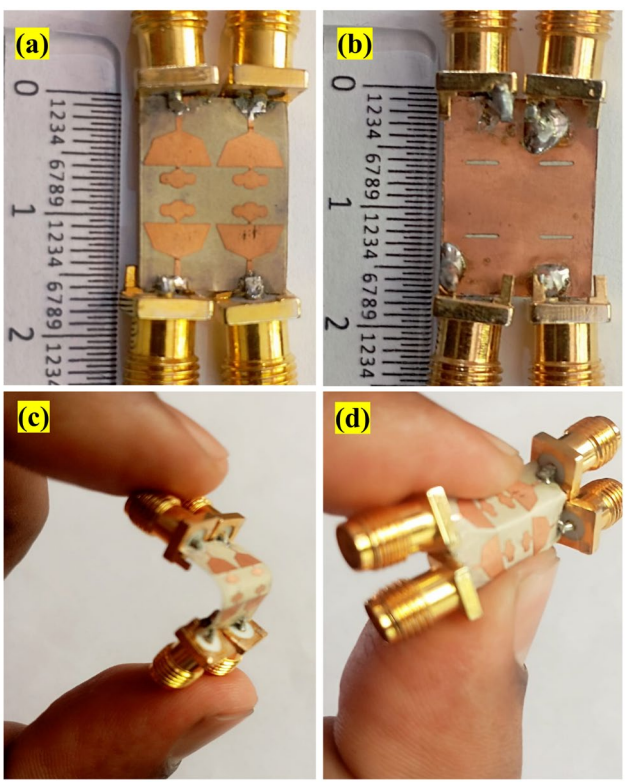

FIGURE 5. Prototype MIMO design, (a and b): flat configuration for top and bottom view, (c and d): deformation along x- and y- direction.

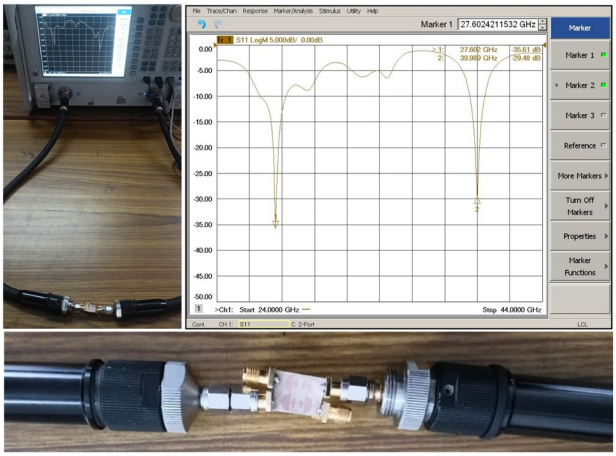

FIGURE 6. S-parameter measurement setup.

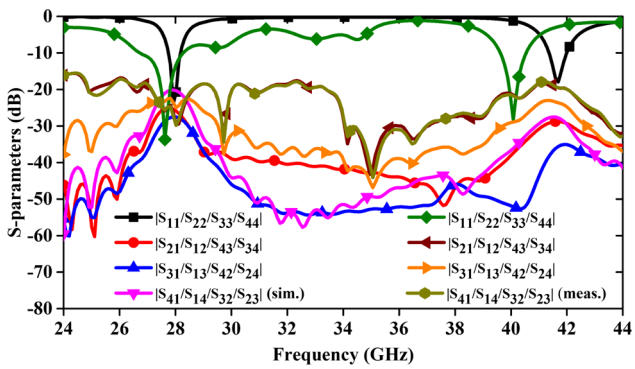

FIGURE 7. Scattering parameters of 4-port MIMO antenna.

The isolation across two frequency bands is >20dB, which is quite good for the MIMO applications. Some mismatch in the simulated and measured results may be due to imperfection in connector soldering and cable loss. Fig. 8 depicts the field density on the radiating elements. The current around the SHMP is maximum which indicates the fundamental lower resonance frequency. On the other hand, the upper resonance is developed due to higher mode. Thus, the resonance frequencies of the antenna can be easily tuned by varying the SHMP dimensions, stub loaded on the top of SHMP and the slots embedded in the ground plane.

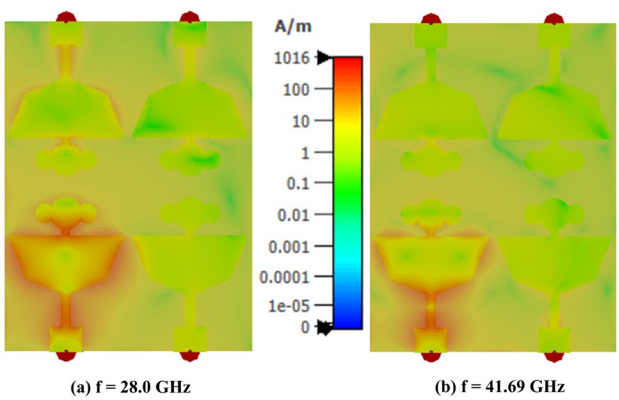

FIGURE 8. Current density variation at 28.0 and 41.69 GHz.

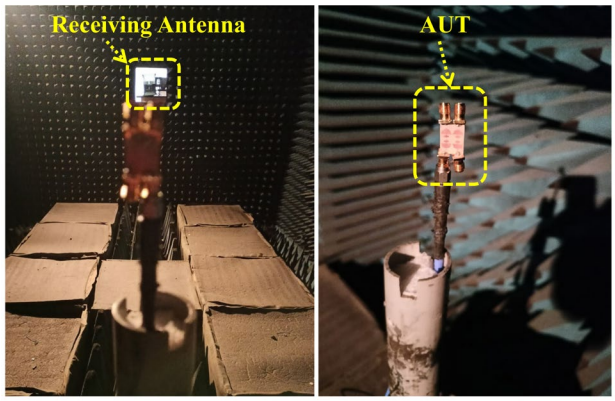

FIGURE 9. Gain measurement setup.

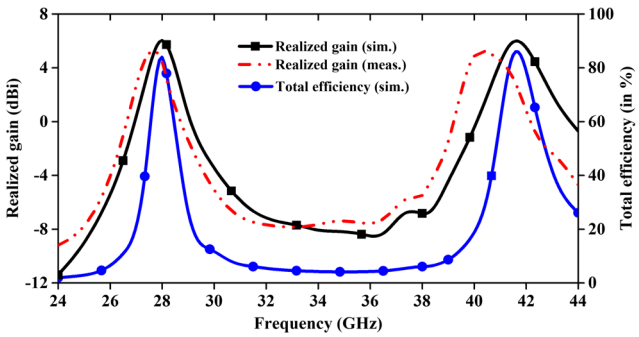

FIGURE 10. Realized gain and total efficiency.

The gain measurement setup is depicted in Fig. 9. The realized gain and total radiation efficiency (Fig. 10) at both the bands are above 6.0dBi and 80%, respectively. Furthermore, the co-and cross-polar E-and H-plane radiation patterns are presented in Fig. 11. The radiation patterns at 28 GHz are plotted for $\phi = 90^0$ and 0^0 and from the curve it is seen that the co-and cross-polarization discrimination is quite acceptable.

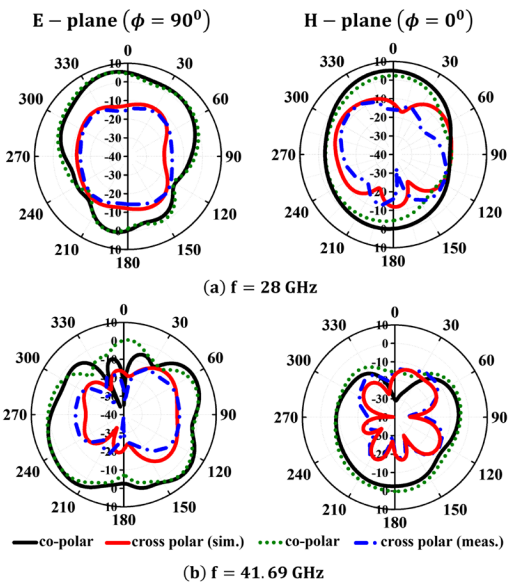

FIGURE 11. Radiation patterns of the proposed antenna.

This work is licensed under a Creative Commons Attribution-NonCommercial-NoDerivatives 4.0 License. For more information, see https://creativecommons.org/licenses/by-nc-nd/4

This article has been accepted for publication in IEEE Access. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3412712

However, at 41.69 GHz the polarization discrimination is > -15dB at the elevation angle 180^0. Some ripples in the radiation patterns may be due to the interference from the electromagnetic waves generated in coupled resonators of MIMO antenna.

V. DIVERSITY PARAMETERS

To access the quality performance of the MIMO antenna, the diversity parameters need to be investigated. In this section, the results of various diversity parameters are evaluated and discussed.

A. ENVELOPE CORRELATION COEFFICIENT (ECC) AND DIVERSITY GAIN (DG)

The ECC (Υ_{ecc}) and DG are evaluated across both the operating bands and shown in Fig. 12. The ECC value is calculated using 3-D radiation patterns [25]

$$\Upsilon_{ecc(pq)} = \frac{\left|\int_0^{2\pi}\int_0^{\pi}\{\mathcal{X}_{pr}\cdot\mathcal{E}_{\vartheta p}\mathcal{E}^*_{\vartheta q}\mathcal{P}_\vartheta + \mathcal{E}_{\varphi p}\mathcal{E}^*_{\varphi q}\mathcal{P}_\varphi\}d\Omega\right|^2}{\mathcal{M}\times\mathcal{N}} \quad (5)$$

here,

$$\mathcal{M} = \int_0^{2\pi}\int_0^{\pi}\{\mathcal{X}_{pr}\cdot\mathcal{E}_{\vartheta p}\mathcal{E}^*_{\vartheta p}\mathcal{P}_\vartheta + \mathcal{E}_{\varphi p}\mathcal{E}^*_{\varphi p}\mathcal{P}_\varphi\}d\Omega$$

$$\mathcal{N} = \int_0^{2\pi}\int_0^{\pi}\{\mathcal{X}_{pr}\cdot\mathcal{E}_{\vartheta q}\mathcal{E}^*_{\vartheta q}\mathcal{P}_\vartheta + \mathcal{E}_{\varphi q}\mathcal{E}^*_{\varphi q}\mathcal{P}_\varphi\}d\Omega$$

and,

$$\mathcal{X}_{pr} = \frac{\mathcal{P}_v}{\mathcal{P}_h} = 1$$

In ideal condition the totally uncorrelated ECC value of the MIMO antenna is zero and DG is 10 dB but the experimental value of ECC < 0.5 is satisfactory. Using these equations Υ_{ecc} found to be ≤ 0.20 at two resonance frequencies. Moreover, the DG is above 9.89 dB across two resonating bands.

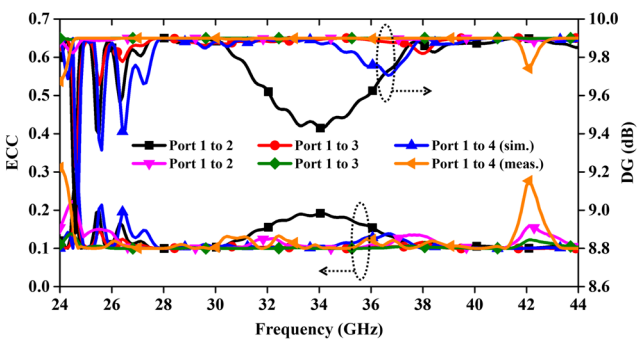

FIGURE 12. ECC and DG values of MIMO antenna for different ports.

B. MEAN EFFECTIVE GAIN (MEG)

MEG ($\psi_{\mathcal{M}}$) is the ratio of accepted mean power to the average incident power by the elements of MIMO antenna as compared to an isotropic antenna. The gain performance of the MIMO antenna can be analyzed considering the atmospheric effect and it is mathematically expressed as [26]

$$\psi_{\mathcal{M}} = \frac{\mathcal{P}_r}{\mathcal{P}_{in}} = \int_0^{2\pi}\int_0^{\pi}\left[\frac{\mathcal{X}_{pr}}{\mathcal{X}_{pr}+1}\times\mathcal{F}_\vartheta(\vartheta,\varphi)\mathcal{P}_\vartheta(\vartheta,\varphi) + \frac{1}{1+\mathcal{X}_{pr}} \times\mathcal{F}_\varphi(\vartheta,\varphi)\mathcal{P}_\varphi(\vartheta,\varphi)\right]\sin\vartheta d\vartheta d\varphi \quad (6)$$

where, $\mathcal{F}_\vartheta$ and $\mathcal{F}_\varphi$ are the power gain patterns of the MIMO antenna elements. The values of $\mathcal{F}_\vartheta$ and $\mathcal{F}_\varphi$ are calculated by varying the angle ϑ and keeping the angle φ constant and vice-versa. The MEG values are calculated and measured for the different ports (Fig. 13). It is to be noted that the difference of MEG between these ports must be <-3dB in 4-port MIMO antenna structure. From this figure, $\psi_{\mathcal{M}}$ values of all 4-ports are <-6dB across the dual frequency bands (simulated and measured).

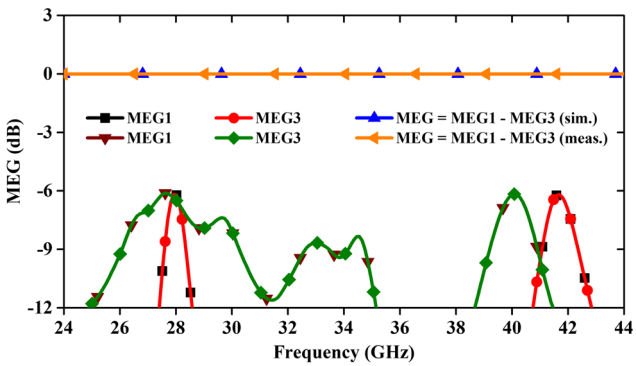

FIGURE 13. MEG against frequency.

C. CHANNE CAPACITY LOSS (CCL)

CCL ($\mathcal{C}_{\mathcal{CL}}$) is the parameter which measures the signal distortion between the transmitted and receiving end. The $\mathcal{C}_{\mathcal{CL}}$ is mathematically expressed as [27]

$$\mathcal{C}_{\mathcal{CL}} = -\log_2 det(\zeta) \quad (7)$$

where,

$$\zeta = \begin{bmatrix}\zeta_{11} & \zeta_{12} & \zeta_{13} & \zeta_{14}\\ \zeta_{21} & \zeta_{22} & \zeta_{23} & \zeta_{24}\\ \zeta_{31} & \zeta_{32} & \zeta_{33} & \zeta_{34}\\ \zeta_{41} & \zeta_{42} & \zeta_{43} & \zeta_{44}\end{bmatrix}$$

here,

$$\zeta_{pp} = 1 - \sum_q^4 |S_{pq}|^2$$

and,

$$\zeta_{pq} = -\left(S^*_{pp}S_{pq} + S^*_{qp}S_{pq}\right)$$

The simulated and measured CCL values are depicted in Fig. 14, and the respective values are 0.31 and 0.28 and, 0.25 and 0.22 bits/sec/Hz across both the operating bands. The simulated and measured value is always ≤ 0.4 bits/sec/Hz.

This article has been accepted for publication in IEEE Access. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3412712

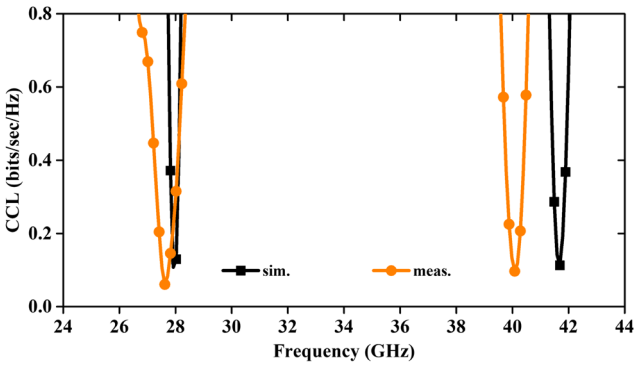

FIGURE 14. CCL against frequency.

D. TOTAL ACTIVE REFLECTION COEFFICIENT (TARC)

The TARC $(\mathcal{T}_\chi)$ is another parameter to express the operational bands of the MIMO antenna when the phase of the input signal is changed. The $\mathcal{T}_\chi$ of the 4-port MIMO antenna can be expressed as [28]

$$\mathcal{T}_\chi = \sqrt{\sum_{i=1}^{4}|\mathcal{R}_{in}|^2} \Big/ \sqrt{\sum_{i=1}^{4}|\mathcal{I}_{in}|^2} \tag{8}$$

where, $\mathcal{I}_{in}$ = incident signal, $\mathcal{R}_{in}$ = reflected signal.

The scattering matrix of the 4×4 mm-wave MIMO antenna can be expressed as

$$\begin{pmatrix}\mathcal{R}_1\\ \mathcal{R}_2\\ \mathcal{R}_3\\ \mathcal{R}_4\end{pmatrix} = \begin{pmatrix}\mathcal{S}_{11} & \mathcal{S}_{12} & \mathcal{S}_{13} & \mathcal{S}_{14}\\ \mathcal{S}_{21} & \mathcal{S}_{22} & \mathcal{S}_{23} & \mathcal{S}_{24}\\ \mathcal{S}_{31} & \mathcal{S}_{32} & \mathcal{S}_{33} & \mathcal{S}_{34}\\ \mathcal{S}_{41} & \mathcal{S}_{42} & \mathcal{S}_{43} & \mathcal{S}_{44}\end{pmatrix}\begin{pmatrix}\mathcal{I}_1\\ \mathcal{I}_2\\ \mathcal{I}_3\\ \mathcal{I}_4\end{pmatrix} \tag{9}$$

From equations (8) and (9), we can evaluate the value of $\mathcal{T}_\chi$ for the proposed antenna as

$$\mathcal{T}_\chi = \sqrt{\sum_{i=1}^{4}\left|\mathcal{S}_{i1} + \sum_{p=2}^{4}\mathcal{S}_{ip}e^{\jmath\vartheta_{p-1}}\right|^2} \Big/ \sqrt{4} \tag{10}$$

$$\mathcal{T}_\chi = \sqrt{\mathbb{A}+\mathbb{B}+\mathbb{C}+\mathbb{D}}/\sqrt{4} \tag{11}$$

here,

$$\mathbb{A} = \left|\mathcal{S}_{11} + S_{12}e^{\jmath\vartheta_1} + S_{13}e^{\jmath\vartheta_2} + S_{14}e^{\jmath\vartheta_3}\right|^2$$

$$\mathbb{B} = \left|\mathcal{S}_{21} + S_{22}e^{\jmath\vartheta_1} + S_{23}e^{\jmath\vartheta_2} + S_{24}e^{\jmath\vartheta_3}\right|^2$$

$$\mathbb{C} = \left|\mathcal{S}_{31} + S_{32}e^{\jmath\vartheta_1} + S_{33}e^{\jmath\vartheta_2} + S_{34}e^{\jmath\vartheta_3}\right|^2$$

$$\mathbb{D} = \left|\mathcal{S}_{41} + S_{42}e^{\jmath\vartheta_1} + S_{43}e^{\jmath\vartheta_2} + S_{44}e^{\jmath\vartheta_3}\right|^2$$

The measured $\mathcal{T}_\chi$ of the MIMO antenna is depicted in Fig. 15. Here, phase of the first port signal is fixed and the rest of the three ports are excited with different phase angles in between 0^0 to 180^0. It is found that $\mathcal{T}_\chi$ of the antenna is least deviated with the change of phase angles and hence the antenna elements are properly decoupled.

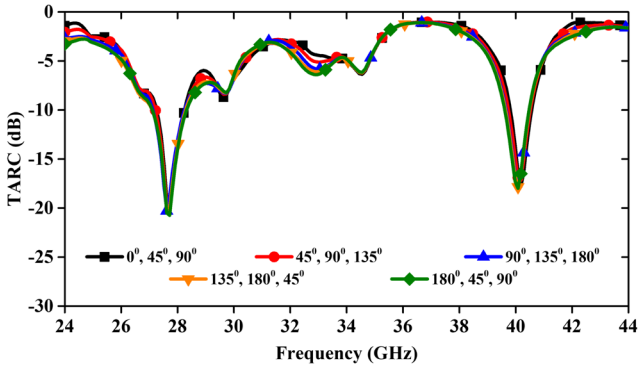

FIGURE 15. TARC against frequency at different signal phase angles.

VI. CHANNEL CAPACITY (CC)

The CC for this MIMO design is calculated using [29].

$$CC = log_2\left[det\left\{\mathcal{I}_{n_{\mathcal{R}_x}} + \frac{(\mathcal{SNR})_{avg.}}{n_{\mathcal{T}_x}}\mathcal{H}\mathcal{H}^\zeta\right\}\right] \tag{12}$$

here, $\mathcal{H}$ and $\mathcal{H}^\zeta$ indicate the normalized channel matrix, and its conjugate transpose. $\mathcal{I}_{n_{\mathcal{R}_x}}$ is the identity matrix and $n_{\mathcal{T}_x}$, $n_{\mathcal{R}_x}$ are the number of transmitted and received antenna elements.

The CC of the single input single output (SISO) and MIMO (in ideal case) are compared with the designed MIMO antenna in Fig. 16. Here CC is plotted at the signal to noise ratio (SNR) for 20 dB (Fig. 16). From the curve we can find that a SISO antenna, 4×4 MIMO structure and the proposed 4×4 MIMO antenna exhibit the CC of 5.85, 22.15, and 20.86 bps/Hz, respectively. Thus, it can be concluded that the CC of the reported 4×4 MIMO antenna is almost four times as compared to SISO antenna. The cumulative distribution function (CDF) is calculated at SNR value of 20 dB and it is shown in Fig. 17. From this figure, it can be observed that the designed mm-wave MIMO antenna is higher CC than SISO antenna. This antenna is more effective for high data rate 5G and beyond 6G technology applications.

VII. BENDING ANALYSIS OF MIMO ANTENNA

In this section, an analysis is presented to investigate the MIMO antenna performance under bending condition (Fig. 18). MIMO antenna is bent in two different orientations i.e. along x-and y-axis and the corresponding simulated S_{nn} parameters are shown in Figs. 19 and 20, respectively.

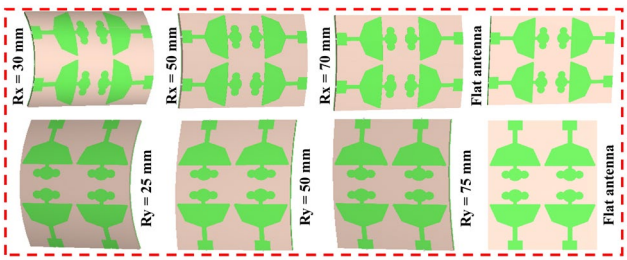

FIGURE 18. Deformation of antenna on multi-layer phantom along x-and y-orientations.

It can be seen that both the resonance frequencies slightly shift towards lower side when the deformation is maximum i.e. Rx = 30 mm (Fig. 19). The corresponding measured S-parameter is also compared at bending radius of 30 mm and found in good agreement with the simulated result. When antenna is bent along y-axis, there is negligible shift in simulated lower resonance frequency, however, the shift in higher resonance frequency is maximum at Ry = 25 mm (Fig. 20). Thus, from the results, it can be concluded that the proposed MIMO antenna is suitable for flexible/wearable electronics [30].

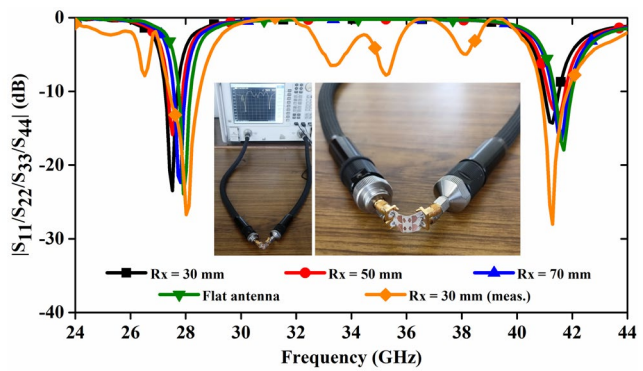

FIGURE 19. Measurement of S_{nn} - parameter against bending radii along x-axis.

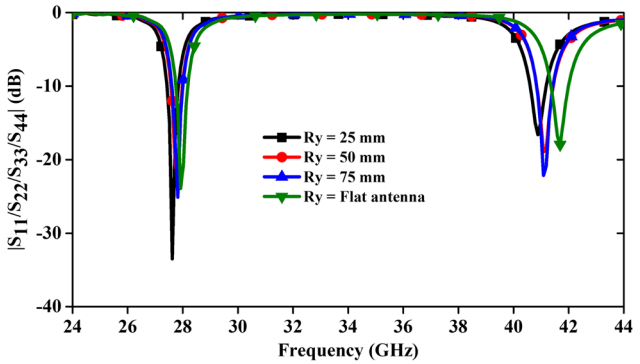

FIGURE 20. Simulated Snn - parameter variation for different bending radii along y-axis.

VIII. LINK BUDGET ANALYSIS

The proposed mm-wave MIMO antenna is designed for high-speed wireless body area network (WBAN). Therefore, it is required to calculate the link budget parameters between the transmitter and receiver (on-body).

TABLE I
LINK BUDGET PARAMETERS

Transmitter		
	Frequency (GHz)	28/41.69
G_t	Antenna gain (dBi)	6.04/5.93
P_t	Transmitter power (dBm)	16
	EIRP (dBm)	22.04/21.93
Receiver		
G_r	Receiver antenna gain (dBi)	4.1
T_o	Ambient temperature (K)	293
k	Boltzmann constant	1.38×10^{-23}
N_o	Noise power density (dB/Hz)	-203.9
Signal quality		
B_r	Bit rate (Mbps)	1, 20, 50, 100
E_b/N_o	Ideal PSK (dB)	9.6
G_c	Coding gain (dB)	0
G_d	Fixing deterioration (dB)	2.5

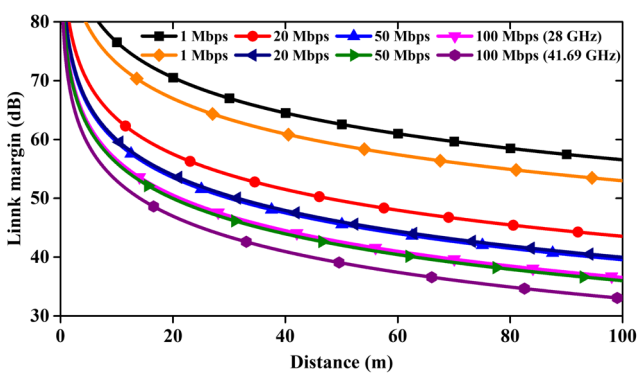

FIGURE 21. Calculated link margin with distance between transmit (T_x) and receiver (R_x) antenna.

The link margin (LM) is calculated using [31, 32] at two resonance frequencies 28/41.69 GHz and the link budget

parameters are given in Table I. Here, we have used the input power of 500 mW to avoid the interference/noise from the other working devices at the same frequency band. The calculated LM is depicted in Fig. 21. From this figure, it is clear that the MIMO antenna achieves a bit rate of 100 Mbps with LM > 33 dB at 41.69 GHz frequency (upto 100m distance). Hence, the designed antenna is suitable for WBAN at two reported frequencies (28/41.69 GHz).

IX. ON BODY MEASUREMENT OF MIMO ANTENNA AND SAR (SPECEFIC ABSORPTION RATIO) Calculation

The proposed mm-wave MIMO antenna can be installed on the human body due to its flexible nature [33]. The measurement setup for the proposed MIMO design on human chest and hand are depicted in Fig. 22. The S-parameters of the antenna on chest and hand positions are presented in Fig. 23. From this figure, it can be observed that both the resonance frequencies are slightly altered and found at 27.91 and 40.54 GHz when antenna is located on hand. However, the shift of resonance frequencies is found slightly more when antenna is placed on the chest. The shift of resonance frequencies may be due to more complex anisotropic behaviour of tissues, bones and muscles on the chest portion of the body.

FIGURE 22. On body measurement of the MIMO antenna.

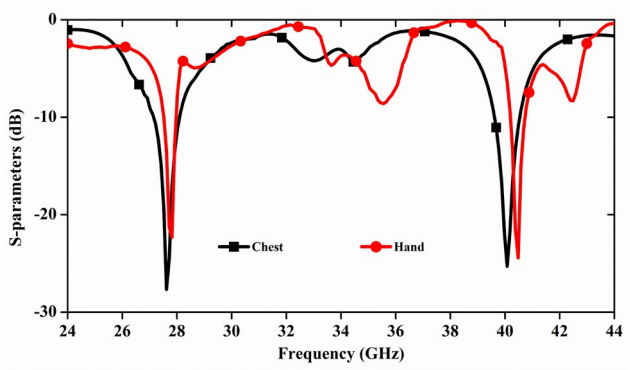

FIGURE 23. Measured S-parameters on human body (chest and hand).

Furthermore, to ensure the appropriate use of the antenna for on body applications, electromagnetic radiation emitted from the antenna should be analyzed. According to the International Commission on Non-Ionizing Radiation Protection (ICNIRP) and IEEE C95.1-2019 standard [34], for on-body application, the average SAR value should be below 1.6 and 2.0 W/Kg (for 1 gm and 10 gm of tissues). The SAR values are evaluated at two different frequencies (at 28 GHz and 41.69 GHz) in the multi-layer of human body phantom. The size of the phantom is 50×50 mm^2 with thickness of muscle, fat and skin of 20, 5 and 4 mm, respectively. To evaluate the SAR value, the electrical parameters for the different layers of human body are taken from [35].

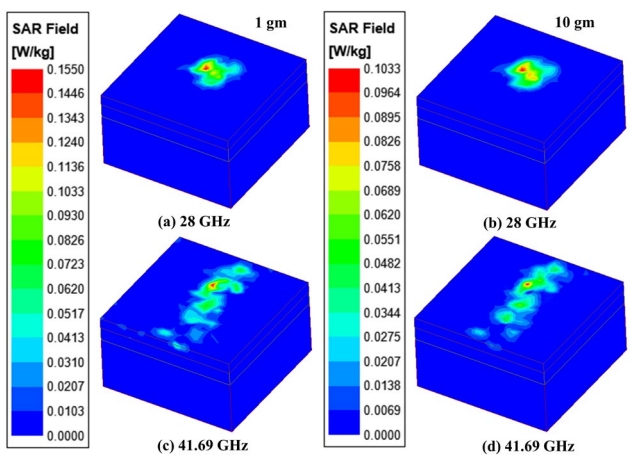

FIGURE 24. SAR calculation at 28 GHz, and 41.69 GHz.

Fig. 24 shows the 1gm/10gm average SAR values at 28/41.69 GHz (for input power of 500 mW) are 0.16/0.10 W/kg and 0.13/0.11 W/kg, respectively. This MIMO antenna is finally compared with recently reported antennas (Table II). None of the design has reported the bending analysis, CC, link margin and SAR analysis which shows the state of the art work in the proposed MIMO antenna.

X. CONCLUSION

A dual-band 4×4 MIMO flexible antenna for millimeter wave applications has been designed, fabricated and measured. Theoretical resonance formula is developed for the proposed radiating structure to design the antenna at specific resonance frequency. The isolation >20 dB is achieved without any decoupling structure. The ECC, DG, MEG, CCL, TARC, CC and CDF of the antenna ensure its candidature for the applications in high-speed communication systems. This antenna demonstrates the transmit/receive data rate of 100 Mbps upto a communication distance of 100 meter at both the resonance frequencies of 28/41.69 GHz. The MIMO antenna is measured on different parts of human body to assert its on-body applications. The SAR values are also calculated on multilayer phantom model and found quite below as compared to the predefined values at 1 and 10 g of tissues. Thus, the proposed simple, ultrathin and flexibile MIMO antenna is suitable for mm-wave 5G communications and wireless wearable electronics.

Determination of Residual Stresses and Surface Roughness Using Chemical Assisted Ball End Magnetorheological Finishing

Anand Sharma and Mahendra Singh Niranjan

Submitted: 14 March 2023 / Revised: 27 May 2024 / Accepted: 2 June 2024

The generation of residual stresses by grinding process on the surface for a soft material results in poor performance and diminished life. Ball end magnetorheological finishing (BEMRF) process is a recently developed process that is effectively used for fine figuring and polishing of a variety of magnetic and non-magnetic materials. In this paper, grinding-induced residual stresses are addressed, and an attempt is made to relieve these residual stresses while achieving high surface finish using chemical assisted ball end magnetorheological finishing (CA-BEMRF) process. The impact of various CA-BEMRF variables on percentage surface roughness reduction and percentage reduction in residual stresses are discussed statistically and graphically. Residual stresses of workpiece surfaces have been measured by using portable x-ray residual stress analyzer. Scanning electron microscopy (SEM) of the finished workpiece before and after CA-BEMRF process is carried out to assess the effects of magnetizing current, tool rotation and working gap on surface topography of machined surface. It has been observed that reduction in residual stress is achieved along with high surface finish on aluminum workpiece surface using CA-BEMRF technique. Significant process parameters affecting the residual stresses and surface roughness during polishing of workpiece are obtained using analysis of variance (ANOVA) and *F*-test. The optimization problem for maximum percentage reduction in surface roughness and maximum percentage reduction in residual stress is formulated as multiobjective, multivariable, nonlinear optimization problem. Maximum percentage surface roughness reduction and minimum residual stress has been found at magnetizing current 2.3A, rotational speed of tool 550 rpm and working gap of 0.5 mm. Confirmatory experimental tests have been conducted and results obtained were found very close to the predicted outcome.

Keywords aluminum, ANOVA, chemical assisted ball end magnetorheological, residual stress, SEM

1. Introduction

There is a significant demand for nano-meter and macro-meter items possessing excellent polished surface and strength in this age of new industrialization revolution. The surface finish has a direct impact on the optical quality, mechanical characteristics, and bio-medical functions of microparts (Ref 1, 2). Engineering materials are utilized in a variety of applications to meet industrial objectives by leveraging qualities like conductivity, ductility, and lightweight (Ref 3). However, some of these characteristics, such as malleability and weak scratch resistance, also provide challenges when polishing metals (Ref 4). For the finishing of copper alloy at the nanometric level, numerous successful attempts have been made (Ref 5, Ref 6). Unfortunately, relatively few research has focused on using chemo-mechanical polishing (CMP) and magnetorheological finishing to achieve nanometric-level finishing on aluminum alloys (MRF). Optical mirror coatings have frequently used silver and gold. Today's high-quality mirrors, however, are coated with aluminum rather than silver to prevent tarnishing caused by air exposure, particularly sulfur, which results in the development of brown colored tarnish spots. These spots also result in a decrease in reflectance and a rise in emissivity (Ref 7). Gold is a precious metal that is often used in jewelry and other decorative items. However, it is very costly as compared to other metals such as aluminum. Therefore, aluminum is often preferred over gold for various purposes. It is lighter in weight, cheaper, and more durable than gold. Additionally, it is easier to work with, making it a popular choice for many applications.

Humans' quest for solar and space exploration has led to a need for nanofinished aluminum alloys (Ref 8). Telescope metal mirrors made of aluminum alloys are completed using the DTM process (Ref 9, 10). These mirrors are thin, highly conductive, very resistant to corrosion, and have a longer fatigue life. Other significant uses of nanofinished aluminum surfaces include diaphragms for optical sensors (Ref 11), very corrosion-resistant marine transportation, microelectronic-based devices (Ref 12), and mass level integration for

This invited article is part of a special topical issue of the Journal of Materials Engineering and Performance on Residual Stress Analysis: Measurement, Effects, and Control. The issue was organized by Rajan Bhambroo, Tenneco, Inc.; Lesley Frame, University of Connecticut; Andrew Payzant, Oak Ridge National Laboratory; and James Pineault, Proto Manufacturing on behalf of the ASM Residual Stress Technical Committee.

Published online: 14 June 2024

conductive wires (Ref 13). It has been discovered that finishing aluminum is a difficult process due to its malleability and flexibility. Nowadays, due to a few drawbacks including burrs, high residual stresses, sub-surface damages, etc., it is not viable to polish soft metals like aluminum up to the nanometric level using standard finishing methods like grinding, sprucing, burnishing, and lapping.

Residual stresses are stresses that remain in a material after it has undergone some process. These stresses can have harmful effects on the material, causing it to break or fail. Residual stresses can be caused by many factors, such as welding, casting, machining, or even just from the materials used in the construction of the item. The effects of residual stresses can be minimized by careful design and engineering of the item, as well as by using materials that are less likely to be affected by them.

To achieve high surface finish and minimum residual stress on aluminum alloys few finishing approaches which were able to control the finishing forces exerted on the workpiece surface are magnetic flow polishing, machining through abrasive flow, magnetorheological-based abrasive flow and jet flow. In those approaches, the finishing forces are managed via way of means of controlling the magnetic flux density by means of the use of permanent magnet or an electromagnet. MRF process have been very successful in finishing of various materials such as glass, molds made of steel, and EN-31, polyamide but very few research has been done on aluminum alloys using this technique. However, these techniques can finish limited geometric shapes as concave, convex, planar, and symmetrical spheres.

Inspired by the favorable features of chemical mechanical polishing (CMP) process, various researchers have made an attempt to hybrid the CMP and MRF process to obtain high surface finish for different materials. Jain et al. (Ref 14) developed chemo-mechanical MR finishing process by associating CMP and MRF process to enhance the surface finish of silicon blanks. It was concluded that operational gap, finishing period and rotational speed of magnets had significant effect and led to a surface finish of 4.8 Å.

Ranjan et al. (Ref 5, 15) super finished a copper alloy using CMMRF technique and developed a mathematical model to study the polishing pressure and other controlling parameters. A delicate chemically passivated layer was created on copper alloy surface by chemically reacting it with ammonia, glycine and nitric acid. The results showed that optimization of pH value of the chemical is important to achieve better surface finish. Results showed that the depth and width of scratches on the surface were a few tens of nanometers size.

Ranjan et al. (Ref 16) theoretically explored magnetism, polishing pad formation and polishing pressure using FEA-CFD simulation, the results of which were validated later experimentally on aluminum 6061-T6 alloy. The results revealed that the polishing pressure is affected by three parameters, viz. Working gap, MR fluid and rotational speed.

Ghai et al. (Ref 17) achieved a nano-level surface finish (0.597 nm) on Al 7075-T6 alloy using CMMRF technique. These results were obtained by optimizing the concentration of chemicals, abrasives, and CIP particles along with working gap. The authors used deionized water, glycine, ammonia, and citric acid to form a brittle passivated layer on workpiece surface and model the experiments with central composite design model technique. It was observed that aluminum alloy could only be finished in alkaline solution.

Kumar and Singh (Ref 18) critically assessed the benefits, futuristic opportunities, and the challenges in improving the capabilities of CMMRF process. They beautifully explained the mechanism and various process parameters affecting the capability of CMMRF process and its applications in the field of aerospace research, solar, medical implants, electronics and optical. It was also discussed that in future more focus can be given to in-depth finishing of ferrous and non-ferrous material, brittle materials, complex structures, etc. It was concluded that this technique can produce a surface finish on both brittle and ductile materials in the range of 2-6 Å.

Although various researchers have carried out the finishing of materials like silicon, copper, aluminum alloy using "CMMRF" process, but no work was found via BEMRF technique. In addition, according to the past work very limited work has been carried out using aluminum 7075 alloy. The present work is aimed to achieve a high surface finish on aluminum 7075 alloy flat workpiece which can be directly used in different applications. The approach described in this study uses a newly created process called chemical assisted ball end magnetorheological finishing (CA-BEMRF), which combines the CMP and BEMRF procedures (Ref 19, 20), to finish the surface of an aluminum alloy workpiece. To see how a chemical reaction affects the residual stresses and surface finish of an aluminum alloy workpiece, the percentage reduction in residual stress and percentage surface roughness reduction obtained before and after the CA-BEMRF process were compared (Ref 21-24).

The BEMRF process is a novel way of reducing residual stress in materials. By passing an electric current through the material, the BEMRF process can help to remove any internal stresses that may be present. This can be beneficial for a number of reasons, including improving the overall strength and durability of the material. Additionally, the BEMRF process can also help to improve the dimensional accuracy of the material, by reducing any warping or distortion that may be caused by residual stress.

2. Magnetorheological Fluid

In CMP, MRF, CMMRF, and BEMRF processes, magnetorheological fluid (MR fluid) is frequently used to polish surfaces to an ultra-smooth finish. The preparation of the MR fluid is the most important factor in completing any surface in the CA-BEMRF. MR fluid enables the control of finishing forces applied on the workpiece surface while finishing through CA-BEMRF process. Table 1 describes the key constituents of MR fluid prepared for the experimentation. MR fluid consists of base fluid, abrasive particles (SiC) and carbonyl iron particles (CIPs) to form semi-solid ball under the effect of magnetic field as shown in Fig. 1(a). The schematic of the formation of ball-shaped MR fluid is shown in Fig. 1(b). The MR fluid stiffens and attains the shape of a polishing ball under the action of the magnetic current before being compressed against the workpiece surface. Because the magnetic force increases as the working gap decreases, ultra-finishing can be accomplished by adjusting the distance between the tool tip and the workpiece. Controlling the tool's rotational speed, working gap, and magnetizing current the finishing forces can be controlled.

Table 1 Constituents of magnetorheological fluid

S. No.	Constituents of MR fluid	Composition	W/W%
1	Base fluid	Paraffin oil (80 wt%) and grease (20 wt%)	55
2	Abrasive	Silicon carbide (SiC)	25
3	Magnetic particles	Carbonyl iron particles	20

3. Mechanism of Finishing

Finishing through CA-BEMRF process is accomplished through a mix of chemical action and mechanical erosion. Under the influence of a magnetizing current, magnetic particles create a semi-solid ball with abrasives, which causes mechanical material removal. A chemical agent then causes the production of a passivated layer, which is removed by the magnetic and abrasive particles.

3.1 Chemical Reaction

Chemical reaction is essential for forming passivated layer to protect the aluminum alloy. A passive layer on the surface of aluminum alloy is formed when the workpiece is dipped in the chemical solution consisting of H_2O_2. Citric acid and phosphoric acid (H_3PO_4) were used as pH buffer solutions. In this process, hydrogen peroxide (H_2O_2) was used as an oxidant for softening the aluminum alloy workpiece surface which in turn increases the surface finish after mechanical action through BEMRF process. Kuo and Tsai (19) showed that a small concentration of H_2O_2 can substantially improve the material removal rate which in turn can quite effectively increase the surface finish of the workpiece. Equation 1, 2, and 3 outline the mechanism's reaction pathway.

$$2Al + 3H_2O_2 \rightarrow Al_2O_3 + 3H_2O \rightarrow 2Al(OH)_3 \quad \text{(Eq 1)}$$

$$Al(OH)_3 + 3H_2O \rightarrow 2Al(OH_2)_3(OH)_3 \quad \text{(Eq 2)}$$

$$Al(OH_2)_3(OH)_3 + H_3PO_4 \rightarrow AlPO_4 + 6H_2O \quad \text{(Eq 3)}$$

This mechanism states that the surface of the Al is first oxidized by H_2O_2 to produce Al_2O_3. Al_2O_3 is next hydrated and reduced (dissolved) by H_3PO_4 to create a water-soluble phosphate salt (i.e., $AlPO_4$), which is then mechanically removed by CI and abrasive particles, concluding the removal cycle.

3.2 Mechanical Action

Using an electromagnet, magnetic field is generated in CA-BEMRF process which shapes MR fluid into a semi-solid ball. Silicon carbide abrasive particles are held in chains of magnetic carbonyl iron particles when the magnetizing current is switched ON. The flexible finishing pad developed a micro-texture due to the average CIPs size of 1 to 5 μm. As seen in Fig. 2(b), microtextures aid in retaining SiC abrasive particles and transferring finishing force to abrasive particles. By applying magnetic force to abrasive particles via CIPs, a passive layer that had formed on the aluminum workpiece surface was removed, and peak levels were reduced to a certain extent. CIPs hold the abrasive particles while also smoothing the workpiece's surface and removing any peaks. Tinier magnetic and soft abrasive particles are usually advised because hard abrasives and substantial magnetic particles will cause scratches. The final finishing force (FF) is a resultant of the normal force (N_F) and shear force (SH_F), as illustrated in Fig. 2(b), based on the abrasive and magnetic particle microstructure. The shear force is responsible for material removal, whereas *Fn* is in duty of determining the depth of penetration of the workpiece surface.

4. Experimental Setup

As a result of the restriction on the relative mobility of the workpiece and finishing tool, the limitations of finishing limited geometries were eliminated by developing ball end magnetorheological finishing (BEMRF), a variation of the MRF method. The original BEMRF configuration contained a MR finishing tool oriented vertically which is powered by a servo motor. The tool consists of a cylindrically formed central core (prepared of iron), an electromagnetic coil rapped around the tool & exterior core orientated concentrically to one another. The electromagnetic coil is intended to achieve around 0.8 Tesla flux density.

Figure 2(a) depicts the configuration of a 3-axis CNC BEMRF tool powered by a servo motor. The electromagnetic coil is enclosed by a tube made of copper through which cold water is pumped to keep the temperature acceptable for experiments. Once the current supply is turned on, the formation of a virtually very viscous MR fluid "ball-shaped" at the tool tip takes place as shown in Fig. 1(a). The viscosity of MR fluid can be controlled or changed by real-time control of the magnetizing current, thereby controlling the intensity of the magnetic field.

4.1 Preparation of Sample

Workpieces of Al 7075 alloy, each measuring 70 mm × 10 mm × 10 mm was cut and pre-finished using precision grinding technique. Table 2 shows the grinding process parameters used for pre-finishing the workpieces. The specimens were then washed with acetone and rinsed with DI water to eliminate any debris or burrs that remained after grinding. The Mitutoyo Surftest SJ-301 equipment is used to measure the first stage surface roughness acquired after grinding.

4.2 Preliminary Experiments

The preliminary experiments were performed on three-axis CNC BEMRF setup developed at Delhi Technological University, Delhi to obtain the ranges and significant process parameters. The effect of key parameters on percentage reduction in surface roughness and residual stress is investigated. The output response, i.e., percentage reduction in surface roughness (%RSR_C) and residual stress (%RRS) after CA-BEMRF process is calculated by Eq (4) and (5), respectively.

$$\%RSR_C = \frac{\text{Surface Roughness after grinding process} - \text{Surface Roughness after CA} - \text{BEMRF process}}{\text{Surface Roughness after grinding process}} \times 100 \quad \text{(Eq 4)}$$

$$\%RRS = \frac{\text{Residual Stress after grinding process} - \text{Residual Stress after BEMRF process}}{\text{Residual Stress after grinding process}} \times 100 \quad \text{(Eq 5)}$$

Bold values indicate the highest percentage reduction in surface roughness after CA-BEMRF process is obtained at these parameters

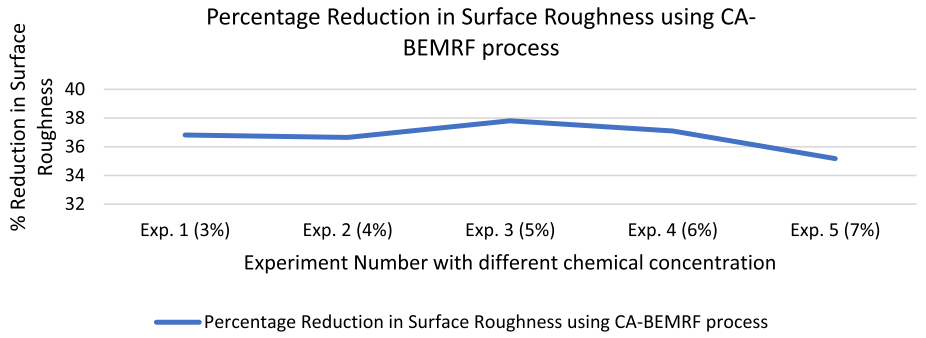

Fig. 3 Variation of percentage reduction in surface roughness using CA-BEMRF process

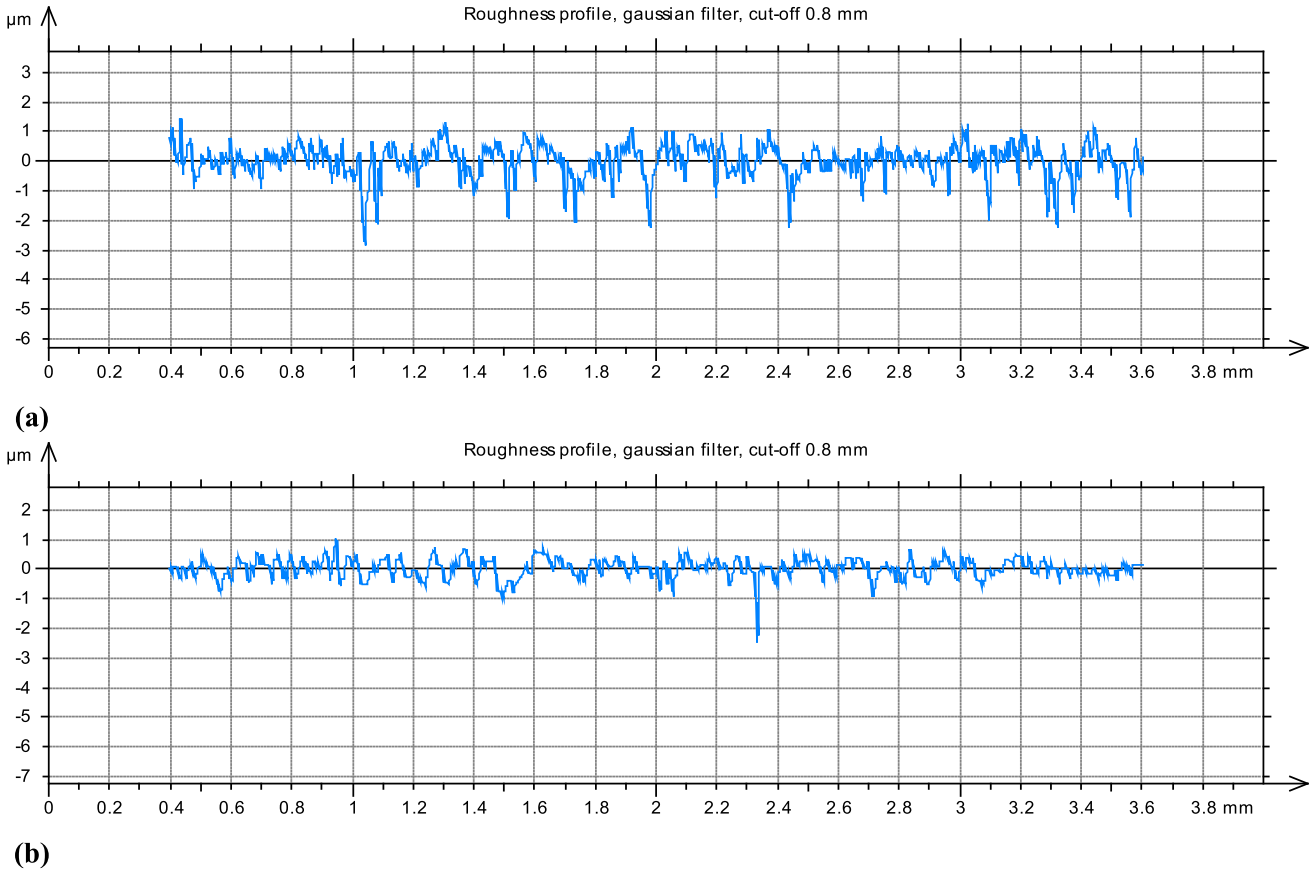

Fig. 4 (a) Roughness profile of Al 7075 workpiece surface after grinding (b) Roughness profile of Al 7075 workpiece surface after CA-BEMRF process at 5% chemical composition, 2.5A magnetizing current, 500 rpm rotational speed of tool and 1.5 mm working gap

It is observed from Fig. 3 that the highest $\%RSR_C$ is found to be 37.81% at 5% chemical composition, 2.5A magnetizing current, 500 rpm rotational speed of tool and 1.5 mm working gap using CA-BEMRF process. The roughness profile of Al 7075 alloy workpiece surface after grinding and after CA-BEMRF process is shown in Fig. 4(a) and (b), respectively. The surface roughness value of 410 nm obtained after grinding the workpiece surface was reduced to 255 nm using CA-BEMRF process.

Comparing the percentage reduction in surface roughness obtained after grinding process and the conduction of preliminary experiments using CA-BEMRF process, it is observed that the surface finish has improved using the assistance of chemical agent. Hence, 5 w/w% chemical composition of hydrogen peroxide was fixed for the detailed experiments.

5. Detailed Experiments

In this work, the experimentation for finishing of aluminum 7075 alloy workpiece is designed according to central composite design (CCD) technique using design of expert 6.0.7 software. A total of 20 experiments designed according to

V_M magnetizing current, T_R rotational speed of tool, W_X working gap, $\%RSR_C$ percentage reduction in surface roughness after CA-BEMRF and *%RRS* percentage reduction in residual stress after CA-BEMRF.

central composite design (CCD) technique are conducted through CA-BEMRF process by varying the input variables, viz. magnetizing current (V_M), Rotational Speed of Tool (T_R), Working gap (W_X) at five different levels as mentioned in Table 4. Each specimen is submerged in chemical agent for a period of 30 minutes to obtain a passive layer in the surface before the mechanical abrasion through MR fluid. Table 5 represents the result of percentage reduction in surface roughness and residual stress after CA-BEMRF process on Al 7075 workpiece.

5.1 Surface Roughness of Al 7075 After CA-BEMRF

A quadratic model was suggested by Design Expert 6.0.8 software for percentage reduction in surface roughness (%RSR$_C$) after CA-BEMRF having F-value of 20.12 and the corresponding p-value which is less than 0.0001. After excluding the non-significant parameters, an empirical relationship (Eq (6)) between the output response and the input process parameters after CA-BEMRF is acquired. With the prediction of the ideal values for the input process parameters, this equation may be used to achieve the maximum percentage reduction in surface roughness when CA-BEMRF of Al 7075 alloy.

$$\begin{aligned} \mathrm{RSR}_C = & 36.264 + 2.989 * V_M + 0.021 * T_R \\ & - 6.441 * W_X - 1.548 * T_R^2 + 1.887 * W_X^2 \\ & - 3.749 * V_M * T_R - 2.699 * T_R * W_X \end{aligned} \quad \text{(Eq 6)}$$

Figure 5(a) interaction graph between V_M and T_R on %RSR$_C$ demonstrates unmistakably that when V_M is maintained at the greatest levels of 3.5A, while T_R is kept at 500 rpm and W_X is maintained at 1.5 mm, %RSR$_C$ achieves a maximum value of 45.83%. This is because hydrogen peroxide used as a chemical agent which softens the surface of the aluminum workpiece and high finishing force is exerted due to increased magnetizing current resulting in better surface finish.

The combined effect of T_R and W_X on %RSR$_C$ as represented in Fig. 5(b) shows that %RSR$_C$ value reduced from 44.15 to 34.4% on increasing T_R from 300 to 700 rpm while keeping W_X at lowest level of 0.5 mm. It is also observed that %RSR$_C$ value decreased to 33.3% from 44.15% once the working gap is increased to the highest value of 2.5 mm, keeping rotational speed of tool constant at 300 rpm.

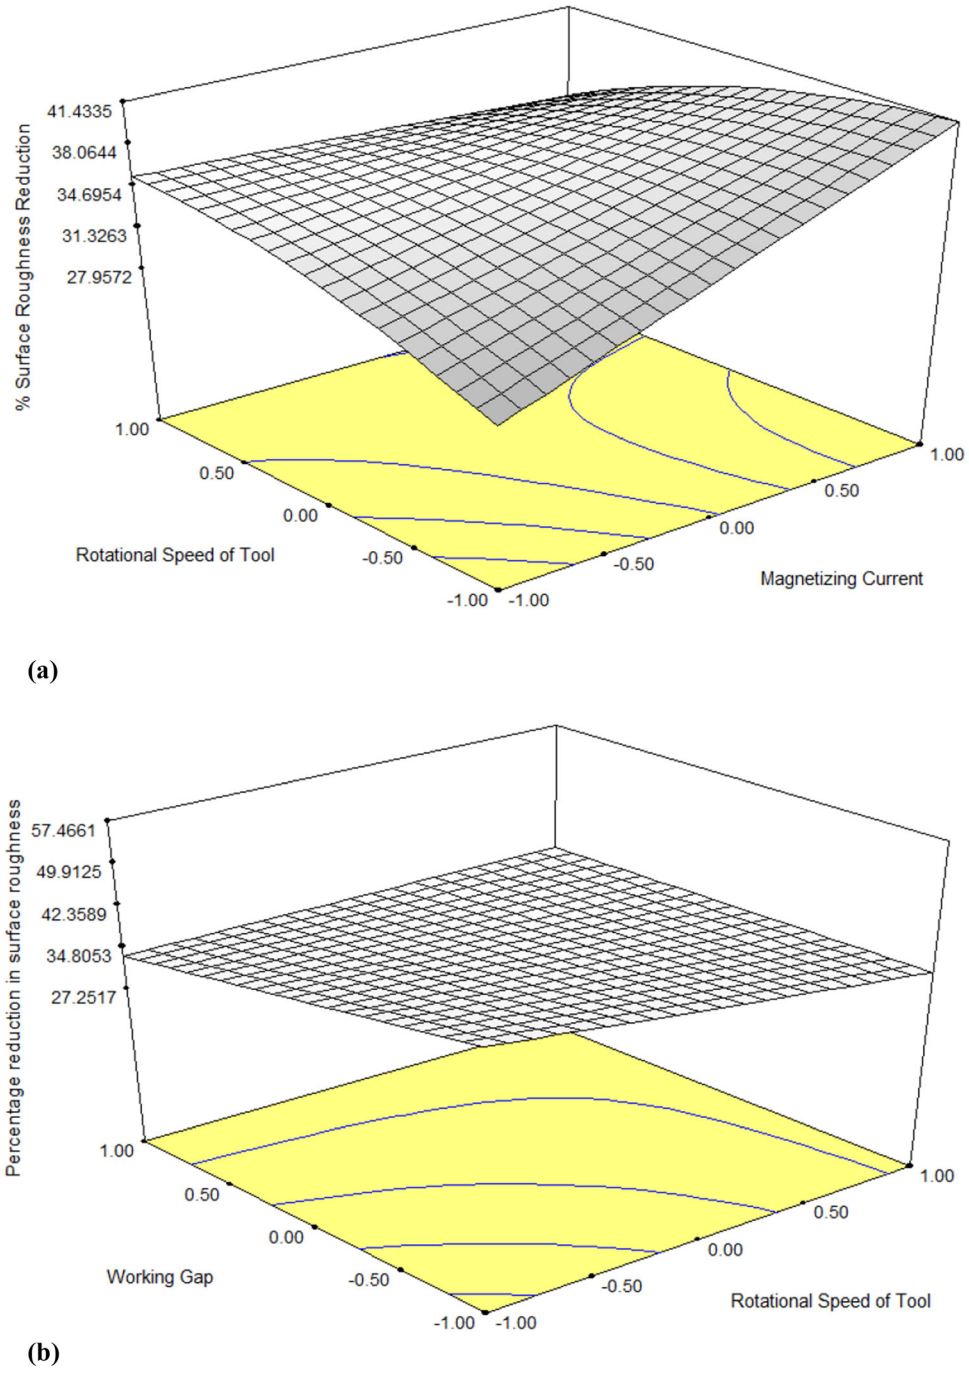

Fig. 5 (a) V_M & T_R interaction graph on percent %RSR$_C$, (b) Interaction graph of T_R & W_X on %RSR$_C$ (c) Individual effect of V_M on %RSR$_C$, (d) Individual effect of T_R on %RSR$_C$ and (e) Individual effect of W_X on %RSR$_C$

The individual effects of chemical concentration, magnetizing current, tool rotation speed, and working gap on %RSR$_C$ are each depicted in Fig. 5(c), (d) and (e), respectively. The individual effect plot had the same slant as the interaction graph and demonstrated that an increase in V_M raised the %RSR$_C$ while an increase in T_R and W_X decreased the %RSR$_C$ for the previously mentioned reasons. The graphs show that the conditions of 5w/w% chemical composition, 3.5A magnetizing current, 500 rpm rotational speed of the tool, and 1.5 mm working gap result in the highest percentage reduction in surface roughness value of 43.9%.

5.2 RESIDUAL Stress of Al 7075 After CA-BEMRF

The results of the percentage reduction in residual stress of Al 7075 alloy workpiece after finishing through CA-BEMRF is shown in Table 6. The quadratic model is significant, as evidenced by its F-value of 19.958 and matching p-value of less than 0.001. The anode used in our system is the workpiece. We carefully selected this anode to ensure optimal performance and accurate measurement outcomes. The computer, sensor unit, and power unit are the major three components of the machine. The system comprises of a 30-KV x-ray tube, a 2-D x-ray sensor, and a power supply unit to generate x-rays. One

reading of residual stress is taken by an x ray in 90 seconds. The machine features an air conditioning element that makes it very effective. The sample was 38 mm away from the x-ray focusing lens, and the X 93 ray tube current was 1 mA. The specimen to be studied was given information on its lattice constant, inter-planar spacing, and diffraction planes (h, k, and l), as well as its crystal structure, Poisson's ratio, and Young's modulus. The incidence angle for x-rays was fixed at 35 degrees. The x-ray machine required an AC supply with the specifications of 240 V and 50/60 Hz to function, although it could alternatively be powered by a battery-powered 24 V source. A unique air-cooling element that was included with the machine ensured its efficient operation. Between the sample and the machine's focusing lens, the incidence angle for x-rays striking the sample surface was adjusted at 35°. Lattice constant 2.86A; inter-planar distance 1.17 m; diffraction plane 2, 1, 1; diffraction angle156.390; crystal structure BCC; Poisson's ratio 0.28; the x-axis Cosα represents cos of azimuth angle of Debye sheerer ring and y-axis represents strain ($\varepsilon\alpha$1). The inclination angle of bend was measured as the residual stress. This selection is integral to achieving meaningful and accurate results in our experiments.

After removing the non-significant process factors, an empirical relationship (Eq (7)) is found between the output response and the input process parameters. By forecasting the ideal values of the input process parameters, this equation can be used to achieve the maximum decrease in residual stress during BEMRF of Al7075 material.

$$\%\text{RRS} = 63.782 + 4.418 * V_M - 3.926 * T_R - 9.727 * W_X - 6.079 * C^2 - 7.519 * T_R * W_X \quad \text{(Eq 7)}$$

After the initial grinding process a high level of residual stress of 46 MPa as induced in the workpiece surface as shown in Fig. 6. The residual stresses on the aluminum 7075 workpiece obtained after the CA-BEMRF process

are shown in Fig. 7 while the tool's rotating speed, working gap, and magnetizing current are maintained at 2.5 mm, 500 rpm, and 0.5 mm, respectively. Although there is a grain size effect in the residual stress before and after CA-BEMRF process, with the aforementioned parametric parameters, a residual stress reduction of up to 78.26% is achieved.

The combined effect of T_R and W_X on %RRS is shown in Fig. 8(a), and it demonstrates that when T_R is increased from 300 to 700 rpm while W_X is maintained at 2.5 mm, the value of %RRS decreases from 59.42 to 36.53%. Contrarily, when W_X was reduced from 2.5 to 0.5 mm and T_R remained constant at 700 rpm, the percentage of residual stress that was reduced dramatically increased to a high value of 71.02%. It was shown that the workpiece experiences shear and Hertzian stress as a result of vibrations with the abrasive particles when the tool's rotating speed increases while the working gap decreases.

The separate effects of V_M, T_R, and W_X on %RRS are depicted in Fig. 8(b), (c), and (d). As seen in Fig. 8(b), an increase in magnetizing current causes a greater percentage reduction in residual stress. The results show that %RRS increases from 59.36 to 68.2% on increasing V_M to 3.5A from 0.5A while keeping T_R and W_X constant at 500 rpm and 1.5 mm, respectively. The individual effect plot, which had the same slant as the interaction graph of T_R and W_X, indicated that increasing T_R and W_X decreases the %RRS.

The plastic deformation occurs at the point of maximum shear stress and thus, since layers below the surface elongate more, the maximum residual stress is observed below the surface. In this case, however, other parameters which are proportional to plastic deformation would be expected to exhibit a maximum at the same depth as the residual stresses.

An alternative explanation is as follows. If the layers near the surface slip with respect to each other because of the high intensity of the operation, i.e., there is unconstrained flow which decreases with depth, the residual stresses will exhibit a maximum value below the surface. With the maximum total plastic deformation occurring at the surface. The depth at which the residual stress is maximum is the depth at which maximum constrained plastic flow occurs.

6. Output Response Optimization

A desirability function approach was presented by Derringer (Ref 25) and used to optimize the response to the output i.e., percentage surface roughness reduction and percentage reduction in residual stress after CA-BEMRF (%SRR$_C$). This method assigns a dimensionless desirability value to the measured features of each expected response where d varies between 0 and 1. According to Montgomery (Ref 26), if the desirability function reaches a value of 0, it denotes an undesired response, and if it reaches a value of 1, the response is exactly what was intended. The value of d increases in direct proportion to how desirable the associated response is. The greater the scenario examined in the current work, the better the percentage reduction in surface roughness. The response is converted into a dimensionless function di using Eq (8) shown as follows:

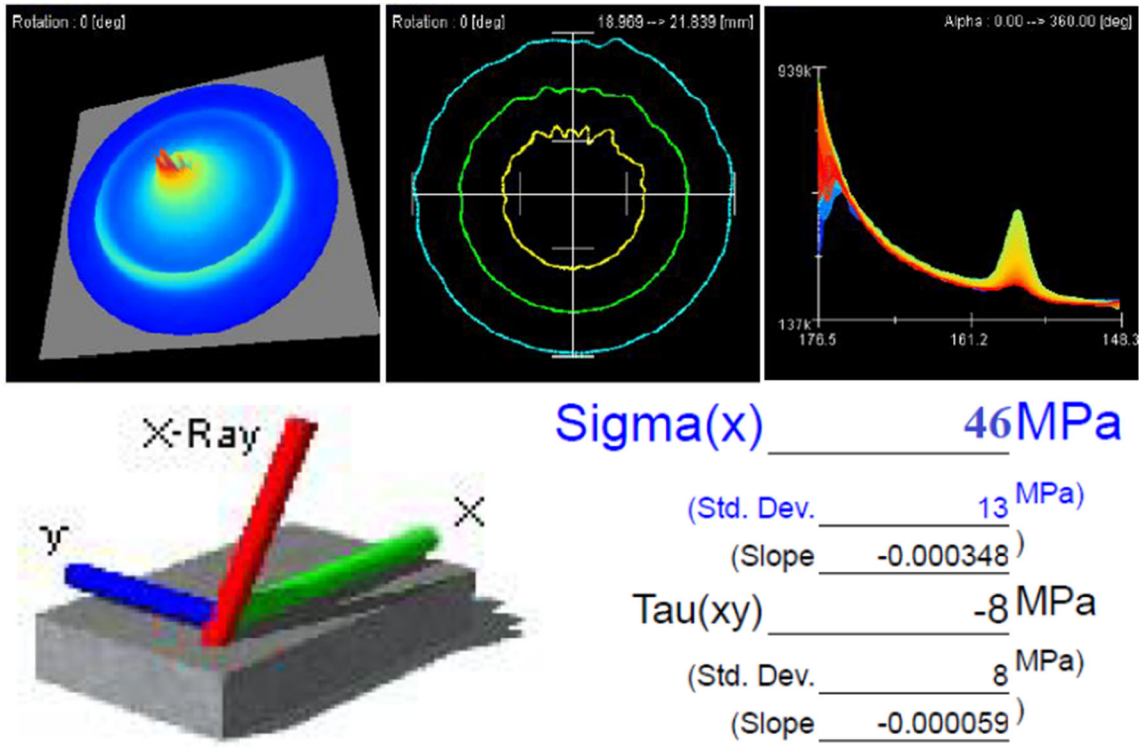

Fig. 6 Residual stress on aluminum 7075 workpiece after grinding process

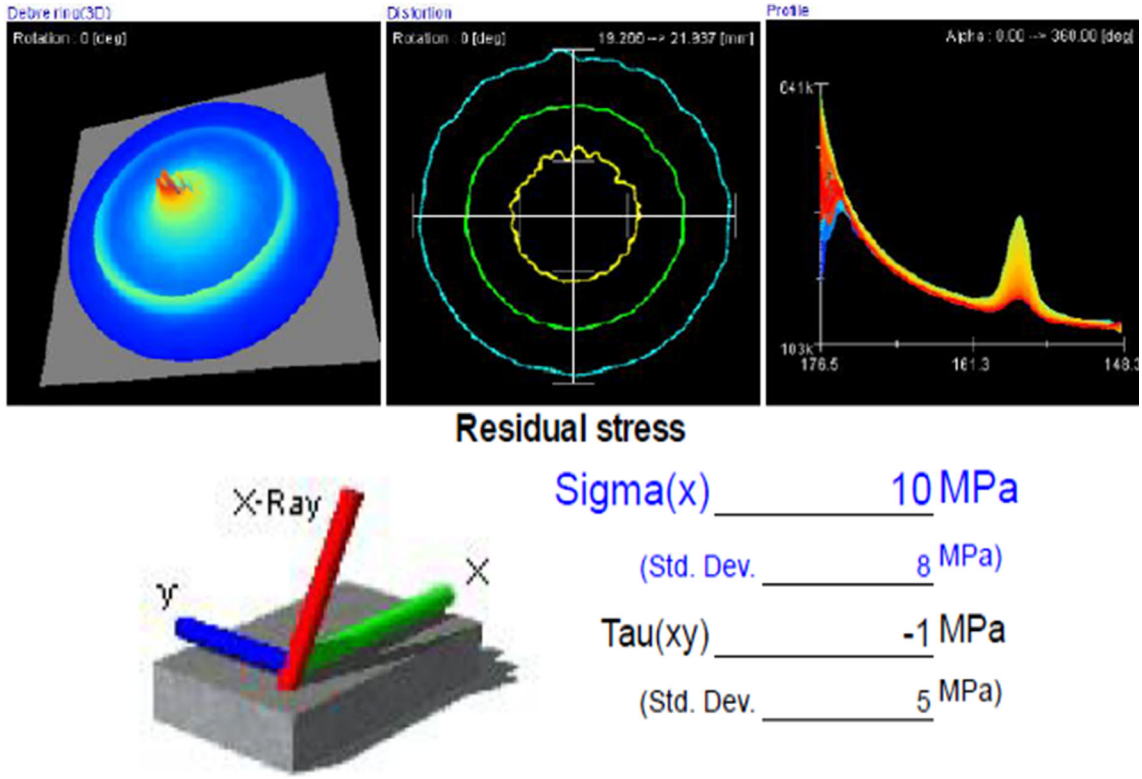

Fig. 7 Residual stress on aluminum 7075 workpiece after CA-BEMRF process

$$d_i = \begin{cases} 0 & Xi < Bi \\ (Xi - Bi/Hi - Bi)^{w} & Bi \le Mi \le Hi \\ 1 & Bi > Hi \end{cases} \quad \text{(Eq 8)}$$

where Bi = Lower response limit, Mi = Upper response limit, Hi = Response goal value. B and M are selected in RSM according to the mathematical.

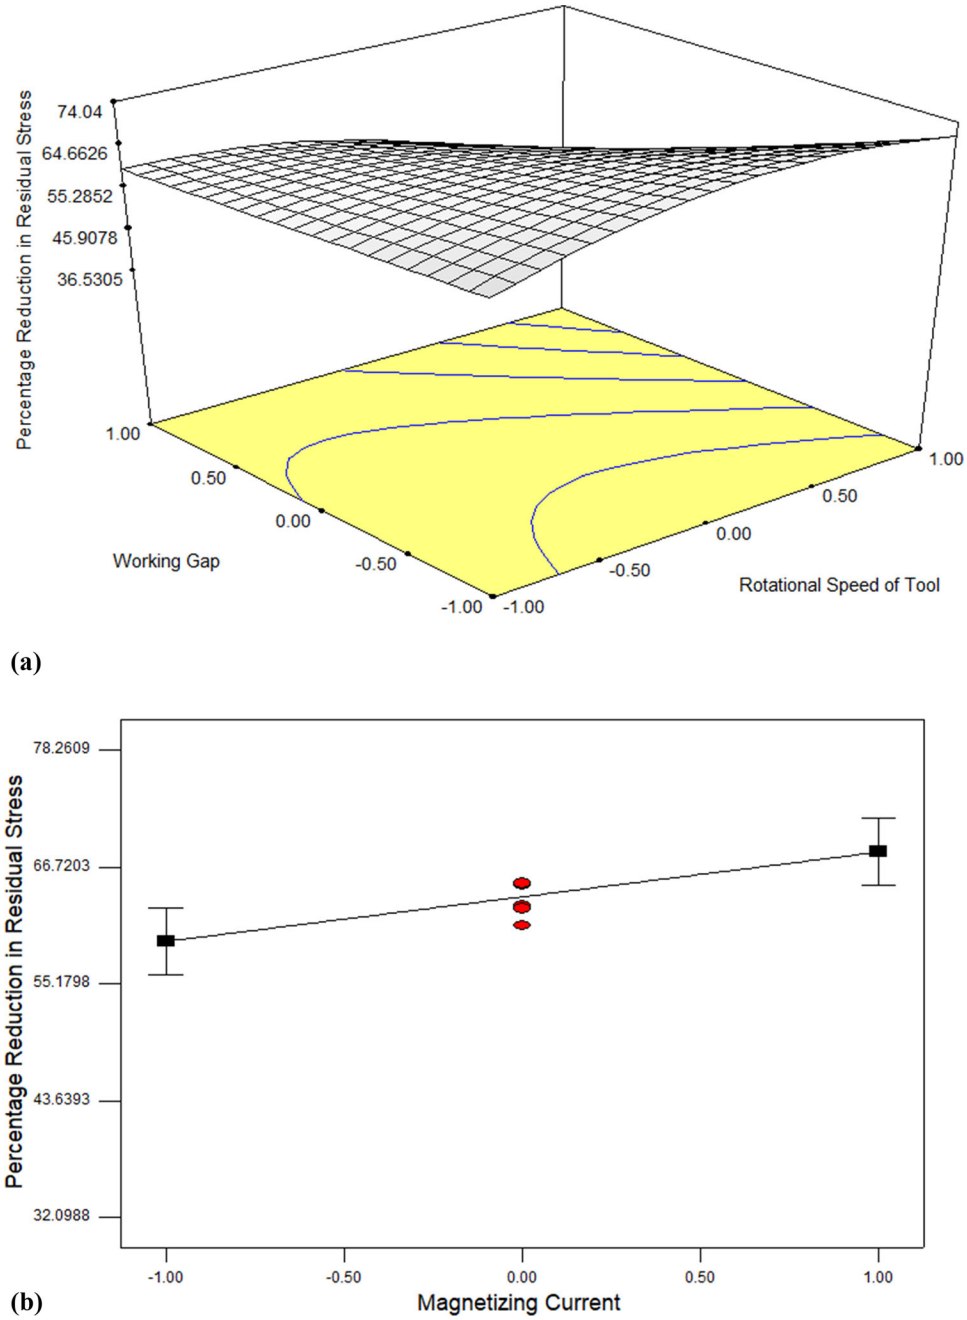

Fig. 8 (a) Interaction graph of T_R and W_X on %RRS, (b) Individual effect of V_M on %RRS, (c) Individual effect of T_R on %RRS and (d) Individual effect of W_X on %RRS

Determining the desirability response value and optimizing the desirability function to find the best potential response value are the first two steps in optimization.

Design Expert 6.0.8 software has been used to perform response optimization. Table 6 shows the 10 best solutions obtained using the desirability method. The highest desirability value obtained is 1, which means that when finishing Al 7075, the maximum percentage reduction in surface roughness and residual stress through CA-BEMRF process can be obtained at V_M = 2.3A, T_R = 550 rpm and W_X = 0.5 mm.

A confirmation experiment was performed for solutions no. 1 and 2 to verify the above solutions. Table 7 summary of the findings from the confirmatory experiments shows that the error was less than 1.5%. These findings support the high repeatability of the beneficial optimization-derived solutions.

7. Surface Topography of Machined Surface

Scanning electron micrograph (SEM) of aluminum 7075 alloy workpiece surface after grinding process and CA-BEMRF process is shown in Fig. 9(a) and (b), respectively.

The lays are visible clearly on the workpiece surface due to the pre-finishing technique i.e., grinding process as shown in Fig. 9(a). It is observed from Fig. 9(b) that more uniform and improved surface finish with very fewer grinding marks is

Table 7 Confirmatory experiments

obtained after CA-BEMRF of the workpiece. When finished with the assistance of chemical agent hydrogen peroxide, percentage reduction in surface roughness increased to 57.32% leading to an improved surface finish as shown in Fig. 9(b). This finish was obtained at 5w/w% chemical composition, 2.5A magnetizing current, 500 rpm rotational speed of tool and 0.5 mm working gap during CA-BEMRF process.

8. Conclusion

This study investigates how to reduce surface roughness and residual stress on the surface of an Al 7075 workpiece caused by grinding by employing the CA-BEMRF technique, which combines mechanical and chemical processes. The effects of input constraints, such as magnetizing current, tool rotation, and working gap, were studied on percentage surface roughness reduction and percentage reduction in residual stress. Additionally, the impact of chemical composition on the percentage reduction in surface roughness reduction after the CA-BEMRF process ($\%SRR_C$) was investigated. With design expert software, the optimization of the percentage reduction in surface roughness was carried out using the desirability technique. The following conclusions are drawn from this investigation.

- The experiments have been conducted on aluminum 7075 alloy workpiece with CA-BEMRF process.
- The CA-BEMRF process was able to provide a better surface finish and reduced residual stresses.
- The residual stress induced by the grinding process was significantly reduced by using CA-BEMRF process.
- Experimental results showed that the average percentage reduction in surface roughness of 38.19% was achieved when Al 7075 alloy workpiece was finished using CA-BEMRF process.
- The results of the confirmatory experiments conducted were found very close to the predicted outcome with a maximum of − 1.24% error.
- The study also provides a set of optimized parameters for CA-BEMRF process to achieve high level surface finish and minimum residual stress for Al 7075 alloy workpiece.
- The study found that the chemical-assisted BEMRF process produced a significantly smooth and more consistent surface finish on the aluminum alloy.
- SEM images of the finished workpieces showed an improved surface finish after CA-BEMRF process.

Abstract

Using the traditional solid-state reaction approach, Dy^{3+} ions doped $KCa(PO_3)_3$ phosphors have been synthesized to investigate their luminescent properties to produce high-quality white light for solid-state lighting applications, particularly in white LEDs. x-ray diffraction (XRD) patterns were used to examine the structure and phase of the phosphors. Using scanning electron microscopy (SEM), the morphology of the as-synthesized phosphor has been investigated. Fourier transform infrared spectroscopy (FT-IR) has been used to investigate several vibrational bands seen in the phosphor. Using diffuse reflectance spectra (DRS), the as-synthesized phosphors' optical band gap values have been estimated. When Dy^{3+} ions are excited at 350 nm, the photoluminescence (PL) spectra characteristics observed for the activated $KCa(PO_3)_3$ phosphor show strong white area emission due to both 575 nm, which is related to the $^4F_{9/2} \rightarrow {}^6H_{13/2}$ and 482 nm that is ascribed to $^4F_{9/2} \rightarrow {}^6H_{15/2}$ transition of Dy^{3+} ions. Additionally, the concentration quenching of Dy^{3+} ions doped at 4 mol% is seen in the PL spectra. Based on the observed PL spectra, the computed CIE chromaticity coordinates for the optimised $KCa(PO_3)_3$ phosphors are located in the deep white area. The lifespan of the as-titled phosphors decreases as the amount of Dy^{3+} ions increases in the host lattice. Additionally, the PL decay profiles shows a dual exponential behaviour when excited at 350 nm, with an emission wavelength at 575 nm. The lifetime values were used to calculate the quantum efficiency of the as prepared phosphors. On the basis of the results of the aforementioned studies, we wish to project Dy^{3+} ion doped $KCa(PO_3)_3$ phosphors as white light generating materials in w-LEDs and for other photonic applications.

1. Introduction

Phosphors are widely used in solid-state lighting, display devices, and anti-counterfeiting applications [1, 2]. White light-emitting diodes (w- LEDs) have gained popularity in recent years due to their low power consumption and environmental benefits. They are expected to replace traditional light sources such as tungsten halogen lamps and incandescent lamps. LEDs have a significantly longer lifespan when compared to other lighting technologies like Low-Pressure Sodium (LPS) and fluorescent lights. The longevity of LEDs far surpasses that of incandescent lights. The latest LED lights can last for over 50,000 to 100,000 h or more. In contrast, incandescent bulbs have a lifespan that is only 1%–5% as long at best, lasting for approximately 1,200 h. The additional features of these properties include a broad spectrum of colors that span from ultraviolet to infrared, a limited spectral bandwidth, a high degree of luminous efficiency, and an extremely rapid response time [3, 4]. The most common method for creating white LEDs is to combine phosphors with UV or n-UV chips made of InGaN. The development process of the standard LED involves three crucial steps: seasoning, selection, and certification. These steps are meticulously carried out to ensure the optimal performance of the w-LED [5–7]. During seasoning, the LED is subjected to a series of tests to stabilize its electrical and thermal properties. The

© 2024 IOP Publishing Ltd

selection process involves choosing the most suitable w-LED based on its characteristics and performance. Finally, the certified LED undergoes rigorous testing to ensure its compliance with industry standards and specifications. Generally, phosphors consist of an activator, a host material, and sometimes a sensitizer. Rare earth or metals are often used as activator ions for doping. Red, green, blue, and white light can be produced by doping one or more rare earth (RE) ions in an appropriate single matrix. Selecting a suitable substrate material is crucial for obtaining energy-efficient phosphors [1].

Phosphates are crucial luminescent materials that offer various crystal-field environments for emission centers. Phosphates doped with rare-earth-elements (REEs) are thermally stable and have a rigid tetrahedral matrix that is ideal for charge stabilization. Moreover, they are excellent host materials for producing phosphors as they require low sintering temperatures [8]. Researchers have recently explored alkali and alkaline-earth-metal phosphate phosphors to develop new materials for UV-based w-LEDs. Many studies have focused on $AB(PO_3)_3$ phosphates, with A representing monovalent cations (Li^+, Na^+, K^+, and Cs^+) and B representing divalent cations (Ca^{2+}, Sr^{2+}, and Ba^{2+}) [9, 10]. These phosphates have efficient thermal and hydrolytic stabilities, making them ideal host materials for w-LEDs.

$KCa(PO_3)_3$ has a unique structure comprising of twisted polyphosphate rings forming a cyclic anion $(P_{12}O_{36})^{12-}$, where non-bridging oxygen atoms point toward the center [11, 12]. This structure creates a distorted octahedral coordination environment for the central potassium ions and distorted octahedral cavities for calcium ions between the rings. $KCa(PO_3)_3$ possesses desirable properties such as low phonon energy, high optical damage threshold, good charge stabilization, and chemical stability, making it a suitable host material for lanthanide activators [13]. Additionally, $KCa(PO_3)_3$ exhibits transparency in the spectra range of interest and low sintering temperature. Ca-based phosphate compounds are of interest to researchers due to their significant UV absorption and serving as an important host for luminescence [14].

Dysprosium (Dy^{3+}) doped luminescence materials have been gaining increasing attention for their superior white emissions [15, 16]. When incorporated in various host matrices, Dy^{3+} ion is known to display two prominent emission bands in its spectra. The first band corresponds to the pseudo-quadrupole transition $^4F_{9/2} \rightarrow {}^6H_{13/2}$, which involves a change in both ($\Delta L = 2$) and ($\Delta J = 2$). This transition occurs at a wavelength of 576 nm and is characterized by a yellow emission color, while the second band is associated with the transition $^4F_{9/2} \rightarrow {}^6H_{15/2}$ at 478 nm (blue) [17, 18]. One can achieve almost white emission using Dy^{3+} doped luminescent materials by manipulating the yellow-bluish intensity ratio (Y/B). Therefore, Dy^{3+-} -activated phosphors have emerged as a promising option for developing white light [2, 19]. Researchers have found that Dy^{3+}-activated phosphors offer advantages over other options in terms of their ability to produce white light. Therefore, they are considered a strong candidate for use in a variety of applications.

In our work, we have synthesized a series of polyphosphates, or $KCa(PO_3)_3$, (KCP) doped with Dy^{3+} phosphors. This study examines the structural and luminescent properties of KCP: Dy^{3+} phosphors, emphasizing the analysis of the concentration quenching mechanism, luminescence decay characteristics, and color perception. The ultimate goal of this study was to achieve white light emission through the utilization of the prepared phosphors. The results of this examination hold great potential for making significant advancements in the field of materials science.

2. Experiment section

2.1. Sample preparation

A series of Dy^{3+} doped phosphors $KCa(PO_3)_3$ at different concentrations of Dy^{3+} ions (i.e. 1.0, 2.0, 3.0, 4.0, and 5.0 mol%) was prepared via solid-state reaction technique using K_2CO_3(99%, Fisher Scientific), $CaCO_3$(98.0%–100.5%, Fisher Scientific), $NH_4H_2PO_4$(99%, Fisher Scientific), and Dy_2O_3(99.98%, Thermo Scientific) as raw materials. After mixing the raw materials in a stoichiometric ratio with acetone for 1 hour in an agate mortar, the powder was then transferred into the alumina crucible. The resulting powder was heat-treated at 673 K for 3 hours in the furnace to eliminate carbonates. And then, the powder was sintered at 873 K for 5 hours in an air atmosphere. Finally, the powder was ground again in an agate mortar into a fine powder for further characterization.

2.2. Experimental techniques

Using the Bruker Model D8 Advance equipment, which was built to produce nickel-filtered Cu-Kα radiation (0.154 nm), the XRD spectra of the prepared materials was observed in the 2θ range of 20° to 80°. Using a JEOL 7610 F Plus SEM machine, surface morphology was recorded. An un-doped phosphor's FT-IR spectrum was captured with a Perkin-Elmer Frontier FT-IR spectrometer, ranging from 400 to 4000 cm^{-1}. DRS was obtained for the Dy^{3+}-doped phosphors in the 200–1400 nm wavelength range using a JASCO model V-923 UV–Vis–NIR spectrophotometer. A JASCO FP-8300 spectrofluorometer with a resolution of 0.1 nm was used to capture

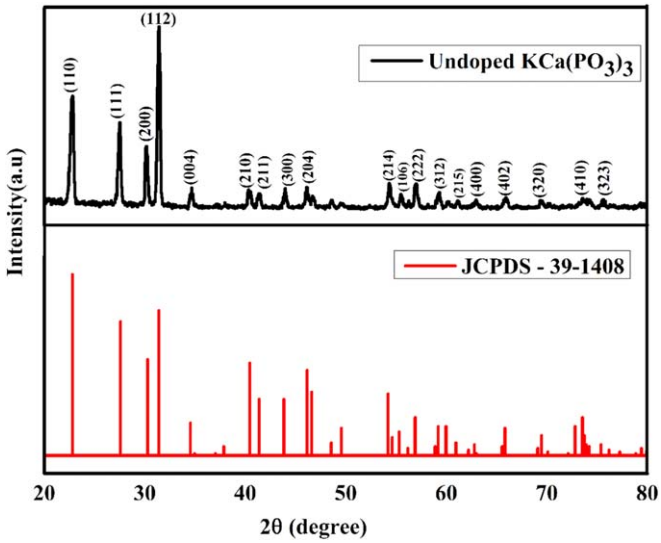

Figure 1. XRD pattern of un-doped $KCa(PO_3)_3$ phosphor along with standard diffraction pattern (JCPDS) 39–1408.

the PL excitation and emission spectra for each Dy^{3+}-ion doped phosphors under a Xenon excitation source. Luminescent decay curves were measured using an Edinburgh FL920 Fluorescence Spectrometer. Each measurement was carried out at room temperature.

3. Results and discussions

3.1. X-ray diffraction (XRD) analysis

The crystallographic arrangement and phase purity of the un-doped $KCa(PO_3)_3$ phosphors were examined using XRD patterns. The hexagonal crystal structure $KCa(PO_3)_3$ (JCPDS No. 39–1408) is a member of the P-6c2 (188) space group. Every diffraction peak is precisely matched to the JCPDS 39–1408 standard card's peaks as shown in figure 1. With the lattice coordinates a = 6.8077 Å, b = 6.8077 Å, and c = 10.3730 Å as well as $\alpha = 90°$, $\beta = 90°$, and $\gamma = 120°$, it suggests the samples are in single-phase. The XRD patterns of the phosphor $KCa(PO_3)_3$ that were in line with the previously described JCPDS database showed that the phosphors had been successfully synthesized with a high level of purity. The addition of Dy^{3+} ions, demonstrates that the synthesized phosphors are devoid of any contaminating phases. One K site and one Ca site were present in the $KCa(PO_3)_3$ host and they both shared the six-fold coordination [20, 21]. Due to the similarity in their ionic radii Ca^{2+}(radii = 1.00 Å) and Dy^{3+}(radii = 0.908 Å), the Dy^{3+} ions chose to occupy the Ca^{2+} site when incorporated into the host, $KCa(PO_3)_3$. The as-titled phosphors exhibit strong and distinct diffraction peaks, indicating their high crystallinity—a prerequisite for comparatively superior luminosity.

3.2. Morphological analysis from SEM

The morphology and particle size information of the prepared phosphors is better understood by examining FE-SEM pictures of an undoped and 4.0 mol% doped $KCa(PO_3)_3$ phosphor. $KCa(PO_3)_3$ powder phosphors have an uneven polyhedron shape and unequal particle size [22], as shown in figures 2(a), (b). The high-temperature reaction method and manual grinding have also resulted in very low agglomeration of some phosphor particles. Most of the phosphor particles available in the market today are between 2 and 10 μm in size. The ImageJ Software is used to find the size of the particle for an un-doped and 4.0 mol% of Dy^{3+} ions doped $KCa(PO_3)_3$ phosphor. The sizes fall in the region of 3–5 μm [18]. As a result ofthe samples' particle sizes being in the micrometer range, these materials can be aptly used for coating white LEDs and display devices [23]. Furthermore, energy dispersive x-ray analysis (EDX) has been used to analyze the elemental makeup of the as-synthesized phosphors. The EDX for the doped $KCa(PO_3)_3$: 4 mol% Dy^{3+} doped phosphor is presented in figure 3. Every precursor elements is visible in the phosphor lattice, according to the EDX picture.

3.3. FT-IR analysis

Vibrational spectroscopy (FT-IR) was conducted to investigate the bonding properties of un-doped $KCa(PO_3)_3$ phosphor. The vibrational spectrum of the prepared phosphor shown in figure 4 was recorded from 400 cm^{-1} to 4000 cm^{-1}, which exhibited multi-vibrational bands. The spectrum showed bands at 493, 764, 1038, 1105, 1251,

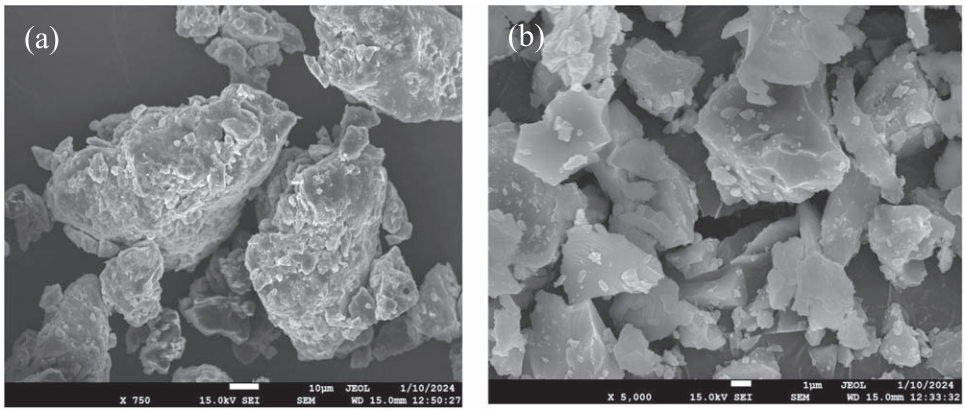

Figure 2. SEM image recorded For (a) an un-doped (b) 4.0 mol% of Dy^{3+} ion doped $KCa(PO_3)_3$.

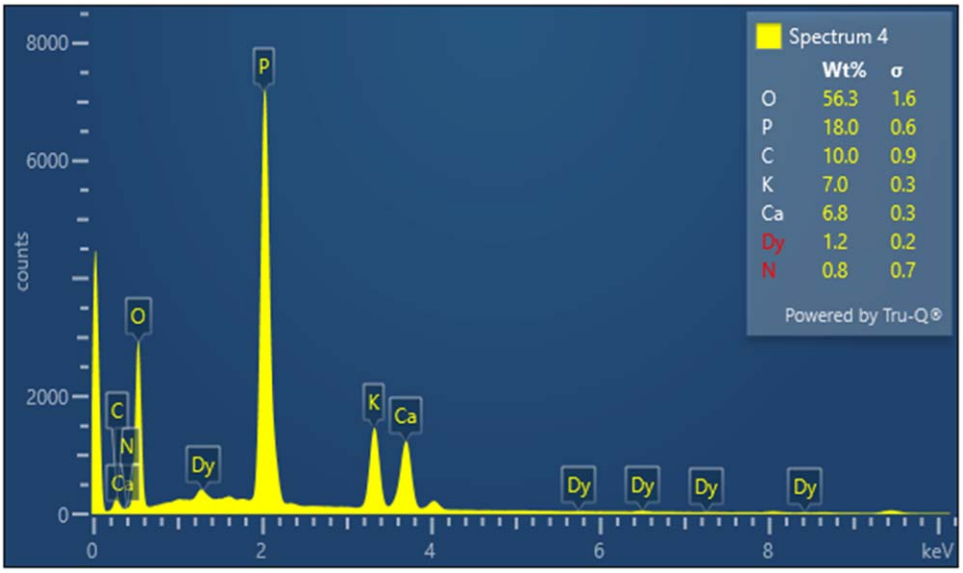

Figure 3. EDX image ofof $KCa(PO_3)_3$: xDy^{3+} (x = 4 mol%) phosphor.

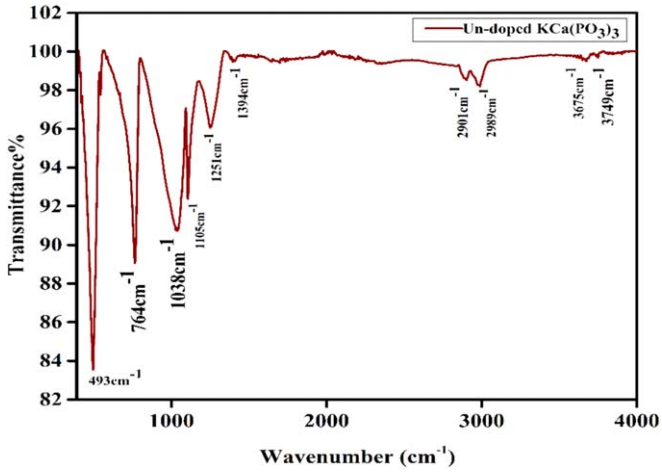

Figure 4. FT-IR spectrum of un-doped $KCa(PO_3)_3$ phosphor.

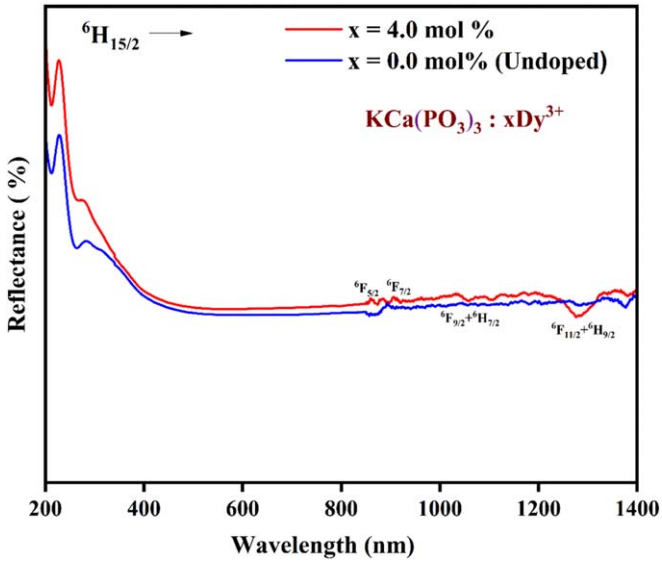

Figure 5. Diffuse reflectance spectra of undoped and $KCa(PO_3)_3$: xDy^{3+} (x = 4 mol%) phosphor.

1394, 2901, 2989, 3675, and 3749 cm^{-1}. The stretching vibrations of the PO_2 were recorded in the 1000–1200 cm^{-1} and 1200–1400 cm^{-1} ranges, for the symmetric and asymmetric stretching, respectively, while the bending vibrations were detected in the range of 400–550 cm^{-1}. The vibrations of the P-O-P oxygen bridges were detected in the region of asymmetric mode (1000–1050 cm^{-1}) and symmetric mode (600–800 cm^{-1}) [21].

The measured FT-IR spectra matched well with the theoretical considerations presented earlier. The observed bending vibrational wavenumbers correspond to specific normal modes, with the asymmetric stretching (O-P-O) showing a strong vibration at 1251 cm^{-1} and the symmetric stretching (O-P-O) exhibiting a very strong vibration at 1105 cm^{-1}. Similarly, the asymmetric stretching (P-O-P) showed a very strong vibration at 1038 cm^{-1}, and the symmetric stretching (P-O-P) had a strong vibration at 764 cm^{-1}. The antisymmetric stretching of bonded water molecules and the presence of hydroxyl radicals were indicated by the peaks observed at 2901 cm^{-1} and 2989 cm^{-1}, respectively. The band observed at 3675 cm^{-1} was responsible for the stretching peak of the hydroxyl group [23]. The multi-component patterns of these spectra showed the same number of bands as those reported in previous works for ABP_3O_9-type compounds.

3.4. Diffuse reflectance spectra (DRS) analysis

Phosphors utilized in w-LEDs have an optical band gap (E_g), a crucial parameter. The DRS of undoped and KCP:xDy^{3+}, x = 4 mol% is shown in figure 5 between 200 and 1400 nm range [24]. The DRS spectral data were converted into the Kubelka–Munk function, and the optical band gap was then calculated using the following equation [25].

$$F(R) = \frac{1 - R^2}{2R} = \frac{\alpha}{S} \tag{1}$$

Here, R stands for sample reflectance, S for scattering coefficient, and α for absorption coefficient. The equation shows the following relationship between energy bandgap (E_g) and absorption coefficient (α).

$$\alpha h\nu = C(h\nu - E_g)^n \tag{2}$$

Here, n can have values of 2 or 1/2, corresponding to indirect and direct transitions, respectively, depending on the kind of transition. C is an energy-independent constant (in the current case, = 1). The unit of photon energy is hν. Since α is exactly proportional to F(R), the above equation can be expressed in this way:

$$F(R)h\nu = C(h\nu - E_g)^n \tag{3}$$

To determine the band gap for the KCP:Dy^{3+} phosphor, a tauc plot was created b/w hν and $[F(R)h\nu]^{1/2}$ [24]. The optical band gap (E_g) can be derived by extrapolating the linear portion of the plot. The plot is shown in figure 6 and the calculated E_g values for undoped and optimised KCP phosphors are 4.60 and 4.49 eV respectively.

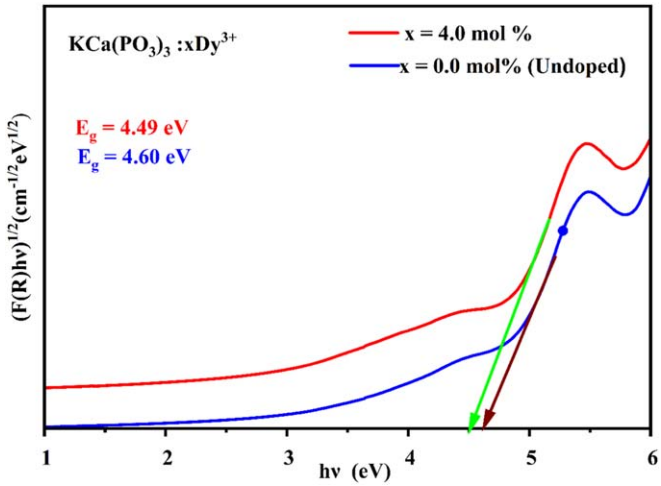

Figure 6. Tauc plot for direct optical band gap of undoped and $KCa(PO_3)_3$: xDy^{3+} (x = 4 mol%) phosphor.

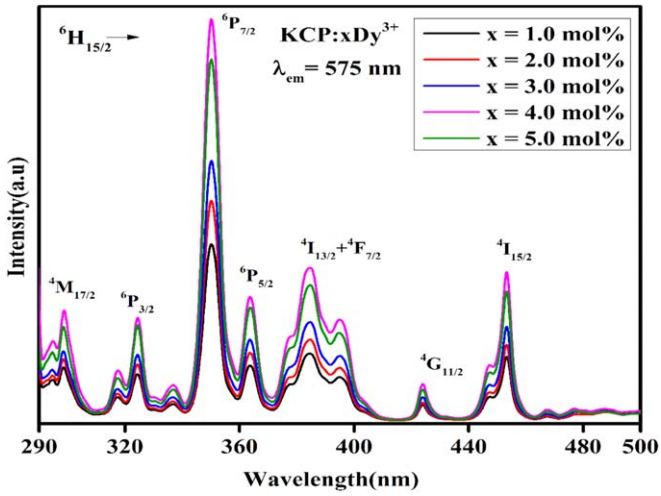

Figure 7. Excitation spectra of Dy^{3+} ions doped $KCa(PO_3)_3$ phosphors under 575 nm emission wavelength.

3.5. Photoluminescence spectral analysis (PL) of $KCa(PO_3)_3$

3.5.1. Excitation spectra

The excitation spectra of KCP: xDy^{3+} (x = 1, 2, 3, 4, 5 mol%) phosphors were shown in figure 7. Several sharp excitation peaks have been detected within a specific range of wavelengths (290–500 nm). There are 5 primary peaks of the excitation spectra that are caused by the f-f electronic transitions of Dy^{3+} ions, with the maximum excitation wavelength situated at 350 nm. The electronic transitions responsible for these peaks are $^6H_{15/2}$ to $^4M_{17/2}$ [298 nm], ($^6P_{3/2}$) [324 nm], $^6P_{7/2}$ [350 nm], $^6P_{5/2}$[364 nm], ($^4I_{13/2}$+$^4F_{7/2}$) [386 nm], and $^4I_{15/2}$[453 nm] [26]. The KCP: Dy^{3+} phosphor is suitable for excitation by near-UV LEDs, as indicated by the main excitation bands at 350–400 nm [27].

3.5.2. Emission spectra

The emission spectra of KCP: xDy^{3+} (x = 1, 2, 3, 4, 5 mol%) shown in figure 8 were examined under 350 nm excitation. We found that the emission shape and position didn't change significantly with the increase in the concentration of Dy^{3+} doping, except for the emission intensity. The spectra shows two strong characteristic peaks; at 482 nm corresponding to blue emission and 575 nm corresponding to yellow emission, which were attributed to the transition from $^4F_{9/2}$ to $^6H_{15/2}$ and $^6H_{13/2}$, respectively and weak peaks observed at 665 nm (red emission) ascribed the transition $^4F_{9/2}$ to $^6H_{11/2}$. Our observations suggest that the optical characteristics of KCP: Dy^{3+} are directly impacted by the configuration of the host material in which they are embedded. When the Dy^{3+} ion is positioned at a site with high symmetry, i.e. a site that has an inversion center, the yellow emission

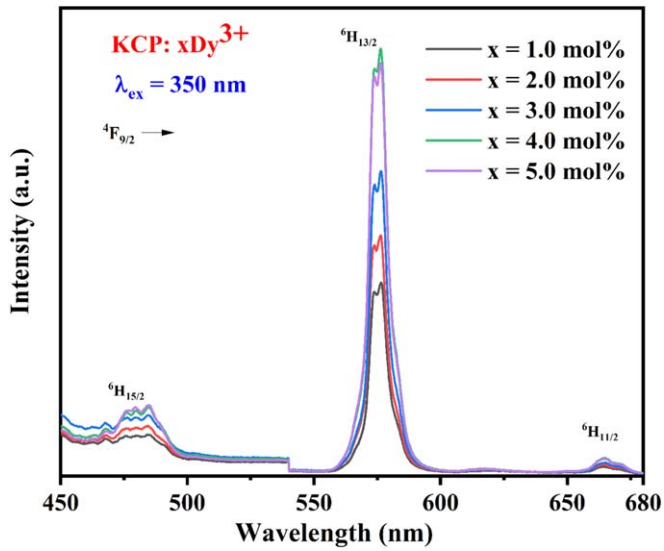

Figure 8. Emission spectra of Dy^{3+} ions doped $KCa(PO_3)_3$ phosphors under 350 nm excitation wavelength.

is the predominant outcome. However, when the Dy^{3+} ion is positioned at a position without a center of symmetry, which is typically a site exhibiting low symmetry, its emission intensity is observed to be considerably amplified [28]. The emission of yellow light with a wavelength of 575 nm ($^4F_{9/2}$-$^6H_{13/2}$) is a result of a forced dipole transition (electric transition). This type of transition happens only at low symmetries without an inversion center. The intensity of this emission is highly dependent on the crystal-field environment. We found that its intensity increases immensely as a function of Dy^{3+} concentration. The blue band's intensity corresponding to the 482 nm ($^4F_{9/2}\rightarrow{}^6H_{15/2}$) dipole transition, (which refers to the change in the magnetic moment during a transition between energy levels), is known to exhibit a relatively low sensitivity to the effects of crystal fields. The analysis of emission spectra suggests that the concentration of Dy^{3+} has a significant impact on the intensity of the blue transition $^4F_{9/2}\rightarrow{}^6H_{15/2}$. Specifically, an increase in Dy^{3+} concentration up to 4% results in increased emission intensity. But beyond this concentration, there is a discernible drop in emission intensity. The strength of the $^4I_{13/2}\rightarrow{}^6H_{15/2}$, $^4I_{15/2}\rightarrow{}^6H_{15/2}$, and $^4F_{9/2}\rightarrow{}^6H_{11/2}$ transitions, however, rapidly dropped as the concentration of Dy^{3+} increased [29–31]. The observed evolution is a result of the concentration quenching phenomenon and the impact of population on the $^4I_{15/2}$ and $^4I_{13/2}$ energy levels. The amplified resonant energy transfer from the excited energy state to the low energy or ground state ($^4F_{9/2}\rightarrow{}^6H_{15/2}$) of the nearby Dy^{3+} ion, as well as the cross-relaxation phenomenon between the excited Dy^{3+} ion (donor) and the ground Dy^{3+} ion (acceptor), are responsible for the increase in quenching intensities with increasing Dy^{3+} ion concentration.

At 4 mol% concentration of Dy^{3+}, concentration quenching occurred. However, when the concentration of these ions becomes too high, the possibility of energy transfer between ions rises. As a result, more excitation energy is transferred via non-radiative processes, resulting in decreased luminescence efficacy. To examine the energy transmission mechanism between Dy^{3+} ions, we computed the critical distance. The Blasse theory equation may be used to determine the critical radius distance R_c [23, 32].

The Blasse equation is:

$$R_c \approx 2\left[\frac{3V}{4\pi X_c N}\right]^{\frac{1}{3}} \tag{4}$$

Where N is the number of cations per unit cell (N = 2), X_c is the threshold concentration of Dy^{3+} ($X_C = 0.04$), and V is the volume per unit cell ($V = 416.33^{*}10^4$ Å).

The critical distance (R_c) between activator ions in $KCa(PO_3)_3$:xDy^{3+} was 21.50 Å, indicating that non-radiative energy transfer predominantly occurs through exchange contacts or multilayer interactions. For energy transfer to occur, the activator and sensitizer need to be positioned close to each other within the lattice. Additionally, there should be significant overlap in their wave functions, which allows for electron exchange to take place. The critical distance for this exchange is less than 5 Å, but the calculated R_c values were much higher, indicating that energy transfer between Dy^{3+}-Dy^{3+} ions in $KCa(PO_3)_3$:xDy^{3+} happens through multilevel interactions. According to the Dexter theoretical model:

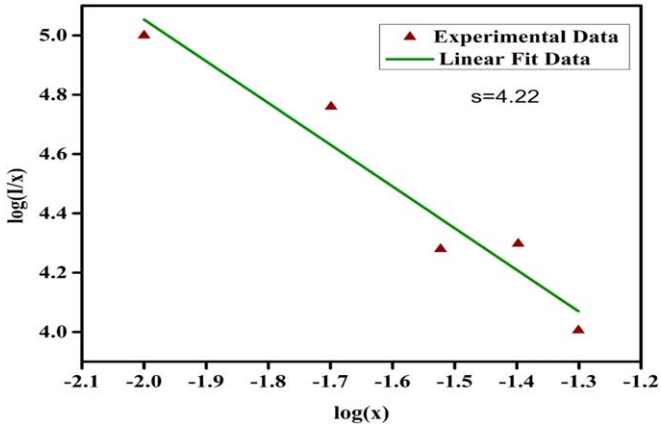

Figure 9. Plot of log (I/x) with log(x).

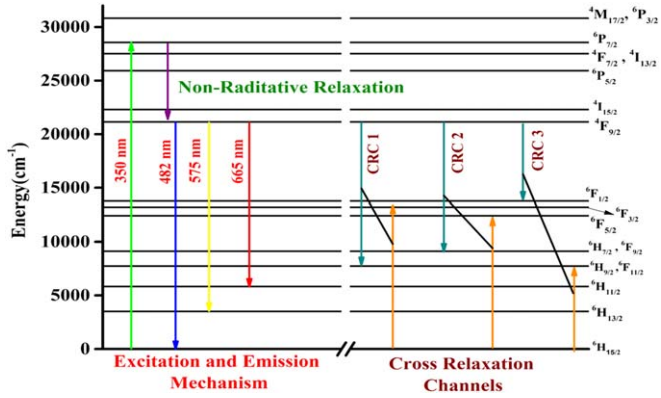

Figure 10. Partial energy level diagram and possible cross-relaxation channels of Dy^{3+} ion doped $KCa(PO_3)_3$ phosphor.

$$\log\left(\frac{I}{x}\right) = A - \frac{s\log(x)}{3} \tag{5}$$

Where A signifies a constant, d represents the mixture's dimensions (= 3) and I is the emission intensity [33, 34]. We use the value of s to identify the type of multilevel interactions. The types of interactions, including closest neighbor ion, dipole–dipole, dipole-quadrupole, and quadrupole-quadrupole interactions, are quantified by their respective multipole moments. Specifically, these interactions are represented by the values of 3, 6, 8, and 10 for the corresponding multipole moments respectively. To study the values of s, we select samples with x = 0.01, 0.02, 0.03, 0.04, and 0.05. Subsequently, we determine the emission intensity and generate a linear graph of KCP:xDy^{3+} that is shown in figure 9 between log(I/x) versus log(x). The (s/3) value is determined by analyzing the gradient of the linear plot b/w log(I/x) and log(x). Upon analyzing the data, we found that the slope is −1.40712. This value helped us determine that the value of s is 4.2214, which is less than 6. This suggests that energy transfer due to nearest neighbouring ions is the primary mechanism causing concentration quenching in the sample [35].

Asymmetric molecules exhibit inherent dipoles because of the unequal distribution of electrons around the positively charged nucleus. The dipole–dipole interaction's dimension is determined by the two dipoles' center distance and relative orientation. The interaction is computed using the potential energy of each dipole. Concentration quenching results from a substantial energy exchange between activators that happens when the concentration of activators reaches a certain level [36]. The schematic energy level diagram shown in figure 10 illustrates the possible electronic transitions of the Dy^{3+} in the $KCa(PO_3)_3$ polyphosphate phosphor [37]. The higher energy level ($^6P_{7/2}$) of the Dy^{3+} ions becomes populated by Dy^{3+} excitation (350 nm). Due to inadequate energy difference between the states to produce a radiative transition, the ions undergo non-radiative transitions (phonon relaxation) from the excited level to the ground state ($^4F_{9/2}$). Ultimately descends to the various ground-level states ($^6H_{15/2}$, $^6H_{13/2}$, and $^6H_{11/2}$) to release blue, yellow, and red photons, which are associated with the Dy^{3+} ion transitions at $^4F_{9/2} \rightarrow {}^6H_{15/2}$, $^4F_{9/2} \rightarrow {}^6H_{13/2}$, and $^4F_{9/2} \rightarrow {}^6H_{11/2}$ [18].

This energy exchange reduces the amount of luminous energy levels and lessens the intensity of the fluorescence. The three cross-relaxation processes of Dy^{3+} are as follows [36]:

$$\text{CRC 1:} \quad ({}^4F_{9/2} + {}^6H_{15/2} \rightarrow ({}^6H_{9/2}, {}^6F_{11/2}) + {}^6F_{3/2})$$

An initial Dy^{3+} ion descends from level $^4F_{9/2}$ to the intermediate level ($^6H_{9/2}$, $^6F_{11/2}$), while another Dy^{3+} ion is excited from the ground state level $^6H_{15/2}$ to level $^6F_{3/2}$.

$$\text{CRC 2:} \quad ({}^4F_{9/2} + {}^6H_{15/2} \rightarrow ({}^6H_{7/2}, {}^6F_{9/2}) + {}^6F_{5/2})$$

An initial Dy^{3+} ion descends from level $^4F_{9/2}$ to the intermediate level $^6H_{7/2}$+$^6F_{9/2}$, while another Dy^{3+} ion is excitedfrom the ground state level $^6H_{15/2}$ to level $^6F_{5/2}$.

$$\text{CRC 3:} \quad ({}^4F_{9/2} + {}^6H_{15/2} \rightarrow {}^6F_{1/2} + ({}^6H_{9/2}, {}^6F_{11/2}))$$

An initial Dy^{3+} ion descends from level $^4F_{9/2}$ to the intermediate level $^6F_{1/2}$, while another Dy^{3+} ion is excited from the ground state level $^6H_{15/2}$ to level $^6H_{9/2}$+$^6F_{11/2}$.

3.6. Y/B ratio

The luminescence intensity and the site symmetry of RE ions are generally inversely related. Solid-state lighting appliances prioritize the Dy^{3+} ion because it emits the main colors that are necessary for the creation of white light [38]. In general, white light can be produced by precisely balancing blue and yellow light. As seen in figure 8, the yellow band's intensity (at 575 nm) is comparatively higher than the blue band's intensity (at 350 nm). The production of white light is significantly influenced by the intensity ratios of the blue and yellow bands, which are the ratios of their combined intensities [39]. The concentration of dopant (in this case, Dy^{3+}) ions, the host phosphor matrix, and the excitation source all have an impact on the yellow-to-blue (Y/B) intensity ratio. The Y/B intensity ratio is significantly impacted by the inversion symmetry and local coordination surrounding nearby Dy^{3+} ions. Moreover, it is found that the local coordinated regions around Dy^{3+} ions are the least symmetric with respect to neighboring atoms in the absence of inversion symmetry. Due to the increased covalency, the emission spectrum exhibits an intense yellow band as opposed to a blue one. Y/B intensity ratios are comparatively more than 1, indicating that light is being generated in the white area. The higher Y/B ratios support the high covalent nature of Dy^{3+} ions. Consequently, the KCP:Dy^{3+} 4.0 mol in the as-prepared KCP phosphors shows the highest Y/B value and, consequently, the maximum covalency.

3.7. CIE Co-ordinate

To understand the colorimetric performance of $KCa(PO_3)_3$: xDy^{3+} ions (x = 1.0, 2.0, 3.0, 4.0, 5.0 mol %) phosphor, the 'Commission Internationale de l'Eclairage' (CIE) chromaticity coordinates at $\lambda_{ex} = 350$ nm were acquired from the emission spectrum data. The figure 11 displays the calculated CIE coordinates for every as-synthesized $KCa(PO_3)_3$ phosphor at $\lambda_{ex} = 350$ nm and $\lambda_{em} = 575$ nm. The coordinates of the as-synthesized Dy^{3+} doped $KCa(PO_3)_3$ phosphors, as indicated in the CIE diagram lie near the central white region. This indicates that $KCa(PO_3)_3$ phosphors doped with Dy^{3+} ions are suitable for solid-state lighting and plasma display panels [40]. Another important component in colorimetric computations used to look into color saturation is color purity (CP) [41]. The estimation of CP can be done using the formula below.

$$Color\ \ purity = \frac{\sqrt{(x - x_{ee})^2 + (y - y_{ee})^2}}{(x_d - x_{ee})^2 + (y_d - y_{ee})^2} \tag{6}$$

where (x, y) represents the color coordinates of the $KCa(PO_3)_3$ phosphor, (x_{ee}, y_{ee}) stands for equal energy point, and (x_d, y_d) indicates points of dominant wavelength. The Dy^{3+} (x = 4.0 mol%) ions doped $KCa(PO_3)_3$ phosphor is found to have 16% color purity under 350 nm excitation. When triggered by blue or n-UV light, Dy^{3+} (x = 4.0 mol%) ions doped $KCa(PO_3)_3$ phosphor can be used as a white emitting component in w-LEDs.

When determining whether a light source is warm or cold, one of the most crucial parameters is the correlated color temperature (CCT) [42]. CCT is determined using the equation below.

$$CCT = -449n^3 + 525n^2 + 6823.3n + 5520.32 \tag{7}$$

The color coordinates are n = (x-0.332)/(0.1858-y). The prepared phosphor is a cool emission source, as indicated by the assessed CCT values as mentioned in table 1. The calculated CCT values of the KCP:xDy^{3+} phosphors are significantly more than 4000 K, indicating that cool white light can be created from these phosphors.

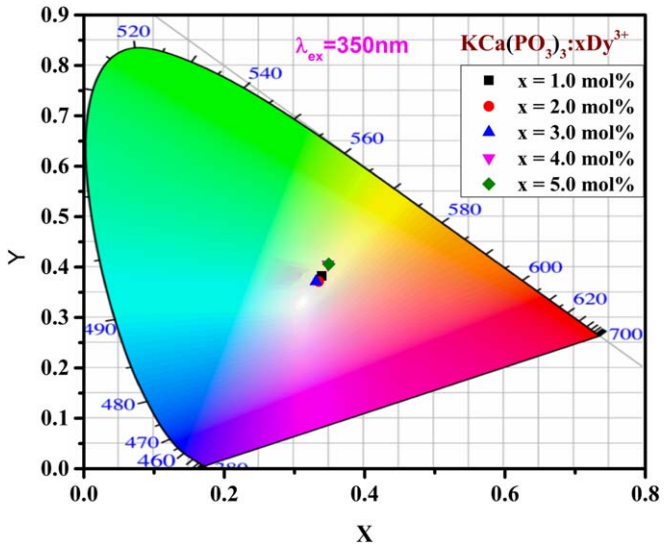

Figure 11. CIE chromaticity coordinates of Dy^{3+} ions in $KCa(PO_3)_3$ phosphors.

Table 1. CIE coordinates, CCT values of KCP: xDy^{3+} (x = 1.0, 2.0, 3.0, 4.0, 5.0 mol%) under 350 nm excitation wavelength.

Sample ID KCP: xDy^{3+}	CIE coordinates (x, y)	CCT values (K)
x = 1.0 mol%	(0.3389, 0.3823)	5287.127
x = 2.0 mol%	(0.3346, 0.3712)	5428.813
x = 3.0 mol%	(0.3307, 0.3715)	5570.698
x = 4.0 mol%	(0.3678, 0.4051)	4497.287
x = 5.0 mol%	(0.368, 0.4058)	5056.40

3.8. Photoluminescence (PL) decay

The PL decay patterns under room temperature $\lambda_{ex} = 350$ nm and $\lambda_{em} = 575$ nm for $KCa(PO_3)_3$: x Dy^{3+} (x = 1.0, 2.0, 3.0, 4.0, and 5.0 mol%) ions phosphor are represented in figure 12. The decay curves were fitted with various exponential equations; however, for all concentrations of Dy^{3+} ions, the bi-exponential equation showed the best fit. This suggests that dopant ions are interacting significantly, leading to energy transfer from excited Dy^{3+} ions (donor) to unexcited Dy^{3+} ions (acceptor) and that the RE ions in the phosphor lattice are probably going to acquire two different crystallographic sites [43, 44].

The following equation can be used to represent the luminous intensity:

$$I = I_0 + A_1 \exp\left(\frac{-t}{\tau_1}\right) + A_2 \exp\left(\frac{-t}{\tau_2}\right) \tag{8}$$

Where I_o and I represent, respectively, the luminescence intensities at time t = 0 and some other point in time. A_1 and A_2 are the fit constants for bi-exponential fitting, and τ_1 and τ_2 are the components for rapid and slow decay, respectively [45]. When modeling a bi-exponential curve, the average lifetime values are provided by:

$$\tau_{exp} = \frac{A_1\tau_1^2 + A_2\tau_2^2}{A_1\tau_1 + A_2\tau_2} \tag{9}$$

The as-synthesized $KCa(PO_3)_3$: xDy^{3+} (x = 1.0, 2.0, 4.0, and 5.0 mol%) phosphor have τ_{exp} values of 377.74, 327.04, 314.21, 308.84, and 293.03 μs, respectively. It was observed that when the quantity of Dy^{3+} ions in the phosphors was increased, the values of τ_{exp} decreased.

The decrement in a lifetime values with the increase inthe concentration of Dy^{3+} ions was further examined by Auzel's model utilizing equation given below [46]:

$$\tau = \frac{\tau_0}{1 + \frac{c}{c_0}e^{-N/3}} \tag{10}$$

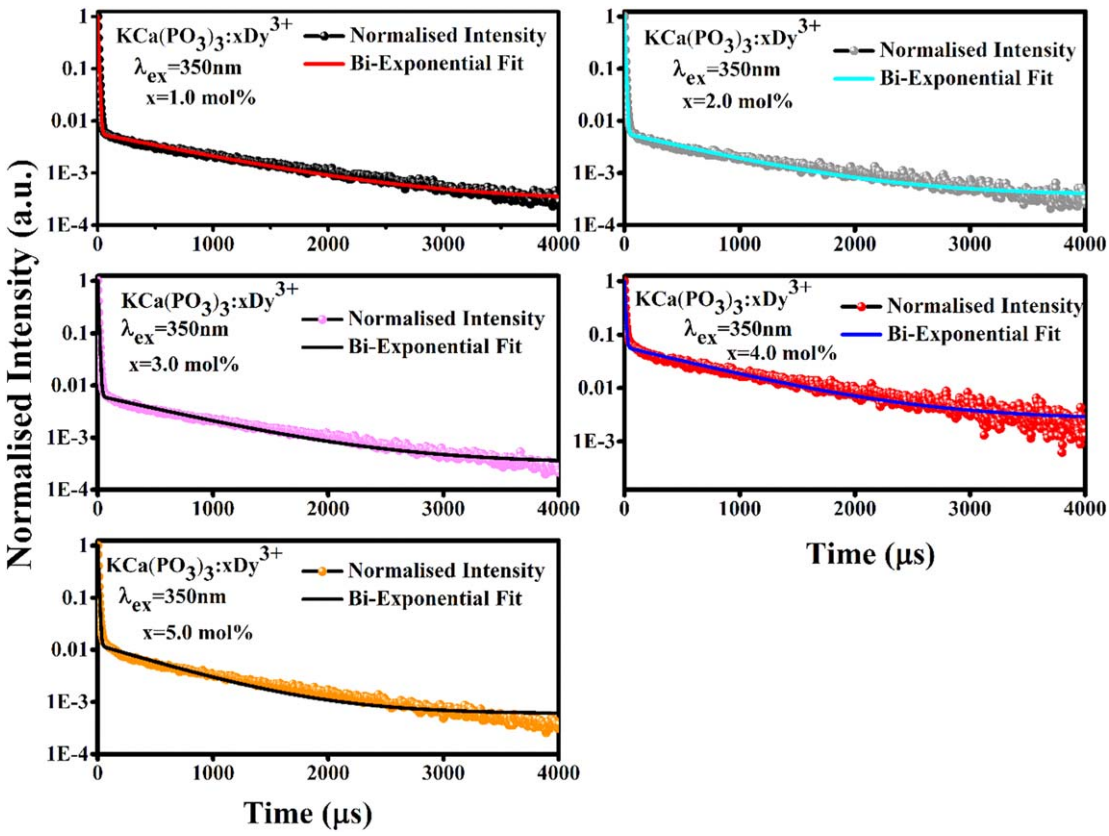

Figure 12. PL decay profiles of Dy^{3+} ions doped $KCa(PO3)_3$ phosphors at $\lambda_{ex} = 350$ nm wavelength.

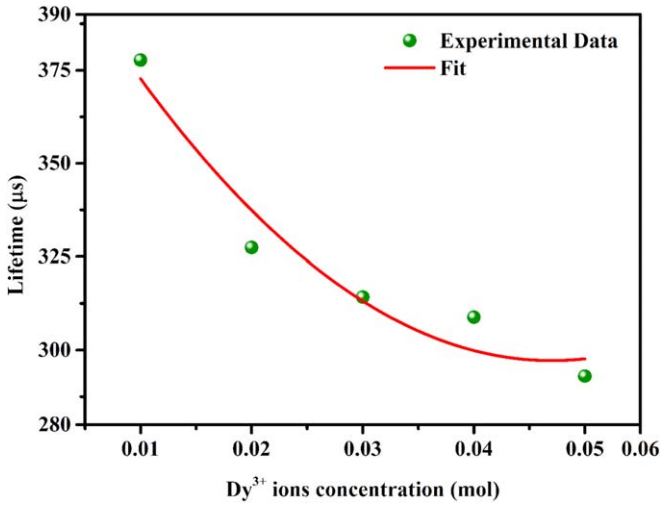

Figure 13. Dependence of photoluminescence decay lifetime of the $^4F_{9/2}$ state on the doping concentration of Dy^{3+} based on Auzel's model.

where τ represents the calculated lifetime, τ_0 represents the intrinsic radiative lifetime, c stands for concentration of Dy^{3+} ions, c_0 represents a constant and N denotes the number of phonons generated during the relaxation. Figure 13 demonstrates that the Dy^{3+} decay lifetime in KCP phosphor fits well with Auzel's model and the value of τ_0 from the fitting is 419.07 μs.

The quantum efficiency (η) is computed using intrinsic lifetime value as follows [47, 48].

$$\eta = \frac{\tau}{\tau_0} = \frac{A_R}{A_R + A_{nR}} \tag{11}$$

Table 2. Photoluminescence decay lifetime, non-radiative rate and quantum efficiency of the KCP : xDy^{3+} (x = 1.0, 2.0, 4.0, and 5.0 mol%) phosphors.

Sample ID KCP: xDy^{3+}	Decay Lifetime (μs)	Non radiative rate (s^{-1})	Quantum Efficiency (%)
x = 1.0 mol%	377.74	261.0874	90.13769
x = 2.0 mol%	327.04	671.4629	78.04026
x = 3.0 mol%	314.21	796.3153	74.97871
x = 4.0 mol%	308.84	851.6643	73.69702
x = 5.0 mol%	293.03	1026.43	69.92292

$$\frac{1}{\tau} = \frac{1}{\tau_0} + A_{nR} \tag{12}$$

here the rate of relaxation by non-radiative and radiative mechanisms are denoted by A_{nR} and A_R, respectively. Table 2 shows quantum efficiency values (%) along with decay lifetime and non-radiative rates (s^{-1}) for $^4F_{9/2}$ state.

4. Conclusions

In our work, Dy^{3+} doped $KCa(PO_3)_3$ phosphors were successfully synthesized via conventional solid-state reaction technique and were investigated their structural, morphological, and PL characteristics. First, the phase purity of the produced samples was confirmed by analyzing the XRD patterns. $KCa(PO_3)_3$: Dy^{3+} formed a hexagonal structure when it crystallized with a P-6c2(188) space group. Using SEM, morphological analysis was performed, and particle sizes were determined to be in the micrometre (3–5 μm) range. Multiple molecular bonds that are present in the structure are shown by the FT-IR spectra. The band gap values, 4.60 & 4.49 eV for undoped and 4.0 mol% of Dy^{3+}, were determined by linear fitting of the tauc plot of Dy^{3+} in the $KCa(PO_3)_3$ host. The excitation spectra show that the previously stated phosphors can be efficiently excited by n-UV light. A number of experiments were used to characterize the samples' luminescence properties. The PL emission spectra findings demonstrated that the samples generated white light with two prominent peaks at 482 nm (blue band) and 575 nm (yellow band) upon excitation by 350 nm UV radiation. The electronic transitions of dysprosium ions at $^4F_{9/2} \rightarrow {}^6H_{15/2}$ and $^4F_{9/2} \rightarrow {}^6H_{13/2}$ were matched by these peaks, respectively. Concentration quenching was observed for Dy^{3+} doping at a concentration of 4.0% mole. The main cause of this quenching was found to be dipole–dipole energy transfer. The computed CIE chromaticity coordinates for $KCa(PO_3)_3$ for 4.0 mol% of the Dy^{3+} phosphor lie in the deep white area. The PL decay profile displays bi-exponential behavior with decay times being in microseconds (μs) range. As the concentration of Dy^{3+} ions increases, the computed τ_{exp} values decrease because of the transfer of energy between Dy^{3+} - Dy^{3+} ions. The results of the aforementioned studies on the as prepared KCP:Dy^{3+} phosphors highlight that these materials can be used for white light generating LEDs and other photonic devices applications.

Acknowledgments

One of the authors, Ms. Sheetal Kumari is very much thankful to CSIR-UGC for the award of a Junior Research Fellowship (JRF) (UGC Ref. 1431/CSIR-UGC NET JUNE 2019). We are really grateful to Dr. Manju Srivastava and Dr. Shyama Prasad for the SEM facility provided by the Department of Chemistry at Dayalbagh Educational Institute (DEI), Deemed University, Agra.

***Abstract*— Federated Learning (FL) quickly gained popularity as a secure distributed learning technology based on insights sharing. The client-level privacy provided by FL has enabled its extensive integration in fields dealing with susceptible data such as E-commerce, the Internet of Medical Things, etc. However, the transmitted insights may still be subjected to eavesdropping since the security of the transmission medium cannot be guaranteed. Using complex techniques, this can lead to the inference of the client data. In many cases, quantization is applied over transmitted payload to hinder such attempts but results in drop of accuracy in the global models. Moreover, the capabilities of client nodes are not considered in most implementations which may lead to under or over-utilization of client resources and cause client dropouts due to exhaustion. When combined, the quantization and client dropouts cause a significant performance loss and make the network less stable. In this paper, we propose a Dynamic Resource-Aware Federated Framework for Secure and Sustainable Learning, which layers the quantization process with an active workload management technique based on the capabilities of the client nodes. The framework minimizes the dropout rates significantly while recovering the accuracy lost in quantization to some extent. Through experiments compared against standard FL and Quantized FL over multiple datasets, the DRAFFSS shows gains in security over the former and in accuracy over the latter while keeping client dropouts negligible.**

Keywords—federated learning, data-sensitive applications, security, resource optimization, artificial intelligence

I. Introduction

Artificial Intelligence (AI) has made its way into every conceivable sphere of life to varying extents in recent years. Ranging from medical domain to automated heavy machinery AI has impacted execution, production, or planning phases section either directly or indirectly [1]. The underlying models in these applications often demand massive amounts of data in their training phase and in some cases, throughout their usage cycle for continuous tuning. In many instances, the required data is sensitive and can be used to infer crucial information about data owners leading to issues including cybercriminal activities. To cater to the growing concern regarding data privacy, Federated Learning (FL) was proposed which makes use of insights sharing in place of raw data [2] in a distributed node-based environment. The insights/gradients shared can then be used to modify the global results as required.

A. Federated Learning

FL had its inception in 2016 when McMahan et al. [2] proposed parameter transmission over a distributed learning network. The method provided a higher level of privacy compared to traditional AI methods and paved the way for collaborative learning efforts expanding both, the dataset variations and computing power. There exist many types and subtypes of FL. On a large scale, FL is categorized as Horizontal FL (HFL) [3] and Vertical FL [4]. In HFL, the training data available to different devices is identical in terms of feature set. In VFL, the data partitioning incorporates varied attributes throughout the subsets which are handled by a host controller. The correlation keys for entries that house data from different owners in separate columns in the same row are calculated by applying Private Set Intersection (PSI) [5]–[7].

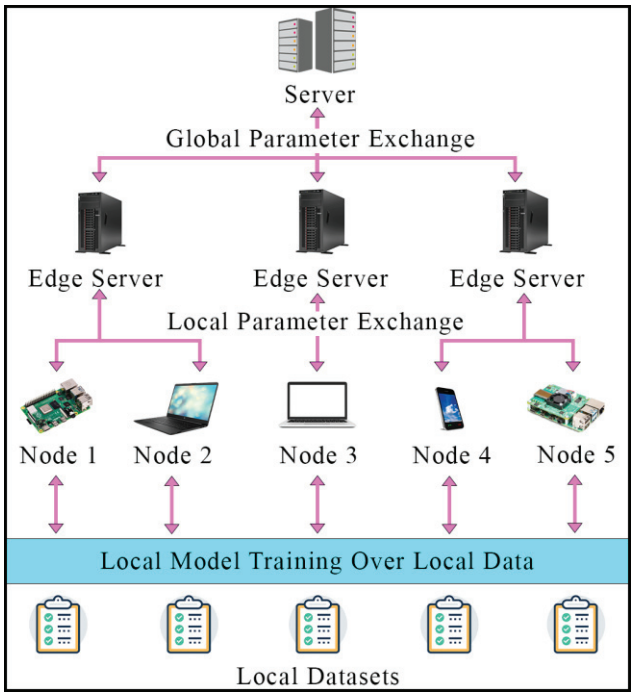

Fig. 1. Standard Federated Learning

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 18,2024 at 09:39:59 UTC from IEEE Xplore. Restrictions apply.

Fig. 1. shows the basic architecture of an FL setup. Here multiple client nodes (mobile, laptop) communicate with a cloud/edge server to synchronize model parameters. These parameters are used to carry out localized training on client nodes. The updated set of parameters is uploaded back to the server for aggregation into the central model. The process is repeated over multiple rounds each time with a randomly selected subset of devices.

Incentive-Aware FL (IFL) [8]–[10] is a special sub-type of FL that tracks the contributions made by the participating nodes in the network. This record is used to allot rewards that may differ depending on the type of contribution or application. The associated reward system attracts new nodes to the network and refreshes dead or idle nodes to participate.

B. Data-Sensitive Applications

A Data-Sensitive Application (DSA) is an application that deals with data that is highly sensitive to the clients. These may include data corresponding to the social footprint [11], medical records [12], or economic status [13]. Most of these applications greatly increase the ease and quality of life. But, also makes private information more susceptible to eavesdropping. FL provides a level of immunity to DSAs from these issues.

However, many analytical methods have been developed to infer confidential data from transmitted parameters in FL setups [14]. One of the often-applied countermeasures is parameter quantization which incurs an accuracy bump proportional to the extent of quantization [15], [16] known as the quantization loss. This loss can be negated to some extent by stabilizing the network and reducing staggering nodes. Among the options available, the most promising optimizing method for less staggering is seen in the works of Li et al. [17] who implemented a modified version of Incentive-Aware FL as Workload-Aware FL. The proposed work adds a layer of server-side computation after each training round presenting a necessary but minimal cost. As evident by studies, the current state-of-the-art techniques focus either on security or efficiency but none tries to balance both. We propose a hybrid framework that employs the workload-aware FL over quantization in an FL setup to balance the quantization loss and ensure security if a gradient/parameter leak is encountered. We summarize the main contributions of this paper as follows:

- We propose a Dynamic Resource-Aware Federated Framework for Secure and Sustainable Learning (DRAFFSS) in DSAs.
- To better balance the quantization loss incurred, Workload-Aware FL is employed.
- Through extensive experimentation on various medical classification datasets, we show that our frame-work provides security at negligible accuracy loss and staggering nodes compared to existing techniques.

The rest of the paper is structured as follows: Section 2 outlines the related work done. Our proposed framework is discussed in section 3 and the experimental setup and results are elaborated in section 4. Finally, section 6 concludes the paper and provides potential future directions.

II. Related Work

New threats, solutions, and improvements emerge daily in technology fields, which make the state-of-the-art systems obsolete rapidly. FL is no stranger to this trend as the eavesdropping of the minimal transmitted parameters can allow attackers to invert the model and recreate the used dataset with perfect accuracy in some cases [14], [18]. Researchers have come forward with many potential solutions to prevent this inference. One of the most widely used techniques is quantization of parameters.

A. Quantization

There has been considerable work done in the field of quantization at certain levels. Initially, quantization was applied to the weights of a Neural Network (NN) model to optimize resources. Works of Li et al. [16] and Bao et al. [19] highlight attempts made toward weight-based model compressions. Choi et al. [20] proposed quantization for activation function, which compresses the activation functions during the training phase, while Li et al. [15] proposed an approach to over-come performance degradation in quantized Super Resolution NN. However, both these approaches are reliant on training, making them computationally expensive. Fang et al. [21] proposed a technique to estimate the quantized parameters and identify the optimal breakpoints to minimize the quantization loss. However, using quantization identically for parameters with dissimilar probability distributions results in limited success. Dong et al. [22] proposed a layer-wise quantization approach using the Hessian spectrum of layers for the selection of quantization precision optimized for each layer. Started as a method for resource optimizing, quantization showcases the potential for boosting security in FL applications.

FL natively improves the security and privacy of the involved data by limiting the data transfer across the network to model parameters. Some recent studies demonstrated the reconstruction of private data inferred from eavesdropping on these parameters. Xu et al. [23] proposed a quantization-based enhancement to put a check on the effectiveness of these inferences. Using 3-bit and 5-bit quantization with clipping over various datasets, the proposed model shows considerably less quantization loss compared to state-of-the-art Apot and Uniform quantizers. The approach however suffers from a loss in accuracy by 0.02% to 15% proportional to the complexity of the dataset used, restricting the utility toward DSAs.

Kerkouche et al. [24] presented another security approach partially focusing on resource optimization in low-powered networks like the Internet of Medical Things (IoMT). The results highlight significant drops in bandwidth consumption. This drop reduces the strain on resources in the network and minimizes the time taken per round of the FL algorithm. However, similar to the works of Xu et al., the experimentations show a loss in accuracy proportional to the complexity. IFL techniques over the base quantizer system can compensate for some of these performance gaps.

B. Incentive-Aware and Workload-Aware FL

IFL is a sub-type of FL that adds a step at the end of the training round to estimate the individual contributions of nodes to the global model. These contributions are evaluated to provide some form of incentive to the nodes to motivate further performance. Wang et al. [9] proposed an IFL

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 18,2024 at 09:39:59 UTC from IEEE Xplore. Restrictions apply.

method by incorporating blockchain technology to induce trust and credibility between nodes. While proving to be a significantly stable, secure, and reliant technique, the overheads of blockchain [25] are difficult to negate in most use cases for resource-starved setups like IoMT. Nishio et al. [26] and Abdulrahman et al. [27] proposed client selection schemes using IFL. But both approaches proved to be either resource intensive or of low convergence due to hard constraints on participating nodes.

A modified implementation of IFL is proposed by Li et al. [17], which implements the contribution evaluation for clients based on their sustainable workloads. The approach enables the allocation of optimal workload in gradual steps to the nodes decreasing the chance of dropouts during training. We couple a modified version of the technique in [17] with a quantizing algorithm to form a hybrid algorithm that improves security and minimizes quantization loss and straggler nodes.

III. Proposed Framework (DRAFFSS)

This section describes in detail, our hybrid approach combining the security aspect of quantization with optimized throughput gained by virtue of workload-aware load selection. A detailed view of the complete frame-work with all the sub-functions is shown in Fig. 2.

At the start of each round, a subset of client nodes is randomly selected and the shortlisted nodes are queried about their capabilities. The client nodes respond with the lower & upper bound epoch, and the maximum sustainable epoch by the device. These nodes are provided with the global model parameters (step 1). The devices taking into account the individually calculated workload for the round, train the model locally. After training the updated models are quantized based on the quantization boundaries of the parameters. These boundaries are employed to serve two purposes; To provide security in case the transmitted parameters are compromised and to minimize the network load. A copy of the original model is stored on the client node and the quantized model is uploaded to the server for aggregation and updating the global model (step 6). The process may run for multiple rounds de-pending on the required level of training and the variety of data in the client nodes.

A. Security: Quantization

The security aspect of the approach relies on the quantization of model parameters while maintaining minimal quantization loss. An element in consideration can be quantized toward the lower or upper bound as feasible. The probabilities of an element x being quantized towards either boundary value is calculated as follows:

$$Pr_{x \to a_i - 1} = \frac{a_i - x}{a_i - a_{i-1}} \tag{1}$$

$$Pr_{x \to a_i} = \frac{x - a_i}{a_i - a_{i-1}} \tag{2}$$

Given that all parameters of the model are arranged in form a vector $\overrightarrow{p_v}$, having a probability distribution $f(x)$. For an element x falling between boundaries a_{i-1} and a_i and the total squared quantization error σ^2 is calculated as:

$$\sigma^2 = \sum_{i=0}^{2^b-1} \int_{a_{i-1}}^{a_i} [-x^2 + (a_{i-1} + a_i)x - a_i a_{i-1}] f(x) dx \tag{3}$$

Using partial derivatives, the authors in [23] derived quantization probability of ith element having minimum quantization loss as:

$$Pr_i = \frac{a_{i+1} \int_{a_{i-1}}^{a_{i+1}} f(x)dx - \int_{a_{i-1}}^{a_{i+1}} x f(x) dx}{a_{i+1} - a_{i-1}} \tag{4}$$

Algorithm 1 elaborates on the quantization employed in an FL setup. At the initiation of each training round 't', a subset of client nodes 'R' is selected by the server. All nodes in R receive the model from the global server. This model is denoted as m_0 or m_{t-1} (line 1). The clients then train the model k times over local data and update the model to m_t (lines 3-6). We then quantize the model by applying (4) and rounding off the parameters accordingly using stochastic rounding (line 7-8) to create $m_{\sim t}$. The final model m_t is kept with the client while quantized $m_{\sim t}$ is uploaded to the server for aggregation.

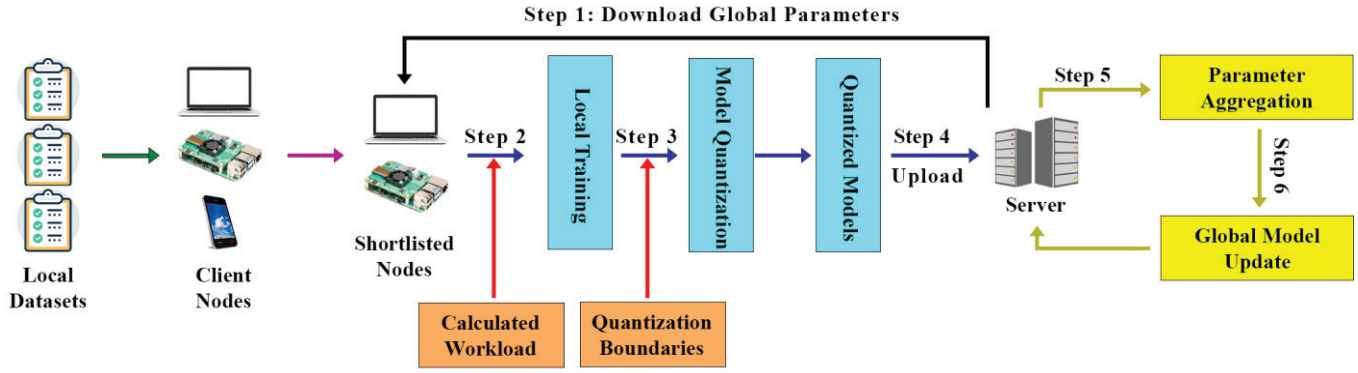

Fig. 2. Architecture of Proposed Framework (DRAFFSS)

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 18,2024 at 09:39:59 UTC from IEEE Xplore. Restrictions apply.

Algorithm 1: Quantization of Parameters in FL Setup (Fed-q)

Input: Initial model m_0;
Output: Final model m_t;

1 **function Fed-q** (m_0)
2 $m_0 \leftarrow m_{t-1}$;
8 $m_{\sim t} \leftarrow Q\left(m_t, \{a_\tau^t\}_{j=0}^{2^b-1}\right)$; //stochastic rounding
9 Uploads $\{a_\tau^t\}_{j=0}^{2^b-1}$ and $f(m_{\sim t})$ to server;
10 **return** m_t;

B. Optimization:Client Selection

Quantization strengthens the security of the data from inference attacks, but the induced compression results in loss of accuracy in the performance of the global model. This restricts the usage in critical applications like the DSAs. To compensate for this loss, a workload optimization technique is integrated based on [17]. The authors propose workload-aware client selection and showed improvements in the accuracy of the trained model compared to traditional FL. The approach also highlights a stable network with minimal stragglers. We layer this approach over quantization to regain the accuracy lost in algorithm 1. The authors define the predicted workload for a client in a particular round by increasing the workload of the same client in the previous round by a fraction of itself. If the client drops out of the network, then the workload for that client in the next round is halved. Both cases are depicted by (5).

$$\hat{E}_k^{t+1} = \begin{cases} \frac{1}{2}\hat{E}_k^t, if\ client\ drops\ out \\ \hat{E}_k^t + \frac{\mu}{\hat{E}_k^t}, otherwise \end{cases} \quad (5)$$

Here $\hat{E}_k^t$ is the workload predicted for client k in round t, and μ is a hyper-parameter defined on an application-to-application basis. The selection of value of μ is crucial because if the value is too high, the stragglers will rise and if the value is too low, the convergence time will be infeasible. Algorithm 2 shows process for calculation of optimal workload for a client in the next round.

The algorithm takes input for the sustainable capacity of the client to process workload: $\tilde{E}_k^t$, the lower and upper limits of epoch for workload assignment: $\hat{L}_k^t$ and $\hat{H}_k^t$. Lines 2-5 initiates the second portion of (5). The first portion of (5) is handled by lines 6-10. Lines 11-14 are triggered when the lower limit exceeds the sustainable workload value for the client. It sets the workload of next round as NULL and halves both limits as per (5) highlighting a client drop from the algorithm.

Algorithm 2: Workload Prediction (Round_Load)

Input: Locally sustainable workload $\tilde{E}_k^t$ of client k at round t, the lower limit of the epoch for $\tilde{E}_k^t$, $\hat{L}_k^t$, the upper limit of the epoch for $\tilde{E}_k^t$, $\hat{H}_k^t$.
Output: the predicted minimum workload $\hat{L}_k^{t+1}$, the predicted maximum workload $\hat{H}_k^{t+1}$, the training workload $\hat{E}_k^t$.

1 **function Round_Load** ($\hat{L}_k^t, \hat{H}_k^t, \tilde{E}_k^t$)
2 **if** $\tilde{E}_k^t$ is greater than $\hat{H}_k^t$ **then**
3 $\hat{L}_k^{t+1}, \hat{H}_k^{t+1} \leftarrow \hat{L}_k^t + \frac{u}{\hat{L}_k^t}, \hat{H}_k^t + \frac{u}{\hat{H}_k^t}$
4 $\hat{E}_k^t \leftarrow \hat{H}_k^t$
5 **end**
6 **else if** the actually affordable workload falls into $[\hat{L}_k^t, \hat{H}_k^t]$ **then**
7 $\hat{L}_k^{t+1} \leftarrow min\left(\hat{L}_k^t + \frac{u}{\hat{L}_k^t} + \frac{1}{2}\hat{H}_k^t\right)$
8 $\hat{H}_k^{t+1} \leftarrow max\left(\hat{L}_k^t + \frac{u}{\hat{L}_k^t} + \frac{1}{2}\hat{H}_k^t\right)$
9 $\hat{E}_k^t \leftarrow \hat{L}_k^t$
10 **end**
11 **else**
12 $\hat{L}_k^{t+1}, \hat{H}_k^{t+1} \leftarrow \frac{1}{2}\hat{L}_k^t, \frac{1}{2}\hat{H}_k^t$
13 $\hat{E}_k^t \leftarrow 0$
14 **end**
15 **return** $\hat{L}_k^{t+1}, \hat{H}_k^{t+1}, \hat{E}_k^t$

C. Hybrid Algorithm

Combining the two aspects of security and optimization from the discussed works, we propose Dynamic Resource-Aware Federated Framework for Secure and Sustainable Learning to allow secure training with minimal straggler nodes and accuracy loss. The framework employs a 5-bit quantizer for parameter compression to optimize bandwidth consumption and prevent inference in case of eavesdropping on the network. The quantization loss induced is compensated by adding a layer for dynamic workload-allotment which reduces the chance of client drop out by allocating gradually increasing workload to the devices. The complete process of DRAFFSS is explained in Algorithm 3. At the start of each communication round a subset of clients is selected based on a probability list and global weights are shared to these clients (lines 1-3). The clients respond with the respective sustainable and minimum workloads (line 4). These values are passed on to a function employing algorithm 2 to determine workloads for the ongoing round which are passed to Fed-q function (algorithm 1) to carry out training (lines 5-7). Finally, the weights returned by Fed-q are aggregated into the global model (line 9).

Algorithm 3: DRAFFSS

Input: Number of Training Rounds T and list of clients in the network R
Output: Global trained model weights w^T

1 **for** each training round t = 1 to T **do**
2 $C_t \leftarrow$ shortlist clients based on probability list generated for R.
3 server passes the global weights w_t to shortlisted clients.
4 $\{(\hat{L}_k^t, \hat{H}_k^t, \tilde{E}_k^t)\} \leftarrow$ receive reply from C_t. // Request initial workloads and sustainable limits
5 **for** each client $k \in C_t$ in parallel **do**
6 $(\hat{L}_k^t, \hat{H}_k^t, \hat{E}_k^t) \leftarrow$ **Round_Load** $(\hat{L}_k^t, \hat{H}_k^t, \tilde{E}_k^t)$ //**Algorithm 2**
7 $\Delta_k^t, H_k^t \leftarrow$ **Fed-q**(m_k) //trained with workload values $(\hat{L}_k^t, \hat{H}_k^t, \hat{E}_k^t)$, //**Algorithm 1**
8 **end**

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 18,2024 at 09:39:59 UTC from IEEE Xplore. Restrictions apply.

9 $w^{t+1} \leftarrow w^t - \frac{\sum_{k \in C^t} \Delta_k^t}{\sum_{k \in C^t} h_k^t}$

10 **end**

D. Baseline Model

We have used Resnet-18 [28], an 18-layer model with ReLU activation. We used SGD optimizer with adaptive learning rate of 0.1 dividing by 10 when error graph plateaus similar to that used in [14]. The exact model used is depicted in Fig. 3.

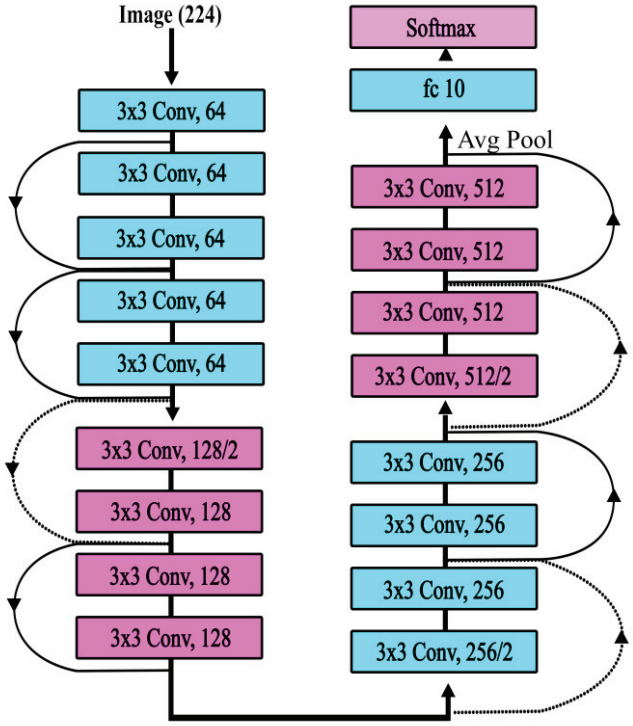

Fig. 3. Architecture of the baseline Resnet 18 model

IV. Results and Analysis

This section elaborates on our experimental environment and results over the various datasets used. We compared our model with standard FL as well as FL with 5-bit quantization to present a detailed view of the gains achieved by the hybrid approach.

A. Experimental Setup

Our simulations are carried out on a system running Windows 11 Pro version 22H2 equipped with an Intel(R) Xeon(R) Silver 4114 CPU @ 2.20GHz, 128GB DDR4 RAM, and two NVIDIA Titan RTX GPUs in SLI-Crossfire having 24GB VRAM each. We implemented our models in Python 3.9.16 with Cuda 12.1 [29], Tensorflow 2.12 [30] , and Pysyft 0.9.0 [31] over Jupyter Notebook in Conda virtual environment.

To replicate a network with heavy traffic and constraints implied by the bandwidth, we simulate 1000 nodes with slightly varying resources such as more or less RAM, CPU-cycles, and data-location (GPU/RAM).

B. Dataset Description

We tested our algorithm against the implementation discussed in [23] and standard FL over two publicly available medical image datasets having dissimilar complexity and sample size. A brief description of the datasets and their composition is as follows.

1) Diabetic Retinopathy

Diabetic Retinopathy Dataset [32] is a collection of high-resolution retinal images labelled 0 through 4 depicting absence or presence of diabetic retinopathy in the patient. There are two separate images for left and right eye for each patient. Fig. 4. Shows some sample images from the Diabetic Retinopathy Dataset.

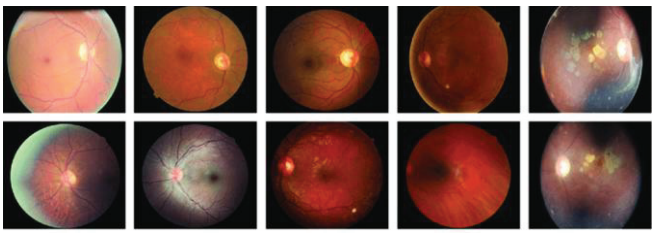

Fig. 4. Sample images from Diabetic Retinopathy Dataset

2) RSNA Bone Age

RSNA Bone Age Dataset [33] is an image dataset housing x-ray scans of hands of multiple children. The aim of the dataset is to predict both age and gender of the individuals by analyzing bone structures. Fig. 5. shows some sample images from the dataset.

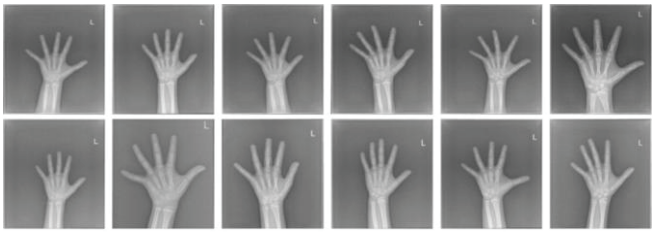

Fig. 5. Sample images from RSNA Bone Age Dataset

C. Results

We benchmarked DRAFFSS over the two datasets discussed in previous section and evaluated it against standard FL and Fed-MSQE[23] with the 5-bit quantization mode. Primarily four metrics are used for evaluation, Accuracy, Straggler node percentage, Precision, and Recall. These are defined as follows.

$$Accuracy = \frac{TrueNegatives(TN) + TruePositives(TP)}{TN + TP + FN + FP} \quad (5)$$

$$Straggler\% = \frac{\sum_1^T \frac{Nodes\ active\ in\ C_t * 100}{1000}}{T} \quad (6)$$

$$Precision = \frac{TP}{TP + FP} \quad (7)$$

$$Recall = \frac{TP}{TP + FN} \quad (8)$$

Our DRAFFSS demonstrated improved accuracy compared to the Fed-MSQE while also showing significantly less straggler nodes in all the comparisons. A summary of results attained by DRAFFSS is shown in table I.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 18,2024 at 09:39:59 UTC from IEEE Xplore. Restrictions apply.

TABLE I. RESULTS ACHIEVED BY DRAFFSS IN VARIOUS DATASETS

Dataset	Accuracy	Straggler Node (%)
Diabetic Retinopathy	79.20	14
RSNA Bone age	82.60	12

a) Comparison in Diabetic Retinopathy Dataset.

Being the simpler of the two datasets, the results of all techniques in comparison appear close, well within the margin of error due to randomness. The standard FL tops the accuracy curve, Fed-MSQE shows loss of roughly 5.70%, and Fed-WALQ shows a loss of just 2.50% highlighting significant improvement in the narrow range available. A comparison of test accuracies of the three techniques over Diabetic Retinopathy Dataset is shown in Fig. 6.

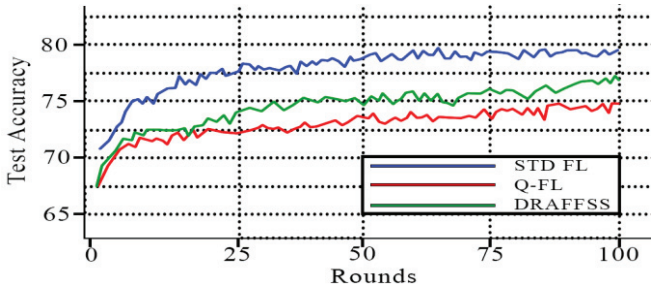

Fig. 6. Test Accuracy Comparison for Diabetic Retinopathy Dataset

Due to quantization and workload allotment, the number of stragglers is also seen to be reduced significantly when compared to traditional FL and Fed-MSQE as highlighted by the graph in Fig. 7.

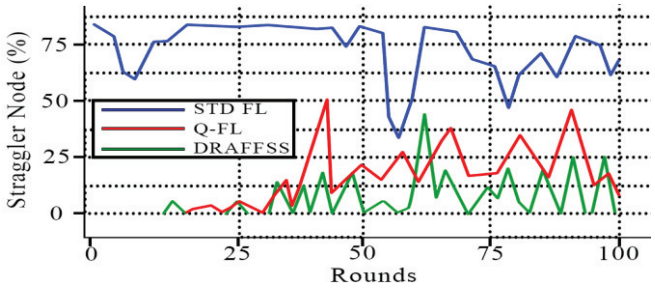

Fig. 7. Comparison of straggler nodes present during training over Diabetic Retinopathy Dataset

b) Comparison in RSNA Bone Age Dataset.

The dataset is designed to predict age of the patient based on x-rays. Hence the accuracy tested corresponds to the predictions that lie within 5.4 months of the actual ages. Here the standard FL attained a testing accuracy of 90%. While Fed-MSQE attained a testing accuracy of 77.2%, DRAFFSS attained an accuracy of 82.6% highlighting a drop of only 8.2% against 14.2 % of Fed-MSQE. The comparison of testing accuracy for all three techniques is shown in Fig. 8.

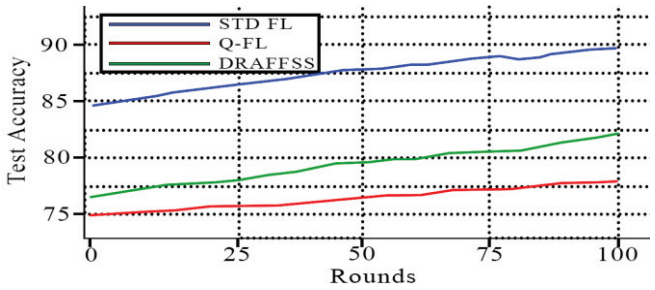

Fig. 8. Test Accuracy Comparison for RSNA Bone Age Dataset

Comparing the straggler percentages, standard FL suffered from 73.5% straggler node presence. While Fed-MSQE and DRAFFSS dealt with 14% and 12% presence respectively. Fig. 9. Shows the straggler node variations throughout training for the three techniques.

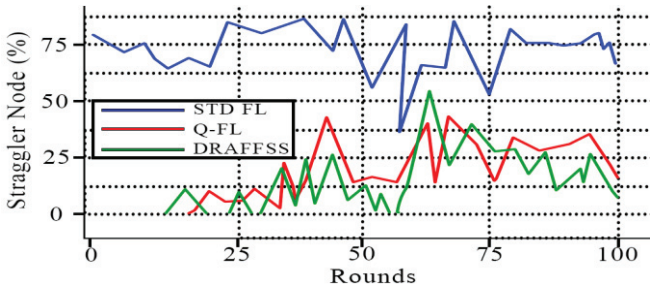

Fig. 9. Comparison of straggler nodes present during training over RSNA Bone Age Dataset

A summary of all the test accuracy results is tabulated in Table II.

TABLE II. ACCURACY AND STRAGGLER% ACHIEVED BY STANDARD FL, FED-MSQE, AND DRAFFSS OVER THE TWO MEDICAL DATASETS

Method\ Dataset	Diabetic Retinopathy		RSNA Bone Age	
	Test Acc	Straggler %	Test Acc.	Straggler %
Std. FL	79.80	72.00	90.00	73.50
FED-MSQE (5-bit)	75.00	17.00	77.20	14.00
DRAFFSS	77.50	14.00	82.60	12.00

TABLE III. PRECISION AND RECALL ACHIEVED BY STANDARD FL, FED-MSQE, AND DRAFFSS OVER THE TWO MEDICAL DATASETS

Method\ Dataset	Diabetic Retinopathy		RSNA Bone Age	
	Precision	Recall	Precision	Recall
Std. FL	79.76	79.79	90.01	90.00
FED-MSQE (5-bit)	75.12	75.12	77.20	77.21
DRAFFSS	77.50	77.49	82.60	82.60

Based on the results observed, DRAFFSS demonstrates its capability to compensate for performance loss induced by quantization. The compensation maybe marginal or significant depending on the complexity of the data used for training. The reduction in straggler nodes however is significant in all the test cases highlighting a stable system compared to the existing techniques. The improved stability allows the network to train more effectively as there are few interruptions due to node dropouts.

Accessing from the point of view of the node devices, the workload allotment helps keep resources from being over utilized. This in turn enables the devices to continue their local routines without issues.

V. Conclusion and Future Scope

A. Conclusion

In this paper, we propose Dynamic Resource-Aware Federated Framework for Secure and Sustainable Learning (DRAFFSS), a hybrid FL framework for DSAs, aimed at hindering inference of private data in case of an eavesdropping attack. In addition, the quantization reduces the transmission load optimizing the bandwidth use for constrained networks like IoMT. The framework uses a state-of-the-art 5-bit quantization scheme (Fed-MSQE) and layers it with adaptive work-load allotment scheme. The client devices are allotted sustainable workloads adapting to the work history of the client device reducing the dropout chances in the network and boosting throughput during training rounds. Experimental results across two medical datasets show significant improvements in straggler node ratio and testing accuracy over pure quantization methods ensuring a substantial level of security.

B. Future Scope

The improvements achieved in accuracy during our simulations are highly dependent on the complexity associated with test datasets. Development of a generic framework less affected by complexities of data is the most prominent direction for future research.

Abstract: Pre-existing density of states for a Quark-Gluon Phase, based on Thomas-Fermi and Bethe mode, is expanded by incorporation of new variables. Results from recent study indicate that perturbations in the form of a finite non-zero chemical potential μ, $\mathbb{B}$, dynamic thermal masses $\mathbb{M}$ and of course Temperature $\mathbb{T}$ are indeed vital to fully comprehend the formation and dynamics of QGP. Simulations depict an overall increase in the stability of QGP in the paradigm of the statistical model. On the top of Free Energy, Entropy and heat capacity are calculated for the phase transition. The overall qualitative behavior, of entropy or Heat Capacity determines the order of phase transition of the QGP. Investigation of order of phase transition is carried out in this study through Monte-Carlo based differential element, which ensures the inclusion of the randomness of the collisions at the particle colliders.

I. INTRODUCTION

Quantum Chromodynamics (QCD) outlays the varying strength of the strong interaction through the QCD Phase Diagrams. Temperature $\mathbb{T}$ and chemical potential μ determine the state of in which hadrons exist. QCD is formulized on the SU(3) group renders the calculations much complex. Incorporating new factors in an already complicated system exorbitantly increases computation time. Moreover, the sheer number of dimensions in the QCD Lagrangian and hence the action integral, suggests a statistical approach would be quite precise. Hence, this study extends the existing statistical model[1], consistent with URHIC experiments at the Brookhaven National Laboratory (BNL) and CERN. The current prevailing statistical model incorporates temperature and chemical potential[2, 3] as the primary thermodynamic variables, in accordance with the QCD phase diagram. The model successfully predicts the order of phase transition from a confined state to a deconfined state. That being first order, which essentially translates to a discontinuity in the entropy S against temperature (T). Recent experiments at CERN and BNL suggest the precise description of QGP evolution necessitates the incorporation of new thermodynamic variables, i.e. Magnetic Field. Heavy Au-Au/Pb-Pb ion collisions, need not be head-to-head collisions.

Hence it is plausible that the magnetic field is playing a critical role in the formation of the QGP and possibly its physical characteristics. It is important to note that the magnetic field considered here is the external magnetic field [4, 5] present in the environment wherein the QGP droplets form. Another motivation for the incorporation of magnetic fields arises from cosmological and astronomical observations. Primordial magnetic fields of the universe have governed the dynamics of the large-scale magnetic fields that are found in galaxies today. More importantly these primordial were also associated with the phase transitions and inflation in the early universe [6]. Since QGP phase transitions are a manifestation QCD interactions, magnetic field [7] must have an effect on the evolution, which interacts through colour charge. Since QGP prevailed in the very early phase of the universe, it is thus crucial to consider this aspect.

With an aim to foster a robust and concise model, simple additions have been made to the existing statistical picture. Temperature is a measure of the energy of the system. The collisions which lead to the formation of QGP droplets are relativistic. Further, again from cosmological constraints, the cosmological environment enabled relativistic regimes. Thus, instead of rest masses, dynamical relativistic masses have been used [8]. Dynamical masses are explicit functions of temperatures. The highlight of this magnetic field study is the parametrization of magnetic

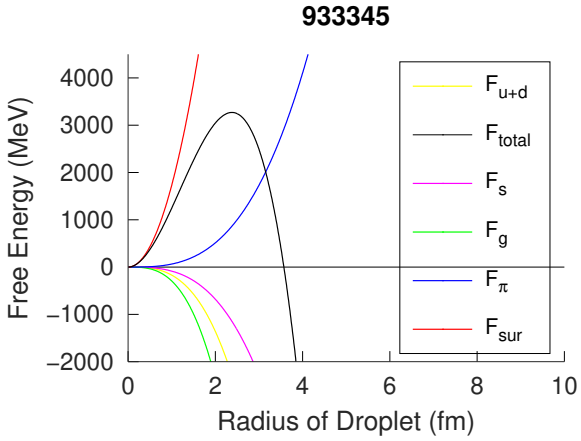

FIG. 1: Variation of Free Energy parametrized by T, μ and B. T = Tc = 175 MeV, μ=400 Mev, $eB = 15m_\pi^2$

field, as an indigenous attempt , strength [9] on the medium and all the constituents contributing to free energy, which in this case is the π-ionic medium.

II. DISCUSSION

A. Free Energy

Through the Thomas-Fermi Model of the atom and the Bethe Model for nucleons, the density of states for quarks and gluons is retained from the previous study cite[1]:

$$\rho_{q,g}(k) = \nu(1/\pi)^2 \left[[-V_{conf}(k)]^2(\frac{-dV_{conf}}{dk})\right] \tag{1}$$

Here V_{conf} is the confining potential [1, 10] for quarks and gluons, given by

$$[V_{conf}]_{q,g} = \frac{1}{2k}(\gamma_{q,g})g^2(k).T^2 - \frac{m_o^2}{2k} \tag{2}$$

All the following parameters are retained:

$$g^2(k) = (4/3)(12\pi/27)\left[\frac{1}{ln(1+k^2/\Lambda^2)}\right] \tag{3}$$

$$k_{min} = (\gamma_{q,g}.N.T^2.\Lambda^2/2)^{1/4} where N = (4/3)(12\pi/27) \tag{4}$$

$[-V_{conf}]_{q,g}$, the confining potential constructed from QCD constraints is retained, due to its apt description of the dynamical nature of quarks. While $\gamma_{q,g}$ are the hydrodynamic flow parameters, which account for the fluid nature of the plasma. Though a minor altercation is done with the original form of the potential, which is the addition of dynamic temperature-dependent masses. In this statistical model, the Peshier, and thus confining potential is invariant. Thus, the perturbative additions of magnetic field do not affect the Peshier potential constructed from Thomas-Fermi and Bethe models. There exists a simple explanation for this striking result. Magnetic field does no actual work, in the confinement of deconfinement processes, on the system. Peshier potential is a confining potential for the quarks and gluons. The thermal dynamic masses

are defined as [8]

$$\mathbb{M}_{d_{q,g}} = \gamma_{q,g}.T^2\left[\frac{1}{log(1+T/T_c)}\right]^2\left(\frac{16\pi^2}{11-\frac{2}{3}N_{f_{q,g}}}\right) \tag{5}$$

where T_c is the transition temperature, while $N_{f_{q,g}}$ is the flavour number which is taken to be 0 for gluons (bosons) and three flavours for quarks (up, down and strange).[8].

Thus the thermal mass modifies the Peshier potential to yield the following expression

$$[V_{conf}]_{q,g} = \frac{1}{2k}(\gamma_{q,g})g^2(k).T^2 - \frac{\mathbb{M}_{d_{q,g}}}{2k} \tag{6}$$

Magnetic field's interplay in the confining potential is disregarded in the context of this simple statistical model. Its interaction with the quark-gluon matter is reflected through the coupling in the partition function and hence ultimately the free energy of the plasma, with a plausible mediation by colour charge.

Through these quantities mentioned above, density of states and Peshier potential, the free energy of the QGP constituents is constructed which incorporates three thermodynamical variables as follows: -

$$F_i = -T.g_g\int dk.\rho_q(k).ln\left(1+e^{-\frac{\left(\sqrt{\mathbb{M}_q+k^2-(\mathbb{B})}-\mu_i\right)}{T}}\right) \tag{7}$$

F_i denotes the free energy for the constituents quarks of the QGP. Here we consider three flavors of quarks [u,d,s]: up, down and strange. Hence index i goes from 1-3. A similar modified construction can be defined for gluons.

$$F_g = T.g_g\int dk.\rho_g(k).ln\left(1-e^{-\frac{\left(\sqrt{\mathbb{M}_g+k^2-(\mathbb{B})}-\mu_g\right)}{T}}\right) \tag{8}$$

An additional negative is needed to make the gluon-ic free energy negative.$\pi - ionic$ medium also exists within the framework of the QGP formation. $\pi - ions$ manifest as a signature in detection of QGP [11] at particle colliders. It is highlighted that in this study the medium follows from the FD and BE statistics, as evident from the free energy integrand. Further, unlike the hadrons themselves, the π meson is not modelled to have the dynamic mass. It carries a fix mass of $\mathcal{M}_\pi \sim 138MeV$ [12].A strong reason for this characteristic is the proximal relation of π-ions to chiral symmetry restoration. Their sensitivity to QGP state variables like Temperature $\mathbb{T}$ and chemical potential $\mathbb{T}$ and magnetic field $\mathbb{B}$ holds vital importance under the context of this study.

The Free Energy Integral for the π-ionic medium is given by,

$$F_\pi = -\frac{3T\nu}{2\pi^2}\int dk.k^2.ln\left(1+e^{-\frac{\left(\sqrt{\mathcal{M}_\pi{}^2+k^2+(\mathbb{B})}-\mu_i\right)}{T}}\right) \tag{9}$$

The Free energy integrals maintain the consistency, which follows from the earlier study. Hence, again statistical distribution functions for Fermi-Dirac (quarks) and Bose-Einstein (Gluons) are being followed. Before addition of a magnetic field, the Free Energy integral follows a positive sign for quarks and a negative sign for gluons. Magnetic Field changes the nature of the integrals and reverses the trend. So, the algebraic signs preceding the integral flip, such an exercise is done on an ad-hoc basis and is vital to ensure the Free energy variation with the QGP droplet radius follows the path towards equilibrium.

Finally, the modified surface energy of the droplets is constructed in the presence of magnetic fields.

$$F_{sur} = \frac{\sqrt{2}R^2}{4}\left[\gamma_f T^3 + B * T\right] \tag{10}$$

In the above equation 10, $\gamma_f = \sqrt{(\frac{1}{\gamma_q})^2 + (\frac{1}{\gamma_g})^2}$ Dimension of magnetic field is MeV^2 in the natural units system. Coupling of the magnetic field with the system is dependent on the constituents. While for quarks, *pi* – ionic medium and surface energy, the field interacts as a square of a coupled quantity $\mathbb{B}$ and $\mathbb{T}$. On the other hand for bosons in the system, i.e. the gluons, the field interacts without a scaled-down factor of the temperature. Suggesting that coupling between fermions and hadrons is stronger as compared to gluons.

Limits in accordance with LHC	Magnetic Field Strength ($\frac{\times m_\pi^2 * 15}{0.303}$)
Minimum	0.98
	1.107
	1.2
	1.46
	1.71
	1.83
	2.00
Maximum	5.00

The range of magnetic field is fixed by the LHC exeperiments [13], while the supremum is imposed by numerical calculations done within this paradigm. π-ionic free energy and gluon-ic free energy are the the most susceptible to change in magnetic, with the former sets a much more substantial constraint.
The total free energy is the summation of all the individual constituents without any considerable interaction among them.

$$F_total = \left(\sum_{i=1}^{3} F_i\right) + F_g + F_\pi + F_{sur} \tag{11}$$

The existing free energies of the *pi* ionic medium and the surface free energy are parametrized with a magnetic field over the existing thermal dependence. Chemical potential does not play a part in the surface energy. It is modelled in a way which approximates the surface of the droplet in the phase space, which means momentum (k) which is ultimately due to temperature. Implying, that the surface energy (per unit area) is calculated for a single droplet is same for any droplet of some arbitrary radius and thus does not reflect a summation of the constituents of the system. Their dependence on the magnetic field is modelled which verifies the expected results. In the presence of large magnetic fields produced during the collisions at BNL and CERN, the QGP formation is significantly changed. Magnetic field, restricts the momentum space thus allowing for a greater density of Baryons and thus a higher energy density. Surface Free energy aptly appears like a parallelism to the surface tension of the Quark Gluon Plasma droplet: whose formation is governed by an interplay of QCD interactions and the three dynamical thermodynamic variables in this model. Chemical potential does not appear in the expressions, as explained above. The magnetic field governs the surface structure of each droplet formed through the deconfinement process.

Since the droplet is charged (QCD colour charge) and consists of charged constituents (quarks), the magnetic field affects its curvature [14]. At the equilibrium of the interplay between QCD forces, thermal energy and magnetic field, the droplet assumes a stable radius. *pi* – ionic free energy.

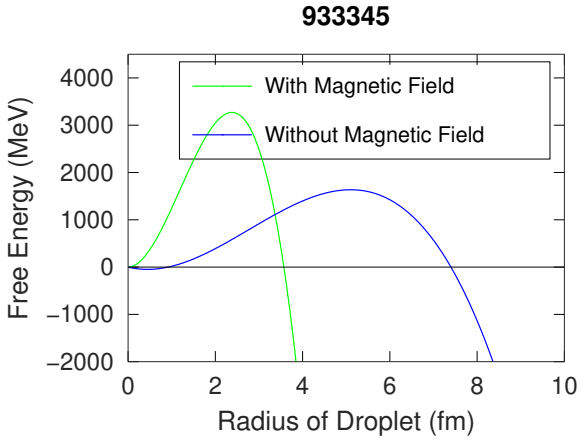

FIG. 2: Comparisson of stability in the absence (blue) and presence (green) of B. With a higher peak indicating a much more stable droplet. T = Tc , μ=400 Mev, $eB = 15m_\pi^2$

Magnetic field does not seem to affect the Peshier potential of the quarks and gluons. Magnetic field is an independent variable. Thus, making the macroscopic states of the fireball system as:
i) Temperature
ii) Chemical Potential
iii) Magnetic Field

B. Entropy, Heat Capacity and Phase Transition

An intricate perspective towards the formation of the de-confined phase of quarks and gluons is presented through the improved statistical model. To render a wholesome perspective though, a complete statistical and thermodynamic set of state functions is needed. Hence, through the free energy integrals, its derivative are calculated. These derivatives represent different thermodynamic state functions. First derivative of the free energy with temperature is computed, this quantity is the entropy (S) of the system. Subsequently, another derivative with temperature yield the heat capacity C_v .

As the system is transitioning towards equilibrium, entropy is expected to rise with temperature. Which means it will have a positive slope, which is nothing but the graph of the heat capacity. Further, the ratio of Entropy (S) and the heat capacity C_v define the speed of sound in the plasma phase. Speed of sound is accurately predicted by the QCD calculations. Hence, this quantity serves as a vital test for this extended simple statistical model.

$$\begin{aligned} S_{entropy} &= -\frac{\partial F}{\partial T} \\ C_{heat\ capacity} &= T\frac{\partial S}{\partial T} = -T\frac{\partial^2 F}{\partial T^2} \end{aligned} \tag{12}$$

Hence, the speed of sound can be defined as,

$$C_s^2 = S_{entropy}/C_{heat\ capacity} \tag{13}$$

In equation 13, C_s^2 is the square of the speed of sound. As per lattice calculations form Quantum Chromodynamics, this quantity has an supremum, capped at 1/3.

Entropy and heat capacity also yield information about phase transition. Since formation of Quark-Gluon Plasma involves a change of phase from a confined state of hadrons to a free or de-confined state, the process occurs through a thermodynamic phase transition. In the

previous study, with temperature as the only parameter, the order was phase transition was first order. Therefore, a discontinuity in the first derivative of free energy, i.e. entropy was observed. Verification of the nature of phase transition is done again. Mainly to check if its behavior is preserved or undergoes a change. Hence, the plots for entropy, heat capacity and speed of sound are studied to find the order.

III. RESEARCH METHODOLOGY

A. Literature Review

The study is reinstated by an overview of the existing statistical model. Followed by a thorough review of new research that has emerged in the field. ALICE experiments at CERN and the RHIC experiments at Brookhaven National Laboratory have fueled the research around this discipline. While the experiments take a long time to run, and an even longer time to collect, analyse annd study the results. Theoretical models, which are developed independently, aid in predicting the result of the experiments. Another vital role played by theoretical models, is in the process of defining constraints. Constraints allow a single run to be effective by dedicating the resources in a dedicated direction which is expected to yield results. Since the experiments reveal new information every time, the review procedure familiarizes with the existing sphere of knowledge around research in QGP. This study presents a novel and indigenous process to comprehend the complex dynamics of QGP formation, so the literature review provided the neccesary outlook which helped in scrutinising existing models and formulating the one employed here.

B. Data for Simulation

Computations form an integral part in the analysis, first mathematical model was formulated. Which was followed by a simulation through numerical and symbolic functions based computation. Hence, much of the data was generated within the framework of the simulation. As a result, there was no immediate need to collect data from previous studies. Though a variety of existing plots pertaining to the paradigm of the study were referred throughout the study.

C. Qualitative and Quantitative Analysis of results

Review process prepared a ground work to be built upon. A brief idea of the variation of Free energy in the position space was obtained. However, with the incorporation of every new variable, the system portrayed a different behaviour. The study concludes with an analysis of stability, through a comparison with previous models, analysis of order of phase transition and estimation of speed of sound near the transition temperature.

IV. RESULTS AND CONCLUSION

In absence of B thermal motion on account of alignment is small. As $\mathbb{B}$ enters the scenario, it competes with thermal energy and counters. So, one expects the degrees of freedom to change, hence the curve shifts to smaller radius values, which is the case. Indeed, this reduction in radius is observed only when the droplet forms i.e. free energy assumes a bell-like behaviour. The quantification of this decrease (in radius) should be proportional to the strength of the field. $\mathbb{B}$ thus has an apparent effect on the height of the peak which is proportional to the free energy of the system.

As a shift towards dynamic temperature-dependent masses is implemented. It is observed that

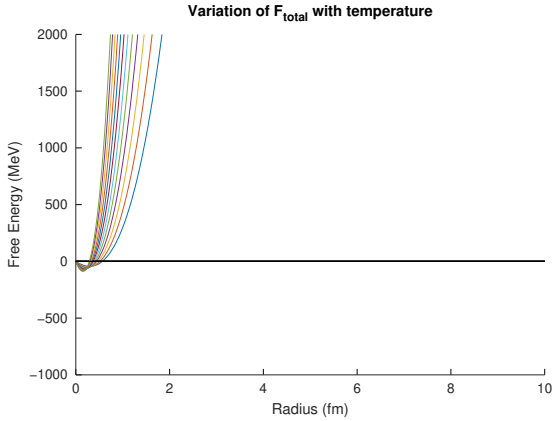

FIG. 3: Variation of free energy for different temperatures with $\mathbb{B} = 0$ and $\mu = 400$, with the ratio of flow parameters as 8.

droplets are not stable (monotonically increasing trends) until chemical potential is added to the distribution function. Which suggests dynamical masses increase the energy content of the system.

To reinstate the bell-shaped trends, chemical potential at first and magnetic field reduces the Free energy and enable formation of droplets with a finite peak. A new observation is $\mathbb{B}$ favours formation of smaller droplets, and hence brings down the mean stable radius of droplets. A high chemical potential is favored by the system ($\mu_q = \mu_g = 400\, MeV$). The constraint is set by the speed of sound, which is highly sensitive of the chemical potential. A numerical comparison reveals that at $T = T_c$, average over entire range of magnetic field for a radius of 4 fm shows a 16 times increase in the free energy peak as compared to the basic simple statistical model.

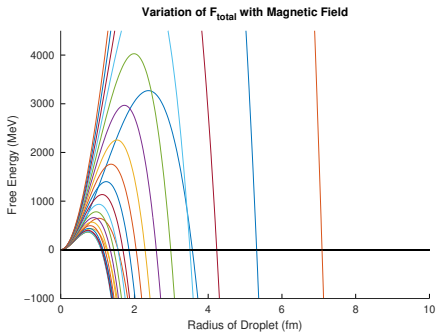

FIG. 4: Variation of Free Energy for various values of B with fixed T and μ

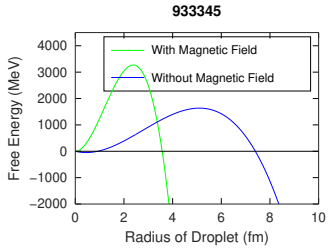

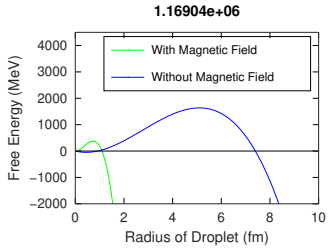

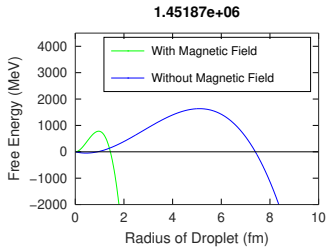

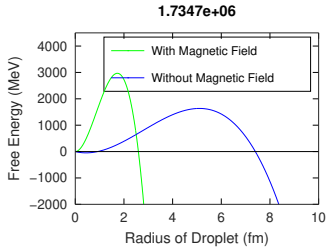

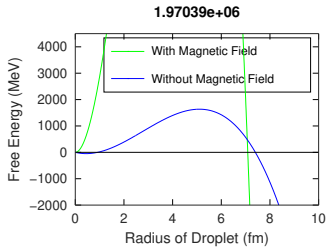

Dependence on the flow parameters has been reduced following the addition of temperature-dependent dynamical masses, chemical potential and magnetic field. The greatest factor affecting this change is chemical potential. Previously, altercation of the flow parameter ratios between quarks and gluons by a difference of 2, the stability of the plasma immensely shifted the trends of the Free Energy curves. The scenario has changed now. Although, the dependence has not vanished entirely, and a factor of $\gamma_g = (6, 8)\gamma_q$, still give a favorable peak, other variables simply assert dominance. Which means if Magnetic field is high enough, within the appropriate bounds, a feasible phase transition is observed outside the previous stable domain of flow parameters.

Finally, the order of Phase transition when all the thermodynamic variables are taken into account is a weakly first-order phase transition. There appears a distinct discontinuity in the trends of entropy near the transition temperature. However, a slight yet continuous deviation in

the case of heat capacity is also observed. The ratio of entropy and heat capacity gives the speed of sound (C_s^2). Comparing from the QCD results, which limits the C_s^2 at 1/3. Under the paradigm of this extended study, it is found that this natural bound is being respected by the trends. Further, the trends obey QCD calculations and computations based on ALICE data. At the effective temperature (222 MeV) [15], $C_{sT_{eff}}^2$ is within 16% margin of error in accordance with the bounds.

Concluding this study, it is emphasized that the stability of QGP is greatly enhanced. There are some new observations: dependency on flow parameters and reduced average stable radius which require further study.

EFFECT OF AGRICULTURAL TRADE LIBERALIZATION ON FARM INCOME IN INDIA: AN EMPIRICAL ANALYSIS USING ARDL APPROACH

Hariom Prakash Verma[1*], Nand Kumar[2]
Delhi Technological University, Bawana Road, Delhi, India-110042

Abstract
This study examines cointigration between farm income and agricultural export using ARDL approach during trade liberalization era (1991-2021) in India. ARDL is one of the most dynamic unrestricted model in economic literature. We have used ARDL approach to account for the non stationary of the data. Several measures and indicators are used to assess farmers' income in the country. Agricultural GDP can provide an approximate proxy for farm income to some extent, but it has limitations. Agricultural GDP represents the total monetary value of all goods and services produced within the agricultural sector. Farmers' income, on the other hand, is the actual earnings that farmers receive from their agricultural activities. This paper considers only Agriculture component of Gross Domestic Product at constant prices as a proxy for farm income. The ARDL Bound test revealed the existence of a long run relationship among selected variables. The coefficient of error correction term indicates that short run shocks could be adjusted towards their long run equilibrium at a rate of 107 percent per annum. The results of the study show that in the long run, agricultural output is positively influenced by exports, fertilizer use, and yield. Imports do not have a significant long-run impact. In the short run lagged differences of imports and fertilizer use have significant affect on farm income. CUSUM test demonstrates stability in the model and diagnostic tests shows that there is no serial correlation as well. While this study has limitations, it provides valuable insights into the relationships between agricultural exports and farm income in India.

Keywords: Liberalisation, Agricultural trade, Farm income, Bounds test, CUSUM, ARDL

1. Introduction

Several countries have carried out economic reform and followed trade liberalisation over last several decades. The impact of trade liberalisation on farmers' income is a significant and complex topic. Trade liberalisation policies include tariff reductions, removal of non tariff barriers, or participation in trade agreements. Trade liberalisation encourages countries to specialise in goods and services in which they have a comparative advantage, which can potentially increase the income. Changes in the factor endowments, such as land, labour and capital may affect farmers' income. Trade liberalisation typically leads to increased market access for agricultural products; this can increase demand and competition, influencing prices

and income. Open markets may lead to greater price fluctuations, affecting farmers' income stability.

Farmers' income refers to the earnings or revenue generated by individuals or households engaged in agricultural activities. This income is primarily derived from the sale of crops, livestock, and other agricultural products, as well as related activities such as agribusiness, agro-processing, and value addition. Measuring farmers' income in India is a difficult task due to the diversity of agricultural practices, landholding sizes, crops grown, and other factors. Several measures and indicators are used to assess farmers' income in the country: Gross income, Net Income, crop income etc. Agricultural GDP can provide an approximate proxy for farmers' income to some extent, but it has limitations. Agricultural GDP is the value of all goods and services produced within the agricultural sector. Farmers' income, on the other hand, is the actual earnings that farmers receive from their agricultural activities.

Agricultural Gross Domestic Product (GDP) stands as a pivotal indicator of the economic health of a nation's agricultural sector, serving as a proxy for the income generated by farmers. In our study we have consider only Agriculture component of GDP, the determination of agricultural GDP is a complex interplay of various factors, each exerting its influence on the overall productivity and economic output of the agricultural sector. This paper examines the factors affecting agricultural GDP and also looks into the cointegration between variables in the long run, employing Autoregressive Distributed Lag (ARDL) approach. The independent variables in this study include Agricultural Export, Import, Yield, and Fertilizer consumption, each contributing uniquely to the agricultural production and income.

Agriculture plays an important role in the process of economic development of countries. The importance of understanding and analyzing the determinants of agricultural GDP lies in its direct correlation with the income of farmers. As the world grapples with evolving global dynamics, such as climate change, trade liberalization, and technological advancements, it becomes imperative to dissect the contributing factors that influence the economic outcomes of those engaged in agriculture.

One of the important variables in this study is Agricultural Export. The volume and value of agricultural exports not only reflect the competitiveness of a nation's agriculture sector but also influence the income generated by farmers. Changes in global demand, trade policies, and market access can significantly impact the export potential of agricultural products, thereby affecting the overall agricultural GDP. Another key variable in our study is Yield which explains the quantity of agricultural output per unit of land. The cost of inputs on seeds, fertilizers, machinery and labor constitutes a significant component of the production process. Fluctuations in input costs can have a direct impact on the on farmers' income.

This study examines the cointigration between the farm income and agricultural export using ARDL approach during trade liberalization era (1991-2021) in India, and also investigates the long run cointegration among the variables. The section two of the study discusses some of the important studies carried out on the topic; section three discusses data sources and methodology which have been used in this paper/research. Results of the study have been

reported and discussed in section four and finally conclusion of the study and its limitations have been presented in section five.

2. Literature Review

International trade has become one of the most important drivers of economic growth of a nation. The overall effect of free trade or regional cooperation may be positive, negative or indifferent, depending on the volume of trade creation and trade diversion Clausing (2001).

Anwor et al (2013) finds in their study that trade liberalization has an impact on the agriculture sector's and its export sub-sector's performance in Nigeria. Yusida et al. (2021) findings indicate that an increase in food crop imports alone could lead to a decrease in farmer income. However, if this rise in food crop imports is accompanied by increased exports and production in non-agricultural products, it could result in an increase in farmer income. Anderson et al. (2006) found that transitioning to free merchandise trade would lead to several positive outcomes in developing countries, like increase in agricultural output and exports.

Khan et al. (2021) discovered that trade liberalization in Pakistan doesn't result in reducing income inequality in the short term. They observed that trade agreements favoring agriculture, while improving income equality, is due to decrease in urban and non-farm household income [21]. The key finding of Dhar (2023) is that India's agriculture sector faces challenges due to WTO agreements, including constraints on domestic support measures like minimum support prices and restrictions on export subsidies, impacting the implementation of national food security initiatives. Faridi (2012) conducted research on the impact of agricultural exports on Pakistan's economy, analyzing data from 1972 to 2008. Contrary to expectations, the study found that increasing agricultural exports hindered economic growth, while non-agricultural exports were found to stimulate economic development. As a result, the study suggested promoting non-agricultural and textile products to foster economic growth in Pakistan.

The agriculture sector's performance is contingent on multiple things. Several researches have been carried out on the factors influencing the agriculture sector. Some of the references include Mehdi (2011) , Udah and Nwachukwu (2014) , Ahmad and Heng (2012) , Raza and Siddiqui (2014) , Kannan (2011) , Tripathi and Prasad (2009) , Solanki (2017) , Kamat et al. (2007) , Aynalem et al. (2019) . Existing research have not reached a clear consensus on the extent and impact of different factors on agricultural production. This section reviews and presents literature from different countries worldwide followed by Indian studies.

Mehdi (2011) analyzes the factors influencing agricultural growth in Iran from 1970 to 2007 using annual time series data and the ARDL model. The study discovered that human capital and investments in the agriculture sector had a favorable and considerable impact on agricultural value addition. Shita et al. (2019) found that in Ethiopia, agricultural technology adoption, arable land area, and real GDP had a positive effect on agricultural productivity (cereal output per hectare). The study utilized the ARDL technique to analyze data from 1990 to 2016. Udah and Nwachukwu (2014) examined factors influencing agricultural growth in Nigeria using time series data from 1960 to 2010. Using OLS approach, researchers discovered that factor productivity and infrastructural development, had a major impact on the expansion

of the farming industry. A study conducted by Ahmad and Heng (2012) utilized the ARDL model to analyze the factors influencing the increase of Agricultural Productivity in Pakistan. The primary influencing elements in agricultural productivity development were identified as fertilizer, human capital, and agricultural credit.

Raza and Siddiqui (2014) used the Johansen Co-integration Approach to examine the factors influencing agricultural output in Pakistan based on data from 1972 to 2012. The findings indicated that the quantity of tractors, enhanced seeds, tube-wells, water supply, and agricultural workforce have a significant and favorable impact on agricultural production.

Kannan (2011) analyzed the factors influencing agricultural growth in India using annual data from 1967/68 to 2007/08 and the Ordinary Least Squares (OLS) method. The projected findings indicate that irrigation, capital formation, rainfall, and fertilizer usage have a considerable favorable impact on agricultural growth.

Tripathi and Prasad (2009) used the OLS regression model with annual data from 1950-51 to 2005/06 to explore factors influencing agricultural productivity in India. Land, labor, and capital were identified as the primary sources of agricultural output.

Solanki (2017) examined factors influencing farm GDP in India from 1990/91 to 2011/12 using a VAR model. The study indicated that public investment, terms of trade, and minimum support price had a positive impact on agriculture GDP, whereas fertilizer subsidy has a negative effect.

Kamat et al. (2007) utilized the Cobb Douglas Production Function with the OLS method to study the factors influencing agricultural GDP in India from 1970/71 to 2002/03. The institutional credit and support price of wheat have a beneficial impact on agricultural productivity, whereas the net irrigated area has a negative effect. A distinct regression model was used specifically for the post-economic reform period. All factors were deemed negligible.

Chand et al. (2015) in his study found that agricultural income earned after adjusting for input costs and wages has been different in the last three decades. Farm income per cultivator increased by 2.74% a year from 1983–84 to 1993–94 and dropped to below 2% in the next decade. From 2004–05 to 2011–12, per cultivator farm income increased by 7.3% a year. Das et al. (2017) discovered a U-shaped relationship between farm size and farm income, suggesting that there is an optimal farm size for maximizing income, and an inverted U-shaped relationship is found between farm income and farm and off farm diversification indicating that there is an optimal level of diversification beyond which income may decline.

Dev (2020) discussed in his paper that in India while the farm laws offer farmers more choices and potential for better prices, uncertainties persist. Addressing imperfections, developing marketing infrastructure and shifting focus from cereal-centric policies to diversified agriculture are crucial for success, aiming to achieve higher agricultural growth and increased farmers' income.

Singh (2020) in his findings suggest that neoliberal reforms and open economic policies have not translated into improved agricultural development or enhanced food security in India, but rather have exacerbated existing challenges and inequalities.

Kumar et al (2021) investigates the major factors affecting the performance of agriculture sector in India by using ARDL approach. There study concludes that certified seeds, fertilizers'consumption, net irrigated area and pesticide have positive effect on agricultural GDP in the long run

3. Data and Methodology

The research work is based on the secondary data obtained from different sources like, Ministry of Agriculture, the Directorate of Economics and statistics, and Reserve Bank of India, Mumbai. For the research work the annual time series data on Agriculture component of GDP at constant prices, export, import, fertilizer consumption and yield have been taken for the time period from 1991 to 2001.

For any meaningful regression model, variable should be stationary because the regression analysis based on non stationary variables may give spurious results. Order of the integration of variables helps to select the appropriate model in the time series. Therefore, we have conducted the stationarity test to establish the order of integration. The study uses Phillips-Perron and KPSS along with Augmented Dickey Fuller (ADF) test to measure unit root. Although ADF test is most widely used unit root test, PP test is considered more robust for the presence of autocorrelation and heteroscedasticity.

If all the variables are stationary at level 1 that is I(I), it implies that they have unit root and are non stationary. In this case, it is generally recommended to use a cointegration analysis or error correction model (ECM) to account for non stationarity of the variables. Cointegration analysis helps identify long term relationship among variables and the ECM allows modeling short term dynamics and adjusting for any deviation from the long term equilibrium.

The most commonly used model for such cases are Engle-Granger two step cointegration test, the Johnsen cointegration test and ARDL Bound test. These test help to determine if there is stable long-term relationship among I(I) variables, and if so an ECM can be constructed to study their short term dynamics. This study uses ARDL model to examine the relationship between farmers income and export, import, fertilizer consumption and yield .The ARDL approach is flexible and widely used method for modeling relationship among nonstationary time series data.

For examining the relationship among the agricultural output and various inputs the following regression model has been specified and estimated.

$$lnAGDP = \alpha_0 + \beta_1 lnEX + \beta_2 lnIM + \beta_3 lnFTZ + \beta_4 lnYLD + \varepsilon_t \quad (1)$$

In the above equation, the dependent variable (AGDP) represents Agriculture component of GDP.EX stands for the agricultural export and IM is agricultural import.FTZ indicates total fertilizer consumption and YLD is yield.

Further, we estimate the equation (2) for ARDL bounds test Proposed by Pesaaran, Shin and Smith (2001). The study assesses the long run relationship between Agricultural GDP, Export, Import, Fertilizer and Yield. As in our study our dependent variable is I(l), we have estimated the equation two for bounds test cointegration.

$$\Delta lnAGDP = \alpha_0 + \sum_{i=1}^{n_1} \alpha_{1i}\, \Delta lnEX + \sum_{i=1}^{n_2} \alpha_{2i}\, \Delta lnIM + \sum_{I=1}^{n_3} \alpha_{3i}\, \Delta lnFTZ + \sum_{i=1}^{n_4} \alpha_{4i}\, \Delta lnYLD + \beta_1 lnEX + \beta_2 lnIM + \beta_3 lnFTZ + \beta_4 lnYLD + \mu_t \quad (2)$$

F statistic obtained from the regressing above equation is compared with critical value obtain from Pesaran et al (2001) if the value of F statistic is greater than the upper Bound we reject the null hypothesis of no cointegration, and the value of F statistic is smaller than the critical value of the lower bound I(0), there is no cointegration. After confirming the existence of cointegration among the variables based on the bounds test we regress ARDL restricted error correction model as given in equation (3) below.

$$\Delta lnAGDP = \alpha_0 + \sum_{i=1}^{n_1} \alpha_{1i}\, \Delta lnEX + \sum_{i=1}^{n_2} \alpha_{2i}\, \Delta lnIM + \sum_{I=1}^{n_3} \alpha_{3i}\, \Delta lnFTZ + \sum_{i=1}^{n_4} \alpha_{4i}\, \Delta lnYLD + \theta ECT_{t-1} + \mu_t \quad (3)$$

The coefficient of error correction term θ shows the speed of adjustment towards the long run equilibrium and remaining coefficient provides short run dynamics.

4. Results and Discussions

4.1.Descriptive Analysis

Figure1. Shows the trend of AGDP, over the past three decades, the Agricultural Gross Domestic Product (GDP) in India has shown both positive and negative trend. In the early

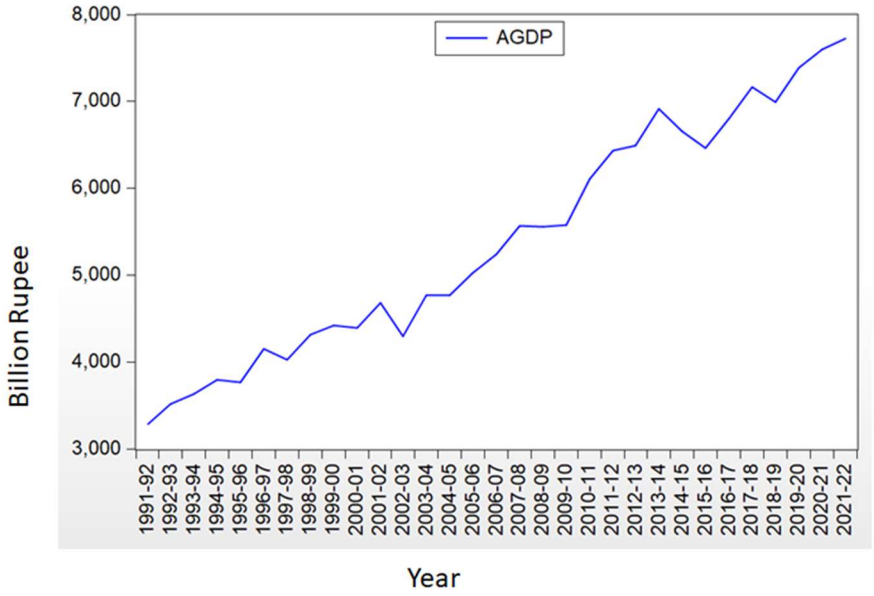

Figure 1. Trend of AGDP

1990s, India faced significant economic reforms aimed at liberalizing various sectors including agriculture. This period witnessed moderate growth in agricultural GDP as the sector started to adapt to new policies and technologies. During 2000 – 2010 the agricultural sector in India saw mixed growth. Factors such as fluctuations in monsoon rains, increased use of technology in farming practices, and government initiatives like the National Agriculture Policy

influenced agricultural GDP growth. Overall, the growth rate was relatively stable but not very high.

The agricultural GDP growth during 2010 – 2020 was somewhat volatile. There were periods of good growth driven by favorable monsoon rains, increased government spending on agricultural infrastructure, and the introduction of schemes like the Pradhan Mantri Kisan Samman Nidhi (PM-KISAN). However, challenges such as agrarian distress, water scarcity, and price fluctuations persisted, impacting overall growth.

The agricultural sector faced significant challenges and transformations during the early years of 2020s, including the COVID-19 pandemic. Despite disruptions caused by the pandemic, the agricultural sector demonstrated resilience, with the government implementing various measures to support farmers and ensure food security.

India embarked on economic reforms in 1991 that liberalized its economy, including the agricultural sector. This period witnessed a gradual increase in agricultural exports as the country started to engage more actively in international trade. Key agricultural commodities exported during this time included rice, wheat, spices, tea, and cotton.

Figure2. shows the trend of Agricultural Export, after 2010 India's agricultural exports saw significant growth in commodities included rice, buffalo meat, spices, fruits, vegetables, and processed food products. The government introduced schemes like the Agricultural Export Policy 2018 to further boost agricultural exports. The COVID-19 pandemic disrupted global trade patterns and supply chains, leading to fluctuations in export volumes and prices. However, India's agricultural exports showed resilience, with certain commodities witnessing increased demand in international markets. The government implemented measures to support agricultural exporters and mitigate the impact of the pandemic on trade.

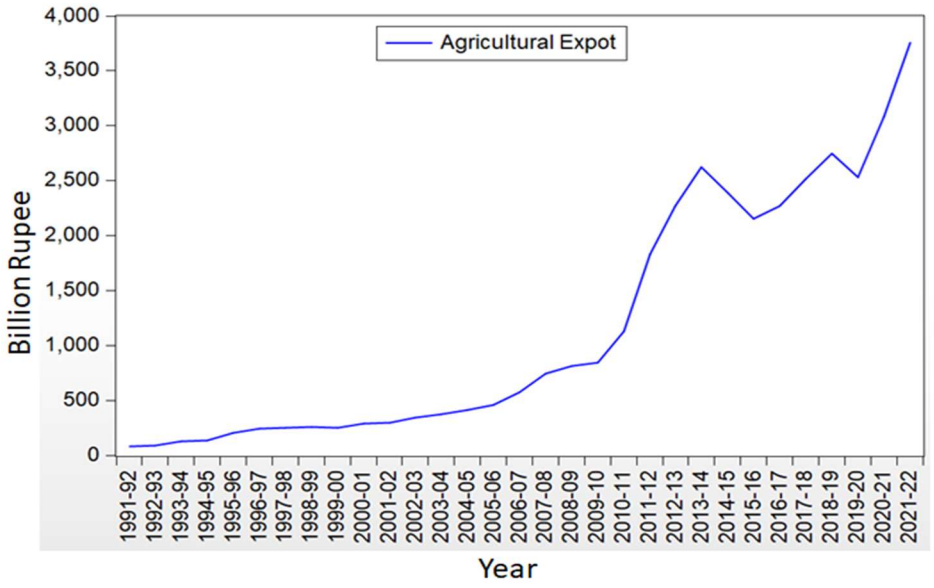

Figure 2. Trend of Agricultural Export

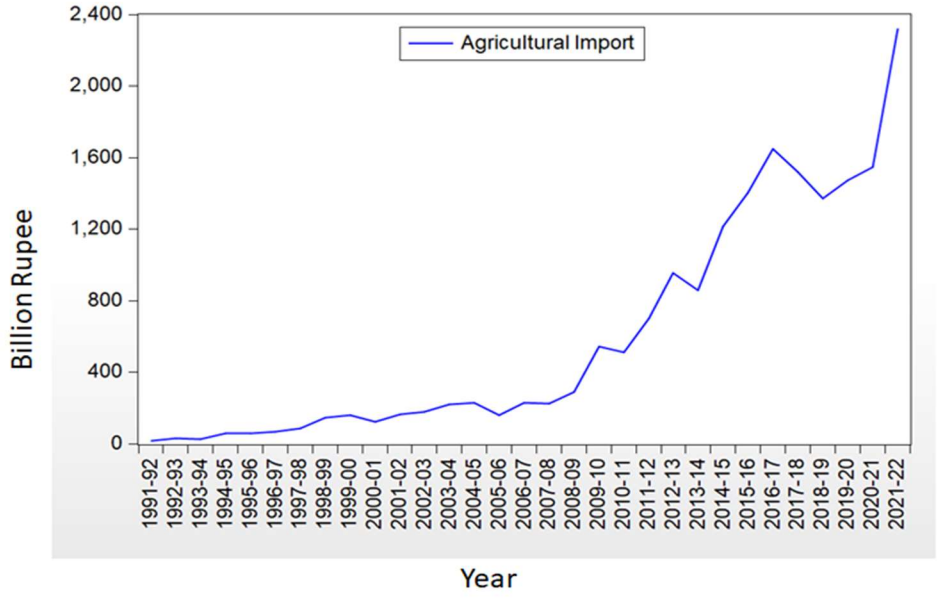

Figure 3. Trend of Agricultural Imports

In the early 1990s, the pattern of agricultural imports underwent significant changes, influenced by shifts in policies, consumer preferences, production capabilities, and global trade dynamics. The general trend over the last 30 years has been one of increasing agricultural imports in India as shown in figure 3.

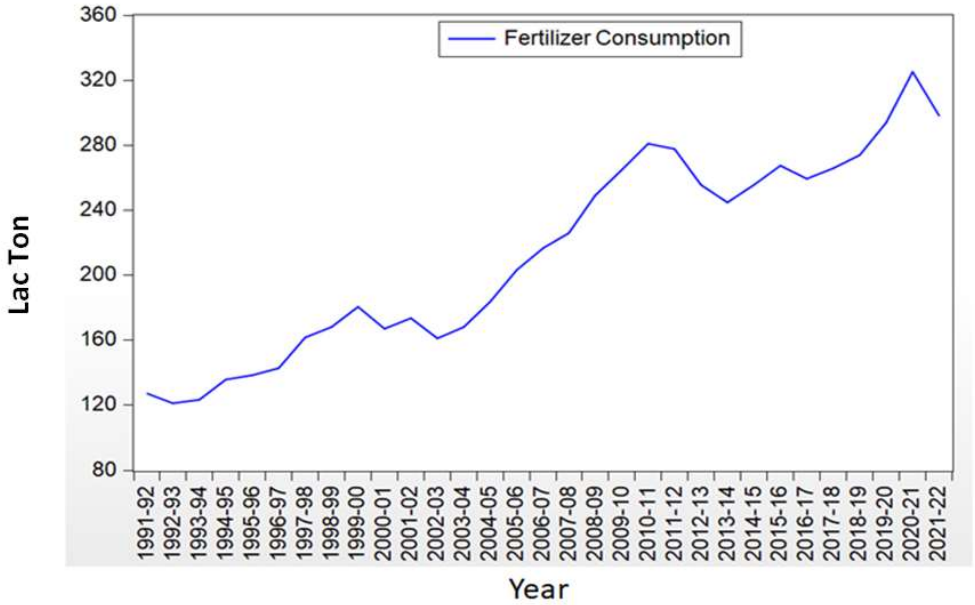

Figure 4. Trend of Fertilizer Consumption

Fertilizer consumption in India has witnessed significant growth due to various factors such as increasing population, expanding agricultural practices, government subsidies, and the adoption of modern farming techniques. Over the past thirty years fertilizer consumption in India has generally trended upwards as shown in figure 4.

Major cereal crops such as rice, wheat, and maize are crucial components of India's food security and agricultural economy. The trend of Yield has shown in figure 5, during 1990s, cereal yields in India experienced moderate growth. The Green Revolution, which began in the 1960s and 1970s, continued to have a significant impact on cereal production during the 1990s. The adoption of high-yielding crop varieties, along with the use of fertilizers, irrigation, and other modern agricultural practices, contributed to yield increases.

India saw a further increase in cereal yields during the 2000s. Government initiatives, such as subsidies for fertilizers, improved access to credit for farmers, and investments in agricultural infrastructure, helped sustain yield growth. Additionally, advancements in

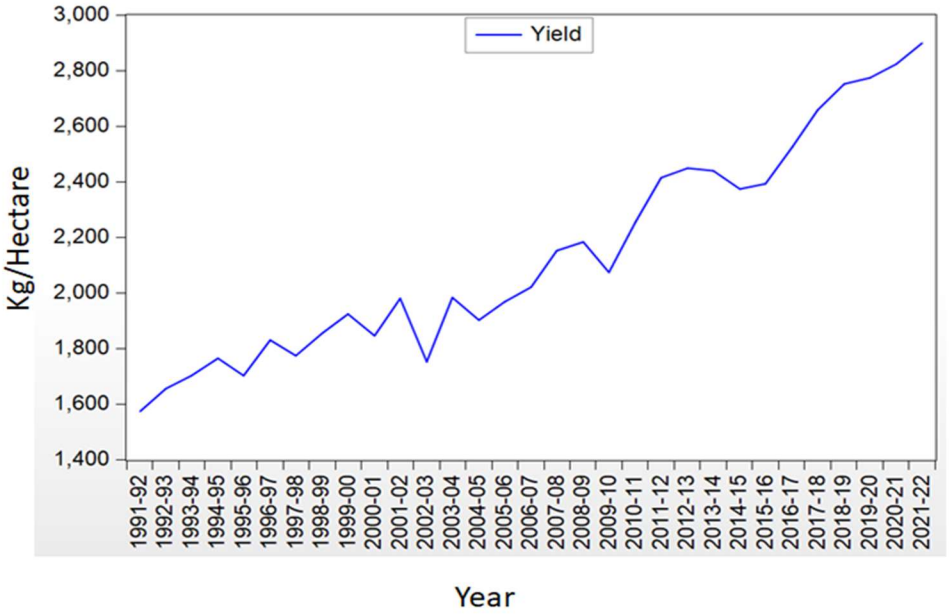

Figure 5. Trend of Yield

agricultural technology and research played a role in boosting productivity. The growth in cereal yields continued during 2010-2020 at a slower pace compared to previous decades. Factors such as climate change, land degradation, and water scarcity posed challenges to agricultural productivity. However, efforts to promote sustainable agricultural practices, including the adoption of precision farming techniques and the use of drought-resistant crop varieties, helped mitigate some of these challenges.

4.2.Econometric Results

4.2.1. Unit Root Test

The Augmented Dicky Fuller Test (ADF) and Phillips Perron (PP) test were used to check the stationarity of the time series data. We have used the ADF and PP tests to check the stationarity of our time series data, examining both levels and first differences. Eviews software has been utilized for this task. The results of the test are reported in the table 1.Based on the results, it is evident that all variables used in the study are stationary at the first difference I(I) and non-stationary at level I(0), according to both the ADF and PP tests. With this information, we have used ARDL to investigate relationships among different variables in the study.

4.2.2. Bounds Test for Cointegration

The ARDL Bound Test, is employed to determine the presence of long-run relationships between two or more variables. This step is necessary to confirm the existence of long-run relationships. The selection of ARDL (2,0,2,2,0) was done using the Akaike Information Criteria (AIC), which is a measure for lag length selection. This selection is done automatically and helps in choosing the most suitable lag lengths based on likelihood considerations. Calculation reveals that the F statistic value is 23.70200 , which exceeds the upper bound critical value at all significance levels. This implies that there is a long-run relationship between the variables in the model.

Notes: P value is denoted in parenthesis

** and *** denotes rejection of null at 5 percent and 1 percent significance level respectively

Table 2: ARDL Bound Test Cointegration Results

Test Statistic	Value	Signif.	Lower Bound	Upper Bound
F-statistic	23.70200	10%	2.525	3.09
k	4	5%	3.058	3.49

1%	4.28	5.84

4.2.3. Long Run Coefficient

After confirming the cointegration among the variables through the Bound Test, we will now analyze the long-run determinants of Agricultural GDP. The results indicate that in the long run, agricultural output is positively influenced by exports, fertilizer use, and yield. Imports do not have a significant long-run impact.

Table 3: Long Run Relationship among Variables (ARDL Bound)

Variable	Coefficient	Std. Error	t-Statistic	Prob.
C	8.642191	1.716785	5.033939	0.0001
LN_AGDP(-1)	-1.076991	0.154996	-6.948508	0.0000
LN_EXPORT	0.095001	0.028731	3.306525	0.0039
LN_IMPORT(-1)	0.010687	0.018094	0.590624	0.5621
LN_FERTILIZER(-1)	0.267970	0.058688	4.566006	0.0002
LN_YIELD	0.387987	0.086453	4.487863	0.0003

4.2.4. Short Run Coefficient

The short-run dynamic model, represented by equation 3, has been estimated, and its results are reported in the in the table 4. The ECM results indicate significant short-term relationships between agricultural output and the lagged differences of imports and fertilizer use. The error correction term is highly significant, suggesting that any deviation from the long-term equilibrium is corrected quickly in the next period.

4.2.5. Diagnostic Tests for ARDL Model

In conclusion, diagnostic examinations for the ARDL model, including autocorrelation, normality, and stability tests, were conducted, and the results suggested that the estimated model is appropriate. Table 5 illustrates that there is no indication of serial autocorrelation or heteroscedasticity. The Jarque-Bera test verified that the error terms conform to a normal distribution, and Ramsey's RESET test supported the correct specification of the functional form.

Table 4: Short Run Relationship among Variables (ARDL-ECM)

Variable	Coefficient	Std. Error	t-Statistic	Prob.
D(LN_AGRI(-1))	-0.128120	0.067632	-1.894365	0.0744
D(LN_IMPORT)	-0.020021	0.011921	-1.679448	0.1103
D(LN_IMPORT(-1))	-0.032523	0.011881	-2.737291	0.0135
D(LN_FERTILIZER)	0.225583	0.052246	4.317742	0.0004
D(LN_FERTILIZER(-1))	-0.137095	0.056989	-2.405653	0.0271

CointEq(-1)*	-1.076991	0.079894	-13.48018	0.0000

Table 5: Residual Robustness

Diagnostic tests	Null Hypothesis	Statistics	Probability	Decision
SerialCorrelation (Breusch-Godfrey Test)	No serial correlation	0.6420	0.43	Accept Null Hypothesis
Heteroskedasticity (White Test)	Homoscedastic	0.9922	0.52	Accept Null Hypothesis
Normalitiy (Jarque-Bera Test)	Normally distributed	0.1640	0.92	Accept Null Hypothesis
Model Specification (Ramsey Reset Test)	Functional form is correctly specified	1.4941	0.17	Accept Null Hypothesis

The stability of the model is validate with the help of CUSUM test, as shown in figures 6 and 7.

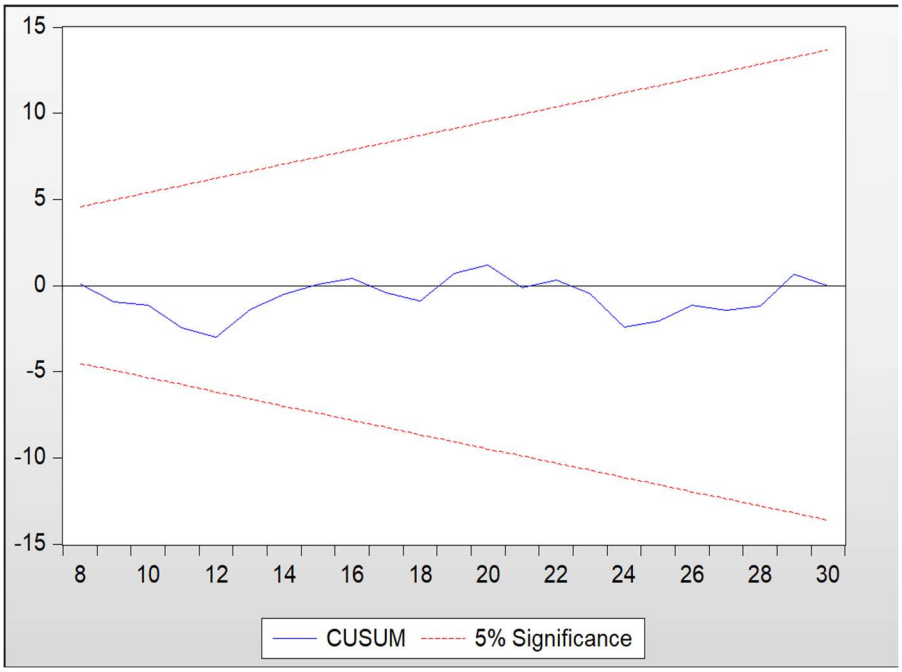

Figure 6. CUSUM Test for Stability

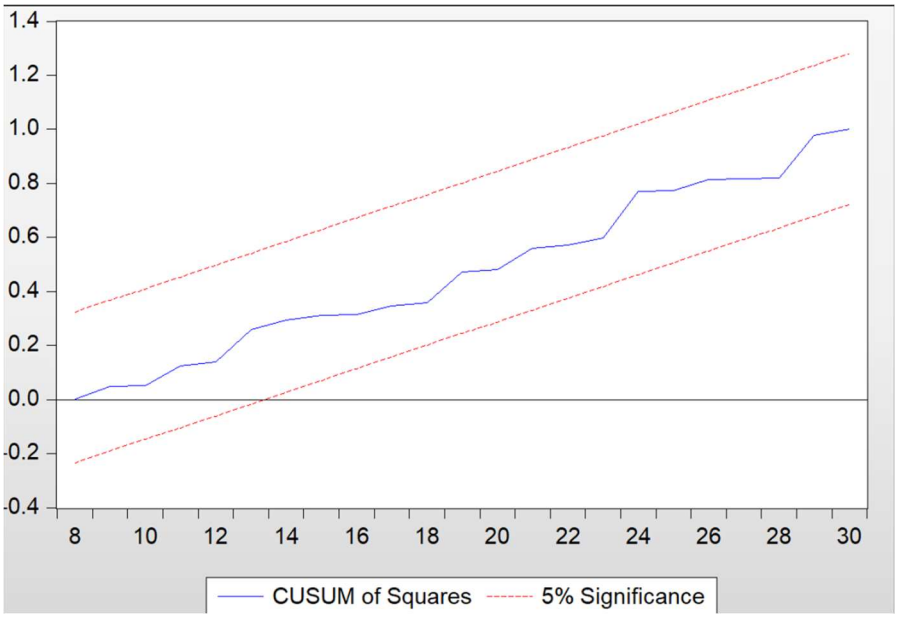

Figure 7. CUSUM Square for Stability

5. Conclusion

In order to understand the impact of trade liberalization on farm's income, this study examined the relationship between farm income and agricultural exports in India during the period of trade liberalization (1991-2021) using the ARDL approach. The ARDL Bound test confirmed the presence of a long-run relationship between farm income and agricultural exports in India. This suggests that changes in agricultural exports have a sustained impact on farm income over time. In the short run, the study identified that lagged differences of Imports and fertilizer use significantly affect farm income.

The results indicate that agricultural exports have a positive and significant effect on farm income in the long run. This underscores the importance of international trade in contributing to the economic well-being of farmers in India. Diagnostic tests, including the CUSUM test, demonstrated the stability of the model. This indicates that the relationships identified in the study are robust and reliable for analyzing the dynamics between agricultural exports and farm income. The study utilized the agriculture component of Gross Domestic Product (GDP) at constant prices as a proxy for farm income. While this approach has limitations, it provides valuable insights into the trends and relationships between agricultural output and farmers' earnings. While this approach has limitations, it provides valuable insights into the relationships between agricultural exports and farm income

ARTICLE INFO

ABSTRACT

The objective of this research is to verify the proposed innovative green product design (GPD) framework by conducting a case study that compares and contrasts the environmental impacts of two juicers manufactured by different companies but possessing identical power ratings and capacities. In accordance with the ISO 14044 standard, the research examines the complete life cycle of the household appliance by utilizing life cycle inventory data acquired from a prior publication (Shaukat et al., 2021). The validity of the proposed GPD framework is established through a comparison of its outcomes with those of a prior study that also utilized the life cycle assessment method (Shaukat et al., 2021). A life-cycle analysis reveals that the environmental impacts of the two juicers are notably dissimilar. The first juicer's energy consumption and environmental impact are lower in comparison to the second juicer. Furthermore, the proposed GPD framework's performance is comparable to the method described in the cited article. This study introduces a novel GPD framework for assessing the environmental sustainability of other products and enhances knowledge about the environmental impact of home appliances.

Keywords: Life cycle assessment, Citrus juicer, Green Product Design(GPD), Framework, Environmental impact.

I.Introduction:

Background and Motivation

Exponential growth in the use of home appliances is a result of rapid urbanisation. In 2020, the market for home appliances was expected to be worth around 283 USD billion. (Priyanka Bisht 2015).
The production, use, and disposal of these appliances, however, are responsible for a number of environmental problems. The demand for environmentally friendly products has increased as people's awareness of the effects of climate change and the depletion of natural resources has grown. Understanding how these appliances affect the environment throughout their entire life cycle is crucial.

A widely used method for calculating the environmental effects of products and processes is life-cycle assessment (LCA). Since its introduction in the 1990s, it has become widely embraced. (Allen and Shonnard 2001). Using life cycle assessment (LCA), potential effects of a product are determined throughout all stages of production, including raw material extraction, manufacturing, transportation, use, and final disposal. LCA helps to prevent the shifting of environmental impacts from one life-cycle stage to another by providing incredibly detailed information about the various environmental impacts produced by each stage of the product life cycle. (Bohm et al. 2010; Cooper 2005). The environmental performance of various products, including refrigerators, coffee makers, hand dryers, etc., has also been compared by a number of researchers using LCA. The manufacturing processes that are employed in the creation of a product are greatly influenced by its design. Consequently, a product's design plays a role in determining how it will affect the environment. Different manufacturers use various design methodologies to create products with the same functionality (Shaukat et al., 2021).

Copyright © 2024 by Author/s and Licensed by Kuey. This is an open access article distributed under the Creative Commons Attribution License which permits unrestricted use, distribution, and reproduction in any medium, provided the original work is properly cited.

Objectives of this research are:

To verify the suggested framework's accuracy by contrasting its findings with earlier LCA research that was published.

To advance knowledge of how household appliances affect the environment and to recommend the new GPD framework as a helpful resource for assessing other items' environmental sustainability.

To assess how two different manufacturers' citrus juicers affect the environment.

To determine which phase of a juicer's life cycle results in the greatest environmental impact.

II. Literature Review

The application of LCA is regulated by the standards of the International Standards Organization (ISO) 14040 series (ISO 14044:2006, 2014). In general, two varieties of LCAs are employed: those with multiple figures and those with single figures, such as the proposed framework. Multiple-figure LCA computes a product's ecological repercussions across a variety of impact categories. When comparing two or more product systems, calculations are performed for each of these multiple impact categories. This can be a voluminous, costly, and perplexing procedure that surpasses the capabilities of the majority of seasoned designers.

The environmental effects of various products, including air conditioners (Grignon-Massé, Rivière, and Adnot 2011), cooking appliances (Favi et al. 2018), domestic boilers (Vignali 2017), domestic solar water heaters (Uctug and Azapagic 2018), and refrigerators (Ma et al. 2012), have all been examined by several researchers using LCA. Subassemblies of these products have also been examined by some researchers. Elduque et al. (2014), for instance, performed a life cycle analysis on the electronic boards of an induction hob. The following is a summary of a few key studies on the LCA of home appliances.

Pina et al., (2015) performed a thorough life cycle analysis (LCA) of five distinct induction hob generations. They discovered that newer induction hob generations had less of an impact on the environment than older ones. This discovery was attributed to the more recent induction hob models' effective use of materials and components.

In a different study, a domestic cooker hood's LCA was carried out by Bevilacqua et al., (2010) The majority of the environmental effects, they discovered, were caused by the manufacturing and use phases. The electricity mix used during the use phase, they added, significantly affected the outcomes. In order to lessen the negative effects on the environment, their study also included a modified design that used LED lamps and a three-phase motor.

LCA was used by Hawthorne and Ameta (2012) to assess the environmental effects of blenders. They came to the conclusion that during the entire life of blenders, the manufacturing phase caused the most environmental harm. Additionally, they came to the conclusion that the overall environmental impacts were primarily determined by the materials used to make these blenders. Using LCA, Favi et al. (2018) compared two types of stoves sold in Italy: induction and gas. They discovered that the induction hob had greater negative effects on the environment than the gas hob.

Similarly, several other studies have compared and analyzed the environmental impacts of various products and/or processes using LCA. An examination of two distinct streetlight technologies was conducted in rural Lebanon by Tannous et al. (2018). Hischier (2015) analyzed numerous display technologies using LCA. Scharnhorst, Hilty, and Jolliet conducted a comparative analysis of multiple mobile phone networks in their 2006 study. Rubin et al. (2014) investigated different techniques for copper recovery from printed circuit boards using LCA. A comparative analysis of the environmental impacts of packaging alternatives composed of polymers and glass was conducted by Dhaliwal et al. (2014). In order to further comprehend the ramifications, the LCA methodology facilitated the incorporation of supplementary environmental effects associated with health services. Twenty-23 (Hernández-de-Anda et al.).

In conclusion, the literature review demonstrates that LCA has been used to assess the environmental effects of numerous goods and procedures. The overall environmental effects of these products depend on the design, materials, and manufacturing techniques used to create them. Reduced environmental impact can also be achieved through efficient energy use during the usage phase.

This paper compares two different methods of life cycle assessment and also compares juicers made by two different manufacturers that have the same functionality and power rating, adding to the body of existing literature. This study will highlight how these juicers' various environmental performances differ and relate those differences to their various designs.

III.Methodology

In this study, ISO14040 was used to perform LCA of citrus juicer. This section discusses goal and scope, life-cycle inventory, and life-cycle effect assessment method which is a proposed novel GPD framework. The study's assumptions and sources of inventory data are also explained. According to the ISO standard, an LCA study consists of four steps: objective and scope definition, life-cycle inventory compilation, life-cycle assessment, and outcome interpretation. (ISO 2006).

A Life Cycle Assessment (LCA) study commences by establishing a well-defined scope, functional unit, and system boundaries. Subsequently, a comprehensive record of the resources and energy consumed at every phase of the product's life cycle is compiled. The inventory is subsequently utilized to conduct the impact assessment and calculate various environmental impacts, such as global warming potential.

In pursuance with the objectives of this research, the subsequent procedures were executed:
a. Information Collection From previous publication for life cycle inventory compilation.
b. Define and implement the Proposed GPD Framework for home appliance life cycle assessment.
c. Validation and Analysis of Data.

Information Collection From previous publication

- The functional unit for this study was extraction of a half-litre of juice per day. The life of each juicer was assumed to be 3 years (given three-year warranty by each manufacturer) (Shaukat et al., 2021).
- First juicer (J1) was produced in Slovenia and the second juicer (J2) was produced in China (Shaukat et al., 2021).
- It is postulated that the two juicers were conveyed from the port of Dammam to the retail establishment via vehicle after coming via sea. Both juicers are presumed to be disposed of via landfilling (Shaukat et al., 2021).
- Simapro software was used for modelling life-cycle inventory.

Figure 1, demonstrates the system boundary for the LCA study of both juicers, and Tables 1 demonstrate the weight of various material used for both the juicers.

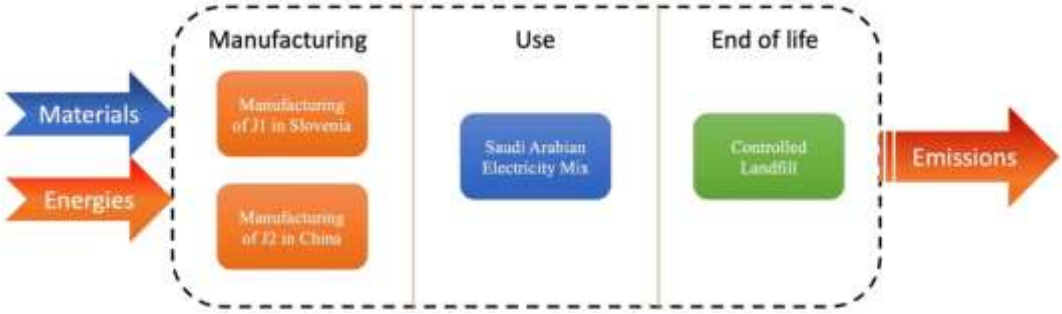

Fig. 1: System boundary for both juicers.

Table1: Life Cycle Inventory for both juicers (Shaukat et al., 2021).

Proposed GPD Framework

A growing awareness of environmental issues such as material scarcity, high energy consumption, rising atmospheric CO2 levels, ozone depletion, population growth, depletion of natural resources, and so forth contributed to the rise in popularity of "green product design (GPD)" during the late 1980s and early 1990s (Toktas-Palut, P., et al., 2022). The term "sustainable" was initially defined during the Oslo Roundtable in 1994

(Aerais, 2010). Subsequently, a multitude of GPD definitions have been presented, accompanied by illustrations of their application across diverse domains.

Vinodh and Rajanayagam (2010) argue that the main objective of a green production system is to minimize the environmental impact by integrating product and process design with process planning and control. This integration allows for environmental waste flow identification, measurement, evaluation, and management. Green product design provides economic and social benefits to customers, stakeholders, and enterprises, while also serving as a realistic and effective method to counteract environmental degradation (Fuller and Ottman, 2004). The GPD framework also encompasses the concept of eco-design, which aims to harmonize environmental considerations with design objectives that are directed towards economic goals (Karlsson and Luttropp, 2006). Howarth and Hadfield (2006) argue that organizations and designers should prioritize the selection of "environmentally friendly" raw materials. This should be followed by implementing suitable manufacturing and distribution systems, as well as specifying the use and disposal of the final product in a way that minimizes its impact on the environment and society. In the present global context, GPD is extensively advocated as a strategy that can yield substantial advantages. Consequently, numerous scholars have made significant contributions to the advancement and study of unexplored domains within the GPD discipline, with the aim of furthering GPD research.

The proposed Green Product Design (GPD) framework is a design-oriented framework that offers a single-figure score for Life Cycle Assessment (LCA) aspects. This score is significantly more efficient and user-friendly compared to using many categories for LCA. The simplicity of this framework allows for easy implementation using only pencil and paper. Designers who employ this approach develop a deep understanding of the facts, which greatly influences their design process.

This proposed GDP framework (Mohd Tayyab et al., 2024) used similar approach which is used by Philip White (White et al., 2013), which were created with modifications to the TRACI (Tool for Reduction and Assessment of Chemicals and Other Environmental Impacts) impact characterization method that was developed by scientists at the US Environmental Protection Agency (EPA). The factors combine ten environmental impact categories in one single-figure score.

This framework categorizes the product life cycle into three distinct stages: manufacture, usage, and end of life. Figure 2 illustrates this division and provides the carbon emission value for each stage. A lower value indicates a greener product.

The GPD framework can be utilized in several ways to comprehend the environmental efficacy of a design concept, spanning from rapid preliminary assessment to comprehensive examination of the entire product system. Various methodologies can be advantageous, depending on the circumstances and the types of questions the designer aims to address. The primary strategy to utilizing this framework is doing a comprehensive life cycle assessment (LCA) of the entire system. However, it can also be employed for simpler screening purposes and for comparing subassemblies (Mohd Tayyab et al., 2024).

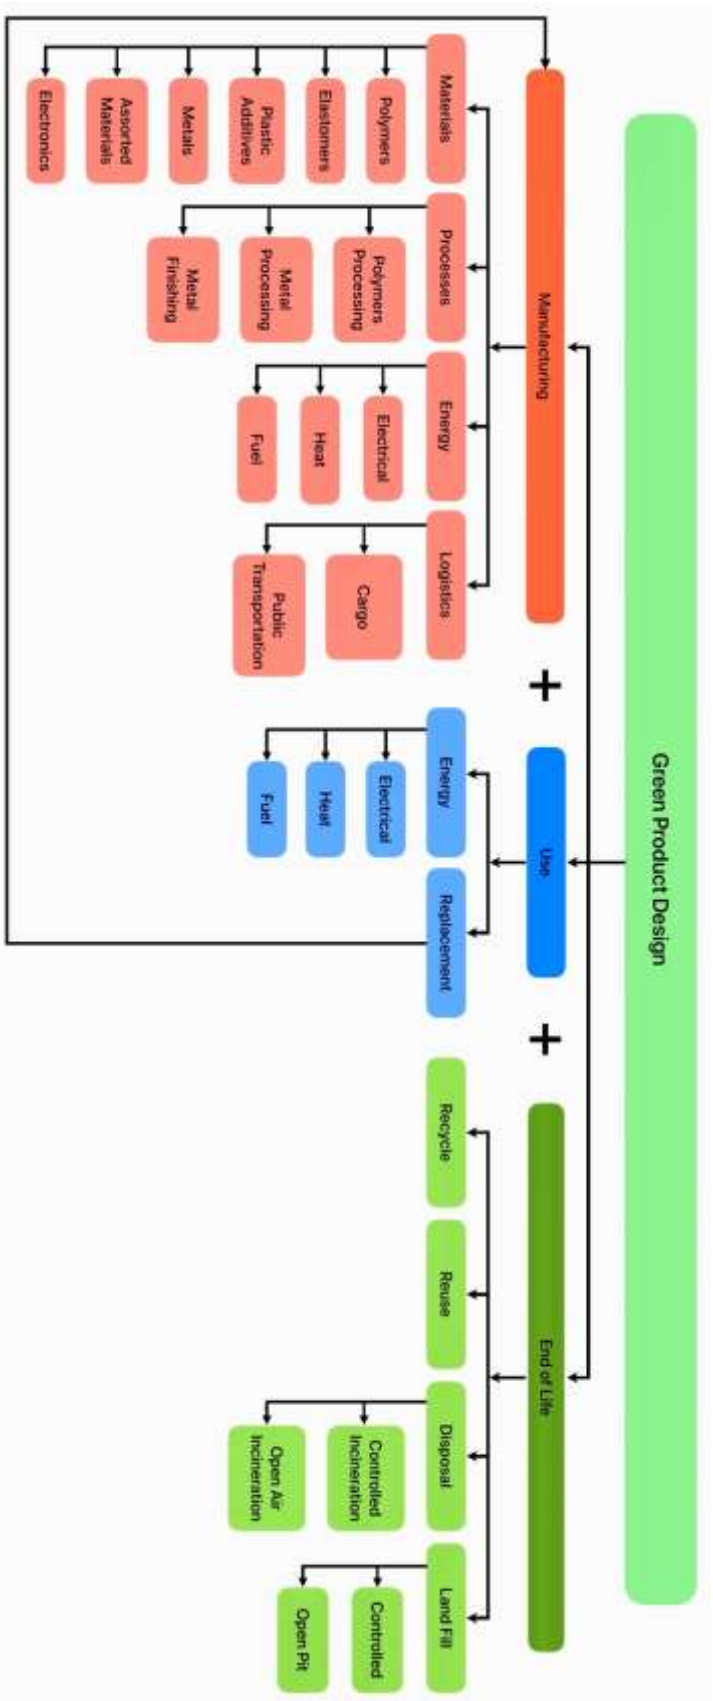

Fig 2: Proposed Framework GPD

The following steps are involved during the life cycle assessment of the product:
Step1: Define lifetime, function unit and system boundaries.
Step2: Make bill-of-materials
Step3: Calculation of estimated impacts

Data Validation and Analysis

The functional unit for this study was extraction of a half-litre of juice per day. The life of each juicer was assumed to be 3 years (given three-year warranty by each manufacturer).
Juicer J1 used an average of 7.5W and J2 used an average of 14W during juice extraction.
Assumed controlled landfill at the end of the life cycle

1. Define lifetime, function unit and system boundaries.

Juicer J1		**Juicer J2**	
Lifetime J1	24 x 365 x 3 = 26,280 hours	Lifetime J2	24 x 365 x 3 = 26,280 hours
Functional Unit	Impacts/life	Functional Unit	Impacts/ life
System boundary	Excludes cleaning during use	System boundary	Excludes cleaning during use

2. Make bill-of-materials

Total impact/life Juicer J1: 13.50kg CO_2 eq | **Total impact/life Juicer J2: 18.57kg CO_2 eq**

The process is only accurate to 2 significant figures, so we calculate the impacts per functional unit and round to two significant figures.
*Due to unspecified cable and magnet, the environmental impact of these is not included.

Figure 3(a) and 3(b) shows the environmental impact of both juicer during the three main life cycle stages. It is a graphical representation of proposed GPD framework.

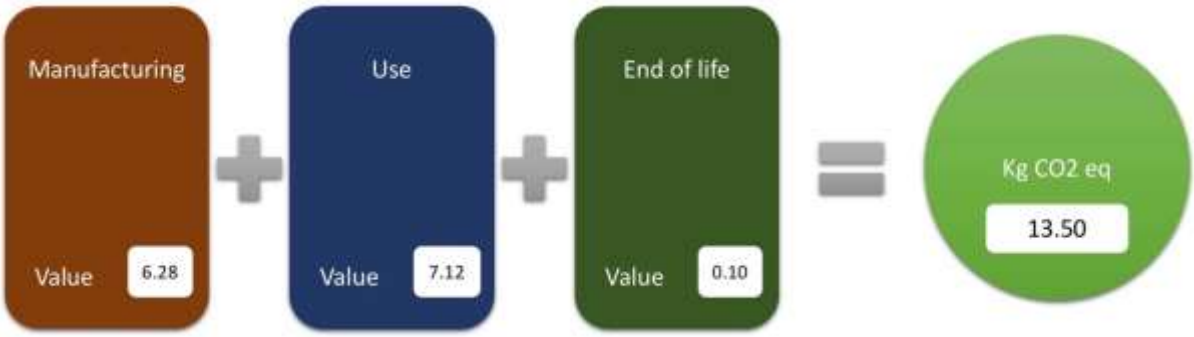

Fig 3(a): Environmental impact of juicer J1 at different stages

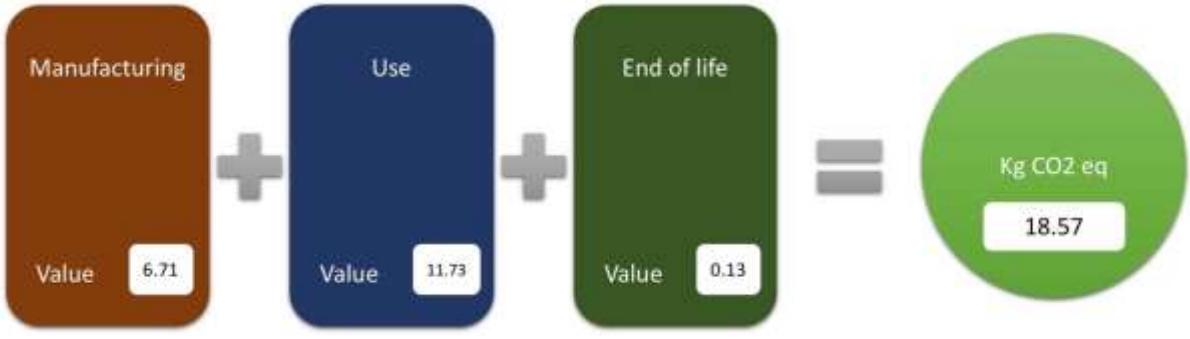

Fig 3(b): Environmental impact of juicer J2 at different stages

IV. Results and discussion

Table 2 presents the characteristics of both juicers, whereas Figure 4 illustrates the respective contributions of different life cycle stages to the environmental impacts of these two juicers. The outcome was determined utilizing the GPD framework and subsequently compared to the outcome of a previously published article that employed the ReCiPe impact assessment technique to ascertain the outcome.

As it is cleared from the result that the juicer J2 which is produced in China having higher environmental impact with compared to juicer J1 which is produced in Slovenia, and it is also cleared from the result that the use phase for both the juicers have majority of environmental impact. On the other hand, the manufacturing phase has second highest environmental impacts during the life cycle of both the juicers, as shown in table 3.

The study also discovered some interesting differences between the two juicers' motors. Compared to the motor used by J2, J1's motor is more effective and uses less power while in use, that's why during use phase juicer J1 impacts lesser than the juicer J2 environmentally.

Table 2: Environmental impact of bicycle at different stages.

Stages	J1 *(Kg CO_2 Eq)*	J2 *(Kg CO_2 Eq)*
During manufacturing	6.28	6.71
During use (for 26,268hr life)	7.12	11.73
At the end of life	0.10	0.13

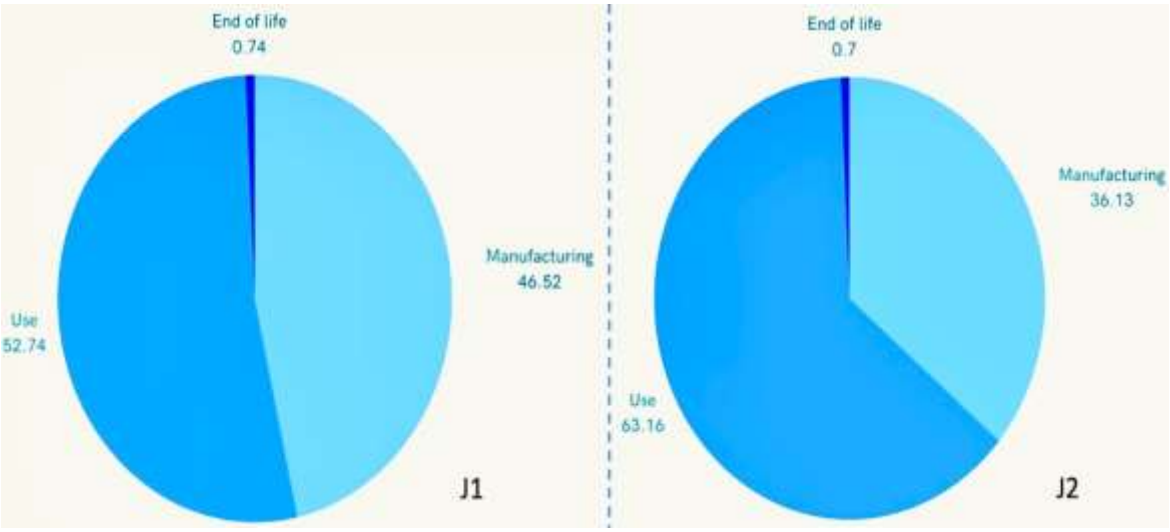

Fig 4: shows the impacts over the entire life cycle of the juicer J1 and Juicer J2.

V. Conclusion

The purpose of this case study was to validate the novel green product design (GPD) framework by assessing the environmental impact of household appliances. The LCI information gathered from a study that was previously published (Shaukat et al., 2021). The research developed a novel GPD framework for life cycle assessment in order to evaluate the ecological consequences of household appliances. Through a comparison of life cycle assessments, it was ascertained that the manufacturing phase had the second-highest environmental impact, trailing only the use phases. The findings revealed that the juicer J2, manufactured in China, exhibited a greater ecological footprint in comparison to the juicer J1, manufactured in Slovenia. This contrast underscores the notion that identically powered and functional products can manifest divergent environmental impacts. The study validated that the results of the revised GPD framework align with those of the previously published framework, indicating that the impacts of transportation and end-of-life phases are inconsequential. The research, which was carried out in Saudi Arabia, encountered obstacles including the scarcity of dependable local datasets, the absence of direct communication with manufacturers, and information regarding supply chain organizations and component transportation from suppliers to final assembly. The results of this study have the potential to contribute to the development of environmentally friendly consumer products by demonstrating that the life-cycle impacts of appliances can be diminished by incorporating energy-efficient motors, optimizing component design, and exercising judicious material selection. This research will help to identify and maintain optimal management and manufacturing practices in the production of household appliances.

ORIGINAL RESEARCH

Examining the Dynamics of India's Major Exchange Rates Using Fourier Nonlinear Quantile Unit Root Test

Abstract
The paper empirically investigates the validity of Purchasing Power Parity (PPP) hypothesis for India with its 20 major trading partners using the Fourier non-linear quantile unit root (FNQKS) test. The study uses daily data for the period 1st January 2020–2nd February 2022. FNQKS test supports PPP in 15 out of 20 trading partners of India. The validity of PPP indicates that it is impossible to obtain unbounded gains from arbitrage in these trading partners because of the adjustment process even in the presence of heavy-tailed distributions, mean breaks, and non-linearity. It also indicates that the impact of shocks on the exchange rates is transitory. Therefore, no interventions in these foreign exchange markets need to be made by the relevant authorities. Thus, non-normal distributions, structural breaks, and non-linear mean reversion appear to be key features for adjustment process of exchange rates of these 15 trading partners.

1 Introduction

As the foreign exchange market is one of the largest financial markets globally, the pursuit to comprehend and foresee the dynamics of exchange rates and their associated volatilities has become a topic of notable distinction. Specifically in the floating exchange rates regime, practical implications of these dynamics hold for investors,

market analysts, international trade and macroeconomic policymakers (Junior et al., 2019). In the last two decades, most of the empirical work carried out to test the dynamics of the real exchange rates has focused on testing the Purchasing Power Parity (PPP) hypothesis (Pérez-Rodríguez et al., 2009). Purchasing Power Parity (PPP), the concept that real exchange rates revert to a constant mean following a shock is intimately connected with the topic of testing for unit roots in economic time series. If the unit root hypothesis can be rejected in favor of a level stationary alternative, then the real exchange rate is mean reverting and PPP holds (Amara and Papell, 2006)

Policy-makers and researchers are interested in the long-run relationship of purchasing power parity (PPP) for several reasons. First, if the hypothesis holds, it means that the shocks to real exchange rates (RERs) would be temporary. A widely held view is that exchange rate stability promotes foreign trade and investments, and countries tend to benefit from financial markets that are broadening, deepening and internationally integrated. Second, PPP has become a prediction model of exchange rate and a popular criterion for judging currency misalignments. Besides, the validity of the hypothesis provides no room to implement a depreciation policy to deal with current external imbalances. Therefore, it is not surprising to find that much effort has been made in the past two decades on the validity of PPP by using a variety of approaches and sampling periods to resolve the unsettled issue (Soon et al., 2015).

Significant theoretical and empirical advances have taken place in the area of exchange rate economics, however, puzzles relating to determination of exchange rate are still unresolved. A range of vital issues like, the link between exchange rates and economic fundamentals, the purchasing power parity (PPP) puzzle, effects of different exchange rate regimes on output and welfare, relation between exchange rates and global prices etc. have been studied using interesting methodologies. Nonetheless, the continuing economic crisis due to the euro zone crisis, headed by the global financial crisis and lately, the Brexit, indicates that imperative work (both theoretical and empirical) on exchange rates needs to be done (Manzur, 2018).

Several methodologies have been used in the empirical literature for testing long-run validity of PPP, like the univariate unit root and panel unit root tests, multivariate cointegration and panel cointegration tests. The first wave of studies of long-run PPP used univariate unit root tests (e.g. Taylor, 1988). However, low power of these tests over short time spans of data resulted in a failure to find strong evidence of PPP. Therefore, panel unit root tests which exploit both the cross-section and time series variation of the data were used to increase the power of these tests (Lothian & Taylor, 1997; Taylor, 1990). Some authors also used long spans of data to increase the power of these tests (e.g. Lothian & Taylor, 1996). While using long spans of data to raise the power, it also enhances the possibility of structural breaks (Hegwood & Papell, 1998), panel unit root tests have also been criticized by Taylor and Sarno (1998), as the rejection of joint null hypothesis of unit root behaviour in favor of the level stationary alternative does not necessarily provide evidence that all individual currencies exhibit mean reversion. Thus, neither long-span studies nor panel unit root studies are perfect (Doğanlar, 2009).

The empirical evidence on PPP as a long-run equilibrium phenomenon is mixed and the lack of empirical evidence is referred to as the PPP puzzle (Bahmani-Oskooee et al., 2018). To solve the puzzle, an important development in the literature is to allow for structural shifts and nonlinearity in RER because changes in exchange rate regimes, long-lived events and unexpected crashes may lead RER to persistently deviate from its long-run equilibrium and may show an asymmetric adjustment pattern. In order to account for asymmetric adjustment along with structural changes, and non-linearity as well as non-normal distributions, a growing strand of the literature has benefited from quantile unit root inference. While the conventional unit root tests assume a constant speed of adjustment and are able to explain an average behaviour of RER, quantile unit root approaches account for the effects of shocks with various size and sign; identify asymmetric unit root behaviour at quantiles of the distribution; and offer large efficiency gains when the data accommodates potential heavy-tailed (non-normal) distributions. More recent studies have employed quantile unit root tests to account for asymmetric adjustment as well as non-normal distributions (Nazlioglu et al., 2021).

Like all exchange rates of the world, India followed a fixed exchange rate regime until the breakdown of the Bretton Woods system in the early 1970s. However, the exchange rate system remained pegged (first with Pound Sterling and then with a Basket of Currencies) till the dual exchange rate system was introduced in March 1992 for the first time, making the rupee partially convertible. Since March 1993, the dual exchange rate system was merged and the rupee became fully flexible in the current account. The removal of capital account controls aimed to treat inflows and outflows of capital differently: controls on the inflow of capital, especially foreign direct investment, were removed faster than the outflow. This was done to hedge against an enhanced indebtedness of the economy due to rapid capital outflow. Flexibility was combined with Central Bank interventions. Coupled with this, India also undertook a massive liberalization programme since the early 1990s, especially with regard to international trade and capital flows. This has led to a sudden spurt in foreign exchange transactions at a time when the exchange rates were far freer to fluctuate than what they were a decade ago. With the possibility of fluctuations, speculative trading in exchange rates also increased manifold during this period, making their markets complex and exposed to a potentially large set of information (shocks), both from home and abroad.

It is therefore interesting to study how emerging markets like India that have experienced several structural policy changes and internal and external shocks caused exchange rates to have heavy tails, structural breaks and non-linear dynamics. To the best of our knowledge, only a few previous studies simultaneously account for these features of RER in emerging markets with an asymmetric persistence framework, therefore, this study tries to fill this gap in the literature. Thus, given the theoretical and operational significance of the issue and mixed empirical evidence, the present study empirically investigates the validity of the PPP hypothesis for India with its 20 major trading partners using the Fourier non-linear quantile unit root test proposed by Bahmani-Oskooee et al. (2020) which is robust to non-normal distributions, structural breaks, and non-linearity.

2 Literature Review

The literature on this area can be divided into four groups. The first group of studies is those that use univariate unit root tests to examine PPP by testing for stationarity of exchange rates. The second group of studies is those that use panel unit root techniques to test for stationarity of real exchange rates. The third group of studies examines stationarity of real exchange rates using nonlinear unit root techniques. The fourth group of studies applies cointegration tests on the relationship between nominal exchange rates and the domestic and foreign price levels.

Su et al. (2012a, 2012b) tested the validity of long-run PPP for a sample of BRICS countries (i.e. Brazil, Russia, India, China and South Africa) over January 1996 to July 2010 using both linear (ADF) and nonlinear unit root tests with stationary covariates as proposed by Hansen (1995) and Tsong (2011). Empirical results from both linear and nonlinear unit root tests indicated that PPP was true for all the BRICS countries.

Narayan (2006) examined the stationarity of India's real exchange rate with 16 of its major trading partner countries for the period 1960–2000. Application of the conventional ADF unit root test, the Lagrange multiplier (LM) unit root test with one structural break and the LM unit root test with two structural breaks provided evidence that India's exchange rate with 15 out of 16 countries supported PPP.

Validity of PPP was re-examined by Öge Güney et al. (2012) for some emerging market economies and African countries by extending the recent works of Doganlar et al. (2009) and Chang et al. (2010a, 2010b) respectively. Unit root tests that allowed for nonlinearities and structural change in the data-generating process suggested that although linear unit root test provided evidence in favor of PPP only in a few cases, the new nonlinear unit root tests suggested that the PPP proposition held in a majority of the sample countries.

Amara and Papell (20062013) tested for purchasing power parity in post-Bretton Woods real exchange rate data from 20 developed countries using univariate tests and covariate augmented versions of the Augmented Dickey–Fuller (CADF) and feasible point optimal (CPT) unit root tests. Very strong evidence is found of PPP using the CPT test while much less evidence is found of PPP with the CADF and univariate tests.

Pérez-Rodríguez et al. (2009) performed the out-of-sample real exchange rate forecasts using an Artificial Neural Network model, an Autoregressive model and a random walk model. The results confirmed the relevance of nonlinear adjustment in the dynamics of the real exchange rate.

Using monthly data from January 1970 to October 2011, Karlsson et al. (2017) employed panel unit root tests developed by Taylor and Sarno (1998) and Månsson and Sjölander (2014) to empirically investigate if the RER followed a stationary linear and ESTAR process. A strong support for the PPP in Northeast and Southeast Asia, Central and South America, and sub-Saharan Africa was found.

Su et al. (2012a, 2012b) applied Panel SURKSS tests, which are the Kapetanios et al. (2003) tests based on the panel estimation method of SUR, to test the validity of PPP for 15 Common Markets for Eastern and Southern Africa (COMESA) and/or

the Southern African Development Community (SADC) countries. Results revealed that PPP did not hold for the 15 countries under study.

Bahmani-Oskooee et al. (2015) applied the sequential panel selection method combined with a Fourier function to test the PPP in six major oil exporting countries. The results supported PPP in all six countries except Russia.

Panel Seemingly Unrelated Regressions Augmented Dickey–Fuller (SURADF) tests advanced by Breuer et al. (2001) were used by Chang et al. (2010a, 2010b) to test the validity of Purchasing Power Parity (PPP) for 15 countries belonging to the Common Market for Eastern and Southern Africa (COMESA) and the Southern African Development Community (SADC) from December 1994 to July 2008. The empirical results indicated that PPP did not hold for these 15 countries; however, Breuer et al.'s (2001) panel SURADF tests unequivocally indicated that PPP was valid for Botswana, Madagascar and Malawi.

Chang et al. (2012a, 2012b) applied a panel SURADF test with a Fourier function to investigate the properties of long-run purchasing power parity (PPP) in a sample of transition countries between January 1995 and December 2008. Results from the panel SURADF test with a Fourier function indicated that PPP was valid for all the countries, except Russia.

Bahmani-Oskooee and Ranjbar (2016) applied six different univariate unit root tests to real effective exchange rates of 23 OECD countries. Stationarity or Purchasing Power Parity theory (PPP) was supported only in five countries.

Hooi and Smyth (2007) applied univariate and panel Lagrange Multiplier (LM) unit root tests with one and two structural breaks to real exchange rates for 15 Asian countries. The univariate LM unit root tests found evidence of PPP for two-thirds of the sample. The results from the panel LM unit root test supported long-run PPP for all the Asian countries.

Soon et al. (2015) showed that over the period of January 1986–July 2010 PPP hypothesis held true in most of the US dollar real exchange rates using cointegration method that accounted for breaks in the models and obtained a mean half-life estimate of about 10 months for PPP to converge to its long-run equilibrium level.

Doganlar (1999) investigated the validity of PPP hypothesis using cointegration techniques for five developing Asian countries. However the study could not find any supportive evidence for PPP for India, Indonesia, Philippines and Pakistan. However PPP was supported for Turkey when the Johansen's maximum likelihood approach was used.

Doganlar et al. (2009) empirically investigated PPP for 10 emerging market economies namely Brazil, India, Indonesia, South Korea, Mexico, Pakistan, Peru, Philippines, South Africa and Turkey by using cointegration technique. The exchange rate and price series did not appear to be cointegrated for most of the countries. Also, PPP was rejected for Brazil, India, Indonesia, Pakistan, Philippines, South Africa, South Korea and Turkey but accepted for Mexico and Peru.

Chang et al. (2010a, 2010b) used the momentum threshold cointegration tests to investigate whether any asymmetric adjustment was discernible for BRICS from July 1992 to December 2006 and showed that while the Engle–Granger test (which assumes only symmetric adjustment) failed to reveal any cointegrational

relationship for BRIC the threshold cointegration test (with asymmetric adjustment) provided clear evidence of long-run PPP for BRIC except China.

Chang et al. (2012a, 2012b) used Autoregressive Distributed Lag procedure for threshold cointegration by Li and Lee (2010) to test the validity of long-run PPP for a sample of BRICS countries from January 1996 to July 2010. The empirical results indicated that PPP held true for most of these countries except Brazil.

Bozoklu and Kutlu (2012) analyzed the validity of PPP for eight developing countries by applying Johansen's linear () and Breitung's non-linear (2001) cointegration tests to the monthly dataset from 1983:01 to 2010:06. Results suggested mixed evidence for long-run validity of PPP. For linear cases, the results of Johansen's test were more reliable when compared to Breitung's test. However, for Korea, Malaysia and Thailand results obtained from Breitung's rank test suggested that once the sources of non-linearities were taken into account, stronger evidence on the empirical fulfillment of PPP could be found.

Johansen's cointegration technique was utilized by Kargbo (2009) with annual data from 1955 to 2005 on exchange rates and GDP deflators to investigate the validity of long-run PPP in emerging markets. The study found support for PPP.

Basher and Mohsin (2004) examined the empirical validity of relative PPP doctrine in the context of 10 Asian developing economies from January 1980 to December 1999 by applying a panel cointegration method. The empirical findings of this study did not support the relative version of PPP.

Hasan (2006) empirically examined the Purchasing Power Parity hypothesis using more than a century span of annual data of Australia, Canada and Britain. Within the framework of both linear and non-linear cointegration tests the study found support for the validity of the Purchasing Power Parity hypothesis in the long-run. The results also indicated non-linear mean reversion behaviour in the case of Canada.

Peng et al. (2017) revisited PPP for BRICS countries over 1995M1 to 2015M2 using a quantile unit root test with stationary covariates proposed by Galvao (2009). The empirical findings indicated a support of PPP for all the BRICS countries under study.

Mike and Kızılkaya (2019) tested the long-run validity of PPP by using Fourier quantile unit root and Fourier cointegration analyses for 12 emerging market economies that practiced a flexible exchange rate regime from 2001Q1 to 2016Q4. Results showed that real exchange rate series were stationary for Colombia, India, Philippines, Poland, South Africa, and Tu0rkey. On the other hand, Fourier cointegration test results revealed that PPP was valid for Brazil, Colombia, India, Mexico, South Africa, Thailand, and Turkey.

Bahmani-Oskooee et al. (2017) tried to establish the stationarity of real effective exchange rates of 29 African countries. Conventional linear unit root tests found support for the PPP in eight countries while newly introduced non-linear quantile unit root test found support for the PPP in 15 countries.

Bahmani-Oskooee and Wu (2017) aimed at solving the puzzle by applying the fourier quantile-based unit root test in 34 OECD countries from 1994:01 to 2016:03. While three traditional unit root tests failed to support the PPP

hypothesis, the quantile tests that accounted for sharp shifts and smooth breaks supported the PPP hypothesis in 18 countries.

Oskooee et al. (2017) applied the Quantile unit root test and revisited the Purchasing Power Parity (PPP) in 20 African countries from 1971Q1 to 2012 Q4. While the traditional unit root tests failed to reject unit root hypothesis in most of the countries, Quantile unit root test rejected unit root null hypothesis in at least five countries.

Bahramian and Saliminezhad (2020) employed a Fourier quantile unit root test to examine the PPP hypothesis for the ASEAN-5 economies using the monthly real effective exchange rate data from 1994:01 to 2018:09. While the conventional unit root tests provided conflicting results in support of the PPP hypothesis, Fourier quantile unit root test indicated that the real effective exchange rate series was stationary for Indonesia, the Philippines, Singapore, and Thailand.

Peng et al. (2022) tested the mean reversion properties of the U.S. EPU (economic policy uncertainty) index and its 11 sub-categories using the Fourier nonlinear quantile unit root test over the period 1985M1-2020M12. The results indicated that the U.S. EPU index responded asymmetrically to shocks.

Goswami and Saha (2022) tested the PPP hypothesis for selected 7 cryptocurrencies in 17 countries using the Fourier Nonlinear Quantile Unit Root Test. The results indicated that the PPP was strongly supported when we pooled the data over cryptocurrencies and countries, which is consistent with the PPP testing result for regular currencies.

In this study, while the aim to investigate the evidence of PPP is steady with the extant literature, the methodology is novel. The attention isn't on disentangling proof for PPP for a range of nations rather the emphasis is on one nation, India and its bilateral exchange rate vis-a-vis its trading partners. The novelty of the approach lies in undertaking a detailed investigation of PPP for a particular country. The second innovation pertains to methodology. To this end, the empirical exercise involves a comprehensive treatment of structural changes, non-linearity and non-normal distribution of India's bilateral exchange rates. To achieve this, the study uses Fourier non-linear quantile unit root test proposed by Bahmani-Oskooee et al. (2020a) which is robust to non-normal distributions, structural breaks, and non-linearity.

The plan of the paper is as follows. Section 3 discusses the methodology and sources of data,

Section 4 reports the empirical results, Sect. 5 concludes.

3 Data and Methodology

The study employs daily data from 1st January 2020 to 2nd February 2022 on bilateral exchange rates of India with its 20 major trading partners namely, Australia, Israel, China Mainland, China Hong Kong, USA, UAE, Russia, Japan, UK, Indonesia, Canada, Mexico, Brazil, Malaysia, Turkey, Thailand, Saudi Arabia, Singapore, South Africa and Switzerland. The data is sourced from www.investing.com.

3.1 Methodology

To capture an unknown number of structural breaks of both sharp and gradual nature, Bahmani-Oskooee et al. (2020) encompassed a Fourier approximation into the non-linear quantile unit root test of Li and Park (2018). To save degrees of freedom, Becker et al. (2006) and Enders and Lee (2012) recommend usage of a single frequency to arrive at

$$y_t = \lambda_o + \lambda_1(\tau)\left(\sin\left(\frac{2\pi kt}{T}\right) + \lambda_2(\tau)\cos\left(\frac{2\pi kt}{T}\right) + e_t\right) \quad (1)$$

where y_t is the bilateral exchange rate of India with its trading partners, $\lambda_1(\tau)$ and $\lambda_2(\tau)$ are the coefficients of the fourier terms, e_t is the disturbance term, T is the number of observations and t is a time trend. The reason to include both $\sin\left(\frac{2\pi kt}{T}\right)$ and $\cos\left(\frac{2\pi kt}{T}\right)$ in the model is based on the fact that a Fourier expression is capable of approximating absolutely integrable functions to any desired degree of accuracy. k denotes the number of Fourier frequency. Equation (1) is estimated by OLS for $k\epsilon[0.1,0.2\ldots,5]$ and optimum frequency $k = k^*$ is selected by minimizing sum of squared residuals. Then construct

$$\hat{e}_t = y_t - \hat{\lambda}_o + \hat{\lambda}_1(\tau)\sin\left(\frac{2\pi k^* t}{T}\right) + \hat{\lambda}_2(\tau)\cos\left(\frac{2\pi k^* t}{T}\right) \quad (2)$$

The non-linear quantile autoregression model is described by

$$Q_{\Delta\hat{e}_t}\left(\tau|\widehat{e_{t-1}}\right) = \alpha(\tau)\widehat{e_{t-1}}^3 + \sum_{j=1}^{p}\alpha_j(\tau)\Delta\widehat{e_{t-j}} + \varepsilon_t \quad (3)$$

where $Q_{\Delta\hat{e}_t}\left(\tau|\widehat{e_{t-1}}\right)$ denotes the τ-th quantile of $\hat{e}_t$ conditional on $\widehat{e_{t-1}}$, $\Delta\widehat{e_{t-j}}$ represents the first difference of the estimated error term $\Delta\widehat{e_{t-j}}$ at lag$j$, the cubic term $\widehat{e_{t-1}}^3$ represents a cubic function of the lagged differentiated error term $\widehat{e_{t-1}}$, $\alpha(\tau)$ denotes a parameter or coefficient that varies withτ,$\alpha_j(\tau)$ captures quantile specific effects of the lagged differentiated error terms $\Delta\widehat{e_{t-j}}$, τ represents different quantiles in quantile regression and p is the number of lags. The null hypothesis of unit root $H_0 : \alpha(\tau) = 0$ is tested against the stationary alternative$H_1 : \alpha(\tau) < 0$. The statistic for testing the null hypothesis is defined as

$$t_n(\tau) = \frac{\hat{f}(\widehat{F^{-1}(\tau)})}{\sqrt{\tau(1-\tau)}}\left(\gamma_{-1}{}'P_x\gamma_{-1}\right)^{\frac{1}{2}}\hat{\alpha}(\tau) \quad (4)$$

where $\gamma_{-1} = \widehat{e_{t-1}}^3$, P_x is projection matrix on space orthogonal to $x = (1, \Delta\widehat{e_{t-1}}, \ldots.., \Delta\widehat{e_{t-p}})$, $F^{-1}(\tau)$ denotes the inverse of the cumulative distribution function F evaluated at τ, f represents the estimated regression function and $\hat{f}(\widehat{F^{-1}(\tau)})$ is consistent estimator of $f(F^{-1}(\tau))$. The null hypothesis is also tested over a range of quantiles by Kolmogorov–Smirnov test, given by

$$FNQKS = \sup_{\tau \in [0.10, 0.90]} \left| t_n(\tau) \right| \tag{5}$$

Since $t_n(\tau)$ and FNQKS have non-standard distributions, resampling procedure is used in Bahmani-Oskooee et al. (2020) to obtain empirical distributions of the statistics.

The analysis has been carried out using the econometric software R.

4 Empirical Results

Initially, the preliminary analysis is reported in Table 1. Jarque and Bera (JB) test results indicate non-normal distribution for all the countries except Israel. Ftrig test rejects the null hypothesis of absence of Fourier terms for all the countries in Eq. 1 (i.e. $\lambda_1 = \lambda_2 = 0$), implying significance of smooth breaks. Also, as apparent from Fig. 1 the exchange rate series' are nonlinear. The selected frequency (k^*) is integer in most of the countries and is fractional for eight countries. Integer (fractional) frequency implies temporal (permanent) effects of breaks on the mean of exchange rates (Bahmani-Oskooee et al., 2020).

The preliminary tests reveal the importance of non-linear quantile unit root framework with Fourier approximation. The test has some advantages that make it adequate to control for the stochastic properties of the exchange rate series. First, it is able to control for two types of structural breaks in the data generating process. By using the Fourier expansions to demean the exchange rate series, the unknown numbers, dates, and forms of breaks in the mean are captured. Also, by using the quantile regression to estimate the non-linear ADF regression model, it allows for structural changes in the autoregressive parameters. Second, it allows for a non-linear mean-reverting process within each quantile and heterogeneous speeds of mean reversion across quantiles, which is a specific property that allows for comparing the degree of persistence of positive and negative shocks. Third, the test has good power when the time series variables are distributed non-normally.

However before proceeding with it we carry out a battery of unit root tests. ADF test of Dickey and Fuller (1979) rejects the null of unit root in 12 countries. Fourier ADF (FADF) and Fourier KSS (FKSS) tests (Table 2) capture structural shifts as a smooth process by using Fourier approximation and FKSS further accounts for non-linearity. While FADF test rejects the null hypothesis for 9 countries, FKSS test rejects the unit root in all the 20 countries. Results from Fourier non-linear quantile unit root test (FNQKS) are presented in Table 3. FNQKS test rejects the unit root in 15 out of 20 countries. FNQKS test gives us a general idea about the mean reversion of exchange rate series.

PPP serves as a prediction model for exchange rates and it supports governments with evaluating whether or not the currency is overvalued, which in turn enables a suitable policy response to be specified. However, the possibility of structural breaks and other forms of nonlinearity in exchange rates reflected in the exchange rate dynamics necessitates the need for a more refined analysis to trace the impact of different shock sizes on exchange rate behaviour, something that the Fourier nonlinear

quantile unit root test can properly provide. In our results, the validity of PPP in 15 countries indicates that the impact of shocks on the exchange rates is transitory. Therefore, no interventions in these foreign exchange markets need to be made by the relevant authorities (Munir & Kok, 2015). However, contrary to the literature while a shift from traditional or the conventional unit root tests to fourier nonlinear quantile unit root test increased the evidence of satisfaction of PPP hypothesis and thus moved the countries closer to solving the PPP puzzle, in India the same shift led to a reduction in the number of countries satisfying the PPP hypothesis thus leading to the conclusion that the conventional tests (FKSS) overestimated the satisfaction of PPP hypothesis while actually it is satisfied by less number of nations (FNQKS). Therefore in India the evidence from FNQKS test moves us one step backward from solving the PPP puzzle.

However, testing for unit root at specific quantiles for a more detailed analysis of asymmetric persistence can be checked through p-values of t_n statistic at different quantiles reported in Table 3. Exchange rates are stationary at low and /or middle quantiles for 4 countries (Hong Kong, USA, UAE, Saudi Arabia) in which positive shocks have permanent effects on the long run equilibrium. The presence of permanent positive shocks illustrates that the long-run path of exchange rate will be unbounded and thus, these countries can improve its trade balance when its exchange rate increases. Exchange rates are stationary in middle and/or high quantiles in 11 countries (UK, Indonesia, Canada, Mexico, Malaysia, Thailand, Switzerland, Australia, Russia, South Africa and Turkey) implying that negative shocks deviate exchange rates from the long run equilibrium. Thus, due to the long-lasting impacts of the negative and transitory effects of the positive shocks, depreciation has a desirable outcome on trade balance of these nations.

5 Conclusion

This study utilizes a novel approach to test for PPP in exchange rate of India with its trading partners by accounting for non-normal errors, non-linearity and structural shifts. While ADF test support PPP in almost half of the countries, fourier non-linear quantile unit root test supports PPP in 15 out of 20 countries. The validity of PPP indicates that in the long run exchange rates are not influenced by monetary policy, however, official intervention can explain the short-run fluctuations in exchange rates. The satisfaction of PPP can also provide information to international investors and speculators for their portfolio allocations. It also indicates that it is impossible to obtain unbounded gains from arbitrage in these trading partners because of the adjustment process even in the presence of heavy-tailed distributions, mean breaks, and non-linearity. The empirical evidence on the stationarity of exchange rates implies that depreciations could increase international competitiveness and improve trade balance in the short-run, but improvements in trade balance are not unbounded in the long-run.

Thus, the results clearly indicate that non-normal distributions, structural breaks, and non-linear mean reversion appear to be key features for adjustment process of exchange rates of these 15 trading partners. Future studies can re-examine the

international parity conditions (such as the interest rate parity) of India with its trading partners within the context of quantile methods that accommodate these key features. There is also scope for the application of more sophisticated panel data unit root tests to examine the robustness of the findings from the panel unit root tests in this study. The fact that researchers remain divided on the existence of PPP will continue to encourage the development of more sophisticated unit root tests to examine this important topic.

Examining the structural viability of recycled fine aggregates in sustainable concrete

Harish Panghal and Awadhesh Kumar

Department of Civil Engineering, Delhi Technological University, Delhi 1100042, India

Abstract This study investigates the potential of incorporating recycled fine aggregates (RFA) into sustainable concrete. In this research, a conventional compaction technique is utilized to establish the order of compressive strength and, consequently, to assess particle packing density in terms of weight within a specific cylindrical volume and evaluate workability, compressive and flexural strengths, splitting tensile strength, elasticity modulus, and microstructural properties (analyzed through XRD, SEM, and EDAX). The study found that RFA can improve concrete properties, hardened characteristics, and microstructure up to an optimum 25 % RFA replacement threshold (RFA 25). Beyond this value, concrete strength and microstructure deteriorate. RFA 25 exhibits significantly higher compressive (14.75 %), flexural (6.61 %), and splitting tensile (13.14 %) strengths compared with the reference concrete, along with a 5.71 % decrease in the modulus of elasticity. Lower replacement levels promoted pozzolanic reactions, enhancing strength through additional hydration products, whereas higher replacements reduced strength.

1. Introduction

The construction industry, which is crucial for global economic growth, is simultaneously contributing to environmental degradation through the energy-intensive production of concrete, which has a substantial carbon footprint [1]. In addition, the surge in construction and demolition waste (CDW) disposal poses challenges [2], straining landfill space and causing negative ecological impacts [3]. This issue is addressed by incorporating recycled aggregate (RA) from CDW in fresh concrete, constituting 70 %–80 % of its volume, which presents economic and environmental advantages by reusing materials such as concrete, asphalt, bricks and tiles [4-6]. This research focuses on recycled fine aggregates (RFAs) generated through an impact crusher at the IL&FS CDW Recycling Plant in collaboration with the Delhi Metro Rail Corporation [7-9]. However, a comprehensive assessment of its performance and compliance with industry standards are necessary before this substitution is considered in civil engineering projects [10-12]. RA concrete (RAC), which employs RA instead of natural aggregate (NA), has been extensively studied. RAC tends to be less workable due to its porous structure and higher water absorption capacity [13]. Various factors, including the replacement ratio of NA, water-to-cement ratio, parent aggregate type, age, exposure conditions, number of crushing stages, and physical and mechanical characteristics of RA, influence its compressive strength [14-16]. Despite flaws in RAC's microstructure compared with that of NA concrete, adding RAs significantly enhances the strength of hardened concrete, offering a viable alternative to natural sand aggregates with lower permeability [17-19]. Concrete formulations containing RFAs and demolished coarse aggregates have shown effectiveness in replacing conventional concrete [20-22]. Studies incorporating fly ash with recycled concrete aggregates reveal increased water absorption and decreased electrical resistivity [23-25]. RFA concrete, with compressive strengths and modulus of elasticity (MOE) ranging from 70 % to 90 % of NA concrete, sur- passes traditional concrete in terms of CO_2 emissions and cost-effectiveness [24, 25]. Introducing waste carbon

fibers into RFAs further improves mechanical performance [26, 27].

Various techniques such as freeze-thaw, mechanical grinding, ultrasonic treatment, heat treatment, and chemical treatment have been employed to enhance the performance of RAC in reducing adherent mortar [28, 29]. Researchers have explored methods such as adding mineral admixtures, altering mix designs, and adjusting the mixing procedure to improve compressive strength and mechanical properties in aggregates [30-32]. Aggregate replacement techniques such as direct weight replacement, equivalent mortar replacement, and direct volume replacement have been studied [31]. A multi-technique method that includes cement paste removal and fly ash treatment significantly enhances the compressive strength and elastic modulus of RFA concrete [33-35]. The choice of method impacts workability and performance [34, 35]. Despite various techniques applied in material processing, mix design, mixing, and curing stages to enhance RA concrete, the particle packing density (PPD) within a specific cylindrical volume using a conventional compaction technique has not been applied to RAC mix design. This study aims to implement this mixing approach because of its simplicity and effectiveness in producing RAC, aligning with circular economy principles of material reuse. However, ensuring industry-standard quality and performance remains crucial. While previous research involved substituting natural fine aggregates (NFAs) with varying proportions of RFA, a technique to determine the optimal replacement percentage for maximal strength has not been proposed. Our study addresses this gap while also exploring mechanical properties and other characteristics.

Our work's novelty lies in the following aspects:

- It investigates the efficient use of RFA for sustainable concrete production with five distinct RFA levels (0 %, 25 %, 50 %, 75 %, and 100 %) within the concrete mix.
- It examines the influence of various RFA ratios on concrete properties, such as workability, and hardened properties such as compressive strength, flexural strength, splitting tensile strength, and MOE, using established compacting procedures.
- It uses X-ray diffraction (XRD), scanning electron microscopy (SEM), and energy-dispersive X-ray spectroscopy (EDAX) to analyze microstructural attributes and identify significant disparities with the control mixture.
- It examines the effects of RFAs on morphology and composition, encompassing chemical and mineralogical dimensions, to understand their role in generating microstructure. This insight can help formulate sustainable concrete with optimized RFA content.

2. Materials and mixing approach

2.1 Materials

The study utilizes ordinary Portland cement of grade 43, adhering to IS 269-2015 [36] standards. The cement's physical properties reveal a 31 % consistency, an initial setting time of 58 minutes—surpassing the minimum requirement of 30 minutes—and a final setting time of 435 minutes, significantly shorter than the standard's maximum limit of 10 hours. With a specific gravity of 3.11, insights into the density and quality of the cement can be derived. Fine aggregate is sourced from natural sand with a particle size of 4.75 mm and below, meeting IS 383–2016 [37] standards. Natural coarse aggregates (NCAs), conforming to IS 383–2016 [37], consist of crushed stone with sizes ranging from 4.75 mm to 20 mm. These aggregates pass through a 40 mm sieve but are retained on a 4.75 mm sieve. Of these, 90.76 % pass through a 20 mm sieve, and 4.52 % pass through a 10 mm sieve. RFAs, obtained from crushed concrete from CDW, undergo processing with an impact crusher. These RFAs meet size specifications, passing through a 4.75 mm sieve. A chemical admixture in accordance with IS 9103-1999 [38], namely, super-plasticizer (C-MAX), is added at a rate of 1 % by weight of cement. Potable water is utilized for the mixing and curing processes.

2.2 Mixing approach

In the formulation of concrete mixes, PPD is a pivotal tool, facilitating the development of high-performance and sustainable blends [39, 40]. This process entails the careful selection of an optimal aggregate mixture and the assessment of particle size distribution to emulate efficient packing. The objective is to attain maximum packing density and minimize void content, thereby yielding dense and durable concrete structures. Employing PPD not only improves workability but also enhances material efficiency and promotes compatibility with RAs, leading to heightened durability, reduced permeability, and enhanced strength in the resulting concrete.

Table 1 presents data on the weight of various fine aggregate mixtures at specific cylindrical volumes, considering a standard compaction effort. The table illustrates the impact of different ratios of RFA to NFA on the weight or density of the mixes after compaction. Notably, the mixture denoted as RFA 25 + NFA 75 exhibits the highest weight (15.27 units), signifying that this blend, comprising 25 % RFAs and 75 % NFAs, achieves the densest composition under standard compaction conditions. Conversely, the mixture labeled RFA 100 displays the lowest weight (13.27 units), indicating that a composition entirely composed of RFAs attains the lowest density given the

Table 1. Weight in specific cylindrical volume by giving the standard effect of compaction.

S. no	Fine aggregate mixtures	Weight (kg)
1	NFA	14.52
2	RFA 25 + NFA 75	15.27
3	RFA 50 + NFA 50	14.74
4	RFA 75 + NFA 25	13.84
5	RFA 100	13.27

RC – reference concrete NFA – natural fine aggregates NCA – natural coarse aggregates RFA – recycled fine aggregates

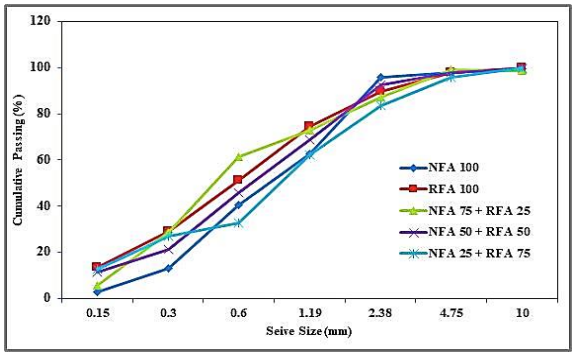

Fig. 1. Fine aggregate gradation curve for various mixtures.

specified compaction conditions. The remaining mixtures, namely, RFA 50 + NFA 50, NFA 100, and RFA 75 + NFA 25, exhibit intermediate weights, arranged in descending order of density. The densest mixture is attained with RFA 25 + NFA 75, and the other mixtures are listed in decreasing order of density. This finding succinctly summarizes the relative densities of the different mixtures. The reference to Fig. 1 suggests the existence of a complementary visual representation, likely in the form of a graph or chart, illustrating the distribution of particle sizes within the coarse aggregates used in the various combinations.

Such a figure would provide additional insights into the physical characteristics of the aggregates and how they influence the density and compaction behavior of the mixtures. The different properties of NFAs, RFAs and NCAs are shown in Table 2.

3. Mix proportions

Five concrete mixtures, with a target strength of 27 MPa, were formulated to examine the viability and influence of RFAs on the mechanical behavior of concrete. The compositions of these mixtures are outlined in Table 3. The reference concrete (RC) comprises NAs, whereas RFA 25, RFA 50, RFA 75, and RFA 100 integrate varying proportions of RFAs (25 %, 50 %, 75 % and 100 %, respectively) in lieu of NFAs. All mixtures maintain a consistent water–cement ratio of 0.50 and adopt the weight batching method [43].

4. Testing methodology

A series of experiments was conducted to comprehensively assess various facets of structural concrete. Key parameters such as compressive strength, flexural strength, splitting tensile strength, and MOE were meticulously measured. In addition, the workability of fresh concrete was evaluated, as depicted in Fig. 2. The microstructural characteristics of concrete samples from different combinations were further scrutinized through advanced techniques, including SEM, EDAX and XRD analyses.

4.1 Workability

The workability of concrete mixtures, incorporating various ratios of recycled CDW as fine aggregates, is evaluated using the IS 1199-1959 [44] standard through a slump test.

4.2 Compressive strength

A set of 30 specimens was generated utilizing steel cube molds with dimensions of 15×15×15 cm. These molds were filled with various concrete mixtures, cast, cured, and then subjected to compressive strength testing. The investigation

(a) (b) (c)

Fig. 2. Testing of various samples: (a) compressive strength cubes; (b) flexural strength beam; (c) splitting tensile strength cylinder.

involved assessing the compressive strength of distinct concrete compositions by utilizing a 2000 KN compression testing machine. Three specimens were tested for each mixture, and the average compressive strength value was computed from these results. The evaluations were performed at intervals of 7 and 28 days after casting.

4.3 Flexural strength

The experimental procedure encompassed the fabrication, curing, and examination of 30 concrete specimens, each shaped in steel rectangular molds measuring 50×10×10 cm. The primary objective of the study was to assess the flexural strength of each concrete blend, gauging its capacity to endure bending or deformation without fracture. With the use of a 2000 KN flexural testing apparatus, three specimens for each mixture were tested, and average flexural strength values were derived from the results. The testing occurred 7 and 28 days after the initial casting.

4.4 Splitting tensile strength

The research entailed the production of 30 concrete specimens utilizing steel cylindrical molds with a diameter of 15 cm and a height of 30 cm. Subsequently, these specimens underwent splitting tensile strength testing to assess the efficacy of diverse concrete mixtures. The tests were performed using a compression testing machine with a 2000 KN capacity, and the splitting tensile strength was determined based on the average value derived from three specimens.

4.5 Modulus of elasticity

This research delved into the nuances of concrete behavior by examining the MOE. Cylindrical specimens measuring 150×300 mm, with a height-to-diameter ratio of 2.0, were utilized for this assessment, following the guidelines specified in IS 516 part 6 of 2006 [45]. These meticulous evaluations yielded essential insights into the structural integrity and deformability of the concrete under various loads.

4.6 X-ray diffraction analysis

XRD is applied to scrutinize the phase characteristics and conduct mineralogical assessments of crystalline minerals present in concrete powder samples, particularly in diverse mixtures incorporating RFAs. The Bruker D-8 advanced diffractometer system is employed to scan the samples across an angular range of 3°–70°, with a scanning speed of 2° per minute and a sampling interval of 0.005° at an angle of 2°. Subsequently, the scans are analyzed using the JADE 7 X-ray diffraction software. The resulting peak intensities are visually represented against 2 theta degrees on the x-axis, spanning from 0° to 70°, with intensity plotted on the y-axis.

4.7 Scanning electron microscopy analysis

SEM analysis was conducted to characterize the materials of RFA, involving a comprehensive examination of the microstructure and surface morphology of concrete samples originating from various concrete mixtures. The analysis was carried out using the JSM 6610V scanning electron microscope at the University Science Instrumentation Centre in Delhi, operating at 30 kV.

5. Results and discussion

5.1 Workability

The slump values outlined in Table 4 indicate a diminishing trend in concrete slump as the proportion of RFAs increases.

This observation suggests that the workability of concrete incorporating RFA falls within a moderate range of 50 mm to 100 mm. This decline is attributed to RFA's higher water absorption capacity compared with NAs, primarily due to the presence of aged adhered mortar on its surface. As the content of RFA rises, the increased water absorption becomes more prominent, leading to a decrease in slump. This pattern aligns with findings from a prior study that noted a slump reduction with increased RCA content in concrete mixtures [46, 47]. The results of the slump test, along with the graphical representation in Fig. 3, provide compelling evidence that the incorporation of RFAs in concrete mixtures contributes to a slump reduction, influencing the concrete's flow and ease of handling.

Table 4. Slump value for various mixtures.

Concrete mix	Slump (mm)
RC	111
RFA 25	104
RFA 50	98
RFA 75	87
RFA 100	76

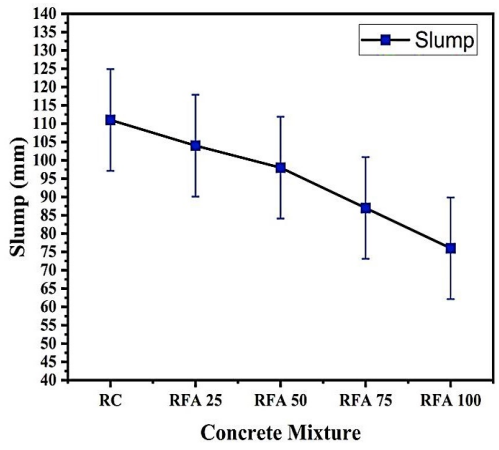

Fig. 3. Slump value for different concrete mixtures.

5.2 Compressive strength

The consolidated data are presented in Table 5, shedding light on how RFAs affect the compressive strength of concrete mixes. The results indicate that, in contrast to the reference mixture, the compressive strength of the concrete diminishes as the proportion of RFA in the mixes increases. Notably, RFA 25 exhibited the highest compressive strength, with a 25 % replacement of fine aggregates being identified as the optimal ratio for RFAs. The enhanced performance of RFA 25 is attributed to improved particle packing and reduced voids. The correlation between strength and the percentage of fine aggregates passing through the 600- to 150-micron range is significant, with a more substantial difference resulting in higher strength within certain limits. Higher replacement percentages of RFA increase void content and hinder strong bonding between aggregates, consequently leading to a reduction in strength. RFA 25 demonstrated the highest compressive strength at 36.71 MPa, while RFA 100 exhibited the lowest compressive strength at 23.01 MPa.

Drawing on the observations of Wagih et al. [48], the introduction of RFAs into concrete mixes led to a reduction in compressive strength of 20 %–34 % at 7 days and 30 %–38 % at 28 days when utilizing 100 % RFA replacement. However, the current study indicates a more moderate decrease in flexural

Table 5. Compressive strength variation in percentage for various combinations.

Concrete mix	Compressive strength (MPa)			
	7 days	% variation concerning RC	28 days	% variation concerning RC
RC	22.71	Reference	31.99	Reference

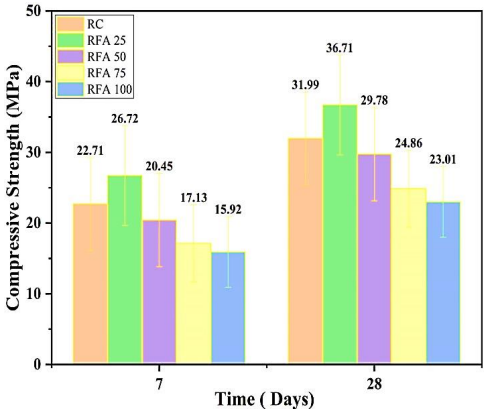

Fig. 4. Compressive strength variations for different concrete mixtures.

Table 6. Flexural strength variation in percentage for different mixtures.

Concrete mix	Flexural strength (MPa)			
	7 days	% variation concerning RC	28 days	% variation concerning RC
RC	3.18	Reference	3.92	Reference
RFA 25	3.41	+7.23	4.16	+4.59
RFA 50	3.12	−1.88	3.89	−0.76
RFA 75	2.89	−9.11	3.75	−4.33
RFA 100	2.60	−18.23	3.48	−11.22

+ Sign represents an increase in strength and – sign represents a decrease in strength

strength, with only a 7 %–10 % reduction after 50 % RFA replacement and a 25 %–29 % decrease with 100 % RFA replacement. These findings underscore the efficacy of the PPD mixing approach through standard compaction, considering weight within a specific cylindrical volume, in preserving flexural strength in concrete mixes. This study aligns with the outcomes of Kessal et al. [49] and lends support to the conclusions drawn by Vintimilla et al. [50]. These earlier studies also emphasized the crucial role of RFAs in achieving desirable concrete strength. Overall, this research contributes to the expanding body of knowledge on optimizing concrete mixtures for enhanced strength characteristics.

5.3 Flexural strength

The detailed outcomes in Table 6 provide a comprehensive understanding of the study. This investigation found that the flexural strength of concrete exhibits variations in terms of time and the amount of RFA replacement. The graphical representation illustrates a consistent pattern of flexural strength diminishing as the percentage of RFA replacement increases, indicating a negative correlation between higher RFA levels and concrete's flexural strength. Notably, after 28 days, RFA 25 demonstrated the highest flexural strength at 4.16 MPa, while RFA 100 exhibited the lowest strength at 3.48 MPa.

This study found a marginal reduction in flexural strength, with only a 1 %–2 % decrease following 50 % RFA replacement and a 10 %–15 % decrease with 100 % RFA replacement. This observation underscores the efficacy of the PPD mixing approach through standard compaction, considering weight within a specific cylindrical volume, in maintaining flexural strength in concrete mixes. This finding diverges from prior research that indicated a 5 %–10 % strength decrease after 50 % RFA replacement and a 15 %–20 % decrease for 100 % replacement [14]. Consistent with earlier research [11, 51], this study establishes a clear association between higher RFA replacement percentages and reduced flexural strength in concrete mixtures, as numerically depicted in Table 6 and visually presented in Fig. 5. These outcomes align with patterns observed in compressive strength studies, reaffirming and contributing to the existing body of knowledge by corroborating similar findings from other researchers.

Table 7. Splitting tensile strength variation in percentage for different mixtures.

Concrete mix	Splitting tensile strength (MPa)			
	7 days	% variation concerning RC	28 days	% variation concerning RC
RC	2.19	Reference	2.51	Reference
RFA 25	2.52	+15.0	2.84	+13.14
RFA 50	2.14	−2.28	2.48	−1.19
RFA 75	1.98	−9.58	2.34	−6.77
RFA 100	1.77	−19.17	2.19	−12.74

Note: + sign represents increase in strength and – sign represents decrease in strength

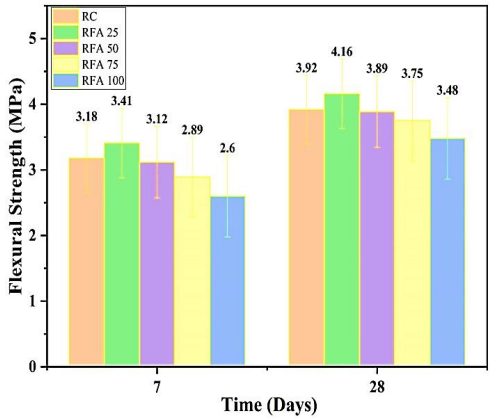

Fig. 5. Flexural strength variations for different concrete mixtures.

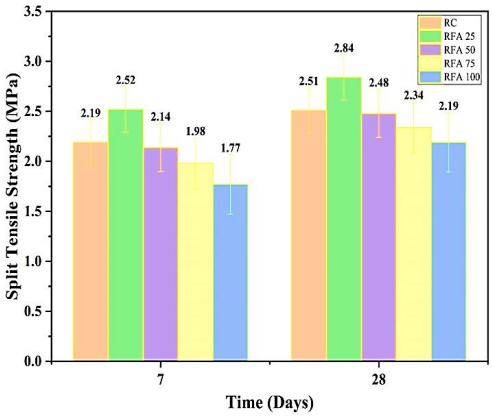

Fig. 6. Splitting tensile strength variations for different concrete mixtures.

5.4 Splitting tensile strength

The findings from these tests are systematically summarized in Table 7. The trends in splitting tensile strength variations over the 7- and 28-day periods are visually elucidated in Fig. 6. This figure effectively portrays the impact of varying percentages of RFA replacement on splitting tensile strength relative to

Table 8. Concrete MOE with different codes.

Concrete mix	Compressive strength (MPa)	Modulus of elasticity (GPa)		
		Experimental (E_c)	As Per IS 456-2000 (E_C)	As Per ACI code (E_C)
RC	31.99	31.42	28.27	26.77
RFA 25	36.71	29.61	30.29	26.68
RFA 50	29.78	24.04	27.28	25.83
RFA 75	24.86	22.68	24.92	23.61
RFA 100	23.01	20.31	23.98	22.72

the reference mixture. The observed trends in splitting tensile strength closely mirror those witnessed in compressive strength variations. Notably, as higher proportions of RFA replacement are employed, the splitting tensile strength of the concrete mixture tends to be lower than that of the reference mixture. Meticulous analysis of the results shows that the concrete mixture labeled "RFA 25" exhibits the highest splitting tensile strength (2.84 MPa) among all the tested mixtures. Conversely, the concrete mixture labeled "RFA 100" demonstrates the lowest splitting tensile strength (2.19 MPa) among the various mixtures examined.

In comparison to this study, where RFA is replaced using the PPD mixing approach through standard compaction in terms of weight within a specific cylindrical volume, only a 12 % reduction occurred at the 100 % replacement level. In contrast, Ashraf M. Wagih's work demonstrated a 24 % decline in splitting tensile strength at a 100 % replacement level [48]. These outcomes align with the findings of Kessal et al., establishing consistency with existing research [49, 50].

5.5 Modulus of elasticity

The MOE serves as a metric to assess the deformation capacity of both conventional concrete and RAC. MOE measures how much a material deforms when subjected to a load and subsequently returns to its original shape upon load release. The primary objective of this study is to ascertain the influence of RFA content on the deformation characteristics of concrete. The MOE at 28 days demonstrates a decline as the RFA content in the concrete increases. Table 8 delineates that RFA's brittleness and water absorption significantly contribute to this reduction, leading to more pronounced deformation in structural components made with RFA compared with those using NA. Consequently, an increase in RFA content correlates with a reduction in the MOE in concrete.

Fig. 7 visually presents the decline in the MOE with increasing RFA content, despite the potential benefits of the particle density method in enhancing strength and hydration. The comparison between compressive strength and the MOE of plain concrete for different RFA substitution percentages reinforces this observed pattern. The findings also suggest that various factors, including aggregate volume and stiffness, binder phase stiffness, and characteristics of the interfacial transition zone between aggregate and paste, contribute to the decrease in

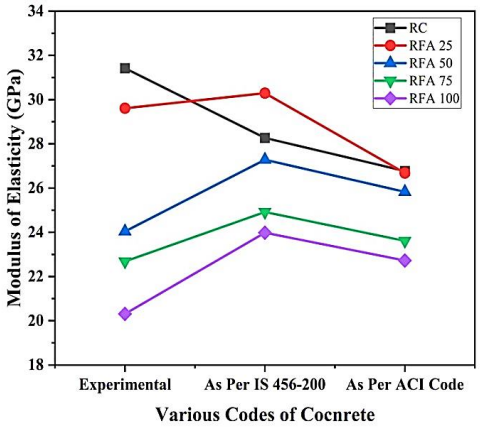

Fig. 7. Modulus of elasticity variation with different codes.

MOE with the increasing amount of RFA replacement. These results align with earlier studies that also identified a similar pattern of decreasing MOE as the quantity of RCA in concrete increased [48, 52].

5.6 X-ray diffraction analysis

XRD is a robust technique for elucidating the phase characteristics and mineralogical composition of crystalline minerals in a concrete sample. This method is particularly valuable when examining the effects of diverse mixtures that integrate RFAs. The angles at which diffraction peaks appear for different compounds in the concrete mixtures are recorded in Table 9. This table provides the degree values for calcium silicate hydroxide (CSH), ettringite, and calcium hydroxide (CH) for each concrete mixture, offering in-depth insight into the mineralogical aspects of the specimens by elucidating the diffraction peak angles for various compounds. The interpretation and discussion noted that the angles for CSH exhibit minimal variation, suggesting a consistent presence of this compound. The slight decrease in angles for RFA 25 indicates a subtle alteration in CSH composition compared with the RC. Ettringite angles show some variation, with RFA 25 displaying a lower angle, suggesting potential modifications in the crystalline structure. Increasing angles with higher RFA content hint at changes in the formation or orientation of ettringite crystals.

CH angles undergo more pronounced changes, notably in RFA 75 and RFA 100, where a substantial increase is ob-

Table 9. Diffraction peak angles of various compounds for different concrete mixtures.

Concrete mix	CSH (degree)	Ettringite (degree)	CH (degree)
RC	26.450	36.780	47.299
RFA 25	26.337	34.146	50.175
RFA 50	26.596	36.606	50.110
RFA 75	26.575	39.385	60.001
RFA 100	26.571	39.523	59.930

Note: CSH – calcium silicate hydroxide CH – calcium hydroxide ettringite – hydrated calcium aluminum sulfate hydroxide

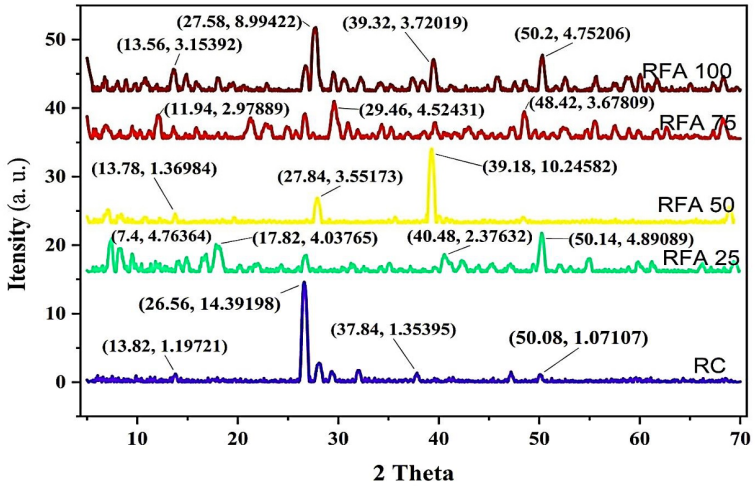

Fig. 8. XRD pattern for different concrete mixtures.

served, and potentially indicating variations in hydration products due to the presence of RFAs. Furthermore, the XRD results demonstrate the influence of RFAs on the phase composition of minerals within concrete. Specifically, the net intensity of peaks corresponding to CSH, CH, and ettringite decreases as the percentage of RFA replacement increases. This finding suggests a diminishing density of total CSH in the concrete with greater incorporation of RFAs. Fig. 8 presents the XRD patterns for various concrete mixtures, including RC, RFA 25, RFA 50, RFA 75, and RFA 100, offering a graphical depiction of how peak intensities and positions vary across these mixtures. These findings contribute to a comprehensive understanding of the effect of RFA on the mineralogical characteristics and overall composition of concrete mixtures.

As revealed by XRD studies, the addition of RFAs induces subtle changes in the phase composition of CSH, CH, and ettringite within concrete. The recorded data exhibit peaks at approximately 26.5°, 36°, and 50° for 2-theta angles, signifying the presence of various compounds such as CSH, ettringite, and CH across all combinations. While the strength of these peaks suggests the substantial presence of these substances, an important detail to note is that the concrete samples utilized in the investigation lacked microscopic homogeneity. This observation aligns with Silva et al.'s [53] study, which examined cement paste containing 12 % concrete floor polishing waste, highlighting comparable findings between the two studies [14]. In summary, XRD results imply that the incorporation of RFAs introduces subtle changes in the composition and crystalline structure of specific compounds, emphasizing the influence of RFA on the hydration process and overall mineralogical characteristics of the concrete. These nuanced insights are pivotal for evaluating the long-term durability and performance of concrete mixtures integrating RFAs.

5.7 Scanning electron microscopy analysis

In this investigation, SEM analysis is employed to scrutinize the characteristics of RFA concrete. Fig. 9 provides micrographs obtained after 28 days for distinct concrete mixtures that underwent SEM analysis.

These micrographs offer valuable insights into the microstructure of different concrete mixtures, revealing the formation of crucial hydration products at this stage. These hydration products, including CH, CSH, and ettringite, play a pivotal role in determining concrete strength. The micrographs illustrate distinctive characteristics: hexagonal crystal shapes correspond to CH, flower-like structures represent CSH gel, and needle-like structures denote ettringite. The test results reveal significant insights into the impact of different proportions of RFA on concrete microstructure and strength. The introduction of 25 % RFA into the concrete mixture enhances its microstructure, fostering the development of a dense cement paste. This

improvement strengthens the bond between aggregates, consequently elevating the compressive strength of the concrete. Conversely, the inclusion of 50 % RFA results in less dense concrete compared with the reference mix, thereby reducing both density and compressive strength. At 75 % RFA replacement, the concrete structure exhibits voids and loose arrangements, further diminishing the compressive strength. A complete 100 % RFA replacement yields a porous microstructure, where the cement surrounding the RFAs undergoes incomplete hydration, resulting in fewer hydration products. SEM analysis elucidates that lower RFA mixture proportions generate a more substantial amount of CSH gel, contributing to a denser cement paste matrix and increased concrete strength. However, excessive RFA proportions weaken the mixture's structural integrity due to inadequate CSH production, resulting in reduced strength. These findings align with a previous study [28, 54], reinforcing the consistency of the results with existing research. In summary, the SEM analysis in this study provides valuable insights into how varying RFA proportions influence concrete microstructure and strength. The micrographs in Fig. 9 highlight distinct features corresponding to different hydration products, emphasizing that optimal RFA replacement proportions can enhance concrete properties, while excessive replacement can lead to weaker structures. These insights bear significance for the design of sustainable and high-performance concrete mixtures.

6. Cost–benefit analysis

Table 10 presents a comprehensive overview of the cost–benefit analysis conducted in this study, comparing the scheduled rate of the Road and Building Department Delhi Division, Government of Delhi with the prevailing market rates for various construction materials. The materials considered in this

Table 10. Cost of mixtures.

Elements	Unit cost per kg	RC (kg/m^3)	RFA 25 (kg/m^3)	RFA 50 (kg/m^3)	RFA 75 (kg/m^3)	RFA 100 (kg/m^3)
Cement	6.6	400	400	400	400	400
Admixture	0.9	4	4	4	4	4
NFA	0.75	444.48	333.36	222.24	111.12	0

Total (INR)		3959.11	3920.21	3881.32	3842.43	3803.54
% variation concerned with RC		-	0.98	1.96	2.94	3.96

RC – reference concrete NFA – natural fine aggregates NCA – natural coarse aggregates RFA – recycled fine aggregates

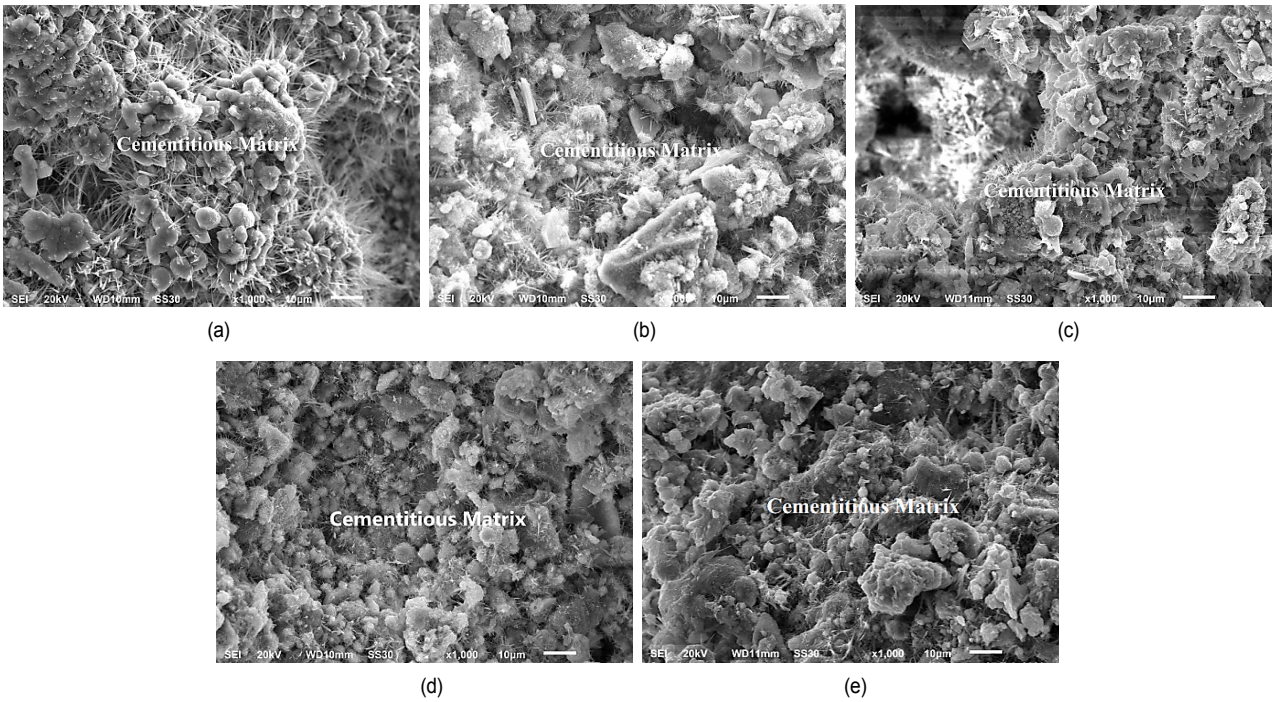

Fig. 9. Different concrete mixtures' SEM micrographs: (a) RC; (b) RFA 25; (c) RFA 50; (d) RFA 75; (e) RFA 100.

analysis include:

- Cement priced at INR 6.6 per kilogram.
- NFAs priced at INR 0.75 per kilogram.
- NCAs priced at INR 0.65 per kilogram.
- RFAs priced at INR 0.40 per kilogram.

RFAs are produced utilizing an impact crusher at the Delhi Metro Rail Corporation's IL&FS CDW Recycling Plant in Delhi, India, using discarded concrete.

The objective of this cost analysis is to quantify potential savings achievable through the utilization of CDW in comparison to NAs. Table 10 illustrates the material costs and the resultant expenses incurred by different mixtures. As depicted in the table, substituting NAs with RFAs can lead to cost savings ranging from 1 % to 4 %, depending on the quantity of replaced RFA. This approach not only offers cost savings but also delivers concrete of comparable quality to the control, making it a favorable choice from both economic and performance perspectives [55].

7. Conclusions

This paper investigates RFAs from CDW in sustainable concrete. The findings highlight reduced environmental impact without compromising structural integrity, emphasizing controlled particle size distribution. From the study, the following conclusions may be drawn:

1) The mechanical properties of concrete exhibit an optimum replacement percentage for RFAs at 25 %. Concrete achieves superior performance at this level, with a decline in strength characteristics observed at 100 % RFA replacement. Careful evaluation of the RFA replacement proportion is essential for ensuring intended concrete mixture performance.
2) A recommended replacement of 25 % RFAs in concrete yields higher strength compared with NFAs. RFA 25 demonstrates a 14.75 % increase in compressive strength, a 6.61 % increase in flexural strength, and a 13.14 % increase in splitting tensile strength compared with RC. The strength of 50 % RFA is comparable to that of 100 % NFAs.
3) The pozzolanic reaction enhances strength at lower replacement percentages by forming more hydration products, while higher levels result in decreased strength due to incomplete hydration. Optimal replacement percentage determination relies on microstructure and chemical composition analysis to achieve maximum strength.
4) The experimental MOE for concrete, incorporating both NA and RA, is lower than the theoretical value due to flaws, irregularities in recycled aggregates, and variations in composition.
5) RAs significantly reduce environmental impact by curbing natural resource demand, conserving resources, and minimizing carbon footprint. Their use promotes sustainable building methods, reduces landfill waste, and encourages resource reuse, resulting in a 10 % cost–benefit ratio and less negative environmental effects in construction projects.

Incorporating RFAs in concrete is a promising sustainable practice, with marginal mechanical property reduction. Microstructural analysis offers relevant insights. Further research is needed for optimal mix designs, long-term performance, and economic feasibility, marking a positive step in reducing construction's environmental impact.

Abstract:

Introduction: Biological Named Entity Recognition (BioNER) is a crucial preprocessing step for Bio-AI analysis.

Methods: Our paper explores the field of Biomedical Named Entity Recognition (BioNER) by closely analysing two advanced models, SciSpaCy and BioBERT. We have made two distinct contributions: Initially, we thoroughly train these models using a wide range of biological datasets, allowing for a methodical assessment of their performance in many areas. We offer detailed evaluations using important parameters like F1 scores and processing speed to provide precise insights into the effectiveness of BioNER activities.

Results: Furthermore, our study provides significant recommendations for choosing tools that are customised to meet unique BioNER needs, thereby enhancing the efficiency of Named Entity Recognition in the field of biomedical research. Our work focuses on tackling the complex challenges involved in BioNER and enhancing our understanding of model performance.

Conclusion: The goal of this research is to drive progress in this important field and enable more effective use of advanced data analysis tools for extracting valuable insights from biomedical literature.

Keywords: Biomedical, BioNER, SciSpaCy, BioBERT, Natural language processing, Named entity recognition.

1. INTRODUCTION

Named Entity Recognition (NER) [1] is a crucial part of Natural Language Processing (NLP) that involves identifying and categorising named items in written text. Named entities encompass several categories such as personal names, organisational names, and geographical places, among others. The primary objective is to do this by transforming unstructured textual content into a machine-readable format. Named Entity Recognition (NER) is a crucial part of Information Extraction (IE) that involves the detection and classification of named items in unstructured text data. Named entities refer to a broad variety of entities, such as persons, businesses, geographical locations, precise dates, numerical values, and other pertinent categories. Named Entity Recognition (NER) is a prominent area of research that has attracted substantial academic attention and has several practical applications in the field of natural language processing. The use of NER approaches varies across different domains, giving rise to distinct difficulties and possibilities

within this subject. Deep learning techniques for NER have demonstrated encouraging outcomes across diverse areas such as healthcare, legal, and chemical fields. There have been proposals to utilise active learning methodologies, specifically Label Transfer Learning (LTP), as a means to mitigate the expenses associated with data annotation in the field of NER. In addition, there are shared projects and benchmarks, such as the ROCLING-2022 shared task focused on Chinese healthcare NER, which furnish datasets and assessment criteria to facilitate the comparison of diverse NER methodologies. Named Entity Recognition is a specific component within the broader field of Information Extraction that falls within the domain of NLP. The primary objective of this system is to discern and categorise designated items, such as individual names, organisational names, geographical places, dates, and other specific nouns, inside the text that lacks a predetermined framework [2-4]. Named Entity Recognition is an essential preprocessing task in several downstream NLP applications, including but not limited to question answering, conversation systems, and knowledge graph generation [3].

The use of Named Entity Recognition algorithms exhibits variability across many domains, owing to the distinctive characteristics inherent to each specific area [4]. Nevertheless, the procedure often encompasses other essential NLP stages, such as tokenization, part-of-speech tagging, parsing, and model construction [4]. In the field of medicine, for instance, Named Entity Recognition encompasses the task of recognising medical terminology, properties such as negation and severity, and establishing connections between terms and ideas inside domain-specific ontologies [5–9].

In the early stages of development, Named Entity Recognition (NER) systems mostly relied on manually constructed rules, lexicons, and ontologies. However, these systems need extensive dictionaries and meticulous manual feature creation, which constrained their ability to expand and reach maximum performance [10, 11]. In the era of Machine Learning, there are solutions that include machine learning concepts as a potential alternative [12, 13]. However, even these solutions required extensive feature engineering work, limiting their flexibility and effectiveness. The scenario saw significant shifts due to the emergence of the Deep Learning revolution. Recent advancements have brought about advanced deep learning structures like Bi-directional Long Short-Term Memory Networks (BiLSTM) combined with Conditional Random Fields (CRF) and GRAM-CNN [14]. The developments have far beyond the capability of older approaches, demonstrating improved precision and resilience. The greatest significant advancement in Named Entity Recognition (NER) technology occurred with the development of the BERT architecture (Bi-directional Encoder Representations from Transformers). BERT has introduced a new age by using contextual information, allowing NER systems to attain exceptional levels of accuracy and recall [15-18]. The capacity to understand subtle contextual signals has transformed NER accuracy, representing a significant advancement in biomedical text comprehension and data retrieval.

Named Entity Recognition can provide difficulties, particularly in situations involving low-resource languages or topics that necessitate a time-consuming and knowledge-intensive annotation procedure [4, 5, 19]. In order to tackle these issues, scholars have undertaken investigations into many methodologies, including few-shot learning. This particular methodology endeavours to train machine learning models with a very restricted amount of accessible data [19-21]. Furthermore, the integration of entity definition information and domain-specific resources, such as medical dictionaries and ontologies [8, 13, 14, 22], has been shown to enhance the efficacy of Named Entity Recognition models within certain domains [18, 23-32]. Multiple strategies are employed in order to enhance the precision of NER. Several approaches can be identified, including:

1. The process of data augmentation encompasses the generation of supplementary training instances through the modification or synthesis of pre-existing examples. This approach has the potential to enhance the generalisation capabilities of the Named Entity Recognition paradigm [33-36].

2. The hybrid approach involves integrating rule-based methodologies with machine learning techniques, namely Conditional Random Fields (CRF), to enhance the precision of Named Entity Recognition [34, 37, 38].

3. The inclusion of domain-specific resources, such as medical dictionaries and ontologies, together with entity definition information, has been found to enhance the effectiveness of named entity recognition models in certain domains [39-41].

4. Semi-supervised learning is a technique that involves training a model using a little amount of labelled data together with a large amount of unlabeled data. This technique has the potential to improve the effectiveness of named entity recognition models in situations typified by restricted resources, such as low-resource languages or domains where the annotation process requires substantial time, knowledge, and expertise [33, 42, 43]. One way to address the problem of noisy data and the introduction of unwanted patterns during training is to use an iterative training process and data-generating tools. This entails retraining the model using a subset of the original annotated dataset [33, 44, 45].

5. Fine-tuning and transfer learning are often employed techniques in the field of named entity recognition to enhance the efficiency and/or accuracy of NER models [46-48]. Researchers have achieved enhanced precision in NER models across several domains, such as healthcare, legal, and chemical domains, through the use of these methodologies [44, 49]. The job of Named Entity Recognition poses significant challenges in the context of clinical writing, primarily due to the intricate and diverse nature of medical language. Nevertheless, many methodologies may be employed to enhance the precision of Named Entity Recognition in clinical discourse [47].

Several approaches can be identified, including the integration of domain-specific resources, including entity definition information and specialised resources like medical dictionaries and ontologies, which have been shown to enhance the efficacy of named entity recognition models within the medical domain [18, 50]. The hybrid approach involves integrating rule-based methodologies with machine learning techniques, namely CRF, in order to enhance the precision of Named Entity Recognition [51]. Data augmentation is a methodology that entails the creation of supplementary training instances through the alteration or synthesis of preexisting examples. This approach has the potential to enhance the generalisation capabilities of the Named Entity Recognition paradigm [9]. Semi-supervised learning is a methodology that entails training a model using a small quantity of labelled data with a substantial quantity of unlabelled data. This approach has the potential to enhance the efficacy of Named Entity Recognition models in scenarios characterised by limited resources, such as low-resource languages or domains where the annotation process necessitates substantial effort, skill, and domain knowledge [50, 52]. Fine-tuning and transfer learning techniques can be employed to enhance the efficiency and/or accuracy of Named Entity Recognition models [53, 54]. The utilisation of a multilevel named entity recognition framework can effectively tackle the difficulties associated with clinical NER. This framework enables the construction of models that are capable of handling more intricate NER tasks [53, 55]. Through the use of these methodologies, scholars have successfully enhanced the precision of Named Entity Recognition models within the medical field. As an illustration, a research endeavour pertaining to the identification and extraction of adverse drug events from clinical literature by the use of medicine and associated techniques yielded F1 scores of 93.45% for Named Entity Recognition [50]. A recent investigation pertaining to the identification of medication names and their corresponding properties from discharge summaries demonstrated a notable F1-score of 0.91 in the context of the 2018 National NLP Clinical Challenges (n2c2) shared task [50]. Identifying uncommon medical conditions and their associated clinical presentations, together with the influence of socio-economic determinants of health, can provide challenges within the clinical literature. Moreover, the intricate and diverse nature of medical vocabulary presents a formidable obstacle for Named Entity Recognition when applied to clinical material. The concept of stupor poses a challenge in terms of its specific clinical definition [5]. Nevertheless, scholars have put forth various methodologies to enhance the precision of Named Entity Recognition in clinical text [56-59]. These methodologies encompass the integration of domain-specific resources, the adoption of a hybrid approach, data augmentation techniques, semi-supervised learning methods, fine-tuning and transfer learning strategies, as well as the utilisation of a multilevel NER framework [58, 60–62]. Identifying abbreviations and acronyms in clinical material is difficult for Named Entity Recognition algorithms. Nevertheless, many methodologies may be employed to enhance the precision of Named Entity Recognition in clinical discourse containing abbreviations and acronyms. Several approaches can be identified, including the use of domain-specific resources, such as medical dictionaries and ontologies, that enhance the ability of named entity recognition models to identify abbreviations and acronyms in the clinical text [37]. The hybrid approach involves integrating rule-based methodologies with machine learning techniques, namely CRF, in order to enhance the precision of Named Entity Recognition [51]. Data augmentation is a methodology that entails the creation of supplementary training instan-ces through the alteration or synthesis of preexisting examples. This approach has the potential to enhance the generalisation capabilities of the Named Entity Recog-nition model [55]. Fine-tuning and transfer learning are two techniques that may be employed to enhance the efficiency and/or accuracy of Named Entity Recognition models [53].The utilisation of a multilevel named entity recognition framework presents a viable solution to tackle the obstacles encountered in clinical NER. This framework enables the construction of models that cater to more intricate NER tasks [63].

Through the use of these methodologies, scholars have successfully enhanced the precision of Named Entity Recognition models when applied to clinical material containing abbreviations and acronyms. As an illustration, a research investigation on clinical named entity identification attained an F1-score of 0.91 on the 2018 National NLP Clinical Challenges (n2c2) shared task [27, 50]. When applied to the field of biomedical research, the Biomedical Named Entity Recognition (BioNER) technique is an essential part of the process of biomedical text mining [44, 64-66]. The enormous task of recognising and categorising the numerous things that can be found in biomedical literature is taken on by BioNER. These entities include genes, diseases, chemical names, and medicinal names. The ever-increasing number of biological entities, their plethora of synonyms, the popularity of abbreviations, the use of lengthy entity descriptions, and the combination of letters, symbols, and punctuation within these texts all contribute to this complexity. BioNER, integral to numerous applications in the field of natural language processing, plays a pivotal role in biomedical literature mining [25, 67, 68]. One prominent application involves biomedical relation extraction, which seeks to uncover intricate relationships between diverse biomedical entities, such as diseases, genes, species, and chemicals. The accuracy and quality of downstream relation extraction tasks are directly contingent on the performance of BioNER systems [69]. Furthermore, BioNER significantly contributes to the identification and classification of drugs and their interactions, critical for applications like drug discovery, drug safety monitoring, and personalized medicine [70]. It also facilitates knowledge base completion, enriching biomedical knowledge bases by automatically extracting and categorizing pertinent entities from text. This enriched knowledge is then harnessed for a multitude of purposes, including semantic

search, question answering, and data integration. BioNER's utility extends to biomedical question answering, assisting in understanding and responding to complex biomedical queries by identifying and categorizing relevant entities from both the question and the relevant text [71]. In the realm of biomedical text summarization, BioNER proves invaluable in identifying and extracting key biomedical entities from texts, thereby enabling the generation of concise, informative summaries [71]. Moreover, it enhances the accuracy and relevance of search results in biomedical information retrieval systems, where it identifies and classifies pertinent entities in both the query and the document collection [51, 67, 71, 72]. A simplified representation for identifying a Named entity can be represented as shown in Algorithm 1

***Algorithm 1**: Named Entity Recognition and Classification using BERT Model.*

Input: Tokens: A sequence of tokens representing the input text

Output: Named Entity Labels: A list of predicted entity labels for each token in the input text

```
function Named_Entity_Recognition_And_Classification(tokens):
  Initialize Named_Entity_Labels as an empty list
  for each token t in a sequence of tokens do
    Calculate the probability distribution over possible entity labels:
      P(label | token, context) = fmodel(token, context)
    Apply softmax function to P(label | token, context)
    Assign the label with the highest probability for token t
    Append the predicted entity label to Named_Entity_Labels
  end for
  return Named_Entity_Labels
end function
```

The actual calculation of these probabilities can involve complex machine learning models such as CRFs, BiLSTM-CRFs, or Transformer-based models, which take into account the token, its context, and various features for labelling.

In Algorithm 1:

- P(label | token, context) represents the probability of a specific label given the token and its context.
- fmodel() represents the function that the machine learning model (*e.g.*, CRF, BiLSTM, Transformer) uses to predict this probability.
- The model represents the machine learning model that has been trained to predict entity labels.

SciSpaCy, a Python library and models tailored for practical biomedical and scientific text processing, makes extensive use of spaCy [73]. spaCy itself employs deep learning techniques and, with the release of version 3, has transitioned to using the Transformer architecture as its deep learning model. It offers a customizable architecture that accommodates various deep learning techniques such as LSTMs, CRFs, and transformers to suit specific tasks [74].

BioBERT, on the other hand, is a pre-trained biomedical language representation model based on the BERT architecture [75]. It has been fine-tuned on an extensive corpus of biomedical literature, incorporating articles from PubMed and PMC as shown in Fig. (**1**). The adaptability of this model enables it to perform very well in many biomedical activities, such as biomedical named entity identification, connection extraction, question answering, and drug discovery. Both BioBERT and SciSpaCy are open-source tools, rendering them important resources for NER.

In this work, we present significant contributions to the domain of Biomedical Named Entity Recognition (BioNER), with prior focus on the utilization and examination of two prominent models, SciSpaCy and BioBERT, addressing the intricate challenges inherent in BioNER.

1. Through meticulous training on diverse biological datasets, we systematically evaluate the performance of SciSpaCy and BioBERT across various domains. Our comprehensive assessment employs key metrics such as F1 scores and processing speed, providing a detailed understanding of their efficacy in BioNER tasks.

2. The study offers valuable insights for the selection of tools tailored to specific BioNER requirements. By optimizing Named Entity Recognition in the field of biomedical research, our work aims to contribute to the broader advancement of this critical domain

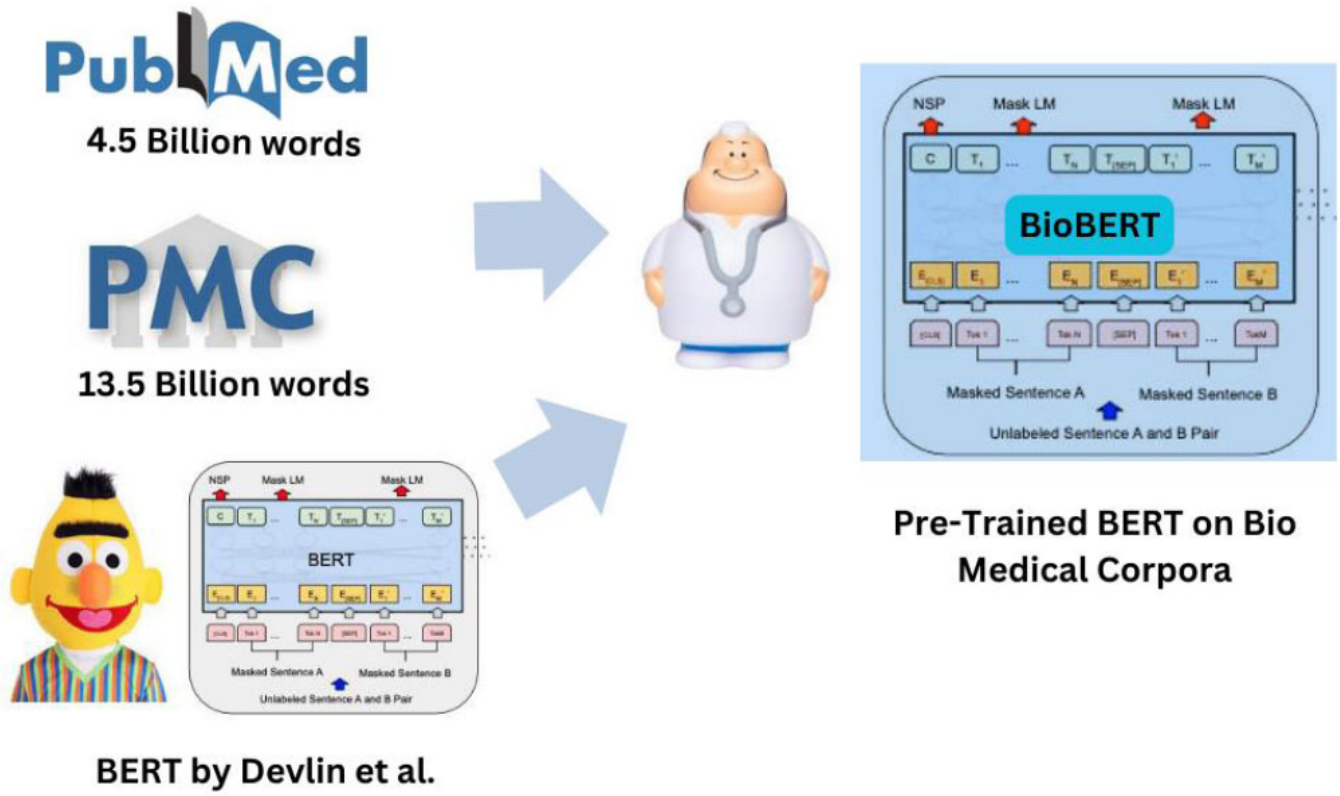

Fig. (1). BioBERT pretraining.

We have performed some literature surveys of the papers that collectively discuss various approaches to biomedical NER. Amith 2017 proposes an ontology-driven method that utilizes information extraction and features of ontologies to identify biomedical software names [76]. Al-Hegami 2017 focuses on the use of machine learning classifiers and a rich feature set to recognize biomedical entities, with the K-Nearest Neighbour classifier showing promising results [77]. Zhang 2013 presents an unsupervised approach to NER, using a noun phrase chunker and distributional semantics for entity extraction and classification [20].

Li 2023 proposes a fusion multi-features embedding method, combining deep contextual word-level features, local char-level features, and part-of-speech features to improve biomedical entity recognition [78]. Kaewphan *et al.*, 2018, published in the "Database Journal of Biological Databases Curation," shows a system for automatically identifying a wide range of biomedical entities within literature, boasting state-of-the-art performance. The study achieved the highest results in named entity recognition, underscoring its capability in biomedical entity recognition and normalization [79].

Priyanka *et al.*, 2021 provided a detailed survey of clinical Named Entity Recognition and Relationship Extraction (RE) techniques, addressing existing NLP models, performance, challenges, and future directions in the context of information extraction from clinical text, offering insights on current research and evaluation metrics [18].

Gong *et al.*, 2009 published in the "International Conference on BioMedical Engineering and Informatics," this study introduces a hybrid approach aimed at recognizing untagged biomedical entities. The approach demonstrates its utility in identifying biomedical entities in the GENIA 3.02 corpus, offering support for biologists in tagging biomedical entities within biomedical literature [80].

Kanimozhi & Manjula in 2018 performed a systematic review that focuses on the identification and classification of named entities within unstructured text documents. The goal is to extract valuable information from such texts by identifying and categorizing the named entities, a crucial step in extracting useful knowledge from unstructured textual data [81].

Overall, these papers highlight different techniques and algorithms for biomedical NER, showcasing the importance of effective natural language processing tools in organizing and extracting information from biomedical literature. Table **1** depicts the core methodology of the above-mentioned research works.

In addition to this study, there are several domains where Named Entity Recognition may be applied. Potential intersections and possibilities for collaboration or cross-pollination exist across the fields, especially in areas such as Visual Named Entity Recognition, cross-modal learning, semantic comprehension, and multi-modal information fusion.

1. Visual Named Entity Recognition (VNER): is a process that involves detecting and classifying named entities in text-based data. There is an increasing interest in Visual Named Entity Recognition, which refers to the process of recognising and categorising named items in photos or videos. The domain might possibly benefit from the application or adaptation of image processing techniques, particularly those that emphasise feature extraction and semantic interpretation.

2. Cross-Modal Learning: Cross-modal learning involves leveraging information from different modalities (*e.g.*, text and images) to improve performance on various tasks. Techniques developed for image processing, especially those involving attention mechanisms and feature extraction, could potentially be integrated with NER systems to improve entity recognition performance, especially in cases where textual context alone may not be sufficient.

3. Semantic Understanding: Both image processing and NER involve understanding the semantic content of data, albeit in different modalities. Techniques developed for image inpainting, super-resolution, or feature extraction may enhance the semantic understanding of textual data, which could indirectly benefit NER systems by providing richer contextual information.

4. Multi-Modal Information Fusion: Another potential linkage is through multi-modal information fusion techniques. Research in image processing often involves integrating information from different sources or modalities to improve the quality of image reconstruction or understanding. Similarly, integrating information from images (*e.g.*, scenes, objects) with textual data (*e.g.*, context, descriptions) could enhance NER systems' performance, especially in scenarios where textual and visual information are both available.

Some interesting works where NER can be combined are done by Yuantao Chen *et al*. in image processing techniques such as image inpainting and super-resolution. In a series of innovative contributions by Yuantao Chen, Runlong Xia, Kai Yang, and Ke Zou, their research endeavors have significantly advanced the field of image processing and restoration. In June 2023, they introduced "DARGS Image inpainting algorithm *via* deep attention residuals group and semantics," proposing a method that combines Semantic Priors Network, Deep Attention Residual Group, and Full-scale Skip Connection to effectively restore missing regions in images. Building on this foundation [82], in October 2023, they presented "GCAM: lightweight image inpainting *via* group convolution and attention mechanism," offering a lightweight approach that utilizes group convolution and rotating attention mechanism to enhance image inpainting while optimizing resource usage [83]. In January 2024, they unveiled "MFMAM: Image inpainting *via* multi-scale feature module with attention module," introducing a network utilizing multi-scale feature module and improved attention mechanisms for enhanced image inpainting, particularly focusing on texture and semantic detail preservation [84]. Their work continued with "DNNAM: Image inpainting algorithm *via* deep neural networks and attention mechanism," published in March 2024, where they introduced a method incorporating partial multi-scale channel attention mechanism and deep neural networks to improve image inpainting accuracy and quality [85]. Lastly, in July 2024, their paper titled "MICU: Image super-resolution *via* multi-level information compensation

and U-net" presented a novel approach for image super-resolution using multi-level information compensation and U-net architecture, significantly improving image reconstruction quality compared to existing methods [86]. Collectively, these papers underscore the author group's commitment to advancing image processing techniques with innovative methodologies and improved performance metrics. These works are very close in the possibilities for collaborating NER in areas such as Visual Named Entity Recognition, cross-modal learning, semantic comprehension, and multi-modal information fusion.

2. METHODOLOGY

The work aimed to rigorously evaluate the performance of BioBERT and SCISpaCy in biomedical Named Entity Recognition, considering the data's origin, preprocessing, training, and evaluation processes. The choice of these models and the training process was guided by the aim of achieving accurate and generalizable recognition of biomedical entities. These considerations are explained as follows:

2.1. Data Collection

The dataset utilized in this study was curated from diverse sources of biomedical Named Entity Recognition datasets. These datasets, including JNLPBA [15], BC4_CHEMD [87], BIONLP13CG [88], EXPERT 206 [70], and BC5CDR [89], were selected to encompass a wide range of biomedical entity types and domains, offering a comprehensive evaluation of BioNER models as shown in Table 2.

Entity Types and Datasets: The evaluation encompassed multiple datasets, each representing distinct biomedical entity types. The datasets included.

- JNLPBA: Targeted entities included DNA, CELL_TYPE, CELL_LINE, RNA, and PROTEIN.
- BC4_CHEMD: Focused on the CHEMICAL entity type.
- BIONLP13CG: Encompassed a diverse set of entity types, such as AMINO_ACID, ANATOMICAL_SYSTEM, CANCER, and more.
- EXPERT 206: Included GENE, DISEASE, and VARIANT as recognized entities.
- BC5CDR: Considered both CHEMICAL and DISEASE entities.

2.2. Data Preprocessing

2.2.1. Data Conversion for BioBERT

To prepare the data for training BioBERT, the datasets were converted into a BIO (Beginning-Inside-Outside) format. This involved annotating each token in the dataset with one of three labels: "B-" for the beginning of an entity, "I-" for internal parts of an entity, and "O" for tokens outside of any entity. This format enables BioBERT to understand and recognize the boundaries of biomedical entities within the text.

2.2.2. Data Conversion for SCISpaCy

For training SCISpaCy, the datasets were transformed into a format suitable for spaCy's NER model. The conversion process required structuring the data as a list of sentences, each followed by a list of (start, end, label) triples, where the triples define the start and end positions of the entity within the sentence and its associated label. For example, ("Tokyo Tower is 333m tall.", [(0, 11, "BUILDING")]) represents a sentence, the start and end positions of the entity "BUILDING," and its label.

2.3. Data Splitting

To facilitate model evaluation, the dataset was divided into training and testing subsets. The data was partitioned using an 80-20 split, allocating 80% of the data for training and 20% for testing. This ensures that the models are trained on a substantial portion of the data while preserving an independent dataset for assessing their generalization performance.

2.4. Hardware and Software Environment

Training of the model was carried out on carefully managed hardware consisting of Google Collab T4 GPUs. The environment had the essential programming languages, libraries, and frameworks for the construction and execution of the models, as well as particular GPU specifications for rapid training.

Table 2. Dataset analysis.

Datasets	Entity Type	No. of Entities
BIONLP13CG	Tissues	587
BIONLP13CG	Organisms	2,093
BIONLP13CG	Gene/Protein	7,908
EXPERT 206	Disease	7,390
EXPERT 206	Gene/Protein	7,393
BC5CDR	Disease	12,204
BC5CDR	Chemical	12,204
BC4_CHEMD	Chemical	84,249
JNLPBA	Cell Line	4,315

Table 3. NER results of SciSpacy and BioBERT.

Model	Entity Types	SCISpaCy F1 Score	BioBERT F1 Score
JNLPBA	"DNA, CELL_TYPE, CELL_LINE, RNA, PROTEIN"	73.1	73.67
BC4_CHEMD	"CHEMICAL"	85.1	86.07
BIONLP13CG	"AMINO_ACID, ANATOMICAL_SYSTEM, CANCER, CELL, CELLULAR_COMPONENT, DEVELOPING_ANATOMICAL_STRUCTURE, GENE_OR_GENE_PRODUCT, IMMATERIAL_ANATOMICAL_ENTITY, MULTI-TISSUE_STRUCTURE, ORGAN, ORGANISM, ORGANISM_SUBDIVISION, ORGANISM_SUBSTANCE, PATHOLOGICAL_FORMATION, SIMPLE_CHEMICAL, TISSUE"	78.13	86.07
EXPERT 206	"GENE, DISEASE, VARIANT"	91.08	91.23
BC5CDR	"CHEMICAL, DISEASE"	85.53	87.83

3. RESULTS AND DISCUSSION

3.1. Model Performance

3.1.1. JNLPBA Dataset

For the JNLPBA dataset, SCISpaCy and BioBERT both displayed competitive performance, with F1 scores of 73.1 and 73.67, respectively. These ratings were uniform across all entity types in this sample.

In the BC4 CHEMD dataset, which concentrates on CHEMICAL items, both models demonstrated excellent performance. BioBERT surpassed SCISpaCy with an F1 score of 86.07, while SCISpaCy received an F1 score of 85.1.

3.1.2. BIONLP13CG Dataset

The BIONLP13CG dataset featured a large variety of entity types, posing a challenge to the models' ability to recognise a wide range of biomedical items. BioBERT's F1 score of 86.07 was superior to SCISpaCy's score of 78.13.

The EXPERT 206 dataset, which consists of GENE, DISEASE, and VARIANT entities, produced high F1 scores for both models. SCISpaCy obtained an F1 value of 91.08, but BioBERT fared somewhat better with an F1 score of 91.23.

3.1.3. BC5CDR Dataset

For the BC5CDR dataset, which involves CHEMICAL and DISEASE entity recognition, both models displayed strong performance. SCISpaCy achieved an F1 score of 85.53, while BioBERT exhibited superior performance with an F1 score of 87.83. These results are showcased in Table **3**.

3.2. Inference and Performance Trade-offs

The evaluation of inference times revealed that SCISpaCy processed an average sentence in approximately 90 milliseconds, while BioBERT required an average of 278 milliseconds per sentence as shown in Fig. (**2**). It is important to note that the relatively longer inference time of BioBERT can be attributed to various internal tasks, including tokenizer loading and token classification.

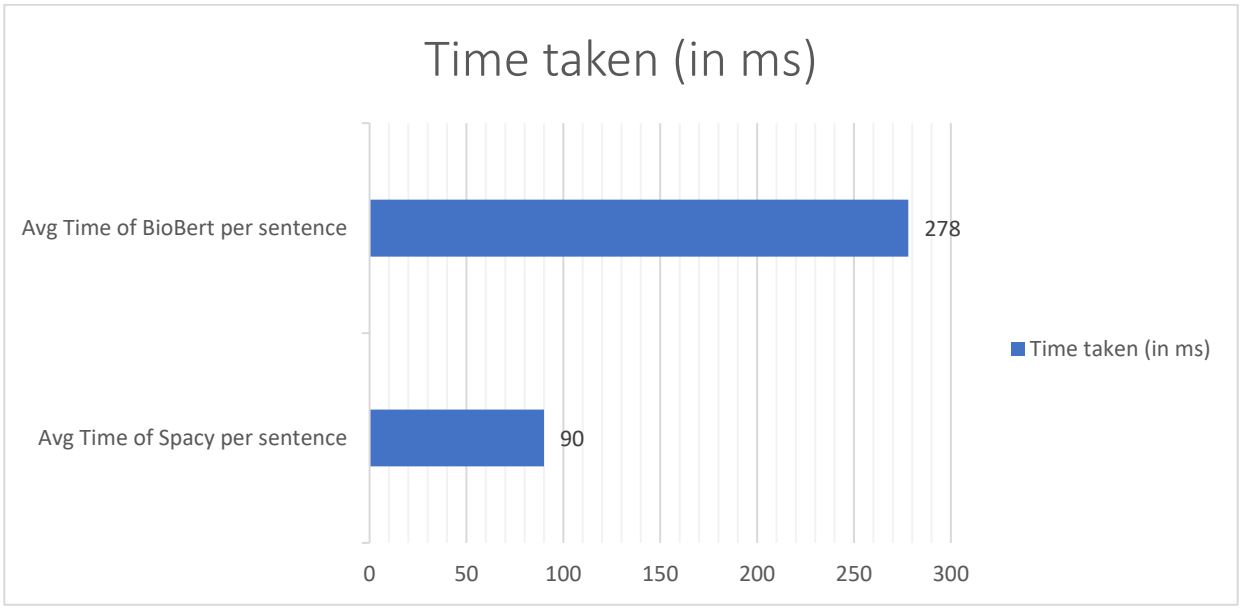

Fig. (2). Time complexity analysis of NER models.

However, BioBERT compensates for this by efficiently processing multiple sentences in parallel. This capability enhances throughput, making BioBERT a favorable choice in scenarios where parallelism is crucial.

4. DISCUSSION

Based on the results showcased in Table **3**. Some inferences have been deduced. These inferences can help to guide the selection of the appropriate model for specific biomedical NER tasks based on the dataset's entity types and performance requirements.

4.1. Entity Types and Specialization

The F1 scores vary across different entity types and datasets. For instance, in the JNLPBA dataset, DNA, CELL_TYPE, CELL_LINE, RNA, and PROTEIN have relatively similar F1 scores, indicating that the model's performance is consistent across these biomedical entity types. On the other hand, in the BIONLP13CG dataset, there is a wide range of entity types with varying F1 scores, suggesting that the model's performance is more specialized for some entity types.

4.2. BioBERT's Consistency

BioBERT consistently achieves higher F1 scores compared to SCISpaCy across all datasets and entity types. This indicates BioBERT's robustness and effectiveness in biomedical named entity recognition tasks.

4.3. High Performance for EXPERT 206

The EXPERT 206 dataset demonstrates the highest F1 scores for both models. This suggests that the entities in this dataset, such as Genes, Diseases, and variants, are well-recognized by both SCISpaCy and BioBERT.

4.4. Strong BioBERT Performance in BC5CDR

In the BC5CDR dataset, which focuses on Chemicals, BioBERT significantly outperforms SCISpaCy with an F1 score of 87.83, indicating its strength in recognizing chemical entities.

4.5. Balanced Performance in BC4_CHEMD

The BC4_CHEMD dataset, consisting of DISEASE and CHEMICAL entity types, shows similar and high F1 scores for both models. This suggests that both SCISpaCy and BioBERT are proficient in recognizing these types of entities.

4.6. Biomedical Specialization

The choice of model may depend on the specific biomedical entity types in the dataset. While BioBERT generally outperforms SCISpaCy, practitioners should consider the nature of the entities they are dealing with when selecting the most suitable model for their task.

4.7. Overall Robustness

Both SCISpaCy and BioBERT demonstrate strong performance in biomedical named entity recognition. However, BioBERT's consistently higher F1 scores and adaptability to various entity types make it a valuable choice for a wide range of biomedical applications.

4.8. Time Complexity on Same Hardware

On the same hardware configuration with a T4 GPU (utilizing Google Colab's default GPU settings), we observed that spaCy demonstrated a faster average inference time per sentence, approximately 50 milliseconds, compared to BioBERT's average speed of 178 milliseconds per sentence. It is worth noting that the apparent time difference in favor of spaCy may be attributed to its streamlined processing for individual sentences. However, it is important to consider that BioBERT exhibits a significant advantage when processing multiple sentences in parallel. This capability compensates for the additional time incurred by BioBERT in various internal tasks such as tokenizer loading and token classification. Consequently, BioBERT's suitability for parallel sentence processing makes it a strong contender in scenarios where high throughput and parallelism are critical.

CONCLUSION

SCISpaCy and BioBERT, along with other BioNER models, have demonstrated their capabilities, benefits, and relevant considerations. This study evaluated diverse datasets, and performance metrics, offering valuable insights to scholars and practitioners in the field of biological natural language processing. The study produced intriguing findings. The selection of a model such as SCISpaCy or BioBERT significantly impacts the detection of many biological events. BioBERT consistently achieved higher F1 scores than SCISpaCy across several datasets, entity types, and domains. The durability and adaptability of BioBERT in the biomedical field make it a highly promising choice for BioNER.The datasets exhibited notable variations in F1 scores across different item categories. The F1 ratings for both models in the EXPERT 206 dataset of Genes, Diseases, and Variants indicate that SCISpaCy and BioBERT effectively recognise and categorise these entity types. The BIONLP13CG dataset exhibited a diverse range of entity kinds, each with distinct F1 scores. The performance of the model may be tailored to specific entities. Parallel processing is an additional advantage of BioBERT. Although BioBERT may have longer phrase inference times, it has the ability to process several sentences simultaneously, which makes it an excellent choice for high-throughput applications. It is essential to assess the different categories within the dataset and determine the optimal trade-off between efficiency and precision when recognising biological entities. The selection of the model should be guided by the intrinsic aspects of the work. Our analysis demonstrates the significance of BioNER in the field of biomedical research and the capabilities of current models. Before making a decision, it is important to thoroughly comprehend the specific criteria and objectives of each biological Named Entity Recognition task, and then select either SCISpaCy, BioBERT, or a combination of both accordingly. The advancement of NLP models in the field of biomedicine provides professionals with a diverse

array of tools to effectively extract pertinent information from texts related to biology.

LIMITATIONS, FUTURE WORK AND RESEARCH DIRECTIONS

To improve the thoroughness of our assessments, it is crucial to further investigate domain-specific algorithms for Named Entity Recognition in the context of future studies. In order to achieve this objective, we suggest a deliberate enlargement of our study scope to encompass notable algorithms such as Bert-PKD, CollaboNet, TinyBert, BERN2, and other state-of-the-art techniques. Integrating these algorithms into our future endeavours will enhance the strength and comprehensiveness of our evaluation system. The limitations in the field of Biomedical Named entity recognition include data availability, expert annotation requirements, and the vast space of biomedical concepts. Our objective is to analyse a wider range of NER algorithms in a systematic manner, in order to reveal subtle variations in performance and find methods that may have distinct benefits in particular biological scenarios. This strategic growth is in line with our dedication to developing the area of Biomedical Named Entity Recognition and guaranteeing that our research offers practical insights for researchers, practitioners, and professionals in the biomedical sector. Integrating new algorithms will enhance the comprehensiveness of our studies and promote a more nuanced comprehension of the advantages and constraints of different techniques. To summarise, more study on domain-specific algorithms for NER is crucial. There are potential intersections and opportunities for collaboration or cross-pollination between the fields, particularly in areas such as Visual Named Entity Recognition, cross-modal learning, semantic understanding, and multi-modal information fusion. We are committed to expanding the reach and significance of our findings in future studies.

LIST OF ABBREVIATIONS

BioNER	=	Biological Named Entity Recognition
NER	=	Named Entity Recognition

RESEARCH PAPER

Fabrication of rGO-decorated hBNNS hybrid nanocomposite via organic–inorganic interfacial chemistry for enhanced electrocatalytic detection of carcinoembryonic antigen

Abstract
Organic–inorganic hybrid nanocomposites (OIHN), with tailored surface chemistry, offer ultra-sensitive architecture capable of detecting ultra-low concentrations of target analytes with precision. In the present work, a novel nano-biosensor was fabricated, acquainting dynamic synergy of reduced graphene oxide (rGO) decorated hexagonal boron nitride nanosheets (hBNNS) for detection of carcinoembryonic antigen (CEA). Extensive spectroscopic and microscopic analyses confirmed the successful hydrothermal synthesis of cross-linked rGO-hBNNS nanocomposite. Uniform micro-electrodes of rGO-hBNNS onto pre-hydrolyzed ITO were obtained via electrophoretic deposition (EPD) technique at low DC potential (15 V). Optimization of antibody incubation time, pH of supporting electrolyte, and immunoelectrode preparation was thoroughly investigated to enhance nano-biosensing efficacy. rGO-modified hBNNS demonstrated 29% boost in electrochemical performance over bare hBNNS, signifying remarkable electro-catalytic activity of nano-biosensor. The presence of multifunctional groups on the interface facilitated stable crosslinking chemistry, increased immobilization density, and enabled site-specific anchoring of Anti-CEA, resulting in improved binding affinity. The nano-biosensor demonstrated a remarkably low limit of detection of 5.47 pg/mL ($R^2 = 0.99963$), indicating exceptional sensitivity and accuracy in detecting CEA concentrations from 0 to 50 ng/mL. The clinical evaluation confirmed its exceptional shelf life, minimal cross-reactivity, and robust recovery rates in human serum samples, thereby unraveling the potential for early, highly sensitive, and reliable CEA detection.

Keywords Organic–inorganic hybrid nanocomposite · Reduced graphene oxide (rGO) · Hexagonal boron nitride nanosheets (hBNNS) · Non-small cell lung cancer (NSCLC) · Carcinoembryonic antigen (CEA)

Introduction

In today's global healthcare landscape, lung cancer, particularly, non-small cell lung cancer (NSCLC), remains a formidable adversary, ranking as one of the leading causes of premature mortality worldwide [1, 2]. With NSCLC accounting for a substantial portion of lung cancer cases (~ 80–85%), urgent attention is imperative to confront the escalating mortality rates associated with this disease. In response to this upsurge, countries across diverse levels of human development are intensifying efforts to bolster prevention rates [3]. Therefore, priorities are being set on developing advanced nano-biosensors that are feasible and can comprehensibly detect proliferating malignant cells at the nascent stage, thereby mitigating the alarming toll of premature mortality. Research consistently emphasizes the significance of over-expressed oncofetal biomarkers in cancer initiation and progression [4, 5]. Notably, monitoring elevated levels of CEA (molecular weight, 200 kDa), typically above 5 ng/mL in blood serum, emerges as a critical tool for early detection of NSCLC [6]. An elevated concentration of protein biomarkers in serum is considered an effective way of differentiating a diseased person from a normal person, estimating quantitative progression in the tumor, and monitoring the recovery rate after treatment.

Published online: 15 June 2024

Traditional methods for CEA detection, like immunohistochemistry, radioimmunoassay, polymerase chain reaction, and enzyme-linked immunoassay, present numerous challenges that include susceptibility to interference, time-intensive procedures, and potential hazards, demand intricate experimental setup, necessitate meticulous waste management, and often yield inefficient outcomes [7]. Realizing the inevitable exigency and limitations of existing diagnostic tools, electrochemical nano-biosensors are being developed on a large scale that can provide highly sensitive response, simple instrumentation, faster monitoring time, miniaturized device, inexpensive charges, and good portability [7, 8]. Electrochemical immunosensors exhibit a non-enzymatic nature that vanishes intervention of any additional modification in the form of the label, mediator, or substrate in buffer solution. This bypasses the lower binding efficiency caused by steric hindrance at the interface and non-specific binding of antibody-antigen complexes [7].

Thus, this work focuses on directly conjugating fragment crystallizable (Fc) receptors to nano-biosensor interface with strong adsorption affinity to achieve enhanced electro-catalytic efficiency, improved diagnostic value, and high chemical stability together with cost-effective fabrication. Nano-engineering innovations have facilitated the fabrication of bio-analytical devices through defect induction, functionalization, structural and morphological architecture modulation, and hybrid composite formation [9]. Despite their promising potential, structural, morphological, and defect engineering methods often encounter challenges in ambient environments such as instability, degradation, complex fabrication processes, difficulty in maintaining precise control over material properties and compromised chemical as well as biological compatibility of nanomaterials, which can hinder their practical applications. Therefore, Synergistically coupled organic–inorganic hybrid nanocomposites (OIHN), enhanced by functionalization, effectively overcome challenges associated with the aforementioned techniques by harnessing unique characteristics enabled by host–guest chemistry between biphasic nano-confined parent materials [8, 10]. Organic materials are typically lightweight and fragile, with a lack of chemical and thermal stability at elevated temperatures. Conversely, inorganic counterparts, though robust, often lack diverse functionalities, demand intricate synthesis, and display limited catalytic efficiency. OIHN formation ingeniously tackles challenges from both counterparts by meticulously engineering interfacial architecture. This approach not only enhanced mechanical, thermal, and chemical stability but also tailors electrical and optical properties. Moreover, it ensures biocompatibility, facilitates surface functionalization, and unlocks synergistic catalytic activity.

Two-dimensional (2D) nanomaterials emerge as a compelling candidate, offering abundant surface-active sites for biomolecule loading, enhanced catalytic efficiency, extraordinary bond tailoring capabilities, and enabled bandgap tunability [11]. Layered materials serve as scalable sources for achieving 2D morphology in OIHN. Layered nanostructures, abundant in both organic and inorganic material families, possess unique properties absent in their counterparts due to their molecular pairing. Among layered organic nanomaterials, reduced graphene oxide (rGO) stands out for its high aspect ratio, providing extensive surface-active adsorption sites, semiconducting bandgap enhancing electrocatalytic activity, and high defect density facilitating enhanced bio-catalytic activity [12, 13]. Complementing the performance of organic counterparts is hexagonal boron nitride (hBN), also known as inorganic graphite. With lattice parameters comparable to rGO, hBN minimizes strain-induced deformation, offering remarkable mechanical strength and thermal and chemical stability, making it an ideal candidate for hybrid nanocomposite formation [14].

Within the domain of organic nanomaterials, reduced graphene oxide (rGO) exhibits a distinctive electronic structure featuring uniformly distributed electrons across each carbon atom, underscoring the presence of numerous redox sites. These abundant redox centers ensure enhanced electron transfer kinetics, making rGO a valuable candidate for OIHN-based nano-biosensors, while electrons in hexagonal boron nitride (hBN) gravitate towards comparatively high electronegative nitrogen atoms, thereby leaving boron atoms with vacant p-orbitals. The intrinsic electronic configurations offer an astonishing bond tailoring opportunity, catalyzing robust crosslinking chemistry between rGO and hBNNS, thereby facilitating the formation of superior hybrid nanocomposite. Such interfacial chemistry consequentially decorates the surface with multi-functional adsorption sites that aid remarkable crosslinking chemistry with bio-conjugates. Crosslinking technique stands out among different immobilization techniques such as entrapment, physical adsorption, covalent binding, and sandwich incubation that elevate diffusion barrier, add up instability in protein interplay, and reduce denaturation in protein to enhance bio-activity, restrictions in conformational changes required during catalysis, the low adsorption efficiency of protein biomarkers and deteriorate charge transfer kinetics, etc. [15]. However, interfacial crosslinking actively promotes surface functionalization that specifically bridges the linking agent with adjacent protein biomarkers and offers high stability, capability to recycle with optimum catalytic efficiency, highly aligned protein conformation, and economical technique as well [15, 16].

The unique capability to engineer interfacial kinetics within OIHN significantly influences charge transfer kinetics. Weak (van der Waals, hydrogen bond, hydrophobic-hydrophilic) or strong (covalent or iono-covalent) interphase bonds are categorized into class I and class II, respectively [10]. These classifications greatly alter molecular dynamics

and sensing performance. Class II materials, resulting from stronger bonding chemistry between parent materials, offer enhanced stability in resulting nanocomposites, efficiently tune physical properties, enhance surface kinetics through proficient crosslinking of interfaces, and decorate multifunctional groups that enhance the loading capacity of protein biomarkers [10]. The synthesis of organic–inorganic nanocomposites plays a pivotal role, yet it presents significant challenges. Various existing methods often suffer from limitations such as the lack of scalability, complex preparation, and elevated temperatures [17–19]. Thus, in our study, we utilized a one-pot hydrothermal approach to simultaneously reduce GO, exfoliate hBNNS and rGO nanostructures, and reinforce crosslinking chemistry between them. This method operates under high pressure at low temperatures, reduces agglomeration, and prevents restacking of layers [20]. Optimized hydrothermal conditions and reducing agents enable simultaneous reduction of highly reactive GO nanosheets and effective bond tailoring, yielding the rGO-hBNNS hybrid nanocomposite.

In the present work, we utilize the synergy of OIHN interfacial chemistry to hydrothermally synthesize rGO-hBNNS hybrid nanocomposite endowed with exceptional electrocatalytic efficiency for label-free detection of CEA biomarker. The amine- and carboxyl-functional terminated groups on rGO decorated hBNNS nano-matrix offer effective site-specific anchoring by crosslinking Fc receptors of monoclonal Anti-CEA using EDC-NHS chemistry, thus preventing time-consuming, expensive, complex labeling procedures in clinical detection and commercial diagnostic kits. Furthermore, optimizing the immuno-interface environment improves binding affinity between rGO-hBNNS nano-matrix and Anti-CEA, thereby enhancing detection sensitivity and signal amplification. The superior electrocatalytic activity, coupled with selective anchoring of Anti-CEA in abundance onto nano-biointerface, augments precise conjugation between Anti-CEA and CEA, resulting in an exceptionally low detection limit of 5.47 pg/mL. Also, the proposed nano-biosensor based on rGO-hBNNS hybrid nanocomposite renders highly selective, stable, reproducible, and reliable outcomes for spiked serum sample analysis that comply with requirements for clinical diagnostics.

Experimental section

Chemicals and reagents

Various chemicals and reagents, including graphite powder (< 20 µm-particle size), bovine serum albumin (BSA), h-BN powder (98%, 5-µm particle size), 1-(3-(dimethylamino)-propyl)-3-ethyl carbodiimide hydrochloride (EDC), carcinoembryonic antigen (CEA), N-hydroxysuccinimide (NHS), and monoclonal antibodies of CEA, were procured from Sigma-Aldrich. Additionally, some chemicals and reagents were purchased from Thermo-Fisher Scientific and Merck, such as potassium permanganate ($KMnO_4$), sulfuric acid (H_2SO_4), hydrazine hydrate ($N_2H_4H_2O$, > 99%), isopropanol ($(CH_3)_2CHOH$), hydrogen peroxide solution (30% w/v H_2O_2), potassium ferrocyanide ($K_4[Fe(CN)_6]\cdot 3H_2O$), acetonitrile (CH_3CN), hydrochloric acid (HCl), sodium phosphate monobasic dihydrate ($NaH_2PO_4\cdot 2H_2O$), ethanol (C_2H_5OH), potassium ferricyanide ($K_3[Fe(CN)_6]$), and sodium phosphate dibasic dihydrate ($Na_2HPO_4\cdot 2H_2O$). All analytical grade reagents and chemicals were utilized, ensuring accuracy and precision. The human blood serum sample was obtained from All India Institute of Medical Sciences (AIIMS), New Delhi, with approval of the study. We utilized ultrapure Milli-Q water for solution preparation, sample washing. Fresh phosphate buffer saline (PBS) solution of different pH was prepared using solution A ($NaH_2PO_4\cdot 2H_2O$), solution B ($Na_2HPO_4\cdot 2H_2O$), and ultrapure Milli-Q water. All as-prepared solutions were stored at 4 °C until further use.

Instrumentation

Various techniques were used to systematically characterize hBNNS, GO, and rGO-hBNNS powder samples. The samples were analyzed to investigate their systematic phase using an X-ray diffractometer (XRD, Bruker Advance D-8). The morphology of the samples was monitored using scanning electron microscopy (SEM, EVO18 Zeiss) and transmission electron microscopy (TEM, TECNAI 200 kV). The chemical composition of the samples was determined using an energy dispersive X-ray spectrometer (EDX) and Fourier transform infrared spectroscopy (FTIR, Spectrum II-Perkin Elmer). Spectroscopic studies were carried out using a WITec Raman spectrometer ($\lambda = 532$ nm) and a UV–visible spectrometer (Perkin Elmer 950). Electrochemical Autolab Galvanostat/Potentiostat (Metrohm, Netherlands) was used to carry out differential pulse voltammetry (DPV) and cyclic voltammetry (CV) measurements. A three-electrode assembly comprising rGO-hBNNS–modified ITO substrates was employed as a working electrode, a platinum (Pt) rod as a counter electrode, and an Ag/AgCl rod in potassium chloride (KCl, 3 M) solution used as a reference electrode. The entire biosensing studies were carried out in ferro-ferricyanide ($[Fe(CN)_6]^{3-/4-}$, 5 mM) redox couple modified PBS solution (50 mM, 0.9% NaCl) of pH 7.0, which exhibits heterogeneous transfer of one electron.

One-pot hydrothermal synthesis rGO-hBNNS hybrid nanocomposite

As-prepared ultrathin multifunctional nanosheets of hBNNS synthesized via facile hydrothermal technique as described

in the previous literature [21]. hBNNS instead of bulk hBN was utilized for nanocomposite formation as partially ionic B-N bonds in bulk hBN limits dispersibility and exfoliation which thereby obstructs interfacial interactions with other precursors. Figure 1 depicts the preparation of nanocomposite, which started with dispersing 122 mg ultrathin nanosheets of hBNNS powder in 10 mL DI water in a beaker. Alongside, 90 mg of GO synthesized via eco-friendly improved Hummer's method (Electronic Supplementary Information, Fig. S1) was added to another beaker containing 10 mL DI water. Ultrasonication-assisted pre-treatment of both samples was carried alongside for 1 h at room temperature to boost up intercalation of hydroxyl ions that abet expansion of interlayer spacing while retaining their pristine crystalline structure. GO was relatively easily suspended in the solvent owing to its hydrophilic nature endowed by covalently functional groups that provide exceptional colloidal stability to them. Well-dispersed GO suspension was then added to the hBNNS solution, and the resulting mixture was again kept for ultrasonication for 1 h to assist reinforcement of intercalated precursors. Then, 1 mL hydrazine hydrate and 15 mL DI water were added to the resultant GO-hBNNS dispersion followed by continuous stirring of 270 rpm for 6 h at room temperature. The homogeneous and stable dispersion was poured into 50 mL Teflon and placed in a stainless steel autoclave vessel. Next, the autoclave vessel was placed inside a high-temperature oven for 12 h at 180 °C to obtain rGO-hBNNS nanocomposite. Interestingly, electron-deficient boron sites (Lewis acid) capped with Lewis base (amine) established stable bond affinity towards electrophilic GO nanosheets that led to the successful synthesis of rGO-hBNNS nanocomposite. The resultant rGO-hBNNS hybrid nanocomposite was washed to remove ionic impurities present with DI water via centrifugation of 7000 rpm until pH 7.0 was attained. The nanocomposite was dried in a vacuum oven at 85 °C for 24 h.

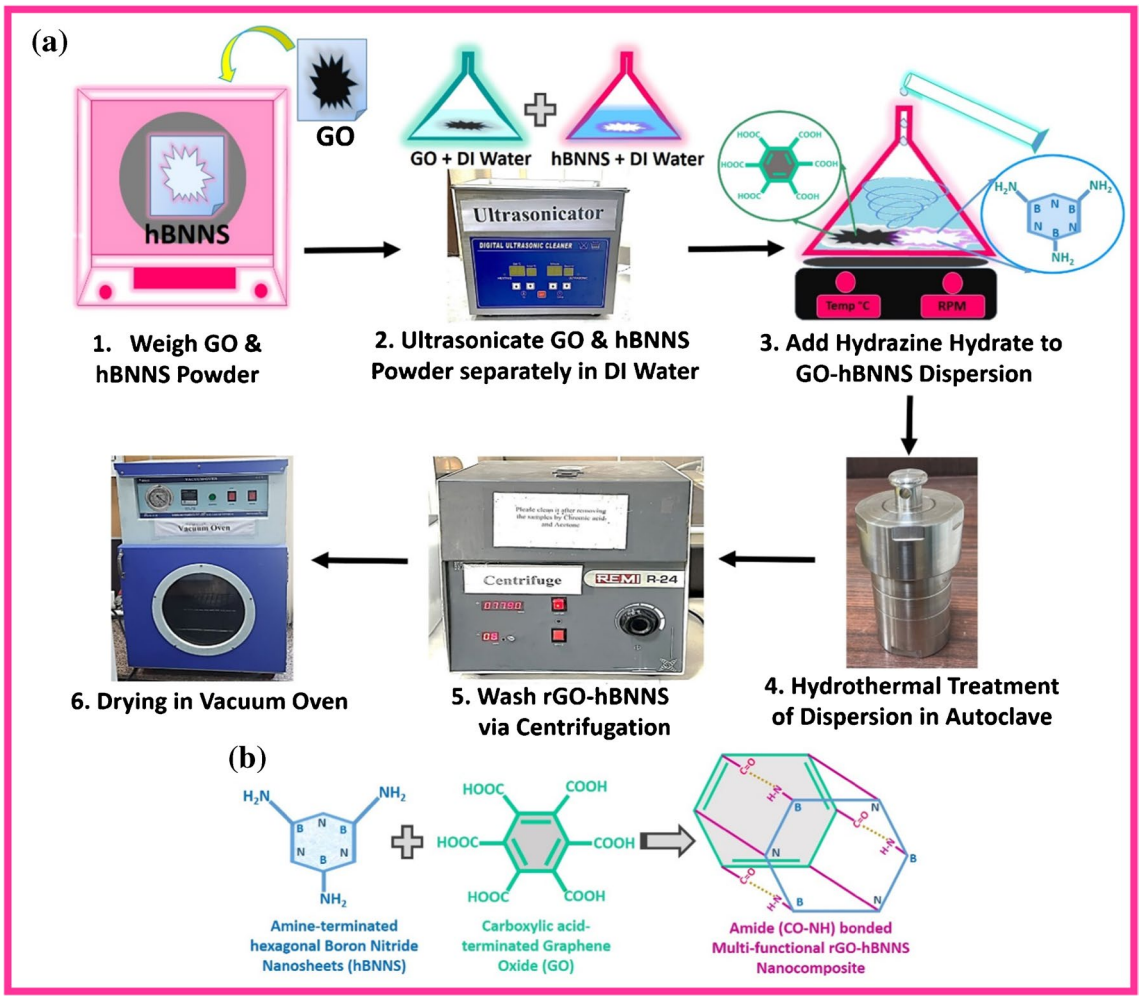

Fig. 1 **a** Steps involved in one-pot hydrothermal synthesis of rGO-hBNNS hybrid nanocomposite and **b** interfacial chemistry between GO and hBNNS for nanocomposite formation

Fabrication of rGO-hBNNS film onto ITO and nano-biosensing platform

The electrophoretic deposition (EPD) technique was employed for fabricating rGO-hBNNS/ITO electrodes utilizing the synergy of dispersion and voltage drifting (Fig. 2a). We achieved the formation of a uniform colloidal suspension containing 0.25 mg/mL of rGO-hBNNS nanocomposite in acetonitrile (CH_3CN) by adding 300 µL of magnesium nitrate ($MgNO_3$, 1 mg/mL). Suspension stability was enhanced through continuous ultrasonication for 1 h. The uniform suspension is poured into a beaker comprising a two-electrode assembly of pre-hydrolyzed ITO (0.8 cm × 2.5 cm) as the working electrode at the positive terminal and platinum rod as the counter electrode at the negative terminal. ITO electrodes were hydrolyzed prior to EPD with hydrogen peroxide, ammonia, and DI water in 1:1:5 ratios. This pre-treatment of ITO substrates helps in activating the radical groups on the surface. In the following step, a homogeneous film of rGO-hBNNS (dimension, 0.8 cm × 0.8 cm) was deposited onto the ITO electrode by applying an external DC voltage of 15 V for 1 min.
