For fabricating an optimized nano-biosensing platform, a stock solution of monoclonal Anti-CEA was prepared in PBS solution (pH 7.4) by activating –COOH, $-NH_2$ groups of antibody utilizing EDC-NHS chemistry (Fig. 2b). Briefly, Anti-CEA (50 µg/mL) was conjugated with EDC (0.2 M) and NHS (0.05 M) in a 2:1:1 ratio at room temperature for 30 min. EDC being a zero-length cross-linker reacts with carboxyl terminated Fc region (L-glutamic acid) of Anti-CEA [22] to form a reactive as well as unstable O-acylisourea ester that becomes stabilized with amine-reactive NHS ester. The EDC-NHS intermediate crosslinks the carboxyl-terminated Fc region of Anti-CEA with an amine-terminated hBNNS interface to form an amide bond (Fig. 3a) [23], while lysine residue on

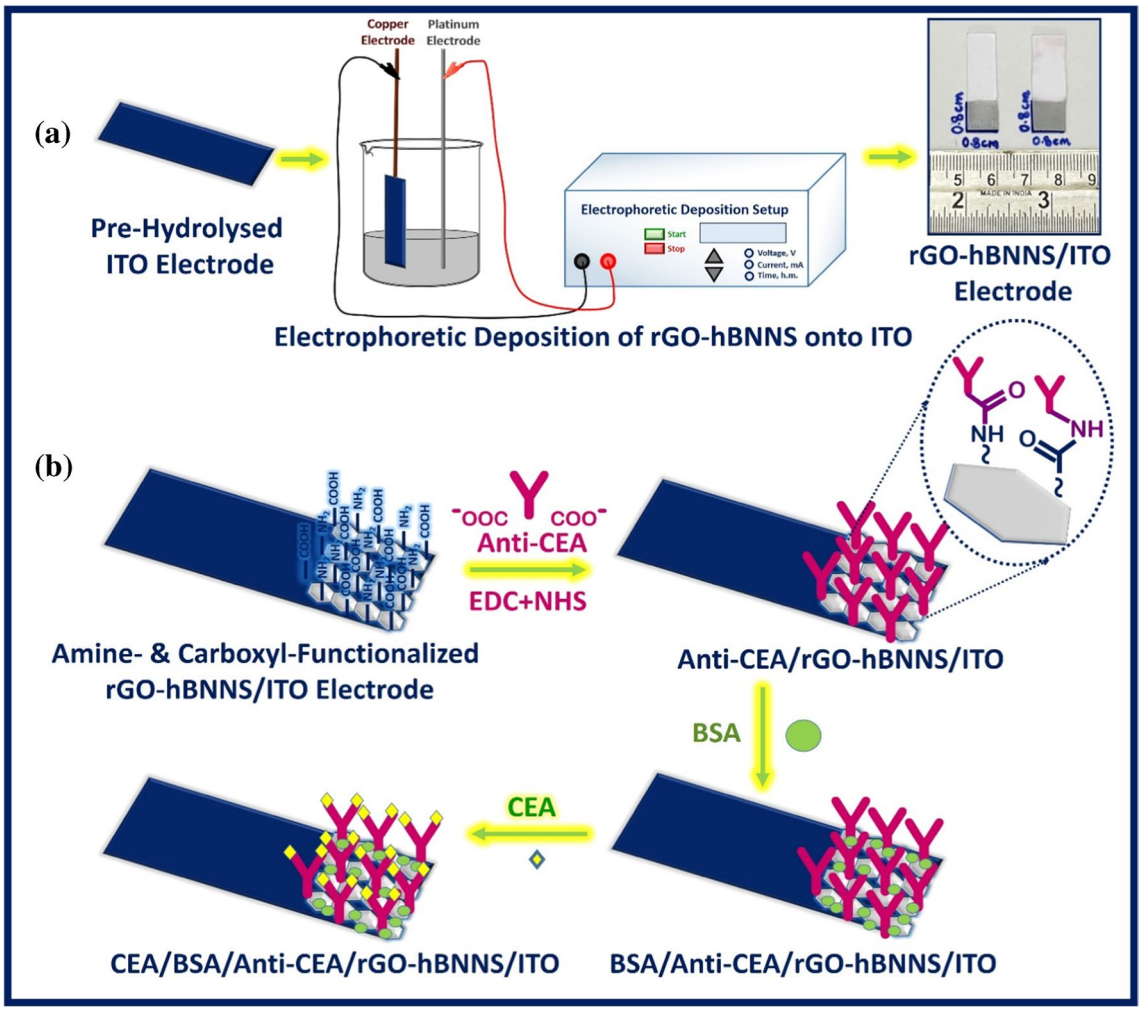

Fig. 2 Schematic diagram on **a** fabrication of rGO-hBNNS/ITO electrode by EPD; **b** modification of rGO-hBNNS/ITO electrode by Anti-CEA, BSA, and CEA to fabricate nano-biosensor

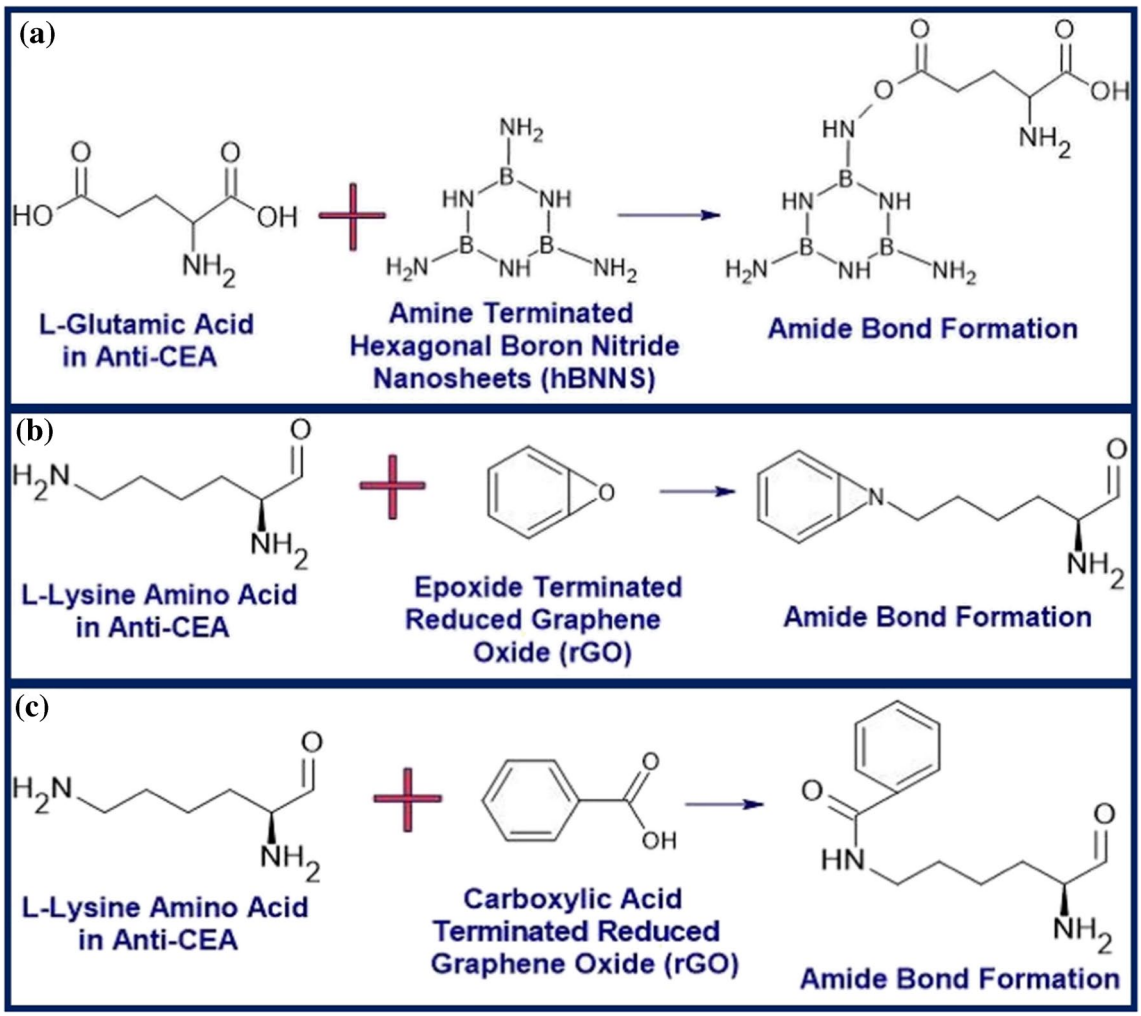

Fig. 3 Amide bond formation between **a** L-glutamic acid and amine-terminated hBNNS, **b** L-lysine and epoxide terminated rGO, **c** L-lysine and carboxylic acid terminated rGO, respectively

Anti-CEA offers amino-groups in side-chains that conjugate to C–O–C and–COOH terminated functional groups on rGO interface via EDC-NHS coupling (Fig. 3b–c) [24]. Then, 20 µL of Anti-CEA was immobilized onto uniform rGO-hBNNS film for 24 h in a humid chamber for optimized immobilization. Figure 2b depicts steps involved in the fabrication of nano-biosensor that include crosslinking of Anti-CEA with rGO-hBNNS/ITO nano-biointerface and CEA conjugation with Anti-CEA. On Anti-CEA/rGO-hBNNS/ITO immunoelectrode, 10 µL BSA (1% w/w in ultrapure Milli-Q water) was added to block the non-specifically adsorbed Anti-CEA sites. In the final step, 10 µL CEA was added and incubated for 30 min onto BSA/Anti-CEA/rGO-hBNNS/ITO immunoelectrode of required concentration. The as-prepared immunoelectrodes were stored at 4 ℃ until further use.

Results and discussion

Material characterization

X-ray diffraction

A systematic XRD investigation was carried out in the range of 5°–80° to study phase formation, phase purity, and crystallinity of as-synthesized (I) hBNNS, (II) GO, and (III) rGO-hBNNS nanocomposite as shown in Fig. 4a. Optimized hydrothermal conditions and efficient intercalation-exfoliation chemistry of IPA and hydrazine hydrate yielded a pure hexagonal phase of BN corroborated by two diffraction peaks at 26.84° and 41.72° as shown in Fig. 4a(I) that index to (002) and (100) crystallographic planes, respectively [JCPDS Card No. 034–0421] [21].

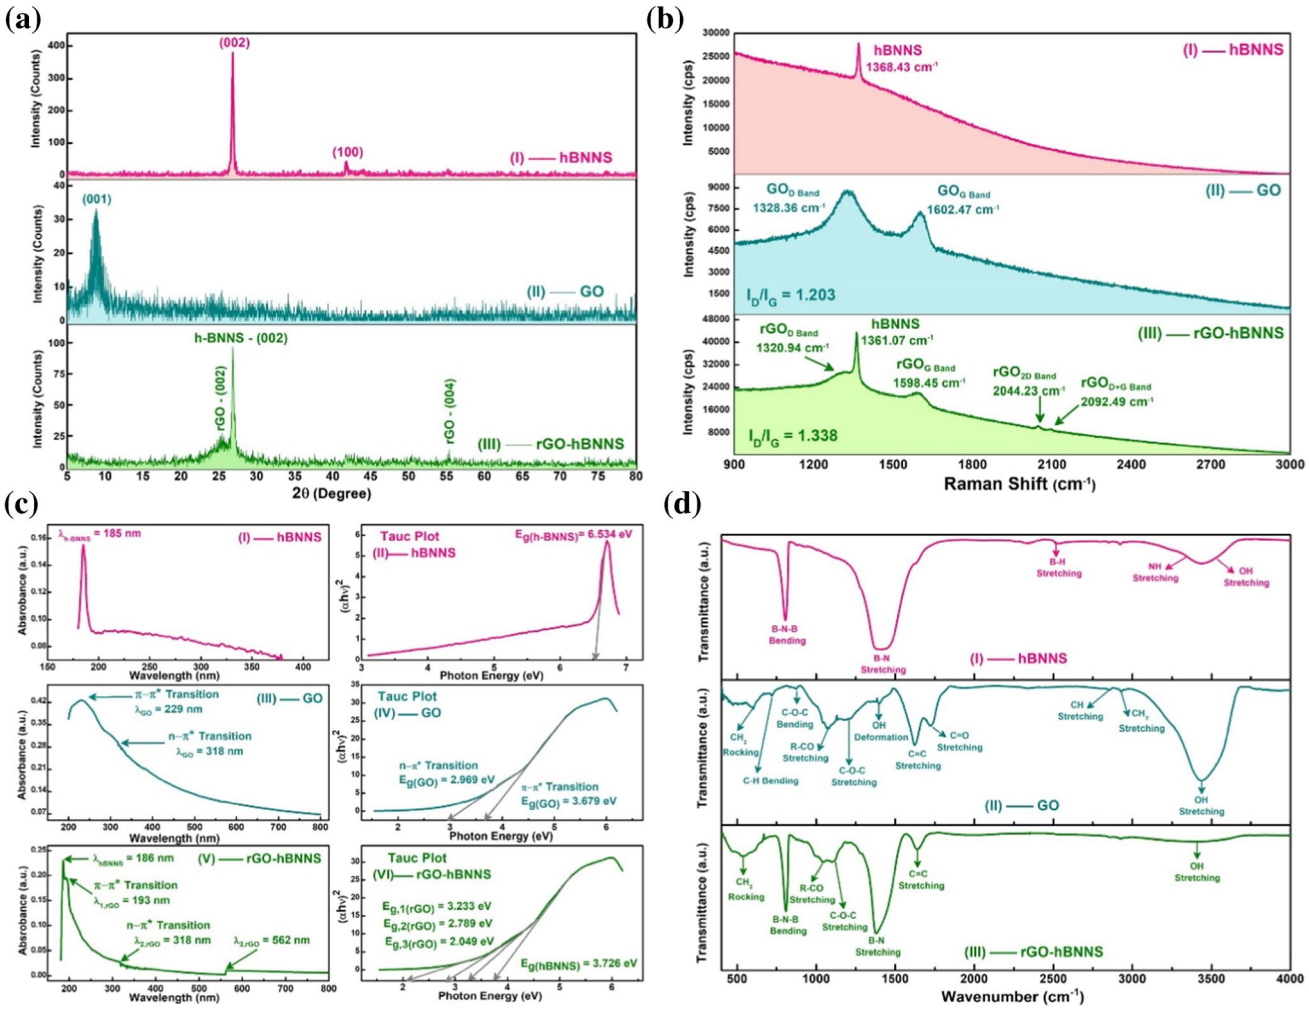

Fig. 4 **a** XRD, **b** Raman, **c** UV–visible, and **d** FT-IR spectroscopy of (I) hBNNS, (II) GO, and (III) rGO-hBNNS samples, respectively

A distinct, intense, broad peak associated with GO significantly down-shifted to a lower diffraction angle at $2\theta = 8.8°$ that corresponds to (001) characteristic plane (Table 1) indicates exceptional oxidation of bulk graphite powder under the influence of harsh precursors comprising $KMnO_4$ and H_2SO_4 as shown in Fig. 4a(II) [25]. A significant down-shift in diffraction peak and large d-spacing ($d_{(001)}$ = 1.004 nm) evaluated using Bragg's relation (Eq. 1) represents characteristic changes GO undergone due to complete intercalation of hydroxyl, carboxyl, carbonyl, and epoxy groups. The intercalation facilitated facile exfoliation of π-bonded bulk graphite consequently boosting oxidation of GO sheets, verified by FT-IR also. The XRD pattern of rGO-hBNNS nanocomposite in Fig. 4a(III) depicted an intense diffraction peak at 26.84° that accord with (002) crystallographic plane of hBNNS, whereas two

Table 1 Intense hkl plane, peak position, FWHM, crystallite size, and d-spacing associated with samples hBNNS, GO, and rGO-hBNNS nanocomposite, respectively

S.No.	Sample		Intense (hkl) planes	Peak position, 2θ (°)	FWHM (°)	Crystallite size (D, nm)	d-spacing (nm)
1	Hexagonal boron nitride nanosheets, hBNNS		(002)	26.84	0.2392	34.171	0.332
2	Graphene oxide, GO		(100)	8.8	1.205	6.616	1.004
3	rGO-hBNNS Nanocomposite	hBNNS	(002)	26.84	0.3187	25.640	0.332
		rGO	(002)	25.4	1.089	7.483	0.350

relatively diminished peaks appeared at 25.4° and 55.3° befits (002) and (004) diffraction planes of rGO indicting preferential growth of relatively poor crystallinity rGO over highly crystalline hBNNS nanostructures by hydrothermal synthesis.

$$Bragg's relation : 2d \times Sin\theta = n\lambda \quad (1)$$

where d stands for interplanar spacing (in nm), θ is Bragg's diffraction angle (in radians), n is the integer for the order of planes, and λ is the wavelength of incoming electron.

Interestingly, the appearance of two diffraction planes in rGO and a profound decrease in d-spacing was observed on substantial hydrothermal reduction of GO ($d_{(100)} = 1.004$ nm) to rGO ($d_{(002)} = 0.350$ nm) on nanocomposite formation that explains disordered stacking of layered nanostructures on restoration of graphitic structure in rGO. In addition, hBNNS nanostructures in nanocomposite attained highly crystalline morphology in crystallographic layers that preferentially oriented in only (002) hkl plane while eliminating (100) crystallographic planes. Moreover, intercalation, growth, and nucleation of rGO nanosheets under in situ hydrothermal constraints improved the quantum confinement effect in rGO-hBNNS nanocomposite by remarkably reducing crystallite size estimated using Debye–Scherrer's formula (Eq. 2) from 34.17 nm in pure hBNNS to 25.64 nm in rGO-hBNNS nanocomposite while retaining the d-spacing of hBNNS (Table 1). These findings indicate the formation of nano-sized flakes comprising fewer layers of hBNNS in the nanocomposite. On the contrary, the crystallite size of rGO increased to 7.483 nm from 6.616 nm in GO which ascribes to increased stacking in crystallographic planes of rGO to accommodate the difference in d-spacing between hBNNS and rGO for attaining stable nano-confined geometry (Table 1).

$$Debye - Scherrer's formula : D = \frac{0.9\lambda}{\beta \times Cos\theta} \quad (2)$$

where D stands for average crystallite size (in nm), λ is the wavelength of incoming X-rays (in nm), β represents full-width half maxima (in radians), and θ is the diffraction angle (in radians). Furthermore, the d-spacing of rGO ($d_{(002)} = 0.350$ nm) was found consistent with the d-spacing of graphite ($d_{(002)} = 0.350$ nm), indicating restoration of graphitic domains in basal planes and adsorption of hydrophilic oxygen moieties on the surface instead of interplanar domains [25].

Raman spectroscopy

Raman spectroscopy is a powerful non-destructive tool utilized for investigating the electronic structure, nanocomposite formation, and ordering of layers by analyzing the appearance of vibrational modes, changes in peak intensity, peak shift, FWHM, and defect density in as-synthesized samples (I) hBNNS, (II) GO, and (III) rGO-hBNNS (Fig. 4b). The appearance of a prominent peak at 1368.43 cm^{-1} in Fig. 4b(I) demonstrates the characteristic in-plane E_{2g} phonon mode of hBNNS. Figure 4b(II) depicts typical Raman peaks in GO at around 1328.36 cm^{-1} and 1602.47 cm^{-1}, which represents the first-order breathing mode of k-point phonons of A_{1g} symmetry due to sp^3 hybridized defect-induced states (D-band) and sp^2 hybridized E_{2g} phonon mode (G-band), respectively [26]. However, an overtone of D-band denoted by 2D band (or G'-band) in GO was absent indicating the formation of highly defect-induced nanosheets due to the lack of ordered stacking along the c-axis [27]. Formation of rGO-hBNNS nanocomposite was marked by three peculiarly red-shift peaks as shown in Fig. 4b(III) that corresponds to the D-band of rGO, in-plane E_{2g} vibrational mode of hBNNS and G-band of rGO at 1320.94 cm^{-1}, 1361.07 cm^{-1}, and 1598.41 cm^{-1}, respectively. Interestingly, two diminished peaks at 2044.23 cm^{-1} and 2092.49 cm^{-1} originated in rGO-hBNNS that corresponds to immensely red-shifted 2D and D + G bands, respectively, implying restoration of ordered stacking in rGO nanosheets directed in prominent (002) orientation of hBNNS along c-axis [27, 28]. A significant red shift in the 2D band of rGO-hBNNS is attributed to the transfer of electron-cloud density from rGO to functionalized hBNNS leading to stable bond alignment in defect-induced domains [29].

The prominent red-shift phenomenon in rGO of about 7.42 cm^{-1} (D-band) and 4.06 cm^{-1} (G-band), respectively, explains the complete reduction of GO to rGO by restoration of graphitic sp^2 hybridized nanostructures, increase in electron density, and successful interface coupling between rGO and hBNNS under influence of exceptional tensile strain on nanocomposite formation [30]. However, a red-shift of 7.36 cm^{-1} in hBNNS on nanocomposite formation indicates synthesis of improved crystalline nanostructures of hBNNS, a remarkable reduction in layer thickness, and expansion in the lateral size of nanosheet morphology owing to in-built tensile strain developed amid hydrothermal treatment. The noteworthy increase in I_D/I_G ratio on reduction of GO (1.203) to rGO (1.338) amid nanocomposite synthesis indicates an increase in layered stacking in rGO due to high-temperature reduction that induced unrepaired defects in rGO [25] and verifies the increased crystallite size in XRD. Additionally, elevated I_D/I_G ratio supports red-shift phenomena observed in Raman peaks on nanocomposite synthesis attributed to the consequence of the effective reduction of oxygen functional moieties in GO that materialize disorder, vacancies, distortion, and defects in sp^2 carbon domains for creating a stable interface between rGO and hBNNS molecules. Interestingly, the I_{2D}/I_G ratio appreciably increased to 0.472 indicating restoration of crystallinity and reduction

of layer stacking in as-synthesized rGO-hBNNS nanocomposite [31]. Furthermore, the absence of any extra peaks in the Raman spectra of nanocomposite indicates exceptional phase purity in as-synthesized samples.

UV–visible spectroscopy

Investigating spectral transmittance profiles via UV–visible spectroscopy before and after nanocomposite formation allowed us to gain more understanding of interaction and transformation that resulted in bandgap tuning and absorption peaks shifting as depicted in Fig. 4c. A red-shift was observed in the sharp absorption edge associated with hBNNS from 185 nm (6.534 eV) in pure hBNNS to 186 nm (3.726 eV) on formation of rGO-hBNNS nanocomposite (Fig. 4c(I, II, V, VI)). From UV–visible spectra of highly disordered GO nanosheets (Fig. 4c(III, IV)), two characteristic absorption peaks positioned at 229 nm (3.679 eV) and 316 nm (2.969 eV) that correspond to π-π^* transitions associated with C = C bonding and n-π^* transitions associated with C = O bonding are observed, respectively. On hydrothermal reduction of GO, the absorption peaks related to π-π^* transition blue-shifted to 193 nm (3.233 eV), while n-π^* transition retained absorbance peak to 318 nm (2.789 eV), and a new peak emerged at 562 nm (2.049 eV), respectively (Fig. 4c(V, VI)) [32]. The bandgap of as-synthesized samples was estimated by extrapolating the linear region in Tauc's plot demonstrated between $(\alpha h\upsilon)^2$ versus $(h\upsilon)$ [14]. An exceptional bandgap tuning from 5.34 eV in pure hBNNS to 3.726 eV and from 3.679 eV in GO to 3.233 eV after rGO-hBNNS nanocomposite formation was observed owing to the removal of hydrophilic oxygen moieties and layer-layer interaction between rGO and hBN nanosheets that induced structural changes in the nanocomposite that lead to dispersion in electronic band as shown in Fig. 4c(II, IV, VI), respectively.

Fourier transform infrared spectroscopy

Analysis of chemical bond formation and functionalization in as-synthesized samples was investigated by FT-IR as shown in Fig. 4d. FT-IR transmittance peaks associated with hBNNS (Fig. 4d(I)) described in Table S1 (Electronic Supplementary Information) demonstrate fingerprint peaks positioned at 804 cm^{-1} and 1413 cm^{-1} in addition to functionalized peaks at 2500, 3200–3500, and > 3500 that corresponds to B-N-B bending, B-N stretching, B-H stretching, N–H stretching, and O–H stretching, respectively [21]. The characteristic skeletal vibration at 1621 cm^{-1} is attributed to the retention of sp^2 hybridized graphitic domains that form the backbone in GO (Fig. 4d(II)) [33]. The bonding configuration of GO was found to exhibit hydrophilic oxygen peaks of epoxy (874 cm^{-1}, 1216 cm^{-1}), alkoxy (1074 cm^{-1}), carboxyl (1729 cm^{-1}), and hydroxyl (1398 cm^{-1}, 3437 cm^{-1}) groups, respectively (Table S1) [33]. Additional functionalized peaks that belong to CH_2 rocking (603 cm^{-1}), C-H out of plane bending (819 cm^{-1}), alkyl (C-H) symmetric (2832 cm^{-1}), and asymmetric (2855 cm^{-1}) stretch emerged in GO [34]. Figure 4d(III) depicts the material-specific peak of (1) hBNNS that include B-N-B bending (808 cm^{-1}) and B-N stretching (1379 cm^{-1}) and (2) rGO that comprises skeletal vibration of graphitic domain C = C (1637 cm^{-1}) that attribute to successful formation rGO-hBNNS nanocomposite. Yet, some alkyl (546 cm^{-1}) and oxygen-containing moieties (1036 cm^{-1}, 1079 cm^{-1}, 3392 cm^{-1}) still appeared after exceptional hydrothermal reduction of GO, indicating a partial reduction of GO nanosheets (Fig. 4d(III)).

Morphological and elemental analysis

The micro- and nano-structure morphology together with the elemental composition of as-synthesized (I) hBNNS, (II) GO, and (III) rGO-hBNNS was investigated using SEM, TEM, and EDAX techniques as shown in Fig. 5a, b, and c, respectively. The SEM micrograph depicted in Fig. 5a(I) demonstrates well-nucleated enlarged flaky nanosheets of hBN, while the surface morphology of GO displays corrugated edges of heaped-up nanosheets, confirming the "extensive peeling" of bulk graphite powder (Fig. 5a(II)). These curls and folds in edges indicate the formation of highly flexible GO nanosheets. A blend of several dark and bright regions in rGO-hBNNS nanocomposite in Fig. 5a(III) depicts the conglomeration of wavy wrinkled rGO nanosheets with relatively sleek disc-shaped hBNNS, respectively. This aggregation in rGO and hBN nanosheets materializes to minimize their surface energy cropped up by the presence of dangling bonds at the surface. Figure 5b(I) displays a more comprehensive view of hBNNS exhibiting transparent circular nanosheets attributing to the formation of ultrathin nanosheets. The TEM image in Fig. 5b(II) displays wrinkled, transparent 2D nanosheets of GO indicating oxygen-intercalated corrugated interlayers. Figure 5b(III) displays intertwined regions of rGO nanosheets with hBNNS, thereby confirming the successful reinforcement to facilitate the formation of rGO-hBNNS hybrid nanocomposite.

The corresponding elemental data (Table S2, Electronic Supplementary Information) obtained from EDX as shown in Fig. 5c(I–III) provides clarity on the formation of pure hBNNS, GO, and rGO-hBNNS. The increment of the C/O atomic ratio from 1.997 in GO to 7.966 in rGO on nanocomposite synthesis indicates a remarkable reduction of oxygen moieties. A significant C/N ratio (0.371) and relatively enhanced atomic % and weight % of nitrogen in rGO-hBNNS ascribe towards hydrazine hydrate-assisted reduction of GO that lead to enhanced nitrogen-mediated

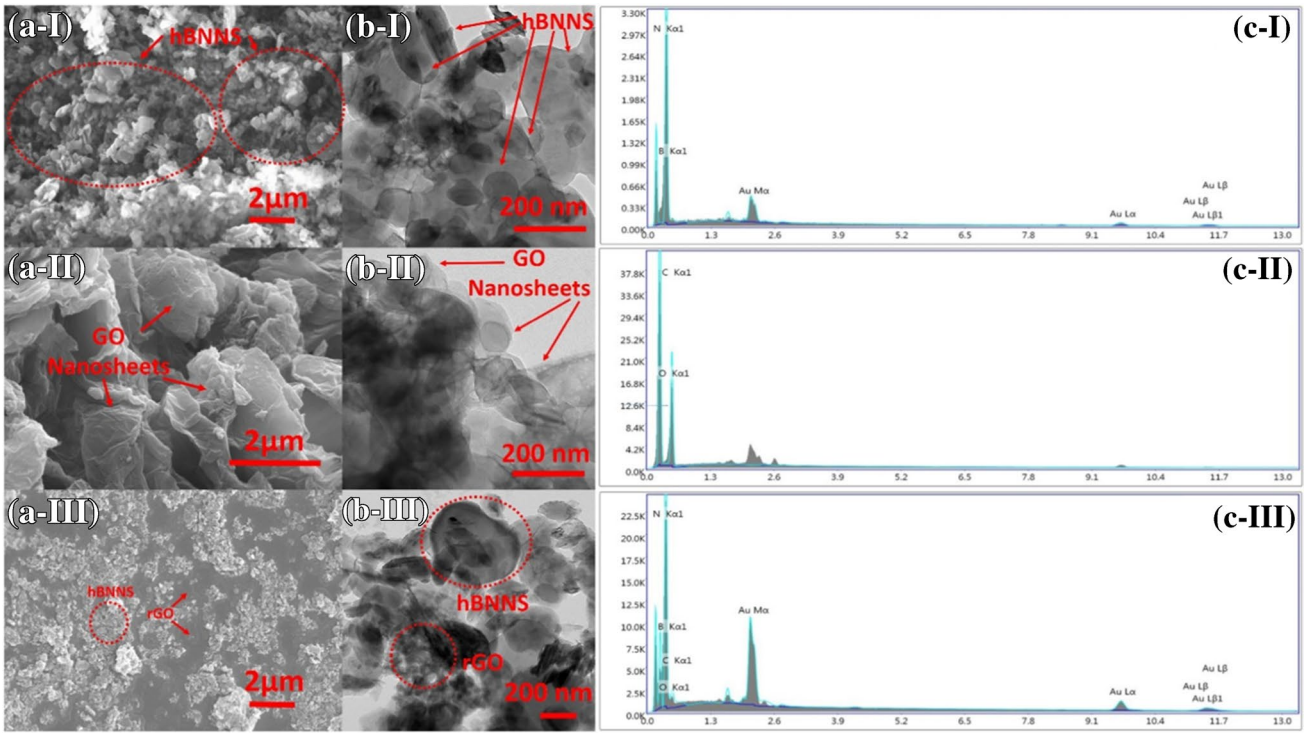

Fig. 5 **a** SEM (2 µm), **a** TEM (200 nm), and **c** EDAX of (I) hBNNS, (II) GO, and (III) rGO-hBNNS nanocomposite, respectively

crosslinking of bond between rGO and hBNNS that significantly promoted nanocomposite formation.

Electrochemical characterization

Electrode study on immunosensor fabrication

To investigate the optimized time required for antibody binding, FT-IR spectra of Anti-CEA were monitored after immobilization time of 12 h (blue) and 24 h (purple) onto rGO-hBNNS/ITO electrodes, respectively (Fig. 6a). FT-IR spectra before and after Anti-CEA immobilization exhibited fingerprint peaks assigned to B-N-B bend, B-N stretch, C = C stretch, alkyl rock, alkoxy stretch, and epoxy stretch group formerly possessed by rGO-hBNNS nanocomposite, while protein-specific peaks in regions II, III, and IV appeared on Anti-CEA immobilization that corresponds to protein phosphorylation (869 cm^{-1}), amide III (NH bend, 1264 cm^{-1}), amide II (CN stretch, 1567 cm^{-1}), and amide I (C = O stretch, 1647 cm^{-1}), respectively [21]. After an incubation time of 24 h, prominent and unique peaks emerged that assigned to EDC-NHS activation (2081 cm^{-1}), aliphatic stretching (2729 cm^{-1}, 2877 cm^{-1}), amide B stretching (2978 cm^{-1}), amide A stretching (3300 cm^{-1}), and OH stretching (> 3500 cm^{-1}) [21, 35], indicating complete immobilization of Anti-CEA. Interestingly, Anti-CEA immobilized for 12 h displayed protein-specific peaks, but the above-mentioned unique peaks were absent, indicating partial immobilization of antibodies after 12 h.

Subsequently, FT-IR investigated immunosensor fabrication on successive protein immobilization onto rGO-hBNNS nanocomposite (Fig. 6b). Immobilization of Anti-CEA modified with EDC-NHS was evident by the appearance of amide bands of protein structure in addition to the characteristic peaks of h-BNNS in Anti-CEA/h-BNNS as discussed above [36]. Following antibody immobilization, transmittance intensity of FT-IR spectra reduced significantly in regions II, III, IV, and V owing to BSA (10 µL) immobilization onto the Anti-CEA/rGO-hBNNS matrix, implying effective passivation of non-specifically adsorbed antibodies [21]. CEA was immobilized onto BSA/Anti-CEA/rGO-hBNNS immunoelectrode that led to a transmittance intensity increase, and shifted region III, IV, V, and VI on addition of CEA onto BSA-modified platform depict successful crosslinking of antibody-antigen complexes [37].

Electrochemical characterizations were performed including CV (Fig. 6c) and DPV (Fig. 6d) performed after each step of immunosensor fabrication that supports FT-IR outcome. Prior to electrochemical investigations, we actively subjected the as-fabricated Anti-CEA/rGO-hBNNS/ITO electrode to a pH study (Electronic Supplementary Information, Fig. S2). This proactive approach ensured meticulous optimization of the sensing environment, resulting in robust and stable measurements. The scan rate study (Electronic

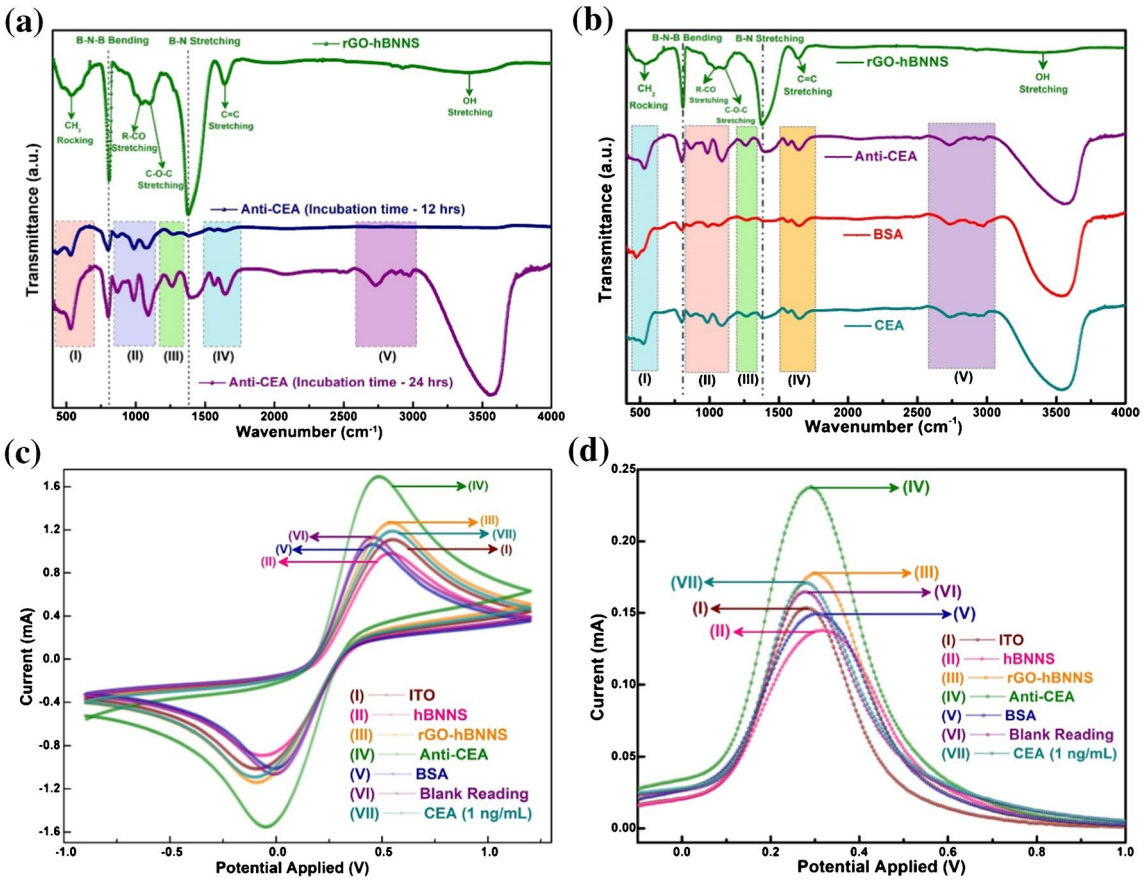

Fig. 6 **a** Optimization of Anti-CEA immobilization time by FT-IR spectra and fabrication of rGO-hBNNS-based immunoelectrode monitored by **b** FT-IR, **c** CV, and **d** DPV, respectively

Supplementary Information, Fig. S3) conducted on the BSA/Anti-CEA/rGO-hBNNS/ITO electrode compellingly demonstrated diffusion-controlled electron transfer dynamics at the interface immunoelectrode. This comprehensive analysis provided insightful evidence of the electrode's superior performance in facilitating efficient electron transfer processes, underscoring its suitability for sensitive and accurate detection applications. Further, we investigated CV study on successive protein immobilization, and the data obtained was utilized to determine diffusion coefficients (Table 2) after the sequential protein modification step by the Randles–Sevcik equation (Eq. 3) to study the interfacial kinetics in preparation of immunosensor [38].

$$I_p = \left(2.69 \times 10^5\right) n^{3/2} A C D^{1/2} \sqrt{\nu} \tag{3}$$

where I_p is the peak (anodic or cathodic) current, n is the number of electrons transferred during the redox reaction ($n = 1$), A denotes the electroactive surface area of the electrode (0.64 cm^2), C stands for the concentration of the

Table 2 Depiction of anodic peak current obtained from CV, evaluation of diffusion coefficient, and DPV current on fabrication of immunoelectrode

Stepwise electrode modification	Anodic peak current (I_{pa}, mA)	Diffusion coefficient (D, $cm^2\ s^{-1}$)	DPV current (mA)
ITO	$1.11 \pm (1.0 \times 10^{-2})$	$3.32 \times 10^{-7} \pm (6.1 \times 10^{-9})$	$0.154 \pm (1.1 \times 10^{-3})$
hBNNS	$0.964 \pm (1.6 \times 10^{-2})$	$2.51 \times 10^{-7} \pm (8.6 \times 10^{-9})$	$0.138 \pm (1.1 \times 10^{-4})$
rGO-hBNNS	$1.25 \pm (1.3 \times 10^{-2})$	$4.23 \times 10^{-7} \pm (8.6 \times 10^{-9})$	$0.177 \pm (3.7 \times 10^{-4})$
Anti-CEA	$1.67 \pm (1.9 \times 10^{-2})$	$7.55 \times 10^{-7} \pm (1.7 \times 10^{-8})$	$0.238 \pm (4.6 \times 10^{-4})$
BSA	$1.07 \pm (0.15 \times 10^{-2})$	$3.07 \times 10^{-7} \pm (8.9 \times 10^{-10})$	$0.149 \pm (1.8 \times 10^{-4})$
Blank reading	$1.13 \pm (0.15 \times 10^{-2})$	$3.44 \times 10^{-7} \pm (9.4 \times 10^{-10})$	$0.165 \pm (9.2 \times 10^{-5})$
CEA	$1.19 \pm (0.08 \times 10^{-2})$	$3.81 \times 10^{-7} \pm (5.2 \times 10^{-10})$	$0.171 \pm (5.5 \times 10^{-4})$

redox species (5×10^{-3} mol cm^{-3}), D is the diffusion coefficient, and ν is the scan rate (50 mV/s). Upon electrophoretic deposition (EPD) of rGO-hBNNS onto ITO, we observed anodic peak currents, DPV currents, and diffusion coefficients of $1.25\pm(1.3\times10^{-2})$ mA, $0.177\pm(3.7\times10^{-4})$ mA, and $4.23\times10^{-7}\pm(8.6\times10^{-9})$ cm^2 s^{-1}, respectively. This deposition resulted in a significant enhancement of approximately ~ 29%, ~ 29%, and ~ 68%, respectively, compared to the deposition of h-BNNS onto ITO, which showed anodic peak currents, DPV currents, and diffusion coefficients of $0.964\pm(1.6\times10^{-2})$ mA, $0.138\pm(1.1\times10^{-4})$ mA, and $2.51\times10^{-7}\pm(8.6\times10^{-9})$ cm^2 s^{-1}, respectively (Table 2).

The observed enhancements indicate the superior electrochemical performance of the electrophoretically deposited rGO-hBNNS film on ITO compared to h-BNNS deposition. This outcome indicates the key role of electron-rich rGO nanosheets within the rGO-hBNNS nanocomposite, compared to bare hBNNS, in enhancing electrocatalytic activity by promoting exceptional electron transfer kinetics. The incorporation of rGO-hBNNS leads to increased electrochemical activity and improved mass transport properties, thereby establishing it as a highly promising material for electrochemical sensing applications. Following the immobilization of Anti-CEA, we observed a substantial increase in the anodic peak current and DPV current, approximately $1.67\pm(1.9\times10^{-2})$ mA and $0.238\pm(4.6\times10^{-4})$ mA, respectively, indicating enhancements of approximately ~ 33% and ~ 34% compared to rGO-hBNNS/ITO electrode. Additionally, there was a significant improvement in the diffusion coefficient to $7.55\times10^{-7}\pm(1.7\times10^{-8})$ cm^2 s^{-1}, representing a nearly ~ 78% enhancement compared to rGO-hBNNS/ITO electrode. The substantial electron kinetics on Anti-CEA binding attribute to increased loading capacity offered by multifunctional (-COOH, $-NH_2$) nano-biointerface sites on rGO-hBNNS mediated with EDC-NHS coupling chemistry.

Upon the addition of globular protein (BSA) onto the Anti-CEA/rGO-hBNNS/ITO immunoelectrode, we observed a significant reduction in the anodic peak current, DPV current, and diffusion coefficient, measuring approximately $1.07\pm(0.15\times10^{-2})$ mA, $0.149\pm(1.8\times10^{-4})$ mA, and $3.07\times10^{-7}\pm(8.9\times10^{-10})$ cm^2 s^{-1}, respectively. This reduction serves as clear evidence for the successful passivation of disoriented antibodies, indicating improved electrode stability and specificity in the detection of CEA. A significant increase in anodic peak current, DPV current, and diffusion coefficient was observed for the blank reading (0 ng/mL) compared to the BSA/Anti-CEA/rGO-hBNNS/ITO immunoelectrode, measuring $1.13\pm(0.15\times10^{-2})$ mA, $0.165\pm(9.2\times10^{-5})$ mA, and $3.44\times10^{-7}\pm(9.4\times10^{-10})$ cm^2 s^{-1}, respectively. The rise in current measurements suggests that ions in the phosphate buffer solution (pH-7.4) aid electron transfer processes, leading to increased current responses in electrochemical measurements. This highlights the vital role of the buffer solution in stabilizing the electrochemical environment and improving measurement sensitivity. Following the subsequent immobilization of CEA, a further increase in the anodic peak current, DPV current, and diffusion coefficient was observed, measuring $1.19\pm(0.08\times10^{-2})$ mA and $0.171\pm(5.5\times10^{-4})$ mA and $3.81\times10^{-7}\pm(5.2\times10^{-10})$ cm^2 s^{-1}, respectively. This increase confirms the successful formation of the antibody-antigen complex, providing clear and unequivocal evidence of specific binding between the immobilized antibodies and the target antigen, thereby affirming the effectiveness of the BSA/Anti-CEA/rGO-hBNNS/ITO detection platform [21].

Response study

Figure 7a depicts the calibration curve monitored using the DPV technique on immobilization of successive

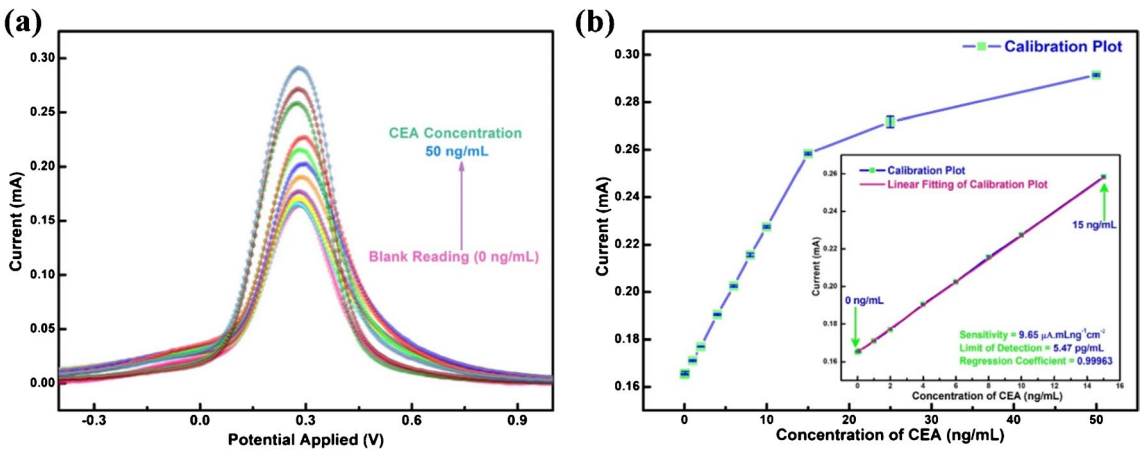

Fig. 7 **a** DPV response on calibrating CEA concentration from 0 to 50 ng/mL and **b** calibration graph between peak DPV current and CEA concentration

concentrations of carcinoembryonic antigen in the physiological range from 0 to 50 ng/mL owing to elevation of CEA beyond 5 ng/mL in NSCLC patients. The DPV current increased in the presence of elevated concentrations of CEA w.r.t. blank reading up to 15 ng/mL indicating linearity in current response owing to proportional electron transfer promoted by enhanced surface active sites of rGO-hBNNS for antibody-antigen mediation on the nano-biointerface (Fig. 7b). However, the linear response in peak current starts to deviate beyond 15 ng/mL ascribing the saturation of crosslinking sites on nano-biointerface (BSA/Anti-CEA/rGO-hBNNS/ITO) due to optimized occupancy of surface functional moieties.

Fitting of a linear plot depicting the calibration curve in Fig. 7b assisted computation of key parameters for assessing the sensing performance of as-fabricated nano-biosensor based on rGO-hBNNS/ITO electrode. The linear range fitted from 0 to 15 ng/mL with regression equation of form $y = mx + c$ having regression coefficient (R^2) of 0.99963 is depicted in Eq. (4).

$$I(mA) = [9.65\mu AmLng^{-1}cm^{-2} \times (CEAconcentration) + 0.165mA] \quad (4)$$

The slope associated with linear relationship aided the calculation of sensitivity (9.65 µA mL ng^{-1} cm^{-2}) attained by as-fabricated immunosensor based on rGO-hBNNS by utilizing slope/surface area (0.64 cm^2) formula. Further, the standard deviation in nano-biointerface (BSA/Anti-CEA/rGO-hBNNS/ITO) together with the sensitivity of the sensor helped in determining the lower limit of detection [39] using Eq. (5),

$$\text{Limit of detection} = 3\sigma/m \quad (5)$$

where σ denotes the standard deviation of blank immunoelectrode (BSA/Anti-CEA/rGO-hBNNS/ITO) and m stands for the sensitivity of the biosensor. Immunosensor based on a synergistic characteristic of organic–inorganic nanocomposite of rGO-hBNNS exhibited remarkably low LOD of 5.47 pg/mL offering a highly sensitive response for minute concentrations of CEA. Also, the performance of as fabricated rGO-hBNNS hybrid nanocomposite was found outstanding in comparison to various rGO-based immunosensors developed for biosensing application (Table 3).

Control, reproducibility, selectivity, stability, serum sample analysis

A series of studies were conducted to assess the practical applicability of the as-fabricated BSA/Anti-CEA/rGO-hBNNS/ITO nano-biosensor for real-time analysis. These studies aimed to evaluate the current reproducibility of immunoelectrodes fabricated under similar conditions, distinguish false responses, determine selectivity among various interferents present in real samples, assess stability over time, and analyze responses to spiked concentrations of CEA antigens in real samples.

Table 3 Comparison of sensing characteristics of rGO-hBNNS hybrid nanocomposite-based nano-biosensor with existing rGO and hBN-based immunosensors

Sensing matrix	Detection technique	Linear range (ng/mL)	Limit of detection	Sensitivity	Stability	Ref
APTES-nYZR	DPV	0.01–50	7.2 pg/mL	0.2 mA·ng^{-1}·mL·mm^{-2}	56 days	[40]
BN-nanosheets/GCE	EIS	0.1–500	0.017 ng/mL	17 pg/mL	60 days	[41]
PtNP(PPy-PPa)-RGO	EIS	10–1000	4 ng/mL	107.08 Ω·cm^2·$decade^{-1}$	30 days	[42]

False responses, where the rGO-hBNNS/ITO electrode exhibits a response similar to that of the BSA/Anti-CEA/rGO-hBNNS/ITO immunoelectrode, were investigated. A control experiment was conducted to measure the current response upon immobilizing three different concentrations (0.1, 8, 15 ng/mL) of CEA onto three bare rGO-hBNNS/ITO electrodes, as depicted in Fig. 8a. The average current obtained from the control experiment was 0.177 mA, indicating no change in the current of the rGO-hBNNS/ITO electrode upon CEA immobilization. This result aligns well with the DPV current obtained in the electrode study (Table 2). The observed RSD of 0.08% in the control

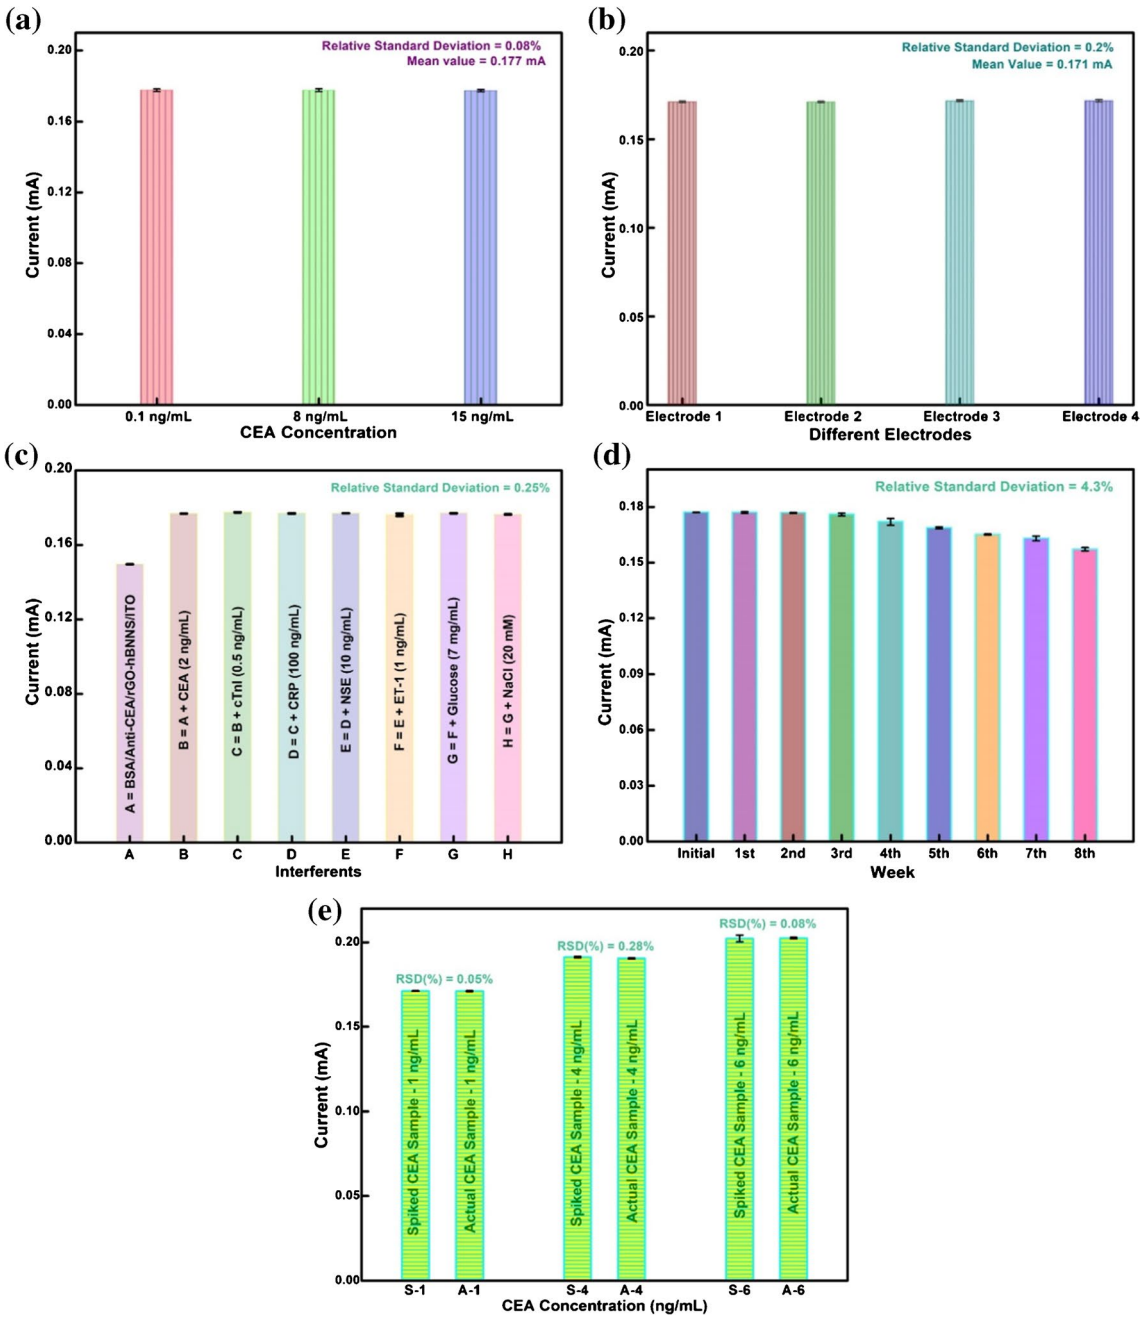

Fig. 8 Bar graph representing **a** control study of rGO-hBNNS/ITO electrode by addition of different CEA concentrations, **b** assessment of current reproducibility in as-fabricated immunoelectrode, **c** selectivity study conducted on successive modification of different interferent in electrode depicted as A = BSA/Anti-CEA/rGO-hBNNS/ITO, B = A + CEA(2 ng/mL), C = B + cTnI (0.5 ng/mL), D = C + CRP (100 ng/mL), E = D + NSE(10 ng/mL), F = E + ET-1 (1 ng/mL), G = F + Glucose (7 ng/mL), and H = G + Nacl (20 mM), **d** stability study performed weekly on BSA/Anti-CEA/rGO-hBNNS/ITO immunoelectrode, and **e** monitoring of spiked serum sample study utilizing by DPV technique

experiment emphasizes the consistent performance and reliability of the rGO-hBNNS/ITO electrode for protein biomarker detection, highlighting its suitability for accurate and precise measurements in this application.

A reproducibility study was conducted to assess the consistency of the electrochemical response in the as-fabricated immunosensor. DPV responses were monitored on four independent BSA/Anti-CEA/rGO-hBNNS/ITO immunoelectrodes after immobilizing 1 ng/mL CEA concentration onto each (Fig. 8b). The as-fabricated immunoelectrode exhibited minimal variation in DPV measurements, with an average value of 0.171 mA. Following the electrochemical investigation, the relative standard deviation (RSD) among the DPV currents measured from the four immunoelectrodes was determined to be 0.2% (< 5%), indicating outstanding reproducibility of the as-fabricated immunoelectrode. This suggests that the immunoelectrode consistently produces reliable results across multiple measurements, validating its suitability for consistent and accurate analysis in this context.

Human serum samples serve as vital clinical specimens for detecting various diseases characterized by diverse biological analytes. Therefore, assessing the specificity of the rGO-hBNNS-based immunosensor for carcinoembryonic antigen (CEA) amidst various interferents, such as cardiac troponin I (cTnI), C-reactive protein (CRP), neuron-specific enolase (NSE), endothelin-1 (ET-1), glucose, and sodium chloride (NaCl), is essential for its clinical utility. The presence of these analytes in serum samples may potentially impede the specific binding between CEA and the BSA/Anti-CEA/rGO-hBNNS/ITO immunoelectrode. Hence, investigating the selectivity of the rGO-hBNNS-based nano-biosensor was crucial, and this was accomplished by assessing the integrated effect upon successive addition of interfering analytes, as depicted in Fig. 8c via the DPV technique. Table S3, presented in the Electronic Supplementary Information, illustrates the outstanding selectivity of the BSA/Anti-CEA/rGO-hBNNS/ITO immunoelectrode towards CEA. The current response of the CEA/BSA/Anti-CEA/rGO-hBNNS/ITO immuno-interface remained unchanged even after the successive addition of interferents. The RSD of 0.25% highlights a highly selective response of the as-fabricated immunosensor. This implies that the immunosensor accurately identifies the target analyte (CEA) while remaining unaffected by the presence of interfering substances, showcasing its outstanding selectivity and reliability in practical applications.

The shelf life study was conducted using the DPV technique to assess the clinical storage stability of the CEA-immobilized BSA/Anti-CEA/rGO-hBNNS/ITO immunoelectrode (Fig. 8d). Testing was performed weekly to evaluate its suitability for real-time applications. During the interim period, the nano-biosensor was stored at 4 °C until subsequent examination. At the conclusion of the eighth week, the DPV current obtained was 88.74% of the initial DPV response, demonstrating a low relative standard deviation (RSD) of 4.3%, which is deemed acceptable (< 5%). These results indicate the robust storage stability of the fabricated immunosensor.

The human serum samples undergo clinical testing that validates their authenticity as real samples. Thus, quantitative determination of the spiked concentration of CEA in human serum samples that are known to exhibit various biological analytes examines the real-time applicability of as-fabricated immunoelectrode. In this study, the DPV response associated with the actual CEA concentration (A) was compared with the CEA concentration spiked into human serum samples (S) of identical concentration, which were then monitored (Fig. 8e).

A remarkable agreement in the average peak current of actual and spiked serum CEA concentrations was observed as shown in Table 4. The observed average peak currents associated with standard CEA concentrations of 1, 4, and 6 ng/mL were $0.171 \pm (5.5 \times 10^{-4})$ mA, $0.190 \pm (5.8 \times 10^{-4})$ mA, and $0.202 \pm (7.3 \times 10^{-4})$ mA, respectively. These values demonstrate a remarkable agreement with corresponding spiked CEA concentrations in human serum sample, where the average peak currents were found to be $0.171 \pm (3.7 \times 10^{-4})$ mA, $0.191 \pm (6.7 \times 10^{-4})$ mA, and $0.202 \pm (3.4 \times 10^{-3})$ mA, respectively. The RSDs for CEA concentrations of 1, 4, and 6 ng/mL were exceptionally low at 0.05%, 0.28%, and 0.08%, respectively. This indicates a high level of precision and consistency in the DPV current measurements obtained for these concentrations. Such low RSD values suggest minimal variability within the data sets, highlighting the reliability and accuracy of the BSA/Anti-CEA/rGO-hBNNS/ITO immunoelectrode towards detection of CEA in clinical serum samples of the patients as well.

Table 4 Recovery current and relative standard deviation (RSD, %) associated with detection of spiked concentration of CEA in human serum samples in comparison to actual CEA concentration

CEA concentration (ng/mL)	Average current for standard CEA sample (A, in mA)	Average current for spiked CEA sample (S, in mA)	RSD (%)	Recovery %
1	$0.171 \pm (5.5 \times 10^{-4})$	$0.171 \pm (3.7 \times 10^{-4})$	0.05	100.07
4	$0.190 \pm (5.8 \times 10^{-4})$	$0.191 \pm (6.7 \times 10^{-4})$	0.28	100.39
6	$0.202 \pm (7.3 \times 10^{-4})$	$0.202 \pm (3.4 \times 10^{-3})$	0.08	99.88

Conclusion

In summary, our present work harnesses the synergistic potential of organic–inorganic hybrid nanocomposites in fabricating nano-biosensing platform for ultrasensitive, efficient, cost-effective, and label-free detection of serum tumor marker associated with NSCLC. We observed an enhanced electrocatalytic performance (~29%) of hydrothermally synthesized rGO-hBNNS hybrid nanocomposite w.r.t. hBNNS owing to their unique crosslinking kinetics at interface. Combining amine-terminated hBNNS with carboxyl-functionalized rGO nanosheets created an environment abundant in surface active sites, facilitating the efficient immobilization of Anti-CEA antibodies. This enhancement significantly boosted the loading capacity of the nano-biosensor, resulting in exceptional sensitivity. Notably, this heightened sensitivity enabled the detection of CEA with an impressive low limit of 5.47 pg/mL. Furthermore, as-fabricated BSA/Anti-CEA/rGO-hBNNS/ITO immunoelectrode exhibited excellent storage stability for 8 weeks and was found to be highly selective in the presence of interfering markers present in serum. Their clinical applicability was unmatched owing to excellent recovery rates achieved for spiked serum sample analysis. This nano-biosensor depicted good analytical and clinical accuracy for monitoring potential biological analytes for real-time diagnostic applications.

Abstract

Application of fertilizers over agricultural fields, domestic sewage, and livestock are major point and non-point sources of nutrients such as phosphate and nitrate in stormwater runoff. These nutrients, specifically phosphate, is the major pollutant triggering eutrophication in freshwater bodies, thus damaging both- the aquatic ecosystem and the environment. The current study investigates the removal of phosphate using biochar-based treatment units, which can be an efficient and cost-effective removal method. The biochar used in this study was produced by slow pyrolysis of bamboo and it was further chemically modified with 1%, 5%, and 10% $FeCl_3$ solutions. The iron modification transformed the biochar surface to be electro-positive. Characterization of both biochar and modified biochars was carried out using proximate analysis, elemental analysis, Fourier transform infrared spectroscopy, and scanning electron microscopy. Furthermore, a series of batch experiments were conducted to evaluate the phosphate and nitrate removal efficiencies from the synthetic stormwater runoff. The removal efficiencies were found to be 29%, 49%, and 61%, with an initial phosphate concentration of 5 mg/L, using 1%, 5% and 10% $FeCl_3$ treated biochar respectively, while the nitrate removal efficiencies (with an initial concentration of 50 mg/L) were found to be 12.4%, 14.6%, and 17.0% respectively. The phosphate removal kinetics by 10% $FeCl_3$ modified biochar indicated that the phosphate removal followed pseudo-second-order kinetics. Isotherm modelling indicated both Langmuir and Freundlich isotherms as best fit for phosphate adsorption using 10% $FeCl_3$ modified biochar thus representing mono-layer and multi-layer adsorption, respectively. Langmuir isotherm reported the maximum phosphate adsorption capacity of 11.57 mg/g by 10% $FeCl_3$ modified biochar. Additional experiments were performed using real urban stormwater runoff from various regions of Delhi, which revealed similar phosphate removal efficiencies. The treated stormwater runoff can be used for water capacity building and non-potable applications in water-scarce urban areas.

Highlights

- Pyrolysis of bamboo has 40% yield.
- Phosphates and nitrates in stormwater runoff can be effectively removed by biochar.
- Biochar requires its treatment with electro-negative chemical species for effective removal of nutrients.

Introduction

The scarcity of water is becoming a challenge throughout the world leading to the crisis of potable water (He et al. 2021). India being the seventh largest country in the world and the most populous country, is rapidly advancing in terms of agricultural growth to feed its citizens (Ministry of Agriculture & Farmers Welfare 2022). Agricultural advancement also leads to the exploited application of chemical fertilizers in agricultural fields. These fertilizers consist of nutrients such as phosphate (PO_4^{3-}) and nitrate (NO_3^-) which when mixed with stormwater runoff degrades the quality of the receiving waterbody. In addition, phosphate is a critical pollutant causing eutrophication of receiving freshwater bodies (Haritash et al. 2017). The runoff from agricultural fields is a non-point source of nutrient pollution and causes excess nutrient loading leading to eutrophication, harmful algal blooms, and fish kills in receiving water bodies such as lakes and ponds (Sinha et al. 2017; Smith et al. 2020).

In addition, during dry seasons when no rainfall is being received in urban areas, pollutants such as pet wastes and biogenic wastes such as leaf litter and grass clippings get deposited on roads, streets, house roofs, trees, etc. During excess rainfall, the nutrients from the unutilized fertilizers, excess urban waste, and overflowing and leaking sanitary sewers get mixed with the stormwater runoff (Yang and Lusk 2018). The runoff traverses its flow path depending on the hydrology and imperviousness of the surface in that area (Kleinman 2006).

Nutrients in stormwater runoff are usually treated using several techniques such as biological treatment, ion exchange, ultrafiltration, membrane separation, and chemical precipitation. Employing some of these chemical techniques removes the pollutants through redox and ion exchange reactions, however, results in the release of harmful chemical species (Romero-Gueiza et al. 2015). Wetlands are also used to remove the nutrients from the receiving water, however, this method requires a large area and higher retention time moreover, the technique is not viable and efficient during the winter season (Haritash et al. 2015; Nandakumar et al. 2019; Pipil et al. 2021, 2023; Jain et al. 2024). Adsorption, on the other hand, is an effective technique that can be employed as a low-cost-efficient method to remove nutrients (Huang et al. 2020).

Among various adsorbents available, biochar, a product obtained from pyrolysis or gasification of biomass in the absence of oxygen, can be an efficient low-cost adsorbent owing to several favourable properties such as high specific surface and internal porosity (Weber and Quicker 2018). The adsorption capacity of biochar depends on several factors like the functional group, the surface charge, and the specific surface area. Few studies were conducted in the past to explore the potential removal of nutrients from wastewater using biochar (Zhang et al. 2020; Reddy et al. 2014). The surface of biochar is negatively charged which makes it unsuitable for the effective removal of anionic chemical species such as phosphate and nitrate, and thus, requires treatment with cationic chemical species like Fe(III) to effectively remove these nutrients from runoff (Mukherjee et al. 2011). $FeCl_3$ can effectively remove phosphate from the aqueous medium. Fe-P coprecipitate shows high stability under high pH fluctuation ($3.0 < pH < 11.0$). Moreover, $FeCl_3$ acts as an alternate terminal electron acceptor oxidising the other chemical species present in aqueous medium (Li et al. 2019).

The characterisation of stormwater runoff is necessary to estimate the suspended solids, pollutants, and nutrient loading in the runoff so that the requisite and necessary treatment can be provided for it. In previously published studies, the stormwater runoff samples were collected from various land uses based on associated activity in Delhi, India, which includes commercial, industrial, institutional, residential, and road/highways (Pipil et al. 2022a). Study shows phosphate concentration ranges between 0.04 and 17.4 mg/L while nitrate concentrations range between 1.6 and 478.8 mg/L. The higher values of phosphates and nitrate can be attributed to the addition from organic matter, mulch, applied compost, etc. in lawns and parks, littering of food waste, and the excretory waste of stray animals and pets. Water-sensitive urban design (WSUD) such as rain gardens and wetlands can remove pollutants such as suspended solids, nutrients, and heavy metals when amended with an adsorbent such as biochar (Pipil et al. 2022b).

In the present study, biochar was produced by pyrolysis using bamboo and was subsequently impregnated with Fe(III). A detailed characterization of the biochar and Fe(III)-modified biochar was performed. A series of batch adsorption experiments were conducted using bamboo-biochar and Fe(III)-modified biochar to determine their phosphate removal kinetics and maximum adsorption capacity. Synthetically prepared stormwater consisting of phosphate and nitrate was subjected to treatment process using biochar. Furthermore real stormwater runoff consisting of phosphate and multiple co-existing chemicals was also treated using the same. The experimental results helped to assess the extent of phosphate removal and the mechanisms responsible for the removal.

Materials and methods

Preparation of biochar

Old refused bamboo was collected from the university campus which was cleaned thoroughly with Type-I water. The pieces were cut out of it to prepare biochar in bulk quantity to have homogeneous characteristics. The bamboo samples were then dried in a hot air oven for 24 h at 105 °C. The dried samples were then placed inside a muffle furnace at 500 °C for 30 min for pyrolysis in an air-tight chamber to ensure the presence of zero oxygen. The temperature was raised in the muffle at a rate of 16.67 °C/minute for 30 min to attain a final pyrolysis temperature of 500 °C. The biochar so formed was allowed to cool freely and naturally inside the muffle. The produced biochar was crushed and passed through IS 4.75 mm sieve but retained on the IS 2.36 mm sieve, which was the chosen grain size range for treatment. A solution of $FeCl_3$ of strength 1%, 5%, and 10% was prepared in which an equal quantity of prepared biochar was added. It was subjected to shaking for 24 h in a bench-top shaker at a RPM of 150 and the temperature was set at 27 °C. This biochar impregnated with Fe(III) was then washed thrice thoroughly with Type-I water. It was then dried in a hot air oven at 105°C for 24 h. In addition, one set of experiments was conducted with untreated biochar. The untreated biochar is indicated with B0%, while biochar having 1%, 5%, and 10% $FeCl_3$ was named as B1%, B5%, and B10%, respectively. The percentage yield and the cost associated with the preparation of biochar were also calculated.

Characteristics of biochar

Proximate analysis

To estimate the moisture, volatile, fixed carbon, and ash content of both untreated biochar and raw bamboo, proximate analysis was conducted following ASTM (ASTM E871-82, ASTM E1755-01, ASTM E872-82) standard methods using ELTRA - Thermogravimetric Analyzer (manufactured in Germany). The temperature for moisture, volatile, fixed carbon, and ash content was fixed at 105 °C, 915 °C, 750 °C, and 750 °C, respectively. The thermogravimetric analysis was conducted using 1100 ± 10 mg of samples in the crucibles.

Elemental analysis

Elemental analysis was performed for the determination of carbon, hydrogen, nitrogen, and sulphur (CHNS) using Eurovector - EuroEA3000 Series elemental analyser at 950 °C. The calibration was performed using L-Cystine as the reference standard material in tin capsules. CHNS analysis was conducted in duplicates using ≈ 2.5 mg samples in tin capsules.

Fourier transform infrared (FTIR) spectroscopy

A non-destructive method was used to identify the various functional groups present in biochar. The FTIR was conducted for untreated biochar and Fe(III) modified biochar before and after the experiments, to characterize the functional groups present. A Thermo Fisher Nicolet spectrometer enabled with a KBr beam splitter was used in the mid-infrared region. All the samples were ground in a mortar pestle which was cleaned thoroughly with an organic solvent. Sample pellets were prepared in the ratio of 1:10 with KBr. Spectra of KBr were run initially to cancel out its effect and its spectrum in the final results. The spectra were collected in the range of 400 cm^{-1} and 4000 cm^{-1} with a resolution of 2 cm^{-1}.

Scanning electron microscopy (SEM)

A non-destructive method for Scanning Electron Microscopy was performed using Zeiss EVO 18 special (Zeiss, Germany). The biochar samples were used to analyse their structure before and after the adsorption in the experiment. The samples were dried in a hot air oven for 24 h and then it was visualised on the copper-coated grid after gold coating between 750x and 1500x magnification.

Experimental setup

Three combinations of concentration for both phosphate (PO_4^{3-}-P) and nitrate (NO_3^--N) were selected while preparing the mixed synthetically prepared stormwater runoff. Phosphate and nitrate were present in the mixed synthetically prepared stormwater having the concentration of 2.0 mg/L PO_4^{3-}-P, 25.0 mg/L NO_3^--N; 5.0 mg/L PO_4^{3-}-P, 50.0 mg/L NO_3^--N; and 10.0 mg/L PO_4^{3-}-P, 75.0 mg/L NO_3^--N. Initially, a dose of 1.0 g/L of biochar was introduced for the treatment which was later increased to 5.0 g/L. The experiments were conducted in triplicates in a conical flask with 200 mL of synthetically prepared stormwater runoff and the respective doses of biochar. The sample with biochar was subjected to shaking at 150 RPM at 27 °C. An aliquot of 1.0 mL was extracted at every 1-hour time interval. pH, electrical conductivity, and total dissolved solids (TDS) were noted using a Labman make (LMMP 30 model) bench-top multiparameter before and after the experiment. The residual concentrations of phosphate and nitrate were analysed using single beam spectrophotometer (Labtronics

make LT-290 Model) at $\lambda_{max} = 690$ nm for phosphate, and at $\lambda_{max} = 220$ nm for nitrate.

Removal of nutrient

The removal efficiency of nutrients from synthetically prepared and real stormwater runoff were calculated using the Eq. (1) given below:

$$\%Removal\ efficiency = \left[\frac{C_i - C_e}{C_i}\right] \times 100 \quad (1)$$

Where C_i is the initial concentration of nutrients in stormwater runoff in mg/L; C_e is the concentration of nutrients at equilibrium after treatment in mg/L. The removal efficiency was calculated based on the extraction of samples at an interval of 1 h which was extracted for 4 h.

Results and discussion

Characterisation of biochar

Proximate analysis

Based on thermogravimetric analysis, raw bamboo has more moisture and volatile content while its biochar has more carbon and ash content as compared to raw bamboo (Table 1). Raw bamboo has moisture, fixed carbon, volatile, and ash content as 7.1%, 16.8%, 76.1%, and 5.1%, respectively. On the other hand, bamboo biochar has moisture, fixed carbon, volatile, and ash content of order 3.5%, 59.6%, 17.4%, and 16.8%, respectively. During pyrolysis, the temperature was raised from room temperature to a peak 500 °C, resulting in the loss of moisture and water of hydration in the form of vapours, while the sample could have under decomposition which released complex organic compounds including CO_2, CO, H_2, CH_4 and other hydrocarbons in the form of syngas. This might have reduced the volatile content in biochar significantly. For the same reason of loss of moisture and water of hydration, the moisture content also reduced to half. The substantial increase in the fixed carbon content of bamboo biochar compared to raw bamboo is a result of the loss of other volatile organics during the pyrolysis (Sun et al. 2014).

Elemental analysis

Based on elemental analysis, as presented in Table 1, it was observed that pyrolysis has significantly changed the elemental composition of biochar. The carbon content of bamboo biochar increased to 73.2% from the 43.0% as compared to raw bamboo. However, the hydrogen and oxygen content in the biochar was reduced from 7.3 to 3.9% and 48.8–22.4%, respectively (Table 1). Nitrogen and sulphur content remained < 1.0% for both raw bamboo and bamboo biochar. O/C and H/C ratios reduced from 1.13 to 0.31 and 0.17 to 0.05, respectively, on the conversion of bamboo biomass to biochar. The lower ratio of O/C and H/C impart greater stability and degree of aromaticity within the biochar (Kumar et al. 2013).

Fourier transform infrared (FTIR) spectroscopy

As a result of pyrolysis, the increase in temperature changes the functional groups in the biochar. Non-destructive FTIR spectroscopy shows the peak intensity of the various organic groups commonly observed in biochar (Table 2). Between 3550 cm^{-1} to 3200 cm^{-1}, organic O-H stretching is a result of contribution from water retained in the biochar. C-H stretching between 3000 cm^{-1} to 2840 cm^{-1} corresponds to the presence of an alkane group. The peak between 2000 cm^{-1} to 1650 cm^{-1} is C = O stretching which consists of aromatic compounds, ketones, and amides for all the types of biochar. FTIR peak from 1400 cm^{-1} to 1000 cm^{-1} corresponds to C-H bending and C-O stretching that corresponds to the aldehyde and alcohol functional groups, respectively. 1000 cm^{-1} to 650 cm^{-1} corresponds to C = C stretching and C-H bending that relates to the alkene functional group (Fig. 1).

Scanning electron microscopy (SEM)

SEM images of biochar samples show the surface morphology of the biochar before and after treatment with $FeCl_3$. In both the biochar, complex surface morphology can be seen along with macro to micropores present over the surface

Table 1 Elemental characteristics of bamboo and its biochar

Particular	Proximate Analysis				Elemental Analysis						
	Moisture (%)	Fixed Carbon (%)	Volatile (%)	Ash (%)	Carbon (%)	Hydrogen (%)	Nitrogen (%)	Sulphur (%)	Oxygen* (%)	O/C ratio	H/C ratio
Raw bamboo	7.1	16.8	76.1	5.1	43.0	7.3	0.9	0.01	48.8	1.13	0.17

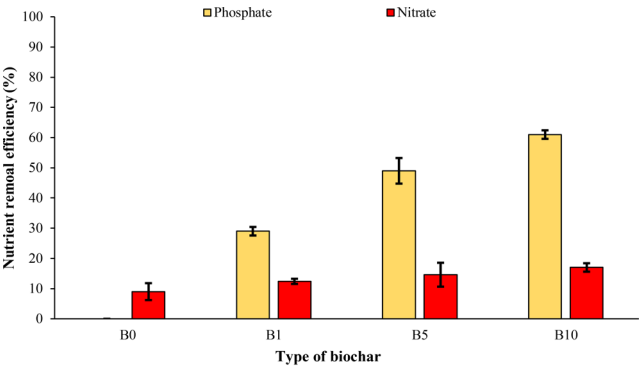

Fig. 3 Phosphate and nitrate removal efficiency of biochar from synthetically prepared stormwater runoff having PO_4^{3-} = 5 mg/L and NO_3^- =50 mg/L strength and biochar dose of 5.0 g/L

which are produced as a result of a vascular bundle of raw bamboo biomass (Hernandez-Mena et al. 2014). However, in biochar treated with $FeCl_3$, agglomeration of this electropositive chemical can be seen (Fig. 2).

Removal of nutrients

Removal from synthetic stormwater runoff

For the phosphate strength of 5 mg/L, different types of biochars have shown different removal efficiencies. B0% biochar without any treatment was not able to remove the phosphate from synthetically prepared stormwater runoff in a period of 4 h. This could be attributed to the non-availability of adsorption sites on the surface of untreated and negatively charged biochar. Negatively charged sites cannot remove anionic species due electrostatic force of repulsion. However, biochar which was pre-treated with $FeCl_3$ was able to remove phosphate. B1%, B5%, and B10% biochars removed 29%, 49%, and 61%, respectively, from synthetically prepared stormwater runoff when initial phosphate strength was 5.0 mg/L (Fig. 3). B10% treated biochar removed phosphate almost twice the B1% treated biochar. This could be attributed to the availability of sites having

Fe(III) present on the porous surface of biochar that can easily remove phosphate from the sample. The increase in phosphate removal efficiency is almost 60 times for B10% treated biochar to that of the untreated B0% biochar in the present study. B10% biochar was further used to study its nutrient removal efficiency for different phosphate strengths of 2 mg/L, 5 mg/L, and 10 mg/L, and the results are presented in Fig. 4. It was observed that biochar can remove almost 63% of phosphate for the initial phosphate strength of 2 mg/L at a dose of 5.0 g/L absorbent and a contact period of 4 h. At the same time, the removal efficiency of phosphates reduced with the increase in the initial strength of phosphate (Fig. 4). For the same dose and contact period, only 59% and 49% of phosphate were removed from synthetically prepared stormwater runoff of strength 5 mg/L and 10 mg/L, respectively. On the other hand, for the initial strength of nitrate as 50 mg/L, biochar without any given treatment was able to remove approximately 9%. Increasing Fe concentration in biochar did not show significant removal efficiency towards nitrate. The removal efficiency of nitrate using B1%, B5%, and B10% was of order 12.4%, 14.6%, and 17.0%, respectively. The lower adsorption of nitrate compared to phosphate can be due to the preferential adsorption of phosphate over nitrate by Fe(III) modified biochar.

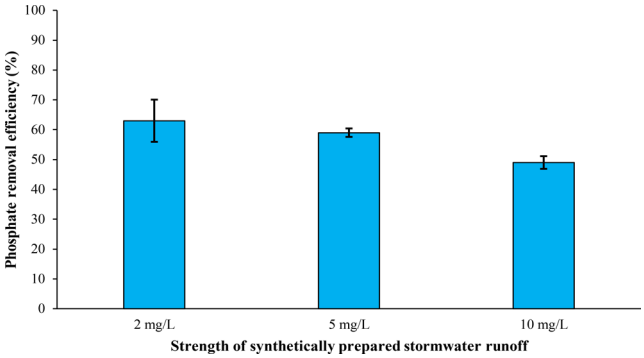

Fig. 4 Phosphate removal efficiency using B10% biochar from synthetically prepared stormwater runoff of varying strength for biochar dose of 5.0 g/L

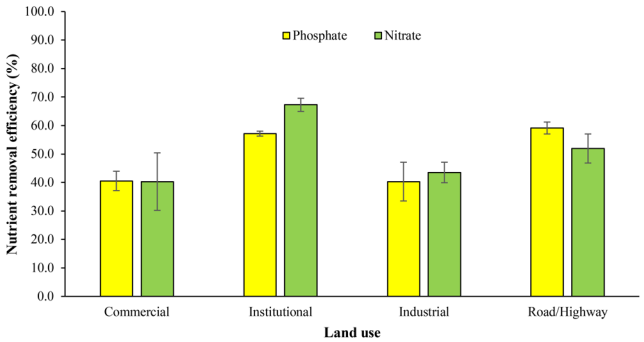

Fig. 5 Phosphate and nitrate removal efficiency (%) from stormwater runoff originating from different land use areas using B10% biochar

Removal from field stormwater runoff

Based on the observations obtained for nutrient removal from synthetically prepared stormwater, real (field) stormwater runoff was treated using B10% biochar, to verify its adsorption capacity in chemically complex real stormwater runoff. The phosphate removal efficiency of biochar for stormwater runoff collected from commercial, institutional, industrial, and road/highway areas of the Delhi region was of order 40.5%, 57.1%, 40.3%, and 59.1%, respectively (Fig. 5). It shows that the removal efficiency observed is relatively similar to that of the synthetically prepared stormwater runoff experiments. Also, up to 67.3% of nitrate was removed from institutional area runoff. The removal efficiency depends upon the initial concentrations of the pollutants. The equilibrium of the reaction shifts towards another side that reverses and releases pollutants from the adsorbed surface of biochar. The shift of equilibrium depends upon the release of pollutants from the solid phase (biochar) to an aqueous phase.

Adsorption capacity

The adsorption capacity q_e (mg/g) of the biochar was calculated using the Eq. (2)

$$q_e = \left[\frac{C_i - C_e}{W}\right] \times V \tag{2}$$

Where q_e is the adsorption capacity of biochar in mg/g; C_i is the initial concentration of nutrients in stormwater runoff in mg/L; C_e is the concentration of nutrients at equilibrium after treatment in stormwater runoff in mg/L; V is the volume of sample used for analysis in litre; and W is the quantity of absorbent in g. The adsorption capacity of biochar for a dose of 5.0 g/L was calculated in batch experiments for varying strength of phosphate in synthetic and real stormwater runoff which varied from 2.0 mg/L to 10 mg/L, and 0.4 mg/L to 3.2 mg/L, respectively. The experiment was conducted at 7.0 pH for synthetically prepared stormwater runoff at 27 °C temperature while the natural pH of real stormwater runoff is considered for this study. The dose of biochar was kept fixed at 5.0 g/L for Fe(III) treated B10% biochar for experimentation. The adsorption capacity of biochar increased with the increase in the concentration of phosphate which may be attributed to the availability of vacant sites for its adsorption which is represented by a strong correlation value ($R^2 > 0.99$) as shown in Fig. 6.

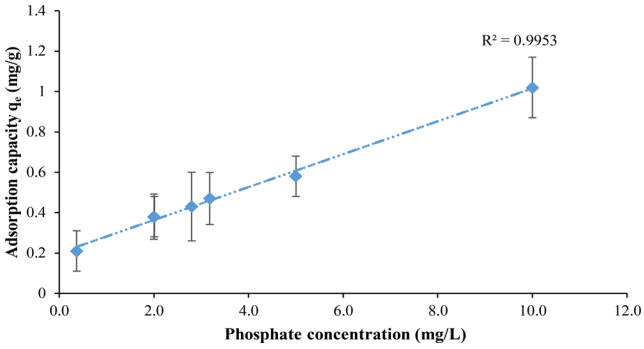

Fig. 6 Adsorption capacity of biochar as calculated during removal of phosphate from synthetic and real stormwater runoff tested in a batch experiment

Mechanism of removal

Removal of chemical species by biochar depends upon the presence of adsorption sites over the surface which is correlated with the specific surface area of the biochar produced. The increase in temperature for biochar production by pyrolysis, the specific surface area of biochar increases that enhances the removal of phosphates (Zeng et al. 2013). However, it was reported in earlier studies that biochar has an electro-negative charge over its surface, and it cannot remove anions (PO_4^{3-} and NO_3^-) by adsorption (Wang et al. 2015; Zeng et al. 2013). The pyrolysis of biomass produces biochar having functional groups such as -OH and -COOH as shown by the FTIR spectrum peak at 3400 cm^{-1} and 1600 cm^{-1}, respectively (Fig. 1), which may result in a negative surface charge. The net negative surface charge may lead to poor electrostatic attraction of PO_4^{3-} and NO_3^- with biochar and thus, require treatment with electropositive chemical species like $FeCl_3$. The impregnation of $FeCl_3$ over the biochar surface has played a role in nutrient removal. The SEM images before and after the adsorption (Fig. 2) revealed that the surface was smooth before adsorption while, after adsorption, the surface was occupied with adsorbed particles. This change in the surface morphology of biochar suggests that nutrients were removed by the action of electrostatic attraction between positively charged Fe(III) ions and negatively charged phosphate ions. FTIR spectrum peak at 1000 cm^{-1} after adsorption suggests the interaction of Fe-OH with P ions (Zhang et al. 2009).

Kinetics of nutrient removal

To find the kinetics of nutrient removal, pseudo-first-order and pseudo-second-order models were applied. Pseudo-first-order kinetic model is given by Eq. (3)

$$\log(q_e - q_t) = logq_e - \frac{K_1 t}{2.303} \tag{3}$$

Where q_e is the adsorption capacity of biochar in mg/g; q_t is the adsorption capacity of biochar in mg/g at any time t; K_1 is pseudo-first order rate constant (min^{-1}).

Pseudo-second-order kinetic model is given by Eq. (4)

$$\frac{t}{q_e} = \frac{1}{K_2 q_e^2} + \frac{t}{q_e} \tag{4}$$

Where q_e is the adsorption capacity of biochar in mg/g; K_2 is pseudo-second-order rate constant (g mg^{-1} min^{-1}) and t is time in minutes. The plots of pseudo-first-order and pseudo-second-order models for the adsorption capacity of biochar are shown in Fig. 7a and b respectively. The various parameters obtained from these models are given in Table 3. Pseudo-first-order model fits relatively poor for the removal of phosphates in which the R^2 value varied from 0.867 to 0.945. Also, the adsorption capacity calculated at equilibrium ($q_{e(cal)}$) and adsorption capacity from the experiments ($qe_{(exp)}$) varied significantly. Thus, it shows that adsorption kinetics does not follow the pseudo-first-order kinetic model. On the other hand, the R^2 value varied between 0.999 and 0.996 for pseudo-second-order kinetics which shows that the plot fits very well. Also, adsorption capacity varied between 0.35 and 0.60 mg/g for phosphate. Thus, the adsorption of phosphate follows pseudo-second-order rather than pseudo-first-order kinetics as reported in another study (Zhang et al. 2012).

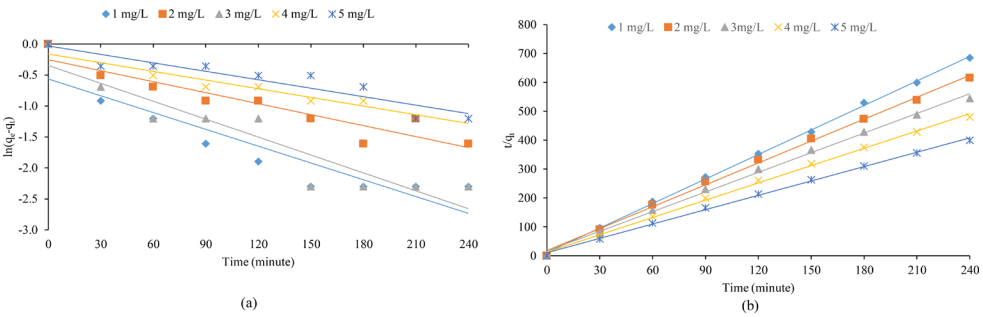

Fig. 7 (a) Pseudo first order kinetics, (b) Pseudo second order kinetics for removal of varying phosphates concentration using B10% biochar

Table 3 Comparison of parameters for pseudo-first order and pseudo-second order reaction kinetics

Order of reaction	Parameter	Unit	Concentration				
			1.0 mg/l	2.0 mg/l	3.0 mg/l	4.0 mg/l	5.0 mg/l
-	$q_{e(exp)}$	mg/l	0.31	0.38	0.45	0.51	0.58
First Order	K_1	min^{-1}	-0.009	-0.0059	-0.0096	-0.0047	-0.0045
	$q_{e(cal)}$	mg/g	0.57	0.78	0.71	0.85	0.97
	R^2	-	0.8431	0.8727	0.8724	0.9457	0.8676
Second order	K_2	g mg^{-1} min^{-1}	0.73	0.35	0.31	0.31	0.27
	$q_{e(cal)}$	mg/g	0.35	0.40	0.44	0.50	0.60
	R^2	-	0.9991	0.9973	0.9968	0.9976	0.9981

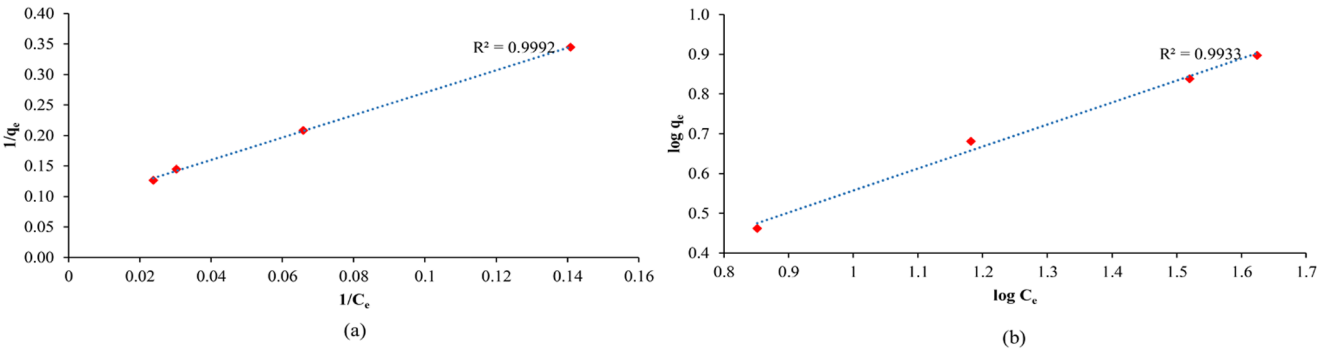

Fig. 8 (a) Langmuir isotherm; and (b) Freundlich isotherm fit for B10% biochar

Adsorption Isotherm

To find the adsorption isotherm, both Langmuir and Freundlich isotherm models were applied. Langmuir isotherm in its linear form is represented by Eq. (5)

$$\frac{1}{q_e} = \frac{1}{K_L q_{max}} \frac{1}{C_e} + \frac{1}{q_{max}} \tag{5}$$

Where q_e is the adsorption capacity of biochar in mg/g; q_{max} is the maximum adsorption capacity of biochar in mg/L; K_L is Langmuir's isotherm constant (L/mg).

The separation factor R_L is given by Eq. (6)

$$R_L = \frac{1}{1 + C_i \times K_L} \tag{6}$$

Where, R_L is Langmuir constant which indicates the adsorption possibility which may be either favourable ($0 < R_L < 1.0$), unfavourable ($R_L > 1.0$), linear ($R_L = 1.0$) or irreversible ($R_L = 0$).

Fruendlich isotherm in its linear form is represented by Eq. (7):

$$log q_e = log K_f + \frac{1}{n} log C_e \tag{7}$$

Where q_e is the adsorption capacity of biochar in mg/g; K_f is the Freundlich's constant $((mg.g^{-1})\ (L.mg^{-1})^{1/n})$; C_e is the concentration of nutrient at equilibrium after treatment in stormwater runoff in mg/L. In general, adsorption isotherm distinguishes the surface properties and affinity to adsorb the adsorbate. Isotherms corresponding to B10% biochar were studied to understand the same. The best curve was obtained by the Langmuir isotherm model with $R^2 = 0.9992$ as against the Freundlich isotherm model with $R^2 = 0.9933$ (Fig. 8). The maximum adsorption capacity q_{max} was obtained as 11.57 mg/g for phosphate (Table 4). The calculated value of Langmuir constant R_L was less than 1.0 which suggests that the adsorption possibility is favourable (Ayub et al. 2020). A brief comparison of studies done in the past for the removal of phosphate is summarized in Table 5.

Table 4 Langmuir and Freundlich adsorption isotherm for B10% biochar

Isotherm	Parameter	Unit	Values
Langmuir	q_{max}	(mg/g)	11.5741
	K_L	(L/mg)	0.0469
	R_L	-	0.3473
	R^2	-	0.9992
Freundlich	K_f	$(mg/g)\ (L/mg)^{1/n}$	1.0097
	1/n	-	0.5531
	R^2	-	0.9933

Yield of biochar

The yield of biochar produced during the experiment was calculated as the ratio weight of carbonaceous biochar

Table 5 Comparison of adsorption capacity of different materials in different studies for removal of phosphate

Adsorbent material	Adsorption capacity for PO_4^{3-} (mg/g)	Reference
Mg corn-cob biochar	56.12	Deng et al. 2021
Al corn-cob biochar	44.79	Deng et al. 2021
Pig manure biochar	9.51	Wang et al. 2015
lanthanum (La) oak biochar	46.37	Wang et al. 2016
Coal Gangue/biochar	3.19	Qiu and Duan 2019
Fly ash/biochar	3.07	Qiu and Duan 2019
Fe(III) Bamboo biochar	**11.57**	**Present study**

produced after pyrolysis to the weight of bamboo biomass before pyrolysis as given by the Eq. (8)

$$\%\ Biochar\ yield = \frac{weight\ of\ carbonaceous\ biochar\ produced\ after\ pyrolysis}{weight\ of\ bamboo\ biomass\ before\ pyrolysis} \times 100 \quad (8)$$

Using the formula mentioned above, approximately 40% biochar was produced from the initial bamboo biomass. The 60% of the initial mass loss can be attributed to the removal of moisture, the production of syngas, and the production of bio-oil during pyrolysis (Panwar and Pawar 2020). Biomass with higher water content will lead to a poor yield of biochar.

Cost of biochar production

Biochar was made through pyrolysis in a muffle furnace having a power rating of 2.0 KW. The muffle furnace was operated for an hour, initial 30 min for raising the temperature at a rate of 16.67 °C/minute, and the next 30 min for the actual process of pyrolysis at 500 °C. Thus, 2.0 KW muffle operated for 1 h implies that 2 units of electricity, i.e., 2.0 kWh was consumed in this process. The average price of electricity units in Delhi ₹6.0 per kWh. Thus, electricity cost accounts for ₹12.0 (Table 6). $FeCl_3$ was also used to impregnate the biochar in various configurations. The cost of $FeCl_3$

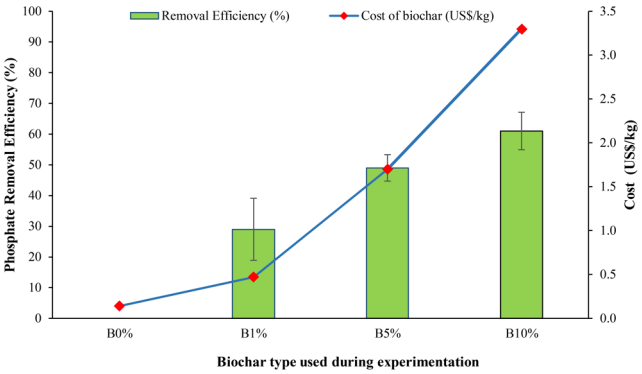

Fig. 9 Removal efficiency (%) and associated cost (US$) of different types of biochar (per kg) for phosphate removal from synthetically prepared stormwater runoff with initial PO_4^{3-}-P concentration is 5 mg/L

used during experimentation was ₹400 per 500 g packaging. Thus, the total cost of biochar includes the cost of electricity used during pyrolysis and the cost of chemicals consumed. Hence, the cost of biochar varies between ₹12.0 per kg for non-impregnated biochar to ₹244.0 per kg for 10% $FeCl_3$ impregnated biochar. Considering the currency exchange rate as US$1 equivalent to ₹83.17, the cost of biochar production becomes equivalent to US$ 0.14 per kg to US$ 2.93 per kg for the present study (Fig. 9).

Conclusions

The current study aimed to evaluate the enhanced phosphate and nitrate removal efficiency by Fe(III) modified biochar from synthetically prepared stormwater runoff containing phosphate and nitrate, and from actual stormwater runoff collected from the field. The biochar used in this study was produced by slow pyrolysis of bamboo biomass at a yield rate of 40%. The bamboo-biochar was then treated with 1%, 5%, and 10% $FeCl_3$ solutions to induce surface electro-positivity. Biochar and modified biochars were then characterized based on proximate analysis, elemental analysis, Fourier Transform InfraRed (FTIR) Spectroscopy, and Scanning Electron Microscopy (SEM). The characterization results indicated that the Fe(III) modified biochars possess favourable surface and chemical properties for phosphate

Table 6 Cost (US$) of $FeCl_3$ treated biochar production for treatment of stormwater runoff

Process	Time (hours)	Power rating of muffle (KW)	Power consumption (KWh)	Average electricity price per unit (₹ per KWh)	Cost of electricity (₹) (A)	$FeCl_3$ treated Biochar	Cost of $FeCl_3$ treatment (₹) (B)	Total cost of biochar per kg (₹) (A+B)	Cost of biochar per kg (US$)
Pyrolysis	1.0	2.0	2.0	6.0	12.0	Without treatment	0	12.0	0.14
						1%	23.2	35.2	0.42
						5%	116.0	128.0	1.54
						10%	232.0	244.0	2.93

removal. Phosphate removal from synthetic stormwater was found to be 29%, 49%, and 61% for an initial phosphate concentration of 5 mg/L using 1%, 5%, and 10% $FeCl_3$ treated biochar, respectively. However, the nitrate removal efficiency was found to be 9%, 12.4%, 14.6%, and 17.0% for B0%, B1%, B5%, and B10% respectively, at an initial nitrate concentration of 50 mg/L. This is possibly due to the preferential adsorption of phosphate instead of nitrate by Fe modified biochar, and the high initial concentration of nitrate. The removal efficiencies were found to reduce with increasing phosphate concentration, while no such trends were observed in the case of nitrate. The phosphate removal efficiency of modified biochar (B10%) for stormwater runoff collected from commercial, institutional, industrial, and road/highway areas of the Delhi region was 40.5%, 57.1%, 40.3%, and 59.1%, respectively, with the variations effected by the initial phosphate loading. A study of the kinetics of phosphate adsorption by B10% biochar showed that the adsorption of phosphate removal follows pseudo-second-order rather than pseudo-first-order kinetics. Both Langmuir and Freundlich isotherm models, which indicate mono-layer and multi-layered heterogeneous adsorption respectively, were found to be well fit for the phosphate adsorption by B10% biochar. The maximum adsorption capacity, obtained from Langmuir isotherm, was 11.57 mg/g for phosphate removal by B10%. Lastly, an analysis of production and modification costs of bamboo-biochar indicated that modification of biochar is economically feasible.

Abstract: Large data collections are stored by people in the modern world utilizing computers. Data may be sent across the globe at a reasonable cost. ATM's have been in use for almost 50 years now since their introduction. Since its introduction, ATM's have made it possible to withdraw money without encountering any problems. In the banking industry, the ability of ATM's to be installed in any location is seen as exceptional since it allows customers the freedom to conduct transactions on their own. While the cash dispenser and visual screen serve as output devices, the card reader and keyboard serve as input devices. Many ATM's can work together on a common level through the host processor, which is owned by the bank. Authenticated Banks provide unique ATM PINS to their customers. The registered phone number is used to send these ATM PINS. if someone saw the PIN notice on the user's phone and knows the card data. They can then access the client's account in full and may be held accountable for any criminal activity that occurs. Criminals have developed a variety of schemes to steal money from ATM's. Due to strict security measures around the money compartment, they are unable to simply steal cash from an ATM; instead, they swipe the cards of several customers. It is far easier to obtain ATM card data than to breach the ATM's security. The practice of card skimming is one that con artists frequently employ. On the card per user space of ATM's, card skimmers are implemented. The data is stored in the memory of the card skimmer and is seen by an electrical circuit on a visually appealing portion of the card. After driving the skimmer out of the ATM, the criminals later duplicate this data. Card skimmers are designed to fit perfectly over each user's unique cards, making it easy for clients to become victims of them.

I. INTRODUCTION

Our goal is to introduce a potent technique that uses fingerprint sensing to enhance the current state of ATM's. It is widely acknowledged that each person has a fingerprint that is distinct from everyone else. Thus, we will lessen the likelihood of thefts occurring in the present day, since the offenders can access systems through technological means and obtain all of the user's private information, but they will be prevented from completing the transaction if the fingerprint is not authenticated. In order to undertake operations only after a comprehensive validation of the user's fingerprint from our database, we are additionally incorporating One Time Passwords that are sent via the registered user's phone number and email address as ATM PIN. Criminals have developed a variety of schemes to steal money from ATMs. Due to strict security measures around the money compartment, they are unable to just take cash out of ATMs; instead, they swipe the cards of various customers. It is much easier to steal ATM card info than to breach directly into the ATM. The practice of card skimming is one that con artists frequently employ. On the card per user space of ATMs, card skimmers are implemented. The data is stored in the memory of the card skimmer and is seen by an electrical circuit on a visually appealing portion of the card. After driving the skimmer out of the ATM, the criminals later duplicate this data. Card skimmers are designed to fit over unique cards perfectly making it easy for customers to become victims of it. In the unlikely event that card spaces appear large or unrestricted, it may be a skimmer device. Additionally, fake key cushions that log all customer inputs are available online from obscure web commercial centers. These can be placed over the ATM's primary key cushion.

Then, thieves take advantage of these logged inputs to withdraw money from the client account. Additionally, thieves can place a tiny camera directly above the ATM keypad, which keeps recording customer inputs, including your PIN. Banks frequently advise their customers to shield the keyboard with their other hand when accessing the PIN. Occasionally, the entire front of the ATM is replaced with a false one that exactly mimics the original. It turns out to be challenging to determine whether an ATM has been compromised in the event of a phony ATM front. Money doesn't flow out of the fake front, and customer inputs are still being recorded.

II. OVERIEW OF FINGERPRINT AUTHENTICATION

- Step 1 Registration: The registration process involves first detecting the user's fingerprint, processing it into a digital image, and then purging any undesirable features from it. After post- processing, store the image in the database.
- Step 2 Authentication: To operate on a fingerprint, we used a fingerprint sensor. It extracted features from the fingerprint and compared them to N fingerprint templates stored in our database.
- Step 3 Confirmation: After a fingerprint was found to match a specific fingerprint in our database, we double-checked the match by comparing the fingerprint to the database once more.

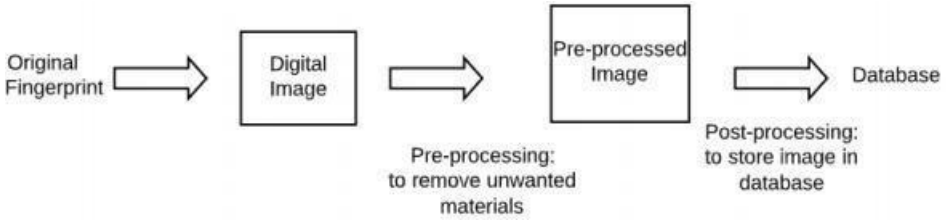

Fig. 1 Registration

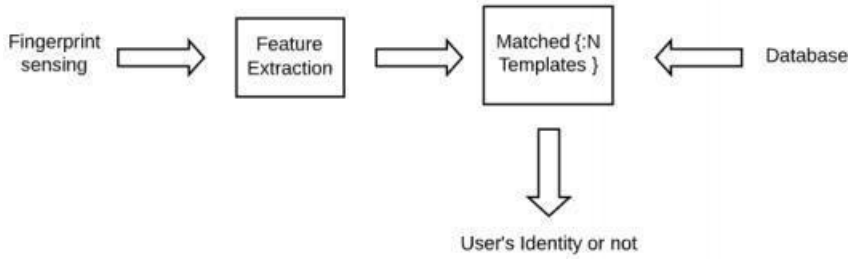

Fig. 2 Authentication

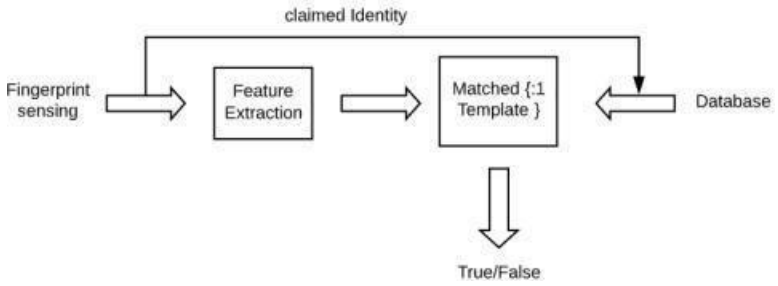

Fig.3 Confirmation

In addition to fingerprint recognition, the matching fingerprint customer's registered phone number, 99XXXXXXXX, and registered email address, customeruser@example.com, will receive three One Time Passwords. By all means, he can complete transactions if he can accurately enter the OTPs on or before the third OTP is transferred.

He will have to start the process over if the amount he inputs to be withdrawn is more than what is already in his bank account.

After the transaction is complete, he will get an email and a text message on his phone saying that the transaction on this account number, 56XXXXXX, was successful and that the remaining amount is what he needs to pay. Conversely, following the collapse ofthe third OTP, he will get a security breach alert email and be instructed to get in touch with the closest branch right away.

Face recognition problems are one way to counteract the existing state of affairs. As a result of biological ageing, the characteristics of a person's face become increasingly out of proportion from the last picture they had taken. For the device to remain productive, the user must periodically re- register their image, which could be extremely difficult for a bedridden patient or someone who has had their face burned. Comparing biometric IDs to more conventional and contemporary approaches has several advantages. Installing it is fairly easy, although it does require some time and effort to locate each finger and fingerprint scanner. Because of this, fingerprint recognition is regarded as one of the easiest biometric verification methods to use.

A webcam was mounted on the ATM, according to [23], and it records the clients' live photos as they pass by. After then, this taken image is compared to the other pictures in the database. An arbitrary password is generated by the contrast and sent to the client's registered phone when it is successful. The customer is then directed to input the identical password on the ATM's screen. The user can carry out transaction actions if they input correctly. However, there are two significant problems with this theory: 1) Unless prompt action is done, it will be impossible to stop theft from occurring if the mobile phone is lost or stolen. 2) The initial image was created because as we age, our face expressions tend to alter. There will be differences between the picture of our faces that was taken at that time and the most recent one.

According to the researchers, the idea of using the PIN as a secure password is not very suitable for the ATM's Palm Print Recognition and Confirmation System [4]. Thus, the idea of fingerprint authorization was established in order to increase security. According to extensive research, a simulator mimics the features of the ATM as it exists today. They compared the cervical recognition program's 89.43% rejection rate to 10.57% in their conclusion [4].

As a result, 53 out of 500 users who visit the updated ATMs after going through this verification procedure may experience issues. The percentage of rejections was increased to ten percent.

To eliminate errors in ATMs' alphanumeric certification, Lalzirtira implemented Graphical User Authentication. His research indicated that an image-integrated code would be easier to understand. He devised a password that would be simple for customers to commit to memory [5]. Although the pass-code that uses photographs to grant authorization in the ATM system has some benefits of its own, it was unsuccessful because of video recordings.

Dyno-password idea was another one that was proven to be true. Here, the bank sends the client a text message on the registered phone number, which contains the passcode. The ATM screen will be used to input this new passcode. The bank's database server will cross-check it once more. It follows that all that is required to withdraw cash from an ATM is the customer's PIN, card, and SIM. This kind of sensitive information can be readily obtained by anyone in the client's social circle. This idea thus provided opportunities for hackers [6].

III. SOFTWARE

A. *Mongo DB*

An open-source record database with excellent performance, high accessibility, and designed scaling is called MongoDB. To put it simply, Mongo DB is a database that is oriented towards records. It is an open-source product that was developed and supported by 10gen. MongoDB can be accessed for free under a general public licence, and it can also be accessed with a commercial licence from the creator. "A document-oriented database system that makes advantage of the NoSQL notion is called Mongo DB. It also offers automatic scaling, great performance, and high availability. This open- source application was created and is maintained by 10gen, a company that was founded in October 2007. MongoDB is a free database management tool offered under the General Public Licence (GPL) and Commercial licence issued by the producer. It was also planned for MongoDB to run on commodity systems. MongoDB is the database of choice for businesses of all sizes and in all sectors worldwide. A database in MongoDB can be thought of as a physical space containing various types of data. Every database has a live assortment of documents here on the record framework. A MongoDB server often houses a number of databases.

B. *Python Spyder*

Like Perl, Ruby, Scheme, or Java, Python is an object-oriented programming language that is powerful and easy to understand.

Among Python's noteworthy attributes are:

- Its elegant syntax makes your programme easier to read.
- The language is user-friendly, making it effortless to get your programme up and running. Because of this, Python is perfect for a variety of ad-hoc programming tasks, including developing prototypes, without sacrificing maintainability. It has an extensive standard library that supports a wide range of common programming tasks, including connecting to web servers, using regular expressions to search text, reading, and editing files, and testing brief code snippets with ease. Additionally, thereis the IDLE packaged development environment.
- Easily expandable with the addition of new modules written in compiled languages like C or C++.
- It is compatible with Mac OS X, Windows, Linux, and Unix, and there are unofficial builds for Android and iOS as well.
- Free software is defined in two ways. The cost of downloading, using, and incorporating Python into your programme is zero.
- Despite being protected by copyright, Python is freely modifiable and re-distributable due to its open- source licence.

C. *Tkinte*r

There are several solutions available in Python for creating a GUI (Graphical User Interface). Tkinter is the most widelyused approach of all the GUI methods. It is a typical Python interface to the Python-bundled Tk GUI toolkit. The quickest and most straightforward approach to construct GUI apps is with Python and Tkinter. Using Tkinter to create a GUI is a simple process.

Making a Tkinter application:

- Bringing in the Tkinter module
- The process involves creating the main window (container), adding any number of widgets, and then applying the event trigger to each widget.

D. *Visual Studio (Node JS)*

Node.js provides a framework for developing efficient and expandable server applications utilizing JavaScript. Acting as the runtime environment, Node.js is complemented by npm, which serves as the package manager for Node.js modules. Visual Studio Code comes pre-equipped with built-in support for both JavaScript and Typescript languages, along with debugging capabilities for Node.js. However, for executing Node.js applications, it's essential to have the Node.js runtime installed on your local machine. This runtime facilitates the execution of JavaScript code outside the browser environment, enabling the development of diverse server-side applications with ease and efficiency.

IV. PROCEDURE

The process via which fingerprints are recognized:

Biometric fingerprint technology is the most widely acknowledged security mechanism to be placed in the ATM. Compared to the current ATM security; it offers a considerably more secure initiative. Because it is so simple to install and use, the technology's ability to blend seamlessly with our modern lifestyle is astounding. It is praised as one of the most effective authentication methods as a result. Since the fingerprint data are not kept in a database, there is no way for the fingerprint to be misused.[7]

Two essential presumptions underpin the unique finger impression ID: peculiarity and in-variance. Constancy. According to in- variance, the characteristics of the finger impression don't alter throughout time. Peculiarity: suggests that the one-of-a-kind mark is remarkable and no two people's distinctive finger impressions are alike.

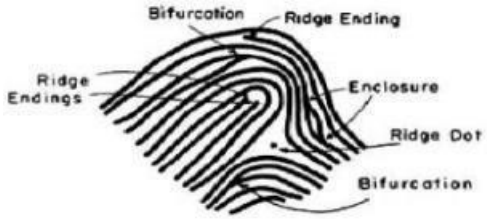

Fig. 4 Fingerprint characteristics [1]

Fig. 5 Fingerprint Types

- Distinctive biometric impression: The biometric's component example is its distinctive pattern. [21]
- Binarization: This refers to the process of converting a greyscale image into a binary image by determining the esteem value. [21]
- Block Filter: This technique effectively extracts minutiae by reducing the thickness of all ridgelines to a single pixel width. [21]
- Minutiae Extractruction: After minutiae are eliminated, details are deduced.[21]
- Minutiae Matching: This compares unique finger impression data. Additionally, the minutiae coordination layout is used. [21]
- Matching Score: This is the relationship used to determine how well the original fingerprint and template data collaborate. [21]

V. APPROACH FOR ATM MODIFICATION

They won't check for a one-time password from the bank using their registered phone number or email ID until their fingerprints have been carefully verified.

Three opportunities will be provided for them to write their accurate OTP in front of the ATM screen. In the event that there is enough money in their accounts, they will be able to withdraw money if they enter it correctly. However, if, despite our giving themthree One Time Passwords, they enter them wrong, we will send them an email saying, "Security Breach and Kindly Contact your nearest branch." API's will be used by us for sending and receiving obtain the customer's uniquely identifiable data.

The framework is introduced to carry out specified assignments, like email correlation, phone compatibility, validation of Python code, and so on. Each method is then reset to begin regulations. Because the intended technology includes fingerprint sensing, it differs from the current ATM system. It will start as soon as the customer walks into the ATM. First, it will be indicated if the person wishing to open an account with our bank is an existing customer or a new one. If the person is already a customer, they will be requested to move straight on to the procedure' fingerprint authentication step. Should they choose not to, they will be required to register with us by providing their phone number, email address, and fingerprint in our database.

The pictures of our encrypted database are as follows:

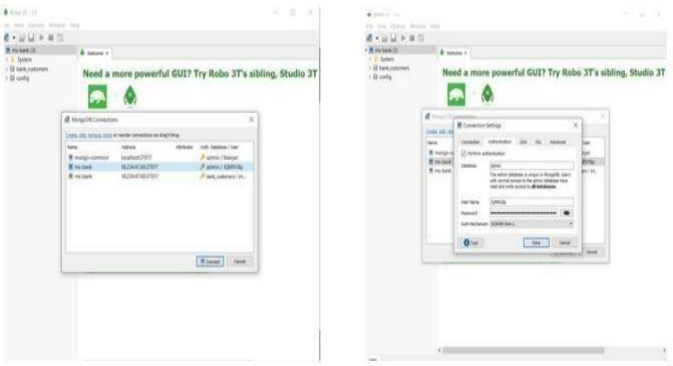

Fig. 6 Database with Password Protection

It indicates that the ability to access the database is restricted to the owner of the verified credentials, such as the admin password. Following that, fingerprints will be requested from both new and current customers in order to confirm their inclusion in our database. As long as their fingerprint scan yields a satisfactory confidence match with our database, they are free to proceed. Their ability to participate in the following phases will be restricted if the fingerprint authentication is unsuccessful. In order to prevent fraudulent activities, it is necessary to ensure that the amount of sensitive information that hackers can readily trace, such as card numbers, personal information security, and mobile numbers, will decrease to the point where people feel safe and secure.

On the successful verification of the fingerprint, they will be asked to enter the first OTP send to their registered Email Address and Phone Number. If they enter it correctly, they will be asked to enter the amount they want to withdraw. If the amount entered is less than the balance present in the bank account, they will successfully withdraw it. On the backend side, we will update the remaining balance in our database. If they fail to enter their first OTP accurately, then a second OTP will be sent to their Email Address and Phone Number again with following the same consequences. On the third OTP, they will have only one chance to enter it fairly. If they failed to do so, then from our side, a security breach mail and a text message will be sent to their registered Email Address and Phone Number, and they will be locked out to proceed for the transaction of money. They have to start over with the whole process again. We are using Python GUI Tkinter as the interface to take the input from the user. We are using API's and Mongo DB to extract and deliver the data of customers on the requirement. We have deployed an online URL for registering using WIFI with us: www.msbank.co.in. This URL is responsible for generating APIs.

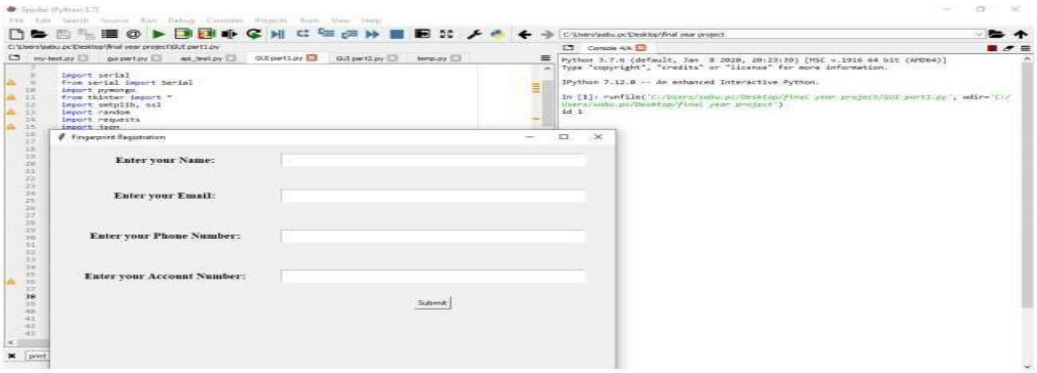

Fig. 7 Illustrates a graphical user interface (GUI) designed in Python for data entry purposes.

VI. RESULTS AND DISCUSSIONS

In this context, we submit the technical input of our research project.

A. *Database*

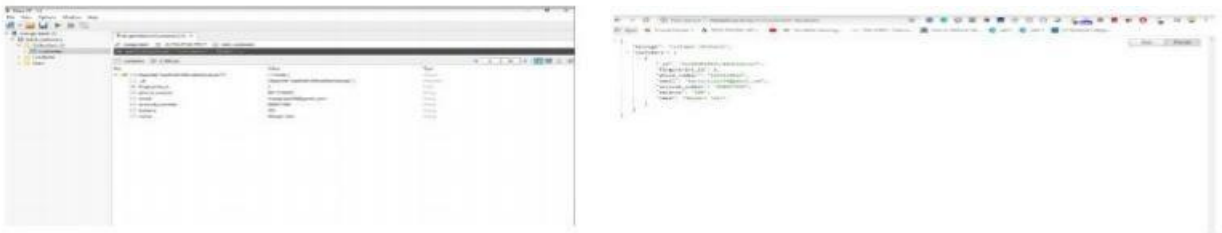

Fig. 8 Our initial database, Mongo DB, is shown in image a) APIs are shown in image b) It displays our database of active MS Bank customers.

B. *Updating the existing database by adding a new entry*

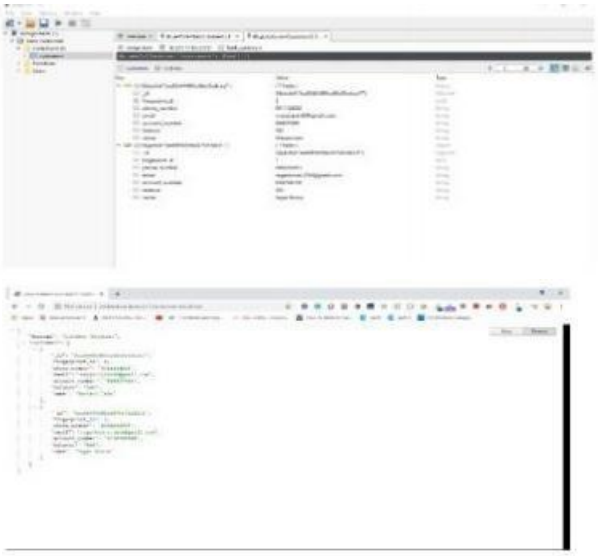

Fig. 9 Shows how the API's are updated with the new user's database in Image b and Mongo DB in Image a. It demonstrates that the new data has been successfully added to our database and API's.

C. *Successfully entering the OTP*

According to the amount in his or her bank account, it indicates that every registered customer who enters the OTP matching from the texts and emails is permitted to perform transactions.

© 2024, IJCSMC All Rights Reserved, ZAIN Publications, Fridhemsgatan 62, 112 46, Stockholm, Sweden

Fig. 10 Effective Fingerprint Verification (A new GUI displays requesting the first OTP to be provided here after the newly registered user's fingerprint is successfully verified.)

D. Incorrect entry of OTP

This is the situation that arises when a registered customer enters the OTP incorrectly for the third time. They will consequently receive an email titled "Security alert, kindly contact your nearest branch as soon as possible."

Fig. 11 First OTP is incorrect The client inputs the initial OTP incorrectly.(The GUI presents a warning saying "Wrong otp 1" when the customer enters the first OTP, which doesn't match the one sent to the registered Email and Phone No. After that, in order to get the second OTP, the consumer must select "Click to Receive OTP.")

VII. CONCLUSIONS

The existing research on enhancing ATM security through fingerprint authentication, as outlined in the Literature Synopsis, revealed certain inconsistencies. Consequently, there was a pressing need to enhance ATM security with a more effective and cost- efficient solution. The proposed approach involves integrating fingerprint authentication, but with a deviation in the method of delivering OTP's compared to previous studies. OTP's are now sent via two channels: the client's registered email address and phone number. The methodology entails offering new clients the option to register with the bank through a Python GUI (ATM Screen). For registered clients, the ATM Fingerprint Sensor first verifies their biometrics. Subsequently, an OTP is sent to their registered contact details. In the event of an incorrect entry for the first OTP, the client has two additional attempts to input it accurately. If the third attempt fails, the client (or suspected hacker) is barred from conducting any transactions, and a Security Theft Alert email is dispatched. Additionally, the URL www.msbank.co.in facilitates online registrations for clients and the creation of API's for securely storing data of new and enrolled clients. This system ensures that clients can still access OTP's even in scenarios where Wi-Fi is unavailable, by utilizing mobile OTP's, or retrieve lost OTP's from their logged email address. In conclusion, the research findings validate the feasibility of this proposed approach.

ACKNOWLEDGEMENT

With immense pleasure and a deep sense of gratitude, we wish to express our sincere thanks to our supervisor Prof. R.K. Singh, DTU, without his motivation and continuous encouragement, this research would not have been successfully completed. We are grateful to the Chancellor of Delhi Technological University for motivating us to carry out research in the Delhi Technological University and also for providing us with infrastructural facilities and many other resources needed for my research. We like to acknowledge the support rendered by our friends and faculties in several ways throughout our research work. We wish to extend my profound sense of gratitude to our parents for all the sacrifices they made during our research and also providing us with moral support and encouragement whenever required.

Summary

In the ever-evolving realm of cloud computing, the challenge of intrusion detection has grown increasingly intricate and vital. With the proliferation of cyber-attacks and the widespread use of virtualized environments, there is a pressing need for network security solutions that are not only innovative and robust but also easily comprehensible. These solutions must possess the ability to effectively detect malicious activities, provide visibility into network operations, adapt to changing requirements, and promptly alert stakeholders to any suspicious behavior. In this study, we introduce a groundbreaking approach known as fuzzy logic-driven optimized long short-term memory (LSTM)—FLOLSTM, specifically designed for hypervisor-based environments. By integrating fuzzy logic with an optimized LSTM neural network, FLOLSTM aims to significantly enhance the detection of attack traffic within hypervisor networks by combining the interpretability and uncertainty management capabilities of fuzzy logic with the temporal pattern recognition prowess of LSTM. The research methodology involves meticulous data collection from hypervisor monitors, followed by rigorous cleaning and preprocessing to enhance data reliability. Subsequently, the preprocessed data is input into the FLOLSTM classifier to identify malicious activities. Furthermore, the performance of the LSTM is fine-tuned using the waterwheel plant optimization (WPO) algorithm. Experimental evaluations compare the efficiency of the proposed FLOLSTM with existing techniques across various metrics including accuracy, recall, precision, F-measure, specificity, false-positive rate (FPR), and false-negative rate (FNR). Overall, the FLOLSTM model represents a significant advancement in intrusion detection for cloud environments, offering a potent blend of interpretability, accuracy, and efficiency. Its superior performance underscores its capacity to enhance network security and effectively mitigate cyber threats in dynamic and virtualized settings, thereby making a substantial impact on the field of cyber security.

1 | INTRODUCTION

Cloud computing systems allow users to access a pool of computing resources on demand on a recurring basis. Cloud service providers manage the resources and users may access them through the Internet.[1] As a result of its multi-tenant nature, cloud computing systems can accommodate multiple virtual machines (VMs) on a single physical infrastructure. Since the world and the internet are deeply integrated, the network framework is always vulnerable to attack. Due to the fact that cloud computing systems are exposed to multiple security threats, cloud computing architecture is characterized by virtualization technology. As a result of this technology, several virtual machines are able to share physical machine resources, such as the CPU, memory, I/O, and network interfaces, between them. For cloud service providers (CSPs), protecting guest operating systems from advanced sophisticated attacks is one of the greatest challenges they face.[2–4]

A key component of virtualization[5] is the hypervisor, which enables resource sharing among virtual machines. Furthermore, it exposes CSP to a higher security risk as a result. As soon as someone gains access to the hypervisor, they are completely in control of the virtual environment as soon as they obtain it. In the context of cloud computing, an intrusion may come from a number of places, such as virtual machines,[6] virtual networks,[7] or malicious hypervisors.[8] Due to their ease of rental and direct CSP connection to the outside world, virtual machines are a favorite target for attackers.[9] Attacker uses a variety of techniques to find virtual machine vulnerabilities so that they can be used as a backdoor to the virtual machine. These days, the area of interest is the technical problem of identifying these attacks. Intruders violate all of the core privacy requirements of secrecy, integrity, accessibility, and denial of service when they violate the trust imposed by the Internet.[11]

Intrusion Detection and Prevention System is a crucial component for safeguarding the entire virtual system from various threats and attacks.[10] This system should be able to identify malware, analyze logs, check files for integrity, analyze incoming traffic, and respond actively, among other things. It should also have the ability to identify both known and unknown assaults. In the absence of prevention, detection alone is insufficient to protect the virtual environment. Numerous methods have been put out in recent years to identify anomalies due to the rise in security concerns and the massive volume of communication.[12] These methods have a disadvantage in that the system must constantly update its knowledge of the attack types when new ones appear. Moreover, these systems cannot detect precise changes within the cloud hosting environment due to their narrow field of view. For the purpose of detecting malicious traffic in hypervisor systems, we provide a Fuzzy Logic-driven Optimized LSTM in order to get around these problems. Fuzzy logic's strengths in handling uncertainty and an optimized LSTM's ability to capture temporal trends are combined in this classifier to effectively detect malevolent conduct.

The main contributions of the paper are as follow:

- We present the integration of fuzzy logic with an optimized LSTM neural network to create a hybrid model that leverages the strengths of both approaches, enhancing the detection of attack traffic within hypervisor networks.
- Initially, data is collected from hypervisor monitors, then cleaned and preprocessed to improve data reliability.
- After that, the preprocessed data is sent into the FLOLSTM classifier to identify the detection of malicious activities.
- To optimize LSTM model, we introduce the waterwheel plant optimization (WPO) algorithm for enhancing both efficiency and effectiveness.
- We perform a comparative evaluation of the proposed FLOLSTM against existing techniques, assessing performance metrics such as precision, accuracy, F-measure, recall, specificity, FNR, and FPR.

The complete paper is structured as follows: The study on privacy intrusion detection in hypervisor networks, which had done by various researchers, is compiled in Section 2. Section 3 provides specifics on the proposed methodology for our research. Section 4 illustrates and explains the consequences and results of several strategies. The conclusions and recommendations for further research are presented in Sections 5.

2 | LITERATURE REVIEW

This section discusses several studies related to intrusion detection in hypervisor networks. These studies focus on various methods for detecting and preventing malicious attacks, as well as on developing algorithms that can be used to analyze network security data.

Pilli et al.[13] proposed Program Semantic-Aware Intrusion Detection at Network and Hypervisor Layer (PSI-Net Visor), a method based on out-VM monitoring, to detect assaults at the network or virtualization levels in cloud computing. PSI-Net Visor performed network monitoring by employing a behavior-based intrusion detection technique at the connection layer of a centralized Cloud Network Server. PSI-Net Visor employed Virtual Machine Introspection libraries using software break point injection to acquire process execution traces from the hypervisor. Depth first search (DFS) was also utilized to generate program semantics using execution trace flow of control graphs. It used dynamic evaluation and machine learning methods to comprehend the nature of anomalies, making it resistant to obfuscation and encryption-based assaults. This method takes a long time to train larger databases of different VM instances.

Garg and colleagues[14] developed a network intrusion detection system model that accurately predicts anomalous attacks with low misclassification error. They started by deleting duplicate entries and one that contained an incident using a local host IP. They employed neural networks,

15320634, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.8194 by Delhi Technological University, Wiley Online Library on [13/06/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

a naive Bayes classifier, a decision tree, an SVM, an extreme gradient boosted tree, an AdaBoost classifier, a random forest classifier, and logistic regression models in this technique. When running cross-validation on each model, random states were employed to avoid over-fitting. The results showed that the extreme gradient boosted tree separated out from the crowd and performed admirably in contrast to the other models in this study. However, the dataset employed in this work lacks real-time data that simulates recent threats.

Singh and Ranga[15] presented a method for detecting assaults and intrusions in cloud computing systems using an ensemble learning methodology. The goal of this work is to implement an efficient network-based intrusion detection system using an ensemble-based machine learning method with four types of classifiers such as boosted tree, subspace discriminant, bagged tree, along with RUSBooted combined using a voting scheme. An aggregated prediction can be made at the end as a result of the voting algorithm's integration into the framework. CICIDS 2017 and CloudSim were used to simulate and test the proposed model. It has been observed that the Intrusion Detection System does not perform well when network packets have been encrypted.

Abbas and colleagues[16] proposed a new hybridized technique for intrusion detection and attack classification. The dataset was first preprocessed with the data transformation methodology and the min–max approach. The random forest recursive feature reduction method was then used in a second stage to select optimal features which improve the model's performance. Then, to detect intrusions, fine Gaussian support vector machine (FGSVM) kinds were utilized, and adaptive neuro-fuzzy system (ANFIS) types were employed to categorize probe, R2U, U2R, and DDOS attacks. As a result, FGSVM and ANFIS could be strong solutions with large efficiency gains. However, there are some limitations to this approach. However, the time required identifying optimal features may be too long, leading to slow intrusion detection.

Niazi and Faheem[17] developed a Bayesian game-theoretic detection of invasions method in smart grids for hypervisor-based software defined networks. The tactical interaction among a hypervisor observing its vSDN controllers with the origin of new traffic requests made by switches infiltrated by a DDoS attacker was modeled as a noncooperative dynamic Bayesian intrusion detection scenario in this work. This game model allowed a hypervisor to optimally deploy the resources it had to track guest vSDN controllers. The simulation findings demonstrated that while this game model allows a hypervisor to raise the chance of identifying distributed attacks and limit false positives, it also has a high monitoring cost.

Suri and colleagues[18] used WLI-FCM and Artificial Neural Networks to create a Cloud Intrusion Detection System for the Internet. A hybrid technique that merged the WLI-FCM clustering method with the back propagation artificial neural network was utilized to enhance the accuracy of detection of the cloud intrusion detection method. This model is made up of three steps. In the first step, a fuzzy clustering module is utilized to partition big datasets into small clusters in order to increase ANN capacity for learning. A variety of Artificial Intelligence modules are trained based on cluster values in the second step. Finally, the final result was derived by combining the results of the different Artificial Intelligence modules from the second step. This method achieved better performance but the complexity of the model can be difficult to manage and may require additional resources to maintain.

Jaber and Rehman[19] created a system for intrusion detection that uses a fuzzy c-means clustering (FCM) method in conjunction with support vector machines (SVMs). Hybrid clustering has been used for the creation of the hypervisor inspector, combining SVM and FCM. In the first phase, the FCM clustering module was used to separate big datasets into small clusters so that SVMs could learn effectively. This process enhanced the performance of the SVM through the fuzzy clustering module. The second phase involved training different SVM modules based on the cluster values. In the third module, the hypervisor inspector's results are combined. As a result, while this technique was capable of detecting diverse threats having high detection accuracy along with low false alarm rates, it was not designed for real-time applications.

Rawashdeh et al.[20] demonstrated an anomalous intrusion detection system in the hypervisor layer as a method for inhibiting DDoS between virtual machines. They created IDS using soft computing approaches, as well as PSO using a feed forward neural network. An evolving neural network was utilized to classify the communication transferred among virtual machines. Particle swarm optimization was combined using neural networks using the evolutionary neural network. By using particle swarm optimization, the neural network weights were selected in such a way that they could achieve high levels of accuracy in both classification and detection. However, it is restricted to only two types of DDoS attacks in this dataset.

The existing models developed by researchers have shown promising results in enhancing security measures and detection capabilities in network environments. The IMFL-IDSCS technique[21] introduces fuzzy logic-based IDS for cloud security, achieving high detection efficiency with accuracy. A hybrid intrusion detection model[22] combines signature-based and anomaly-based detection methods, demonstrating high detection rates across various datasets. Cloud-based IDS with ML techniques[23] explores performance evaluation and enhancement opportunities, proposing a system with improved performance. A hybrid deep learning approach[24] achieves high accuracy rates in network security, particularly effective in preventing DoS/DDoS attacks in SDN environments. Additionally, the CoAP-IoT Anomaly Detection Dataset[25] offers a comprehensive dataset for anomaly detection in CoAP traffic, utilizing shallow machine learning techniques for validation and analysis.

3 | PROPOSED METHODOLOGY

This research introduces a novel methodology that combines fuzzy logic and LSTM recurrent neural networks to detect attack traffic in hypervisor network. Figure 1 shows the overall structure for proposed methodology. The process begins with data collection from hypervisor monitors, followed by data cleaning and preprocessing. Then the preprocessed data is sent into the FLOLSTM classifier, an innovative fusion of fuzzy logic

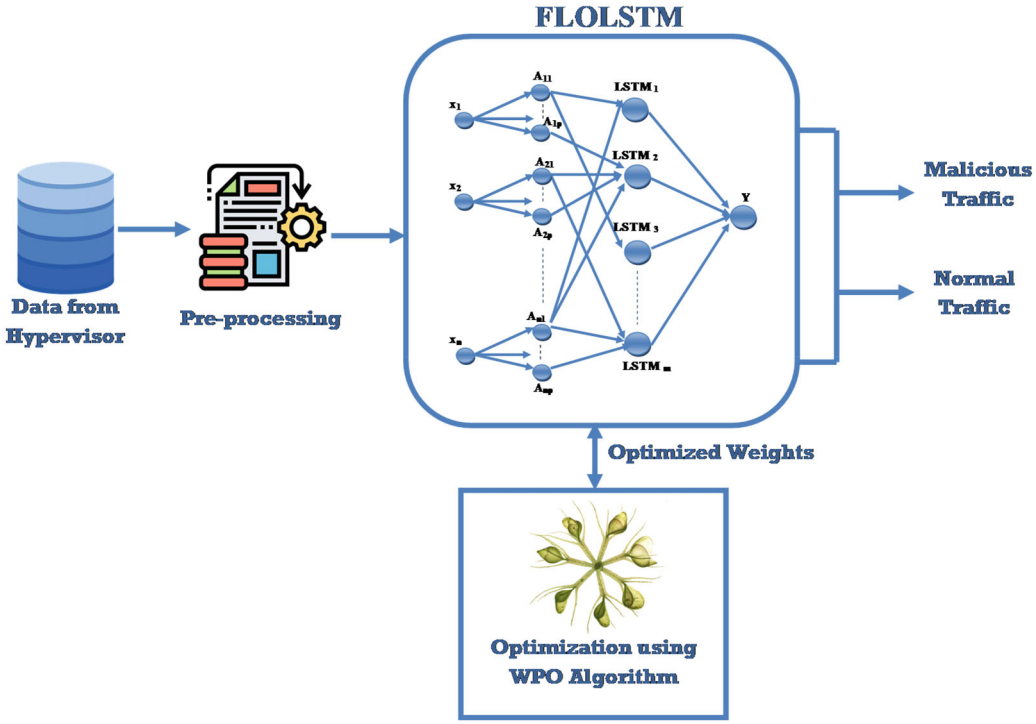

FIGURE 1 General structure of proposed methodology.

and optimized LSTM, designed to identify the detection of malicious activities. Moreover, the performance of the LSTM is optimized by using WPO algorithm. Fuzzy logic lends interpretability and adeptly manages uncertainties, while optimized LSTM excels at capturing temporal patterns. This classifier combines the strengths of fuzzy logic for handling uncertainty and optimized LSTM for capturing temporal patterns, enabling effective detection of malicious behavior.

3.1 | Data collection

In this work, we gather data from the hypervisor monitors, which are responsible for monitoring the traffic flow in the hypervisor network. These monitors continuously capture network-related metrics and events, such as "size" (packet size), "fragmented" (whether the packet is fragmented or not), "seqNumber" (sequence number of the packet), and "ackNumber" (acknowledgment number of the packet).The data collected here would typically consist of a mix of normal traffic and instances of attack traffic. Attack traffic includes any malicious or abnormal network activities that can potentially harm the system or compromise its security.

3.2 | Data cleaning and preprocessing

In this step, we clean and prepare the collected data from the hypervisor monitors for further analysis and modeling. Data collected from hypervisors may not always be in a perfect state. It may contain errors, contradictions, or missing values. Data cleaning entails operations such as deleting duplicates, dealing with missing data, and fixing errors in order to guarantee that the information remains accurate and reliable. After cleaning, the data might still need additional processing to be useful for further analysis. Preprocessing can involve tasks such as normalization and scaling data to a standard range and converting data into a suitable format.

- **Null Value Removal:** We check the dataset for any missing or null values. If any are found, we apply appropriate techniques (e.g., imputation) or simply remove the affected data points.
- **Remove Duplicate Values:** Sometimes, data collected from monitors might contain duplicate entries due to network latency or other reasons. Removing duplicates ensures that our model does not learn from redundant information.

15320634, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.8194 by Delhi Technological University, Wiley Online Library on [13/06/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

- **Label Encoder:** Categorical data (if present) is frequently converted into numerical format to aid in the training of machine learning models using approaches such as Label Encoding.
- **MinMax Scalar:** To make sure that all features are of a same scale, feature scaling is used. The MinMaxScaler scales numerical features to a range typically between 0 and 1.
- **Random Over Sampler:** If we encounter class imbalance in the dataset (i.e., when the number of samples in one class outweighs the other significantly), we use techniques like Random Oversampling to create synthetic examples of the minority class. It assists in balancing the class distribution and keeps the model from favoring the majority class.

3.3 | FLOLSTM model implementation

After preprocessing, the preprocessed data is sent into FLOLSTM for further classification. FLOLSTM is a novel methodology that combines fuzzy logic and optimized LSTM recurrent neural networks to detect malicious traffic in hypervisor network. Fuzzy modeling using LSTM cells is a technique that combines the principles of fuzzy logic with the capabilities of optimized LSTM neural networks. Fuzzy logic is a mathematical framework for dealing with uncertainty and imprecision, while LSTM is a type of recurrent neural network that is well-suited for modeling sequences and time series data.

Fuzzy logic plays a key role in interpreting linguistic variables and defining rules for decision-making based on expert knowledge or data-driven approaches. By fuzzifying input variables, applying fuzzy inference rules, and defuzzifying outputs, fuzzy logic helps the model make sense of complex data and generate actionable insights. On the other hand, LSTM networks are adept at capturing temporal dependencies and patterns in sequential data, making them well-suited for detecting anomalies and suspicious activities in intrusion detection.

By employing LSTM's ability to learn long-term dependencies, the FLOLSTM model can effectively analyze network traffic over time and identify potential security threats. The synergy between fuzzy logic and LSTM in the FLOLSTM model enhances decision-making by combining the interpretability of fuzzy rules with the predictive power of LSTM. Fuzzy logic provides a transparent framework for reasoning and rule-based decision-making, while LSTM offers the capability to learn from historical data and make predictions based on sequential patterns. Combining these two approaches can be useful in situations where we need to make predictions or decisions based on uncertain or imprecise information.

The FLOLSTM system, depicted in Figure 2, consists of four key layers, each with a specific role.

- **Input Organization:** The first layer of FLOLSTM arranges incoming data, gathered from hypervisor monitors, ensuring it is ready for processing.
- **Fuzzification:** Fuzzification is the process of converting crisp input signals into fuzzy sets using membership functions. In the second layer of FLOLSTM, data is transformed into fuzzy representations, allowing the system to handle uncertainty more effectively. The Gaussian membership functions define the degree of membership of each input signal to each fuzzy set.
- **IF and THEN Calculation:** The third layer of FLOLSTM is the core of the system, where it evaluates fuzzy rules, determining the degree of rule satisfaction and deriving corresponding actions. The fuzzy logic operation "AND" is used to calculate the value of the IF and THEN portions.
- **Output Estimation:** In the final layer, the FLOLSTM system combines fuzzy logic's interpretability with optimized LSTM's ability to capture temporal patterns, resulting in precise predictions and decisions, making it valuable for tasks like malicious activity detection in a hypervisor network.

In discrete time, a nonlinear function can be used to depict a system in this way:

$$y(k) = \varphi[X(k)] \tag{1}$$

Further, in addition, we define the state vector as $X(k)$: where $\varphi[\cdot]$ is a nonlinear difference equation of unknown variables.

$$X(k) = \left[y(k-1), \ldots y(k-a_y), x(k), \ldots, x(k-a_x)\right]^T = [x_1. \ldots x_n]^T \tag{2}$$

Assuming that $x(k)$ and $y(k)$ represent the system's input and output values, respectively, a_y represents the delayed output value, a_x represents the delayed input value, and n represents the total amount of items x_n in $X(k)$.

To represent the system, we employ fuzzy IF-THEN rules identical to those used in a normal TS fuzzy system, with the pth rule having:

$$\text{Rule}_p : \text{If } x_1(k) \text{ is } A_{1p} \,\&\, x_2(k) \text{ is } A_{2p} \,\&\, \ldots\ldots \,\&\, x_n(k) \text{ is } A_{np}, \text{ then } h_p(k) = \rho_p(k).$$

15320634, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.8194 by Delhi Technological University, Wiley Online Library on [13/06/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

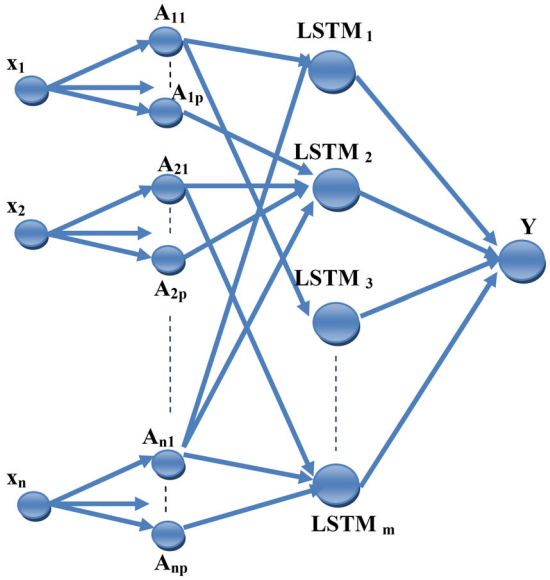

FIGURE 2 FLOLSTM classifier.

Assuming that each fuzzy rule's subsequent component is represented by the function $\rho_p(k)$, where $h_p(k)$ is the estimation function. The fuzzy sets for each x_n in (2)'s fuzzification is the sets A_{np}, for $n = 1 \ldots k$.

The following describes the membership functions associated with each A_{np}.

$$\mu_{A_{np},x_n}(k) = \exp\left(-\frac{\left(x_n(k) - \varsigma_{np}\right)^2}{2v_{np}}\right) \tag{3}$$

The value of the width is $v_{np} \in \Re+$, while its center is $\varsigma_{np} \in \Re$ in this Gaussian function. The T-norm yields the influence of every input element to the assumption part (IF part) of a fuzzy rule in (3) for the final assessment of the system.

$$z_p(k) = \prod_{n=1}^{k} \mu_{A_{np},x_n}(k) \tag{4}$$

It is possible to describe the values of each member of (4) in each fuzzy set more broadly using vectorial methods:

$$\varsigma_n = \exp\left[\left(X(k) - \chi_n\right)^2 \otimes \left(-\frac{1}{2}\gamma_n\right)\right] \tag{5}$$

Using $\chi_n, \gamma_n \in \Re^n$ as the corresponding width and center vectors for $\varsigma_n \in \Re^n$. In the fuzzy set A_n, every element of $x_n(k)$ is represented by the vector ς_n, and $\otimes$, the operator for the element-to-element product in vectors is denoted by gf. The fuzzy-network's parameters can be adjusted with the help of this representation. $h_p(k)$ is a representation of the following part (THEN part) of one fuzzy rule in (3).

The fuzzy system (3) is defuzzified using p rules to yield the estimate of (1).

$$\hat{y}(k) = \frac{\sum_{p=1}^{n} z_p h_p(k)}{\sum_{p=1}^{n} z_p} = \sum_{p=1}^{n} \bar{z}_p h_p(k) \tag{6}$$

Where,

$$\bar{z}_p = z_p/(z_1 + z_2 + \ldots \ldots + z_n) \tag{7}$$

Additionally, Figure 3 depicts the LSTM cell in the subsequent section. The "gate" mechanism is used by the cells to process data and allows useful information to flow through their structure. Compared to a traditional RNN, this cell can handle both short- and long-term data dependencies more effectively. The cells can be arranged as an array or as a network to cooperate with one another.

15320634, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.8194 by Delhi Technological University, Wiley Online Library on [13/06/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

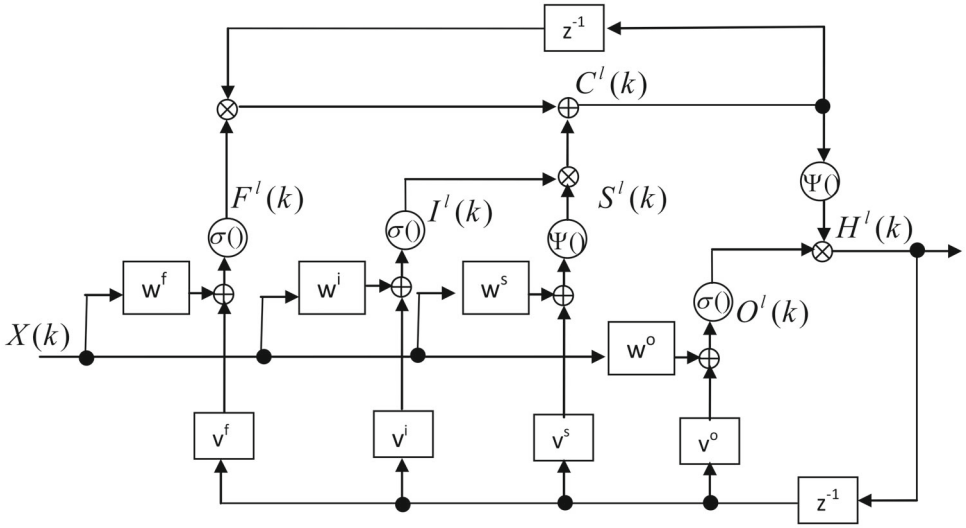

FIGURE 3 LSTM cell for the THEN part.

There are several stages in the LSTM network, which are described as follows:

$$F^l(k) = \sigma\left(w^f X(k) + u^f H(k-1)\right) \tag{8}$$

$$I^l(k) = \sigma\left(w^i X(k) + u^i H(k-1)\right) \tag{9}$$

$$S^l(k) = \psi\left(w^s X(k) + u^s H(k-1)\right) \tag{10}$$

$$C^l(k) = F^l(k) \otimes C^l(k-1) + I^l(k) \otimes S^l(k) \tag{11}$$

$$O^l(k) = \sigma(w^o X(k) + u^o H(k-1) \tag{12}$$

$$H^l(k) = O^l(k) \otimes \psi\left(C^l(k)\right) \tag{13}$$

In this case, the parts of the network represented by the, $I^l(k), F^l(k) S^l(k), O^l(k), C^l(k), H^l(k) \in \Re^p$ are the internal input fitness, internal state fitness, internal input, output fitness, internal state, and output of the LSTM network, respectively. As diagonal matrices, $u^f, u^i, u^s, u^o \in \Re^p$ as vectors, $w^f, w^i, w^s, w^o \in \Re^{p \times n}$; $u^f, u^i, u^s, u^o \in \Re^{p \times p}$ depending on the situation, are the synaptic weights. Since $X(k) \in \Re^n$ is the input in Equation (2), the functions $\sigma(\cdot)$ and $\psi(\cdot)$ are the hyperbolic tangent function and sigmoid function, respectively.

The fuzzy system's output is derived from (6).

$$\hat{y}(k) = Z_F H^l(k) \tag{14}$$

The elements of the IF sections are represented by $Z_F \in \Re^n$, while the THEN parts are represented by $H^l(k) = \left[h_1(k), \ldots, h_p(k)\right]^T$. Both the total number of fuzzy rules and the amount of LSTM cells can be expressed as $p = k^n$ for a single estimation; for multiple estimations, the definition is $p = m(k^n)$, where m represents the total number of estimations ($\hat{y}(k) = \Re^m$), as was previously mentioned (6). Based on fuzzy systems function approximation theories, the detected nonlinear process (1) can be expressed as follows:

$$Y(k) = Z_F(w^*) H^l(w^*) + \mu(k) \tag{15}$$

The unmodeled dynamic $\mu(k)$ can be minimized by the unknown weights, represented by w^*. In this stage, this system effectively combines the strengths of fuzzy logic, adept at managing uncertainty and interpreting data, with the temporal pattern capturing capabilities of LSTM cells. As a result, the system is well-equipped to make informed and precise predictions, decisions, or assessments, making it especially valuable in complex scenarios such as the detection of malicious activities in a hypervisor network.

3.3.1 | Optimization with the WPO algorithm

To enhance the performance of the FLOLSTM, its weights are optimized by using WPO algorithm. This process fine-tunes the weights, aligning them for optimal efficiency and effectiveness. It empowers the FLOLSTM to capture intricate temporal patterns and expertly manage uncertainties in data sequences. The main source of inspiration for the basic idea of WPO is the method used by waterwheel plants to discover, catch, and subsequently move its prey of insects to a more convenient position prior eating it.

The tiny, translucent flytrap-like traps which waterwheel plants carry are attached to broad petioles. In order to guard against damage or accidental activation from other water plants, a ring of hair-like bristles encircles the trap. The outside edges of the trap are coated in many hook-like teeth this, like flytrap teeth, interlock when the trap shuts over its prey. In Figure 4, the waterwheel plant is shown.

The steps involved in WPO are explained as follows:

Initialization

The population, also known as the Q matrix, is initially initialized by Waterwheel plant. Consequently, every waterwheel stands for a vector-based solution. Here, weights of the FLOLSTM (w^f, w^i, w^s, w^o) in the network should be taken into account as the solutions in this study. The initial solution format is

$$Q_i = \{q_1, q_2, \ldots, q_n\} \tag{16}$$

Here, Q_i is the population of the solution, n represents the variables, then

$$q_1 = \left\{w_1^f, w_1^i, w_1^s, w_1^o\right\} \tag{17}$$

Fitness function

In each iteration, the fitness value of a solution is meticulously calculated, and the overall fitness function is determined by selecting the maximum accuracy score achieved among these solutions and it can be represented as;

$$fitness = Max(Accuracy) \tag{18}$$

Updation phase

Phase 1: Position identification and hunting of insects. Waterwheels have an excellent sense of smell, which allows them to track and detect pests with ease. When an insect gets close to the waterwheel, its strikes and follows its prey. Through the integration of the waterwheel's assault on the insect, the WPO improves its capacity to investigate the ideal area and prevents itself from becoming stuck in local optima.

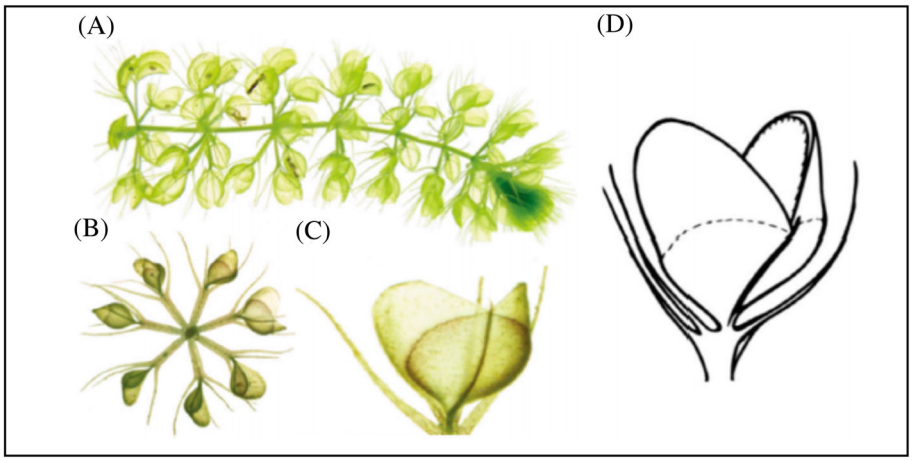

FIGURE 4 Image of a waterwheel plant (A) Lateral view of a shot floating freely and equipped with many traps. (B) Front view with both closed and open traps. (C) A solitary open trap. (D) Schematic illustration of an exposed trap.

15320634, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.8194 by Delhi Technological University, Wiley Online Library on [13/06/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

An equation is used to calculate the waterwheel's new location as it gets closer to the bug. The prior site is abandoned if moving the waterwheel to this alternative position increases the value of the objective function.

$$G = r_1 \cdot (Q(t) + 2E) \tag{19}$$

$$Q(t+1) = Q(t) + G \cdot (2E + r_2) \tag{20}$$

where the random variables r_1 and r_2 have values in the range of [0, 2] to [0, 1]. Additionally, E is an exponential variable having values in the range of [0, 1], and G is a vector that represents the circumference of the circle where the waterwheel plant would search for possible places. If the solution does not change shortly after three iterations, Equation (21) can be used to shift the placement of the waterwheel.

$$Q(t+1) = Gaussian(\mu_Q, \sigma) + r_1\left(\frac{Q(t) + 2E}{G}\right) \tag{21}$$

Phase 2: Position identification and hunting of insects. Waterwheels capture and transport insects to feeding tubes. WWPA uses this simulated behavior during local search to enhance its exploitation capability, enabling it to find solutions that are near to those previously discovered. By simulating the insect transport mechanism, a little shift in the waterwheel's location inside the search space is introduced. The WWPA designers assign each waterwheel in the population a random location in order to replicate the natural activity of waterwheels. If the objective function value of the waterwheel is higher at this new site, it will be transferred there and replace its old placement, as indicated by the equations that follow:

$$G = r_3 \cdot \left(EQ_{best}(t) + r_3 Q(t)\right) \tag{22}$$

$$Q(t+1) = Q(t) + EG \tag{23}$$

where the best solution is P_{best}, the current solution at iteration t is $P(t)$, and r_3 is a random variable having values in the range [0, 2].

Like in the exploration phase, the next mutation is applied to prevent being stuck in specific local minima if the solution fails to enhance after three repetitions.

$$Q(t+1) = (r_1 + E)\sin\left(\frac{B}{D}\theta\right) \tag{24}$$

where the random variables F and C have values between [−5, 5]. Equation 10 also shows that the value of K falls exponentially.

$$E = \left(1 + \frac{2 * t^2}{T_{\max}} + F\right) \tag{25}$$

Termination

The population update process persists until the algorithm's last iteration. At the conclusion of the WPO run, the output is the optimal solution, which encapsulates the optimized FLOLSTM model's weight configuration, reflecting the maximum attainable accuracy score.

Pseudo-code of WPO

Input: Weight parameter of FLOLSTM
Output: Optimized weight parameter of FLOLSTM

Initialize the weight parameter of FLOLSTM, the maximum number of iterations (T_{max}) and objective function f_n, the positions for n waterwheel plants, among other parameters.
Calculate the fitness f_n;
Find the optimal position Q_{best};
INITIALIZE t = 1;
While $t \leq T_{max}$ **Do**
  For ($i = 1: i < n + 1$) **Do**
  If ($r < 0.5$) **Then**
    Evaluate the waterwheel plant search space with equations (19) and (20);

15320634, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.8194 by Delhi Technological University, Wiley Online Library on [13/06/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

If the solution remains unchanged for three iterations, then adjust the location using equation (21);
End If
Else
Utilize the existing solutions to determine the optimal solution using equations (22) and (23);
If the solution remains unchanged for three iterations, then adjust the location using equation (24);
End If
End If
End For
Reduce the value of E exponentially by equation (25);
Update the parameters;
Calculate the f_n for each position;
Identify the optimal position Q_{best};
$t = t + 1$;
End While
Return the optimal solution Q_{best}.

Therefore, FLOLSTM weight parameters are optimized through the WPO algorithm. FLOLSTM performs exceptionally well in classifying input datasets using these optimized weights, effectively distinguishing normal network traffic from malicious traffic. In this manner, the model can make informed and accurate decisions regarding the nature of the incoming information.

For an illustration

Our input dataset consists of various network-related metrics and events, such as, "size (x_1)" "fragmented (x_2)," "seqNumber (x_3)," and "ackNumber (x_4)." This each input having fuzzy set which has three sets of linguistic variables "small," "medium," and "large" which can be represented as A_{np}.

Layer 1: Each of this input attributes x_1, x_2, x_3, and x_4 is mapped to a fuzzy set, which in this case comprises three linguistic variables. For example, x_1 having fuzzy sets of $\{A_{11}, A_{12}, A_{13}\}$ and x_2 having fuzzy sets of$\{A_{21}, A_{22}, A_{23}\}$, and so on.

$$\text{i.e.}, x_1 : \{A_{11}, A_{12}, A_{13}\} \text{ where}, A_{11} \rightarrow \text{small}, A_{12} \rightarrow \text{medium}, A_{13} \rightarrow \text{large}.$$

Layer 2: In this layer, the crisp numerical values of the input attributes, such as x_1, x_2, x_3, and x_4 are transformed into fuzzy sets based on the linguistic variables. Fuzzification involves quantifying the degree to which each data point belongs to these fuzzy sets, effectively capturing the uncertainty and imprecision in the data.

Layer 3: In this layer, the system evaluates the "IF" part of fuzzy rules for each input attribute. In parallel, the "THEN" part of fuzzy rules is determined, representing the action or decision that follows the fuzzy rules. For example:

$$\text{RULE} : \text{IF } x_1 \text{ is } A_{11} \& x_2 \text{ is } A_{23} \& x_3 \text{ is } A_{32} \& x_4 \text{ is } A_{41} \text{ THEN } h_p(k) = \rho_p(k).$$

This part synthesizes the linguistic terms and membership functions to produce numerical outcomes.

Layer 4: The final layer involves the estimation of the overall system behavior based on the results of the previous layers whether they represent normal or malicious network traffic. If the output is −1 then it signifies normal data; else if it is 1 then designates the data as malicious.

4 | RESULTS AND DISCUSSIONS

To evaluate the effectiveness of our proposed framework, we discuss the results of the proposed framework and compare it with existing frameworks. The Python language was utilized to implement the system. The experiments were conducted within an environment comprising an Intel Core i5 processor running at 2.21 GHz, 8 GB of RAM, operating on the Windows 10 platform. The ISOT Cloud IDS (ISOT CID) dataset is used here which is a cloud intrusion detection dataset that contains over 8 TB of data collected in a real cloud environment. The dataset includes network traffic at VM and hypervisor levels, regular traffic, activities, and multiple attack scenarios. Table 1 represents the parameter settings of our experiment.

Sample output window

Figure 5 displays the graphical user interface (GUI) when the data is categorized as benign, and Figure 6 displays the same GUI when the data is classed as malicious. The metric values shown next to each figure represent the accuracy, recall, F-measure, precision, FPR, and FNR of the GUI when classifying the data as either benign or malicious.

4.1 | Temporal analysis: Proposed FLOLSTM versus existing methods

In this research, we analyzed the hypervisor data in 4 phases that is Phase 1 (Day 1), Phase 2 (Day 2), Phase 3 (Day 3), and Phase 4 (Day 4) in order to observe how these metrics change over time or remain consistent over a period of time. We found that the proposed FLOLSTM model was able to predict the hypervisor attacks more accurately than the other approaches. We also observed a consistent trend in the data over the 4 days, indicating that the proposed FLOLSTM model is more reliable than the other approaches.

4.1.1 | Phase 1 analysis

Figure 7 showcases a robust performance of our proposed FLOLSTM model in differentiating between benign and malicious instances on Day 1. With 419,334 instances correctly identified as benign (True Positives), and an impressively low count of only five benign instances misclassified as malicious (False Positives), the FLOLSTM model displays high precision in its predictions. Notably, there are no instances of benign data incorrectly labeled as malicious (False Negatives), indicating an accurate identification of benign data. Moreover, the FLOLSTM model successfully identifies 418,809 malicious instances (True Negatives), demonstrating its proficiency in pinpointing harmful data.

The ROC curve of our proposed method in Day 1 can be seen in Figure 8. The ROC curve measures the accuracy of the model, and the higher the curve, the more accurate the model is. Our proposed FLOLSTM method has a ROC curve that is higher than other models, which indicates its accuracy.

4.1.2 | Phase 2 analysis

As shown in Figure 9, our FLOLSTM model performed well on Day 2 in identifying benign and malicious instances. Only 57,740 benign instances were misclassified as malicious (False Positives) in the FLOLSTM model, indicating high precision in its predictions. In addition, 15,633 benign data items were mistakenly classified as malicious (False Negatives), indicating accurate characterization of benign data. In addition, FLOLSTM is capable of identifying 620,239 malicious instances (True Negatives), proving its capability to identify malicious data.

See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

Our proposed method's ROC curve in Day 2 is shown in Figure 10. The ROC curve measures how well our model can distinguish between true and false predictions. Our proposed method achieved a high AUC value, which indicates that it is highly accurate in predicting the outcome of each day.

4.1.3 | Phase 3 analysis

Based on Day 3 results, Figure 11 shows a powerful performance for our proposed FLOLSTM model in distinguishing benign from malicious instances. FLOLSTM accurately identified 270,653 benign instances (True Positives), and misclassified only seven benign instances as malicious (False Positives). There are 27 instances of benign data mistakenly labeled as malicious (False Negatives), indicating accurate identification of benign data. Furthermore, FLOLSTM identifies 270,981 malicious instances (True Negatives), demonstrating its ability to identify harmful data.

The ROC curve demonstrates the performance of the proposed model in Day 3, which has been shown in Figure 12. It shows that the proposed model was able to correctly classify the samples with an overall high accuracy.

4.1.4 | Phase 4 analysis

Our proposed FLOLSTM model differentiates benign from malicious instances on Day 4 as shown in Figure 13. It accurately identified 312,386 benign instances (True Positives), and identified only 3975 benign instances misclassified as malicious (False Positives). There are 5082 false

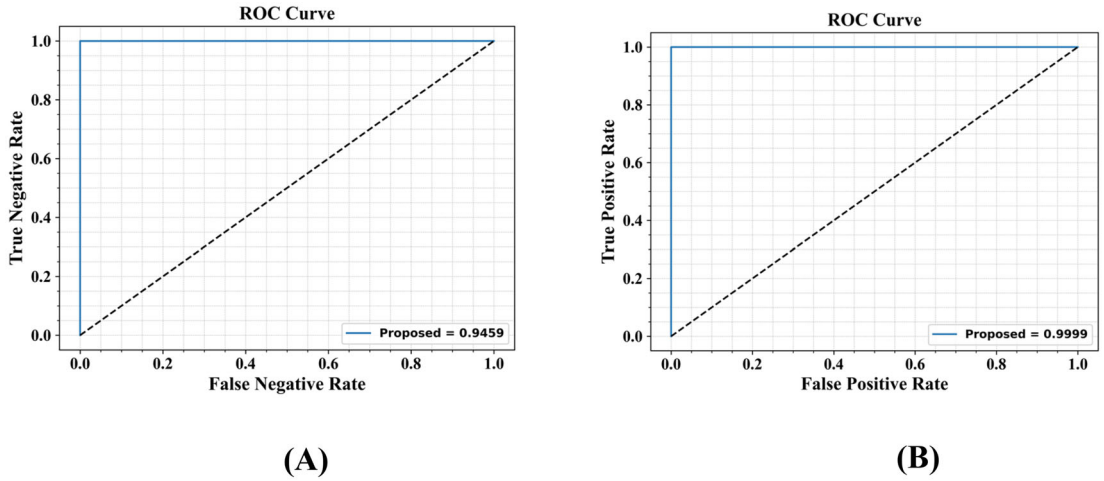

FIGURE 12 ROC curve of proposed FLOLSTM on Day 3 (A) TNR versus FNR (B) TPR versus FPR.

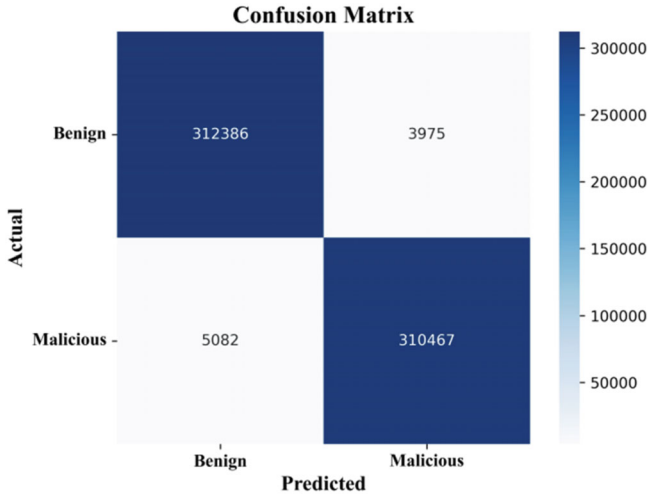

FIGURE 13 Confusion matrix of proposed FLOLSTM on Day 4.

negatives indicating an accurate identification of benign data. FLOLSTM also identified 310,467 malicious instances (True Negatives), demonstrating its effectiveness.

As can be seen in Figure 14, we are able to see the ROC curve for our proposed method in Day 4 of the analysis. The ROC curve shows that the method has high accuracy in predicting the Day 5 outcomes. This suggests that our method is effective in predicting the outcomes of similar scenarios.

4.2 | Metric-based evaluation: Proposed FLOLSTM versus existing methods

In this section, the performance of our proposed FLOLSTM is evaluated against Fuzzy-LSTM, LSTM and ANFIS in terms of accuracy, precision, recall, F-measure and specificity, FPR, and FNR. Figure 15 provides a comparative analysis of the proposed and existing techniques.

When analyzing Figure 15, our proposed "FLOLSTM" model achieves the highest accuracy of approximately 98.19%. Comparatively, "Fuzzy-LSTM" follows with an accuracy of about 91.9%, "LSTM" with 90.8%, and "ANFIS" with 89.3%. The proposed model outperforms all other models in accurately predicting both positive and negative instances.

Across precision, our Proposed "FLOLSTM" model attains about 98.24%, while "Fuzzy-LSTM" demonstrates 92.2%, "LSTM" with 91.2%, and "ANFIS" with 89.7%. For recall, "FLOLSTM" model exhibits approximately 98.19%, whereas "Fuzzy-LSTM" reaches around 92.1%, "LSTM" with 91.1%, and "ANFIS" at 89.5%.

15320634, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.8194 by Delhi Technological University, Wiley Online Library on [13/06/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

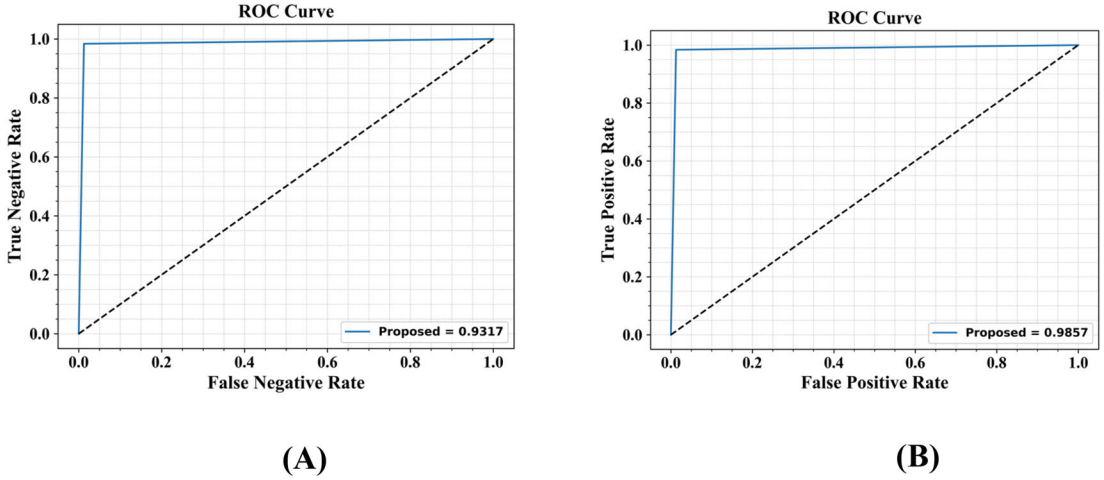

FIGURE 14 ROC curve of proposed FLOLSTM on Day 4 (A) TNR versus FNR (B) TPR versus FPR.

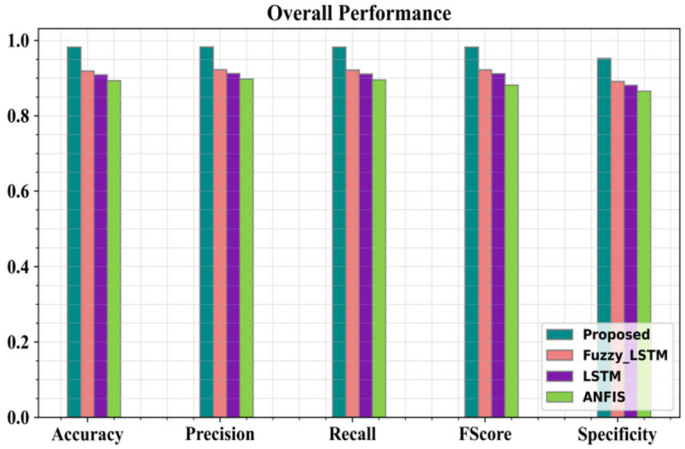

FIGURE 15 Comparative analysis of the proposed and existing techniques.

In terms of F-measure our "Proposed" model demonstrates about 98.22%, whereas "Fuzzy-LSTM" achieves around 92.2%, "LSTM" with 91.1%, and "ANFIS" at 88.1%. For specificity, our "FLOLSTM" model records approximately 95.19% specificity, while "Fuzzy-LSTM" shows around 89.1%, "LSTM" with 88.1%, and "ANFIS" at 86.5%.

The effectiveness of the "FLOLSTM" model over "Fuzzy-LSTM" might be attributed to its higher values across all metrics. This suggests that the proposed model performs better in both correctly identifying positive instances and accurately ruling out negative instances, signifying its superior predictive capability.

Based on an analysis of Figure 16, performance metrics such as FPRs and FNRs, our proposed approach is found to have a low FPR, 0.018, indicating a low probability of misclassifying benign instances as malicious.

The FNR for our proposed FLOLSTM method is 0.048, reflecting moderate misclassifications. Comparatively, the Fuzzy-LSTM method has a FPR of 0.079, suggesting higher false-positive rates, but a FNR of 0.049, which is higher rate than our method. In contrast to our proposed approach, the LSTM method displays marginally higher rates, registering 0.089 FPRs and 0.059 FNRs, suggesting a relatively high misclassification rate of benign instances.

The ANFIS method displays the highest FPR, 0.105, suggesting a pronounced tendency to misclassify benign instances as malicious, accompanied by 0.105 FNR. This shows that the proposed methodology can identify malicious instances more accurately than other approaches.

Figure 17 presents a comparative analysis of the proposed and existing techniques regarding both latency and memory usage. FLOLSTM stands out with significantly lower latency compared to other models like Fuzzy-LSTM, LSTM, and ANFIS. This decreased latency results in quicker processing times, enabling FLOLSTM to deliver rapid predictions or responses crucial for time-sensitive applications. Additionally, FLOLSTM demonstrates superior memory efficiency in comparison to Fuzzy-LSTM, LSTM, and ANFIS. Despite its lower memory requirements, FLOLSTM maintains high predictive accuracy, highlighting its ability to efficiently utilize computational resources without compromising performance.

15320634, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/cpe.8194 by Delhi Technological University, Wiley Online Library on [13/06/2024]. FIGURE 16 Comparative analysis of the proposed and existing techniques in terms of error metrics.

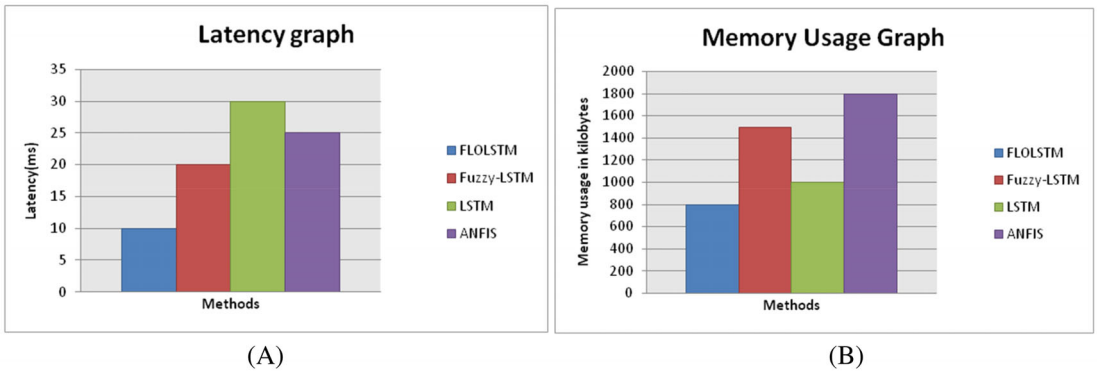

FIGURE 17 Comparative analysis of the proposed and existing techniques (A) Latency (B) Memory usage.

Therefore, the combination of low latency and minimal memory usage positions FLOLSTM as a model with high computational efficiency, making it an ideal choice for applications prioritizing speed, accuracy, and resource conservation.

The Figure 18 depicts a graph for accuracy versus epoch, while the Figure 19 depicts a graph for loss versus epoch. The graph for accuracy shows a steady increase in accuracy as the epochs increase. The graph for loss shows a decrease in loss as the epochs increase, indicating that the model is learning.

4.3 | Comparative analysis of proposed model with existing models

The comparative analysis presented in Table 2 showcases the performance metrics of the proposed FLOLSTM model in contrast to existing models for malicious traffic detection in hypervisor environments. The table provides insights into the accuracy, precision, recall, F-score, and specificity of various models, including PSI-NetVisor, WLI-FCM, FCM-SVM, IMFL-IDSCS, HIDM, and the proposed FLOLSTM model.

Among the existing models, WLI-FCM and FCM-SVM demonstrate high accuracy rates of 97.71% and 97.37%, respectively. While FCM-SVM exhibits notable precision and recall values, other models like PSI-NetVisor, CNN-GRU, and HIDM also show competitive performance in specific metrics. However, the proposed FLOLSTM model outperforms all existing models with an impressive accuracy of 98.19%, precision of 98.24%, recall of 98.19%, and F-score of 98.22%. This superior performance of the FLOLSTM model highlights its effectiveness in detecting malicious activities within hypervisor environments, showcasing its potential as a robust and reliable solution for enhancing network security. The results clearly indicate that the proposed FLOLSTM model excels in multiple key metrics compared to existing models, emphasizing its superiority in accurately identifying malicious traffic and distinguishing between benign and malicious instances.

4.4 | Discussion

During the implementation of the FLOLSTM model, several challenges emerged, each demanding unique solutions for successful deployment. One of the primary challenges faced was ensuring the quality of the data collected from hypervisor monitors. Incomplete or inaccurate data could significantly impact the effectiveness of the classifier. To address this challenge, improved data collection methods were implemented, along with rigorous data cleaning and preprocessing techniques to enhance data reliability. The FLOLSTM classifier exhibits promise in various applications, yet it is not without its limitations.

First, its performance heavily relies on the quality of data collected and preprocessed from hypervisor monitors. Incomplete or inaccurate data can significantly undermine the classifier's effectiveness, highlighting the need for improved data collection, preprocessing, and quality assurance techniques. Second, the computational complexity of the WPO algorithm poses a challenge, leading to longer processing times. Addressing these limitations presents avenues for future research. Enhancing data quality could involve refining data collection methods, implementing robust preprocessing techniques, and exploring data augmentation strategies. Similarly, optimizing the computational complexity of the optimization algorithm may require algorithmic enhancements, parallel computing approaches, or alternative optimization techniques. By tackling these challenges, future work can enhance the reliability, efficiency, and applicability of the FLOLSTM classifier across diverse domains, including real-time monitoring, anomaly detection, and predictive maintenance.

5 | CONCLUSION

In this work, we introduced Fuzzy Logic-driven Optimized Long Short-Term Memory called FLOLSTM for hypervisor-based environments. In order to enhance data reliability, data from hypervisor monitors was first carefully collected, cleaned, and preprocessed in order to improve their reliability. Following that, the preprocessed data have been sent to a FLOLSTM classifier, which will identify any malicious activities in the data that have been detected. Further, the performance of the LSTM was optimized by using a WPO algorithm known as WPO. We have compared the performance of FLOLSTM against other existing techniques such as Fuzzy-LSTM, LSTM, and ANFIS in terms of accuracy, precision, recall, F-measure, specificity, and FPR. According to the experimental results, FLOLSTM is more accurate than existing techniques, has a greater precision of 98.24%, a greater recall of 98.19%, a greater F-measure of 98.22%, and a greater specificity of 95.19%. Further, it was shown that the proposed FLOLSTM is essentially a promising device for detecting malicious activities that can be applied across a wide range of sectors. For future work, the focus could be on improving data quality through enhanced collection and efficient preprocessing methods, along with exploring optimization techniques to reduce the computational complexity of the WPO algorithm. These efforts aim to enhance the reliability and efficiency of the FLOLSTM classifier for various applications.

***Abstract*—Biometric authentication is critical for secure access in diverse domains, emphasizing the need for high accuracy to prevent security breaches. Multimodal biometrics fuse traits to fortify security, vital across diverse domains, surpassing unimodal systems' vulnerability. This paper introduces a novel approach that combines Contrast Limited Adaptive Histogram Equalization (CLAHE) and Harris Hawk Optimization(HHO) (CLAHE-HHO) for image preprocessing. It is followed by an innovative score-level fusion designed for the classification of Iris and Palmprint Biometric Modalities, using Transfer Learning based Lightweight ShuffleNet and MobileNetV3 Architecture. Initially, the Iris and Palmprint images undergo preprocessing using CLAHE, with the clip limit optimized through Harris Hawk Optimization. After preprocessing, Iris images are classified using ShuffleNet, while Palmprint images undergo classification using MobileNetV3. Scores from Palmprint and Iris modalities are fused using Weighted sum Score-level Fusion, with fusion weights determined via the novel Cauchy Search-based Golden Ratio Optimization (CGRO) technique. The performance of the system is evaluated on accuracy, Detection Error Tradeoff (DET) Curve, Equal Error Rate (EER), Total Training time. The proposed methodology proves that the multimodal authentication outperformed unimodal identification with a recognition accuracy of 100 % surpassing results obtained from individual iris and palmprint modalities.**

***Index Terms*—Multimodal biometric authentication, CLAHE, Metaheuristic Optimization, Transfer Learning, Score-level Fusion**

I. Introduction

In today's digital era, traditional authentication methods like passwords and tokens are increasingly vulnerable to cyber threats. Biometric recognition offers a robust alternative, leveraging unique human characteristics for identification. Biometrics can be broadly categorized into physiological and behavioral approaches [1]. Physiological modalities (e.g., fingerprints, iris scans, and facial geometry) analyze unique physical attributes, while behavioral modalities (e.g., signature recognition, keystroke dynamics, and gait analysis) focus on individual behavioral patterns. Biometric systems authenticate individuals by capturing and analyzing their unique biometric data, comparing it against stored templates for identity verification[2]. However, relying solely on a single biometric modality (i.e. unimodal biometrics) can introduce vulnerabilities. Factors such as sensor noise, environmental variations, and potential spoofing attempts can compromise system accuracy [3].

Multimodal biometric systems address limitations by combining two or more modalities, harnessing each trait's unique strengths for enhanced authentication robustness and security [4]. For example, the combination of palmprint and iris recognition significantly improves accuracy and security compared to individual modalities [5]. Deep learning algorithms play a crucial role in extracting complex patterns from multimodal biometric data, facilitating continuous learning and adaptation to enhance precision and robustness [6].

This paper explores a multimodal biometric recognition system utilizing palmprint and iris modalities. Our approach leverages the strengths of deep learning and metaheuristics for accurate classification and identification. Firstly, Harris Hawk Optimization (HHO) fine-tunes the clip limit parameter of Contrast Limited Adaptive Histogram Equalization (CLAHE) for image contrast enhancement, improving the quality of iris and palmprint images. Subsequently, efficient transfer learning-based ShuffleNet and MobileNetV3 architectures are employed for classification of iris and palmprint images, respectively. Finally, a novel cauchy search-based golden ratio optimization is employed for score level fusion, combining the classification scores from the individual models to enhance robustness and accuracy. The proposed methodology is thoroughly evaluated using various performance metrics.

The key findings of this research are outlined below:

1) *A Novel combination of CLAHE optimized by Harris Hawk Optimization is proposed for image contrast enhancement.*
2) *Efficient transfer learning based ShuffleNet and MobileNetV3 Lightweight Convolutional Neural Network (CNN) architectures are used for classification.*
3) *An innovative Cauchy Search based Golden Ratio Optimized Score level fusion is used for combining the scores from palmprint and iris modalities.*

The paper is organized as follows: Section II provides an overview of previous studies. Section III outlines the proposed methodology, including preprocessing, classification, and score level fusion. Section IV discusses the experimental setup, while Section V reports the obtained results. Section VI summarizes key findings and proposes future research directions, concluding the paper.

II. Literature Review

Numerous studies have explored various techniques and methodologies to improve the accuracy, robustness, and efficiency of biometric recognition systems. In this section, we review the existing literature related to multimodal biometric recognition, metaheuristic algorithms, and deep learning models.

Image enhancement, particularly contrast enhancement, plays a significant role in biometric-recognition systems. Lionnie et al. [7] conducted a study on contrast enhancement methods in various color spaces for biometric recognition systems. They evaluated techniques such as mathematical morphology, histogram equalization, image adjustment and CLAHE in the HSV, YCbCr, and RGB color spaces. Their findings indicated that histogram equalization yielded the best results, achieving approximately 89% precision in recognition. Fan et al. [8] introduced a method for smart image enhancement utilizing CLAHE based on an F-Shift transformation during decompression.

Many researchers have used CLAHE with predefined parameters for biometric recognition (Rahman et al.[9]; Ganesan et al.[10]; Devi et al.[11]). Automatic parameter selection for CLAHE is an area of limited exploration in the literature. However, Surya and Muthukumaravel [12] introduced Adaptive Sailfish Optimization-Contrast Limited Adaptive Histogram Equalization (ASFO-CLAHE) for hyperparameter tuning in image enhancement. This study focuses on improving the mammography image quality for early breast cancer detection.

Chollet [13] emphasized that deep learning models are often not trained from scratch due to the substantial datasets and time-intensive procedures. Researchers typically prefer pre-trained models like Inception, VGGNet, AlexNet, and DenseNet to expedite training. Training from scratch entails complex experimentation with parameters like weights, filters, and layers, which can be impractical for many applications. Nguyen et al. [14] demonstrated the effectiveness of utilizing five distinct pre-trained CNN models for iris recognition. The selected models included VGGNet, Inception, AlexNet, ResNet, and DenseNet, and their performances were compared.

Michele et al. [15] investigated the utilization of MobileNet V2 deep convolutional neural networks for palmprint recognition. Specifically, they explored the effectiveness of fine-tuning a pre-trained MobileNet neural network to adapt it to palmprint recognition tasks. Zang et al. [16] introduced a novel approach called Shuffle Dense Networks (SDN) for biometric authentication, combining ShuffleNet's computational efficiency and DenseNet's hierarchical feature utilization to enhance system performance.

In multimodal biometrics, integrating data from various modalities is crucial. Lip and Ramli [17] outline three fusion levels: feature, score, and decision. Feature-level fusion concatenates modalities' features before pattern matching, while score-level fusion averages biometric scores after pattern matching. Decision-level fusion combines modalities' final decisions using logic AND and OR operations. The study highlights the effectiveness of score-level fusion in discriminating between genuine and imposter scores compared to other fusion levels.

Peng et al. [18] simplified multimodal biometric score fusion by utilizing t-norms, reducing computational complexity while enhancing authentication accuracy. Eskandari and Toygar [19] improved recognition accuracy by combining face and iris modalities, employing particle swarm optimization (PSO) for feature selection and the weighted-sum rule for score fusion. Anzar and Sathidevi [20] proposed an optimization scheme for determining integration weights in multibiometric systems with score-level fusion, optimizing weight factors using linear programming techniques to improve recognition accuracy with fingerprint and voice biometrics.

III. Proposed Methodology

The proposed methodology introduces a novel combination leveraging Harris Hawk Optimization (HHO) to optimize the clip limit parameter of Contrast Limited Adaptive Histogram Equalization (CLAHE) for the preprocessing of Iris and Palmprint datasets. Following the preprocessing, Iris images undergo classification using ShuffleNet and Palmprint images are classified using MobileNetV3. The classification scores from both models are ensembled using a novel Cauchy based Golden Ratio Optimized (C-GRO) Score level fusion. The architecture of the proposed model is depicted in figure 1.

A. Image Preprocessing

The proposed model implements the novel combination of CLAHE and Harris Hawk Optimization (HHO). CLAHE [21] is a histogram equalization technique applied locally to enhance the contrast of images while limiting the amplification of noise in specific regions. Clip limit parameter sets the threshold above which histogram bins are uniformly redistributed, preventing excessive contrast enhancement.

Harris Hawk Optimization [22] is a relatively new population based metaheuristic algorithm. It is a nature-inspired optimization algorithm that mimics the collaborative hunting behavior of Harris's hawks.

The objective function measures the Features Similarity Index Matrix (FSIM) between the original and CLAHE-enhanced images. The FSIM includes calculations for the Gradient Magnitude (GM) features and Phase Congruency (PC). PC evaluates the similarity of local patterns and edge information using corner harris[23] while GM is a measure of the strength of intensity variations in the images based on Scharr operator.

$$FSIM(x,y)= \frac{2\cdot T_1\cdot PC_a(x,y)+T_2\cdot GM_a(x,y)}{T_1\cdot PC_a(x,x)+T_2\cdot GM_a(x,x)+T_1\cdot PC_a(y,y)+T_2\cdot GM_a(y,y)+\varepsilon} \quad (1)$$

$$PC_a(x,y) = \frac{\sum_i x_i \cdot y_i}{\sqrt{\sum_i x_i^2}\cdot\sqrt{\sum_i y_i^2}+\varepsilon} \quad (2)$$

$$GM_a(x,y) = \frac{2\cdot\sum_i \sqrt{x_i^2+y_i^2}}{\sum_i \sqrt{x_i^2}+\sum_i \sqrt{y_i^2}+\varepsilon} \quad (3)$$

where x and y represent corresponding pixels in the two images being compared. T_1 and T_2 are positive constants

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 11,2024 at 09:57:22 UTC from IEEE Xplore. Restrictions apply.

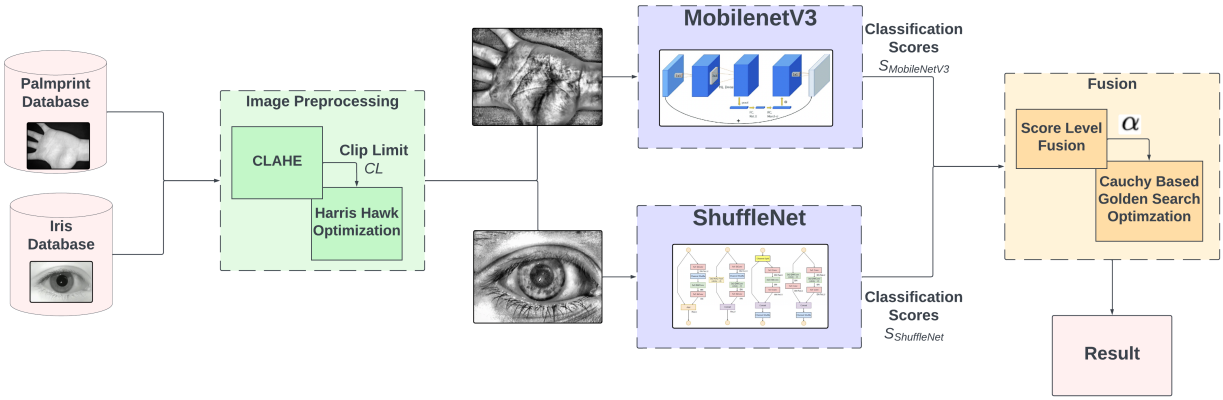

Fig. 1: Proposed Model

controlling the relative importance of PC and GM, typically set to 1. $PC_a(x, y)$ and $GM_a(x, y)$ denote the normalized similarity measures for PC and GM, respectively. ϵ is a small constant to avoid division by zero. FSIM values range from 0 to 1, with higher values indicating greater similarity between the images.

Hunting behavior of Harris hawk can be divided into 2 phases: *Exploration* and *Exploitation*. HHO dynamically balances exploration and exploitation based on a parameter called "Levy Flight or Espace Energy(E)".

$$E = |F_{rabbit(t)} - F_{avg(t)}| \tag{4}$$

Where, $F_{rabbit(t)}$ is the fitness of the rabbit at current iteration and $F_{avg(t)}$ is the average fitness of hawks. The rabbit is the leader hawk in the population.

1) **Exploration**
When the energy is high, exploration is prioritized. Hawks use a Levy flight mechanism to search for prey in a wider area. Levy flights allow for long jumps, enabling exploration of distant regions in the search space. The updated position of each hawk is calculated as:

$$X_i(0) = \text{rand}(1, d) \cdot (ub - lb) + lb \tag{5}$$

$$X_i(t{+}1) = X_{rabbit(t)} - S{*}Levy(d){*}(X_{rabbit(t)} - X_i(t)) \tag{6}$$

$$Levy(x) = 0.01 \times \frac{u \times \sigma}{|v|^{\frac{1}{\beta}}} \tag{7}$$

$$\sigma = \left(\frac{\Gamma(1+\beta) \times \sin(\frac{\pi\beta}{2})}{\Gamma(\frac{1+\beta}{2}) \times \beta \times 2^{(\frac{\beta-1}{2})}}\right)^{\frac{1}{\beta}} \tag{8}$$

Where, ub and lb are the upper and lower bounds respectively, $X_i(t+1)$ is the position vector of hawks in the next iteration t, $X_{rabbit(t)}$ is the position of rabbit, $X_i(t)$ is the current position vector of hawks, S is a random vector by size $1 \times d$, $Levy(d)$ is the levy flight function with d as the dimension of the problem, u, v are random values inside (0,1) and β is a default constant set to 1.5.

2) **Exploitation**
In the exploitation phase, hawks focus on refining their positions around the current best solution. Two main strategies are employed:
a) Soft Besiege: The hawks gradually encircle the prey, progressively reducing the search space. The updated position is calculated as:

$$X_{i(t+1)} = X_{rabbit(t)} - |Q| * E * (X_{rabbit(t)} - X_{i(t)}) \tag{9}$$

Where, Q is a random vector uniformly distributed between [-1, 1].
When the Levy flight energy value is low but not zero, the algorithm chooses to apply the "rapid dives" strategy. It involves attempting two jumps with varying degrees of randomness and modifying the hawk's position based on these jumps, while ensuring the positions stay within the specified boundaries.
b) Hard Besiege: If the prey escapes, a sudden attack (hard besiege) is simulated by randomly choosing a hawk from the population (excluding the best one) and updating the prey's position:

$$X_{rabbit(t+1)} = X_{rand(t)} - R{*}abs(D_{rabbit(t)}){*}levy(d) \tag{10}$$

Where, $X_{rand(t)}$ is the position of a randomly chosen hawk, R is a random scaling factor uniformly distributed between [0, 2] and $D_{rabbit(t)}$ is the difference between the current prey position and the average position of all hawks.

Algorithm 1 demonstrates working of the harris hawk optimization algorithm. The search space for clip limit ranges between [1, 40] , and the number of hawks is set to 50 while total number of iterations for finding the optimal clip limit equals 10. Figure 2 and 3 shows the original and preprocessed images. These image grey level features are further used for classification.

B. Classification

The proposed architecture employs two different lightweight neural architecture for classification of Palmprint and Iris biometrics to provide a contrast between the efficiencies of the neural networks and leverage advantages of both to provide an accurate and computationally efficient model. The preprocessed palmprint dataset undergoes classification through mobileNetV3[24] while iris

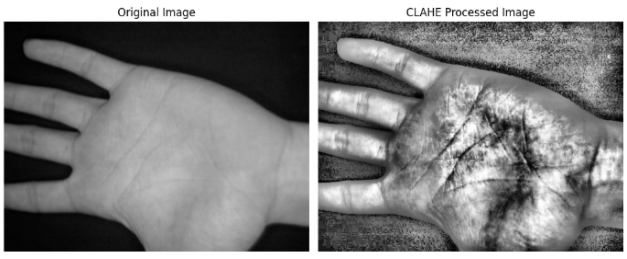

Fig. 2: Original and Preprocessed Palmprint Image

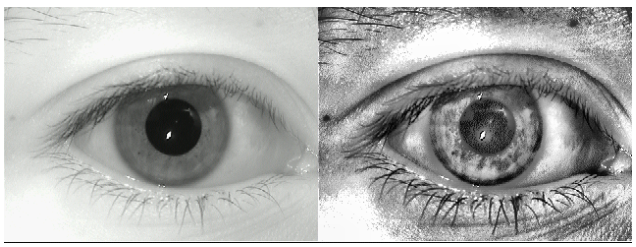

Fig. 3: Original and Preprocessed Iris Image

dataset uses shuffleNet[25] for classification. Both ShuffleNet and mobileNetV3 are lightweight CNN architecture suitable for mobile and edge devices.

MobileNetV3 prioritizes efficient feature extraction and leverages the Squeeze-and-Excitation (SE) blocks for adaptive recalibration of channel-wise feature representations. Mathematical equation for an SE block:

$$SE(x) = \sigma(F(pool(x))) * x \tag{11}$$

where,
x: Input feature map
$pool$: Global average pooling
F: Fully-connected layer with reduction ratio
σ: Sigmoid activation.

These blocks enhance the model's capacity to emphasize informative features. The architecture adopts the H-Swish activation function, a blend of ReLU and hard-tanh, offering improved performance with reduced computational cost.

$$\text{h-swish}\,(x) = x\frac{\text{ReLU6}\,(x+3)}{6} \tag{12}$$

It incorporates efficient inverted bottleneck blocks, employing depthwise separable convolutions and linear bottlenecks to reduce computational complexity while preserving accuracy.

Other classification technique used is shuffleNet. It optimizes computational efficiency by utilizing group convolutions and channel shuffling. Channel shuffling involves rearranging feature maps along the channel dimension, promoting efficient communication across the network while preserving performance. The channel shuffle operation is mathematically defined as follows:

$$\text{Step 1: } Y = \text{reshape}(X, (B, G, \frac{C}{G}, H, W)) \tag{13}$$

$$\text{Step 2: } Z = \text{transpose}(Y, (0, 2, 1, 3, 4)) \tag{14}$$

$$\text{Step 3: Shuffle}(X) = \text{reshape}(Z, (B, C, H, W)) \tag{15}$$

Here, B is the batch size, C is the number of channels, H is the height, W is the width, and G is the number of groups. Apart from the channel shuffle operation, ShuffleNet also incorporates depth-wise separable convolutions and point-wise group convolutions to further reduce computation and parameters.

C. CGRO Score Level Fusion

A score-level fusion approach is employed where the classification scores obtained from each network are combined to make a final decision. The fused score S_{fusion} can be computed as:

$$S_{fusion} = \alpha * S_{MobileNetV3} + (1-\alpha) * S_{shuffleNet} \tag{16}$$

where α are randomly assigned weights fine tuned using novel Cauchy based Golden Ratio Optimization for robust classification.

The golden ratio optimization exploits the mathematical constant known as the golden ratio (φ).

$$\varphi = (1 + \sqrt{5})/2 \approx 1.61803398875 \tag{17}$$

After intializing golden ratio left and right exploration is prioritized.

$$c = b - \varphi(b - a) \tag{18}$$

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 11,2024 at 09:57:22 UTC from IEEE Xplore. Restrictions apply.

$$d = a + \varphi(b - a) \tag{19}$$

$$\alpha = \frac{c + d}{2} \tag{20}$$

Where, a, b are exploration interval bounds; c, d are Golden Ratio derived exploration bounds within $[a, b]$; α is the midpoint of exploration interval.

CGRO exploits cauchy distribution to generate step size for exploration in GRO. Cauchy distribution defines the step size as :

$$step_size = \gamma \cdot \tan(\pi \cdot (u - 0.5)) \tag{21}$$

where u is a random number between 0 and 1, γ is the scale parameter which influences the spread or width of the distribution and lies in $[0, \infty]$. We optimize score-level fusion with CGRO to find the optimal α value using accuracy as the objective function, and exploit the fused score to calculate final results.

IV. Experimental Setup

The proposed methodology was executed in Python3 on Google Colab CPU runtime with 12.7 GB system RAM. A single class represents an individual and has been trained on dataset comprising 10 images, including both right and left images. The database for iris was obtained from MMU1[26] which consists of 5 images each of left and right IRIS of 46 subjects, totalling 460 images. CASIA-palmprint V1[27] is used as a dataset for palmprint images. It contains 5,502 images captured from 312 subjects. 8 left palm images and 8 right palm images were obtained from each subject. In this work, a novel multimodal database MMU-CAS has been created by combining iris images of 45 subjects selected from the MMU1 with palmprint images of another 45 subjects selected from the CASIA-palmprint V1. Another palm-print dataset-IIT Delhi Touchless palmprint [28], consists of left and right hand images of 230 subjects. Hence, a multimodal database MMU-IIT has been created using the same method used for preparation of MMU-CAS database. 360 iris images from MMU-iris database were trained using pre-trained-shuffleNet CNN architecture, while 90 images of both left and right iris were used for testing and evaluating performance metrics. Similarly, 450, 360 palmprint images from CASIA, IIT respectively, were trained using pre-trained MobileNetV3 neural network architecture and performance was evaluated on 90 test images each. The existing model will be utilized to train new individuals without retraining the entire model. The Train to test ratio that has been maintained for every biometric dataset is 80:20.

V. Result

The performance of the proposed methodology is evaluated in terms of Accuracy, EER, FRR, FAR, Macro F1 score and total training time.

A. Impact of preprocessing on performance Metrics

Table I illustrates the impact of preprocessing on the performance metrics of the model. It is evident that a preprocessed biometric database yields superior performance concerning accuracy, FAR, FRR, and F1 score, all achieved within a relatively shorter training time as compared to unprocessed dataset.

B. Results of Preprocessed Unimodal Biometric Recognition using Different Models

The performance metrics of multiple models trained on MMU iris dataset are summarized in Table II. Analysis of Table II reveals that Densenet achieves the highest accuracy, followed by ShuffleNet. However, it is noteworthy that training the Densenet model requires a total of 25 minutes, with an average of 2.14 minutes per epoch. This is significantly higher compared to the total training time of the ShuffleNet and MobileNetV3 models. As a result, we fused the scores predicted by the ShuffleNet model trained on iris images and the MobileNetV3 model trained on palmprint images, achieving an accuracy of 1, as demonstrated in Table IV.

Table III compares test results with and without transfer learning for various datasets. It demonstrates that transfer learning yields superior performance and stability in biometric recognition.

C. Comparison of performance of Unimodal and Multimodal Biometric datasets

Table IV illustrates the accuracy achieved for the CASIA palmprint dataset trained on MobileNetV3 (93.34%) and the MMU iris database trained on ShuffleNet (98.89%). Remarkably, the accuracy of the multimodal MMU-CAS dataset is 100 %c, outperforming the unimodal results. Similar results are observed for the MMU-IIT dataset as well.

To evaluate the performance of the multimodal MMU-CAS database, the final score used for class prediction is calculated as the average of the scores predicted by the ShuffleNet(Iris) and MobileNetV3(Palmprint) models.

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 11,2024 at 09:57:22 UTC from IEEE Xplore. Restrictions apply.

Subsequently, the class with the highest score is assigned to the respective test image. In equation 16, we set alpha to 0.5 after observing figure 4 that accuracy peaks (100%) within an alpha range of 0.45 to 0.85, with deviations resulting in decreased accuracy.

FAR (False Acceptance Rate) arises when an imposter is mistakenly accepted as genuine, while FRR (False Rejection Rate) occurs when a genuine person is wrongly rejected. EER (Equal Error Rate) indicates the point where FAR equals FRR. The decision threshold is set at this EER value. Scores below this threshold are classified as imposters, while those above are classified as genuine. Table V shows that the EER for multimodal databases is lower compared to unimodal datasets and hence perform better. The FAR/FRR vs Threshold graph (Figure 5) helps in evaluating the EER and decision threshold.

The performance of both unimodal and multimodal datasets were evaluated using the Detection Error Tradeoff(DET) curve, which is a graphical representation that illustrates the relationship between FAR and FRR. Figure 6 demonstrates that the FAR-FRR tradeoff for the MMU-CAS multimodal database is better than that of the unimodal MMU and CASIA datasets.

D. Comparison with previous studies

Table VI highlights the robustness of our model by comparing its results with those from other recent models. In 2020, Xu et al. [29] achieved an accuracy of 98.84% with an end-to-end CNN model for multimodal biometric recognition. In 2021, Hsiao et al. [30] used a YOLO-based detector and VGG-16 model for iris recognition, achieving 98% accuracy. In 2022, Xu et al. [31] introduced the PRSCNet (Palmprint Recognition Fusing Spatial and Channel Features Network) model with SE (Squeeze-and-Excitation) modules for palmprint recognition, attaining 99.2% accuracy. In 2023, Mukahar [32] used PCANet-based deep learning and classic techniques, reaching 99.77% accuracy and Alshakree et al. [33] combined GoogLeNet, SqueezeNet, and AlexNet with gray wolf optimization for palm print analysis, achieving 96.72% accuracy. Table VI shows that our proposed model, CLAHE-HHO + Lightweight CNN + CGRO, achieves the highest accuracy and surpasses previous models.

VI. CONCLUSION

For efficient and comprehensive recognition, our research employs a multimodal biometric system utilizing a novel combination of CLAHE, with the cliplimit determined by the HHO metaheuristic technique for image contrast enhacement followed by transfer learning based ShuffleNet and MobileNetV3 architectures for classification of iris and palmprint images respectively. Finally a novel CGRO is used to determine the weight for score level fusion that combines the scores from palmprint and iris modalities. Our approach demonstrates high efficacy by achieveing 100% accuracy with lower EER, FAR, and FRR compared to unimodal systems. The DET curve for our multimodal dataset outperforms individual iris or palmprint datasets. Moreover, by employing lightweight deep learning models, our system achieves superior performance in less training time compared to other CNN models, making it highly efficient. The scalability of this approach to recognize individuals depends on dataset diversity, potentially accommodating a large number of classes/individuals but subject to computational resources and task complexity.

As a future improvement, the equal error rate can further be reduced by incorporating more biometric traits like finger vein, palm vein, face features etc for biometric recognition and authentication.

Abstract*— In a quickly progressing digital world, the arrival of virtual assistants has become a revolutionary principle for human-computer interactions. In this research project, an AI Desktop Assistant inspired by Jarvis's concept is presented, with the focus on helping users through voice commands. Specifically, this initiative aims to address the requirements of people with disabilities and enhance the computing experiences. The Desktop Assistant seamlessly integrates speech recognition model, OpenAI GPT models, and other functionalities to provide extensive and user-friendly interactions. The architecture of the system is adequately designed to suitable users, comprising of speech recognition modules and models for turning text to speech. The desktop assistant model supports additional features, involving locating and managing files, playing music, moving mail, and storing the requests-responses made via OpenAI's API in the system. The system also supports surfing the web, allowing an environment that allows different users to use the technology efficiently and emphasize the safety of those users. The results reveal that the AI desktop model is running effectively in addressing the weaknesses of the existing models. Our model's capabilities include responding to commands while making the navigation and engagement of disabled persons. The system features a performance rate up to 90-95 percent, enabling interactions with users of varying dialect and accents.

Keywords*— Speech Recognition, Artificial Intelligence, Desktop Virtual Assistant, OpenAI

I. INTRODUCTION

Given that the involvement of desktops/laptops is becoming increasingly prevalent in the modern technological era, these technologies are proving to be a crucial source for work, communication, and information. Additionally, the profound and increasingly urgent need for users to have a holistic, all-in-one computing experience is made evident in the lack of inclusivity in the form of a vocal assistant that can be utilized through a PC/Laptop. As such, users and particularly those with disabilities and other special needs, who are looking to enhance their experience need a specific option to assist their journey [1]. After consideration of this vital issue, the IRIS project arose as a necessary and ambitious step into the reality of smart AI desktop assistants.

Inspired by the concept of a visionary, referred to as Jarvis or AI Assistant, the IRIS or Intelligent Responsive interface solution aims at revolutionizing desktop assistants. The IRIS has been designed to emphasize the overall accessibility, inclusivity, and computing experience for its users. This model addresses an important void, as it serves as a vital response to the growing need for solutions that accommodate people with disabilities [2]. Generally, this research project is fuelled by the current development of the intelligent virtual assistants, in particular, by providing a model that helps in managing day-to-day operations of individuals while addressing their varying capacities.

IRIS focused on the fact that it has features specific usability attributes relative to data management and search. Therefore, IRIS could handle numerous tasks by the user, from intelligent web application tasks to effective data management. Unlike some of the models that requires hard-built proprietary methods to collect data [3][4], IRIS tapped the potential of advanced speech recognition and language processing technology to provide users with authentic and seamless data search and retrieval opportunities. As such, IRIS could work as a desktop assistant that would actually perform well and function effectively for the computer.

One of the key theoretical concepts that IRIS employed is speech recognition that facilitates the user's interaction with the model through vocal commands. Furthermore, IRIS uses the Google speech-to-text engine, which offers multi-language options for data detection [5]. Finally, IRIS is connected to various APIs for quick real-time updates related to weather, news, music, journals, mails, etc [3][6]. It is crucial to note that integration of GPT-3.5-turbo-instruct from OpenAI has transformed IRIS into a conversational assistant, promoting effective interaction. Moreover, IRIS can additionally save any prompts on the desktop automatically, making it comfortable for users to reuse and refer to later. Overall, the model focuses on the features observed in other virtual assistants, including Cortana and Copilot, to overcome their drawbacks delivering a promising desktop assistant for people with disabilities.

Issues related to keeping the security of the data and privacy of the users is kept as a top priority in IRIS. The technology has been developed using the highest possible safety measures to ensure that the experience is safe and secure for users. In contrast to the other models where there can be some outside interference [7], all the functionalities and implementation in IRIS are contained in a remote level. This feature of the IRIS model allows limited control over any given flow of data . Also, it is important to state the fact that the model's focus on inclusivity naturally makes provision for its increased accessibility. The purpose of this paper is to demonstrate an in-depth examination of its architecture and functionalities to provide a detail understanding of the contribution of IRIS to the field of intelligent virtual assistants [8]. In the following sections, we will examine the structure and implication of the IRIS model, focusing on its advanced technology and aspects that are unique and value for all users, enhancing their productivity.

The research encompasses a conclusion consisting of a comparative analysis with other DVAs, reflecting on how IRIS outperforms the existent types of desktop virtual assistants such as Copilot & Cortona, in terms of its performance and unique features, specifically in relation to serving users with disabilities. The exploration of IRIS is guided by efforts in both the academic research and the pursuit of technological breakthroughs.

II. LITERATURE REVIEW

Desktop voice assistants emerge as innovative tools that bring about rapid changes to human-computer interaction, by the means of natural-language interaction, and human task automation. The domain reveals a vivid multitude of advancements, which, nonetheless, seem to face as many challenges, as those encompassing the development from voice recognition to the speech impediments and linguistic differences or accents. Among the observed privacy concerns, security lapses and data gathering are very relevant. The necessity of understanding past work is indispensable in developing the future virtual assistants and making them a part of our everyday life. Some of the notable work done with different visions are listed below:

Inclusivity and Accessibility: Yadav et al. (2020) [1] worked on the needs of diverse users by designing their desktop assistant model for the visually impaired users, integrating screen reader assistance and customizable audio feedback. Kumar et al. (2023) [2] focused on exploring alternative input methods beyond voice commands, aiding accessibility for individuals with disabilities. These efforts ensured DVAs benefit for a large variety of users.

Context Awareness and Personalization: Biradar et al. (2023) [4] and Belkadi et al. (2020) [8] intended on personalizing the DVA experience through focusing on users and context-aware decision-making. The ability to understand individual needs and adapt responses accordingly allows new approaches for personalized assistance. However, user data plays a vital role in this aspect, potentially raising concerns about privacy and hinder the upscaling of the model (Biradar et al., 2023 [4]).

Multi-Domain Capabilities and Intelligence: Gupta et al. (2022) [3] and Mahesh (2023) [7] highlight DVAs' ability to handle complex tasks across email management, web browsing, and file manipulation (Gupta et al., 2022) [3]. So, by integration with other software, the scope of DVAs is only destined to grow, essentially transforming them into personal assistants. Furthermore, the emergence of a safe cloud-based architecture, as proposed by Mahesh (2023) [7], promotes the principles of scalability and continuous learning. Thus, by being part of a cloud-centered architecture, DVAs will access significant computing power. This will promote their ability to solve complex problems, and simultaneously, quickly and seamlessly respond to user actions and information changes.

Challenges and Drawbacks: The progress, however, is accompanied with several limitations. Their inability to grasp the true meaning of language, inaccessibility to complex tasks [1],[9], and high dependence on the user [3], make autonomous functioning of these models impossible. In addition, reliance on external services [6] and usage of cloud [7] increase the problems of data privacy and security. Currently used desktop assistants Cortona and Copilot are inefficient in using voice prompts to perform activities such as file retrieval. This requires an individual to spend a lot of time looking for files manually, which is unproductive particularly to persons with disabilities.

Future Directions: The future of desktop assistant models should concentrate on addressing these concerns whilst reaffirming their areas of strength. Further research is necessary in natural language processing to accommodate local languages and accents, decision-making algorithms, and ethical considerations. Model presented by Kunekar et al. (2023 [10]) involving an open-source base, can accelerate development and community-driven innovation. The Desktop Assistant models present a glimpse into the future of DVAs, where intelligence, personalization, and accessibility converge to create truly intelligent and user-centric assistants. Addressing the identified challenges and embracing responsible development practices will be crucial for unlocking the full potential of this technology and shaping the future of human-computer interaction. Taking into consideration the significant work done towards building better desktop assistants, our focus was to eliminate the shortcomings or the drawbacks of most of the other present models. Thus, developing a more optimized and efficient desktop assistant that ensures accessibility, inclusivity, and multi-domain operability.

III. PROPOSED METHODOLOGY

The development of the IRIS model was a meticulously planned and executed process, driven by a synthesis of innovation, research, and hands-on development. In **Figure 1,** the stages through which the model operates can be observed. Each stage is explained further, along with the parametric values used.

1. **Speech Acquisition:** The microphone captures the sound signals as the voice input. This step can be achieved by using either an external or a built-in microphone. The sound signals are then converted into speech input based on several parameters that can be configured for different users or environmental settings. **Table 1.** represents the various parameters and their values used in our model. The Energy threshold was initially kept very high at **300 decibels** in order to eliminate any noise possible and after that, it adjusts to an ambient threshold to retrieve the speech input. Other parameters were also worked with to obtain the best results.

TABLE 1. SPEECH RECOGNITION PARAMETERS

Parameter	Value
Energy_threshold	300 decibels
Dynamic_energy_adjustment_damping	0.15
Dynamic_energy_ratio	1.5
Pause_threshold	0.75 seconds
Operation_timeout	600 seconds
Phrase_threshold	0.3 seconds
Non_speaking_duration	0.5 seconds

2. **Speech Recognition Module:** The speech input was then passed into the speech recognition module where the signals are analyzed and broken into tokens based on various characteristics such as frequency, amplitude, and other patterns. The speech recognition module used was highly trained for multilingual support and allowed quick and accurate speech recognition.
3. **Command Matching/Hub:** The speech input after being converted into text is then matched with the corresponding functionality to be executed, some of them are: “search and open”, “use AI”, “news”, “play music”, “send email”, etc. In case the input doesn’t match with any of the existing tags for separate functionalities, the input is then passed onto ChatGPT using OpenAI’s API as a prompt from where a new variety of tasks can be achieved.
4. **Command Execution:** Based on the input, whichever command is triggered executes very quickly, and based on different types of commands, different kinds of output might be generated. In case of file searches, the command will print out the path of the file and even open it, web searches retrieve data and display them in an organized manner, and prompts sent to OpenAI’s API

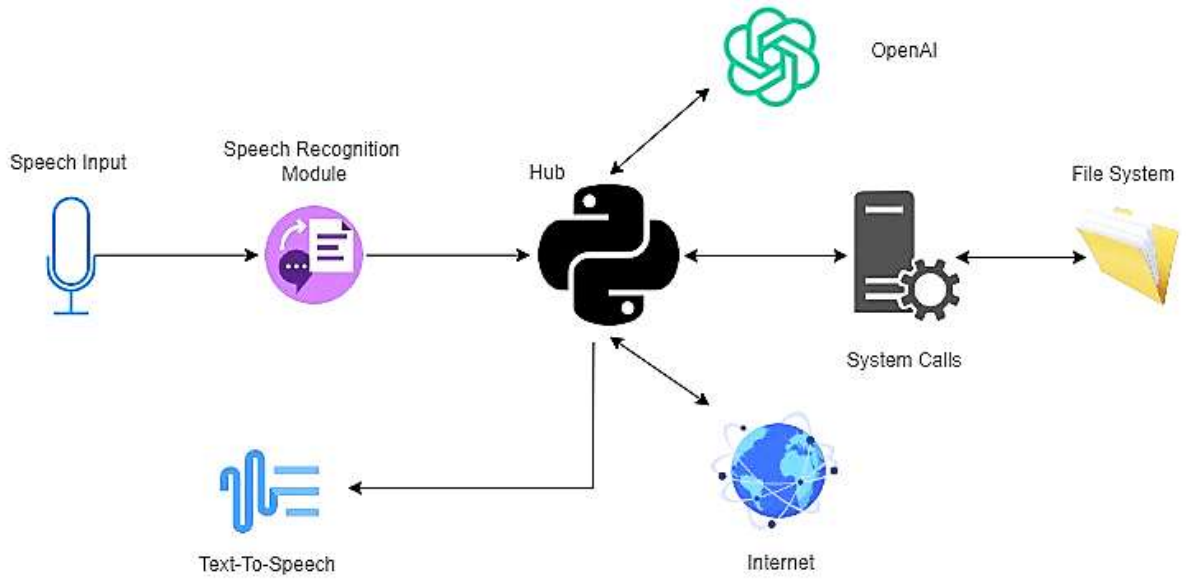

Fig.1. Model Architecture

for properly constructed responses get saved at the designated path.

5. **System Interaction:** Many of the functionalities require the model to interact with the kernel, this is done using the OS library in Python language, and many tasks such as file management including opening files, applications, etc, or retrieving environment variables for the system are fulfilled using this library.
6. **Text to Speech output:** The final output is then converted back into speech using the pyttsx3 python library, the model allows various voice settings based on the accent, volume, and speed of the output.
7. **Iterative Development and Testing:** - The development of IRIS was an iterative process, characterized by continuous testing, refinement, and user feedback. Regular iterations allowed us to address bugs, enhance functionalities, and adapt to the evolving needs of the model. User testing played a crucial role in ensuring that IRIS was not only technically robust but also user-friendly.

The model under the specified parameters was able to recognize multiple accents and languages with an appreciable accuracy of up to **90%,** the model thus delivers an impactful solution in the field of desktop virtual assistants targeted toward people with disabilities.

IV. RESULTS

The performance of our model is evidently superior to the other present models in various aspects such as accessibility, inclusivity, and multi-domain operability. The model is developed to perform many new functionalities that in turn overcome many limitations of the existing models. **Table 2.** highlights the key shortcomings present in the other models that were tackled during the development of this model.

TABLE 2. LIMITATIONS OF OTHER MODELS

PAPER/MODEL	SHORTCOMINGS
Yadav et al. (2020) [1]	Difficulty handling complex tasks, and constant wake-up calls required for the assistant.
Kumar et al. (2023) [2]	Not equally effective for all kinds of users, reducing inclusivity, unable to handle complexity.
Gupta et al. (2022) [3]	Significant user involvement and guidance are required for tasks.
Biradar et al. (2023) [4]	Heavy reliance on user data, also raises privacy concerns.
Kulhalli et al. (2017) [5]	Only provides basic commands and limited scope of usage
Sai et al. (2023) [6]	Relies on external services for tasks, thus potentially impacting performance and reliability.
Mahesh (2023) [7]	Potential security vulnerabilities, and difficulty ensuring offline functionality.
Belkadi et al. (2020) [8]	Limited features and accessibility for the users.
Co-Pilot	Difficulty accessing File systems, can't open files directly.
Cortana	Makes the overall system slower, resource demanding, and has trouble with file systems.

The limitations faced by the older models listed in **Table 2.** were worked upon and most of them were eliminated, like the model presented by Yadav et.al [1] faced challenges of the continuous need for wakeup words otherwise the instructions were not delivered, our model makes use of continuous hearing periods with an operation timeout value at **600 seconds** while keeping a high threshold value of **300 decibels** which adjusts automatically to ignore minor noises or background conversations but pick up directed instructions easily, also ensuring privacy. One of the biggest shortcomings that were common amongst almost all models was the inability to perform or respond to complex tasks, in our model we addressed this issue by seamlessly integrating it with the OpenAI API that makes use of the **gpt-3.5-turbo-instruct** model to respond to complex queries by allowing users to send custom prompts of up to **256 tokens** and also helps users to save the responses to the prompts for future use in any desired format such as JSON, .txt, etc.

The desktop assistant model IRIS is capable of recognizing various accents and languages, the model was thoroughly tested using a large sample space of people with different accents and languages which resulted in an accuracy of up to **90-95**% for the English-India language and close to **85-90%** for Hindi. File searching optimization was one of the main targets during the development of the model. Though none of the existing modern-day desktop assistant models provide an

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 20,2024 at 06:21:41 UTC from IEEE Xplore. Restrictions apply.

efficient and effective voice-controlled file retrieval functionality, Modern-day commercial desktop assistants like Cortana and Co-Pilot only allow opening root applications and not the file itself, such as PowerPoint, Adobe Reader, etc. causing a huge limitation in these models. **Table 3.** highlights the time taken by the modern-day desktop assistants to perform the same task of searching and opening a file, since only our model could open the exact file in one command, the other models opened the application required for the file. Our model outperformed the other commercially available desktop assistants as the average time taken for searching and opening the file was only **2.62 seconds** whereas the other models like Cortana took **7.16 seconds** and Co-pilot took **5.24 seconds** after an average of **10 readings** which can be seen in the graph **(Figure 2.)** as well.

TABLE 3. TIME COMPARISON FOR FILE RETRIEVAL

Runtime (seconds)	IRIS	CORTONA	COPILOT
Reading 1	2.4991	7.6022	5.3898
Reading 2	2.7731	6.8121	5.1006
Reading 3	2.5181	7.1568	5.1221
Reading 4	2.7499	6.5643	5.4167
Reading 5	2.5415	7.3389	5.3754
Reading 6	2.5732	7.4977	5.3487
Reading 7	2.7362	7.6054	5.0652
Reading 8	2.7901	7.2689	5.3391
Reading 9	2.4598	7.5771	5.4299
Reading 10	2.5260	6.9396	5.3166
Average	**2.6270**	**7.1690**	**5.2455**
Standard Deviation	**0.1103**	**0.3355**	**0.2392**

The file search algorithm was made possible with the help of the OS Python library, the search algorithm was further optimized in our model by including several changes such as case-insensitive matching and parallel searching, which also

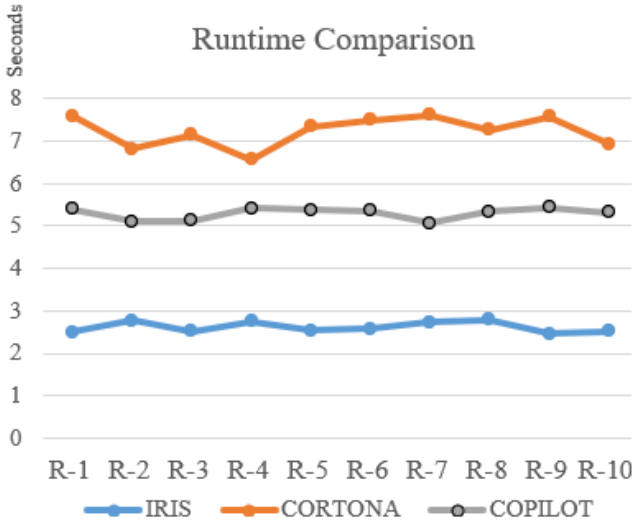

Fig.2. Runtime Comparison in File Retrieval

ensures offline functioning eliminating drawbacks faced in [7]. Many of the other applications inculcated into the model such as controlling system settings, music player, reminders, alarms, executing code scripts, file management, etc., were designed such that they function even with offline conditions. Apart from this, the model provides access to the latest news, weather reports, blogs, websites, send mails, etc. Our model increases the efficiency and quality of the work done by the users by providing AI-generated grammar corrections, text paraphrasing, language translation, math solving, etc. in desired local files such as Word, PowerPoint, Excel, etc. Thus, our model has performed better than all the existing desktop assistants in the functionality domains that have been implemented and thus it provides an optimistic signal towards further research and development.

V. CONCLUSIONS AND FUTURE WORK

In conclusion, our desktop assistant model IRIS stands as a groundbreaking AI desktop assistant, seamlessly blending advanced speech recognition technology with diverse functionalities, and engaging personality. Its commitment to inclusivity is evident in aiding individuals with disabilities and breaking down barriers to technology access. IRIS is multifunctional since it has a lot of features which make work and using it accessible. The latest and the pivotal one is considered an integration with the OpenAI's GPT-3.5-turbo-instruct model which makes possible more refined conversations. On the other hand, there is a constant update of such features as language translation and interactions with the file system within IRIS signifies the trait of adaptability and makes the technology's use diversified and productive. Apart from being an exceptional assistant, IRIS enriches lives of it users, which suggests that AI is a transforming technology. The results obtained with the model are indeed promising since IRIS calls for further research which could develop the existing applications.

The future development of the IRIS model suggests numerous opportunities for advanced interaction and functionality. Among the ideas for further development, it could be possible to consider the development of a new desktop access management system, safely integrating third-party services, users' self-created APIs for personalization, online payments and orders, and most importantly security. The development of these ideas would help in taking IRIS to a new level, allowing users to have a more effective and interesting AI desktop assistant. The development of the interaction and attraction are possible, and this is part of the next generation of intelligent virtual assistants.

ARTICLE INFO

ABSTRACT

This study provides a comprehensive review of the key elements driving modern car design. The study aims to offer crucial perspectives for designers of automobiles by pinpointing important factors in several aspects of user experience design. The paper highlights the essential variables that effect the design of vehicle exteriors and interiors, human-machine interfaces, safety features, connectivity, and other crucial elements through the use of extensive surveys and in-depth talks with over 20 industry experts. This in-depth exploration of these foundational issues is intended to function as a comprehensive manual for designers tasked with the difficult undertaking of producing user-centered car designs.

Keywords: Automobile Design, User Experience, Product Development, Key Factors

Introduction

In the pursuit of creating innovative and competitive vehicles, designers and engineers grapple with a myriad of considerations, navigating the delicate balance between form and function. The field of automotive design is influenced by a myriad of factors that have evolved over time. From the early days of the horseless carriage to the present, influences such as new technology, lifestyle, culture, and consumer preferences have played a pivotal role in shaping the aesthetics and functionality of automobiles (Muscad, 2023). In the contemporary context, the focus on user experience design has become increasingly important, with factors such as safety, regulatory requirements, technological advancements, and ergonomic considerations significantly impacting the design process. As automotive design continues to evolve, designers are faced with the challenge of integrating new materials, safety features, and infotainment systems while ensuring that the design remains adaptable and complies with changing regulations and customer needs. Therefore, this research paper seeks to provide a comprehensive analysis of the essential factors that every designer must consider when designing a new automobile, considering the dynamic nature of the automotive industry, the evolving demands of consumers, and regulatory standards (Design Considerations - Automotive OEM & Tier | 3M US, n.d.).

This study endeavours to conduct a comprehensive analysis of the factors that significantly influence automobile design, with a particular focus on the pivotal role of user experience design in shaping the contours of new product development. In a world where vehicles are no longer just modes of transportation but extensions of users' lifestyles, understanding the intricate nuances of design becomes paramount.

The factors influencing automotive design are rooted in the dynamic and multifaceted nature of the automotive industry. External factors such as political, economic, social, technological, legal, and environmental influences play a pivotal role in shaping the design of automobiles. Additionally, the history of automotive design has been marked by significant engineering advances, technological shifts, and changes in consumer preferences, making it a continuously evolving field (Jaafarnia & Bass, 2011). Moreover, the influence of different markets around the world on automotive design highlights the need to understand and adapt to varying consumer tastes, climates, and historical trends.

Copyright © 2024 by Author/s and Licensed by Kuey. This is an open access article distributed under the Creative Commons Attribution License which permits unrestricted use, distribution, and reproduction in any medium, provided the original work is properly cited.

The significance of this study lies in its potential to provide valuable insights for designers, manufacturers, and investors in the automotive industry (Ilić et al., 2024). By comprehensively analysing the essential factors that every designer must consider in automobile design, the study aims to contribute to the development of vehicles that not only meet regulatory standards and consumer preferences but also align with the rapidly changing technological landscape and environmental considerations. Understanding the historical and global influences on automotive design can help stakeholders anticipate future trends and make informed decisions in the design and production of automobiles (Vicky, 2023). Therefore, this study seeks to shed light on the interconnectedness of various factors influencing automotive design, ultimately aiming to enhance the quality, safety, and sustainability of vehicles in the ever-evolving automotive landscape.

The primary objectives of this research are:
To provide a comprehensive analysis of the factors that every designer must consider when designing a new automobile (Papadaki, n.d.).
To highlight the importance of a user-cantered approach in automobile design and the need for designers to consider various aspects such as safety, regulatory requirements, technological advancements, and ergonomics.

Extensive surveys and discussions with 20+ industry experts, focusing on their perspectives on user experience design factors in automobile design (Papadaki, n.d.) has been done. The results of the surveys and interviews to identify common themes and key factors influencing automobile design (Mohammed et al., 2017) have been analysed.
Reviewing literature on automobile design, including consumer user experience design factors has been the main focus of this study.
The research aims to provide a thorough understanding of the factors that designers must consider while designing a new automobile, ultimately contributing to the development of vehicles that meet consumer preferences and the rapidly changing technological landscape.

Literature Review

Automobile design has undergone a profound evolution since the inception of the automotive industry. This section of the research delves into the existing body of literature, tracing the historical trajectory of automobile design and exploring contemporary perspectives on the key factors influencing this dynamic field (Mohammed et al., 2017).

The history of automotive design is a fascinating journey that has been shaped by various influences and technological advancements. In the early days of the automotive industry, the line between art and design was not clearly defined, and vehicles were expected to balance aesthetic, market, performance, functional, and legislative considerations (Erdal, 2023). Since the inception of automobile manufacturing, influences such as new technology, lifestyle, culture, and consumer preferences have played a significant role in shaping the aesthetics and functionality of automobiles.

One of the significant developments in car design came in the 1920s and 1930s with the introduction of streamlining, inspired by the aerodynamic shapes of airplanes. Subsequently, the 1960s and 1970s saw cars featuring more futuristic designs and advanced technology, while in recent years, there has been a renewed focus on sustainability and eco-friendliness, leading to the integration of hybrid or electric powertrains and designs prioritizing aerodynamics and fuel efficiency (Kunze, 2021).

The evolution of the automotive design process has also been marked by significant changes, from an entirely manual craft to an almost entirely digital craft, with the introduction of new tools and techniques to enhance the design process. Throughout history, automotive design has mirrored the evolution of society, with changing lifestyle choices impacting design paradigms and consumer preferences influencing the direction of car design.

Below Figure 1, the steps involved in the automobile car design industry are illustrated. This figure outlines the comprehensive process, from initial concept development and market research to detailed design phases, prototyping, testing, and final production. Each step is crucial for ensuring that the final product not only meets aesthetic and functional requirements but also adheres to safety standards and user experience expectations.

Figure 1. The steps involved in the automobile car design industry are illustrated

History of automotive design is a dynamic and multifaceted narrative, influenced by a wide array of factors such as technology, culture, consumer preferences, and regulatory standards. This evolution has led to the creation of vehicles that are not only functional but also visually appealing, safe, and environmentally sustainable.

The roots of automobile design can be traced back to the early 20th century, when vehicles were primarily utilitarian, devoid of the aesthetic considerations that define contemporary designs. Over time, the automotive industry witnessed a paradigm shift from the functional designs of the Model T era to the sleek and aerodynamic forms of the mid-20th century. The incorporation of design elements, such as streamlining and tail fins, reflected not only aesthetic considerations but also the influence of societal trends and technological advancements (Kunze, 2021)..

In recent decades, the integration of advanced materials, manufacturing processes, and digital technologies has further revolutionized automobile design. The advent of computer-aided design (CAD) has allowed designers to visualize and iterate complex designs more efficiently, contributing to the sophistication of modern vehicles.

Advancements in technology, including artificial intelligence, connectivity, and electrification, have reshaped the automotive design landscape. The literature highlights the role of technology as both an enabler and a disruptor. The integration of smart technologies, such as infotainment systems, autonomous driving features, and electric powertrains (Sajjad, 2024), necessitates a re-evaluation of design principles to accommodate new functionalities while maintaining a cohesive user experience . The rise of electric and autonomous vehicles introduces novel challenges related to the reimagining of vehicle interiors, the elimination of traditional design elements like the internal combustion engine, and the exploration of innovative materials for sustainable manufacturing.

Synthesizing the insights from the literature, it becomes evident that the evolution of automobile design is a dynamic interplay between historical legacies, technological advancements, and the ever-changing landscape of consumer expectations. This foundation sets the stage for a deeper exploration of the specific factors influencing contemporary automobile design, with a keen focus on the role of user experience design in new product development (Rarecars & Rarecars, 2023). The subsequent sections will delve into the theoretical framework that guides this study, shedding light on the principles and methodologies that underpin the intricate process of designing automobiles in the 21st century.

Methodology

The research methodology employed in this study is a mixed-methods approach, combining quantitative and qualitative methods to provide a comprehensive understanding of the factors influencing automobile design,

with a specific focus on user experience (UX) design. The methodology encompasses surveys and subjective question-answer discussions with industry experts, aiming to triangulate insights and achieve a nuanced perspective on contemporary design practices.

Survey Design: A purposive sampling method was employed to select participants for the survey. Professionals with expertise in automobile design, engineering, and user experience were targeted. A diverse group of respondents, representing various roles within the automotive industry, including designers, engineers, and product managers, were included to capture a holistic view of the design process. Twenty industry experts were selected based on their extensive experience and expertise in automobile design, Colour material Finish, Modelling (Digital and Physical Modelling). The experts represented a diverse range of perspectives, including professionals from leading automotive companies, design in start-up, and academic institutions.

Subjective question-answer discussions were conducted through semi-structured interviews. The interviews were designed to elicit detailed insights into the challenges, priorities, and future trends in automobile design. Topics included the role of user experience in the design process, integration of emerging technologies, and the balance between aesthetics and functionality. These discussions were audio-recorded and transcribed for thorough analysis.

Questionnaire Structure: The survey questionnaire was designed to gather both quantitative and qualitative data. Multiple-choice questions were utilized to collect quantitative data on participants' perceptions of the importance of different design factors (Wiss et al., 2018), while open-ended questions allowed respondents to provide in-depth insights into their experiences and perspectives.

The survey covered key aspects such as aesthetic considerations, technological integration, safety features, environmental sustainability, and user experience design. Likert scales were employed to assess the degree of importance attributed to each factor, providing quantifiable data for analysis.

List of questions for survey listed below:

1. Designer Name
2. Experience
3. Company Names
4. Why do you design?
5. What do you think when you start creating new designs for cars, Bikes, and other objects?
6. What are the fundamental elements/factors that inspire you to create a design? (one word/Sentences)
7. How important is the user in automobile design process? (Scale 1-10)
8. When you start sketching/Developing new automobile/Product. You think about user?

(a) Comfort
(b) Aesthetics
(c) Feasibility
(d) Ease of use
(e) _____

4. Factors Influencing Automobile Design:

Several factors influence automotive design, encompassing a wide range of considerations that shape the appearance, functionality, and regulatory compliance of motor vehicles. These factors include:
Consumer Preferences: Consumer preferences play a pivotal role in automotive design. Designers must consider factors such as styling, functionality, and features that appeal to consumers and differentiate their vehicles from competitors (Muscad, 2023).

Safety and Regulatory Requirements:

Safety considerations are paramount in automobile design, adhering to both industry regulations and consumer expectations. Survey participants emphasized the importance of safety features such as advanced driver assistance systems (ADAS), crashworthiness, and collision avoidance technologies. Ensuring that vehicles meet safety standards and regulatory requirements—including crash tests, emissions standards, and other mandated regulations—is a crucial aspect of automotive design (Muscad, 2023).

The survey indicated a high level of importance attributed to safety features, reflecting the industry's commitment to enhancing vehicle safety standards. Expert discussions underscored the ongoing challenges and opportunities in integrating evolving safety technologies while maintaining a focus on overall design coherence.

Technological Integration:

Advancements in technology have significantly influenced automobile design, as highlighted in both the survey and expert discussions. The integration of cutting-edge technologies, including infotainment systems, connectivity features, and driver assistance technologies, is considered paramount in contemporary vehicle design. It includes innovations in materials, electronics, and software, significantly impact automotive design. Designers must integrate these advancements to enhance the functionality and appeal of vehicles.

Survey results revealed a consensus among respondents regarding the high importance placed on technological integration in the design process. Industry experts emphasized the need to strike a balance between incorporating innovative technologies and ensuring user-friendly interfaces that do not overwhelm users with complexity.

Ergonomics and Human Factors:

The ergonomic design of automobile interiors, focusing on user comfort, safety, and ease of use, emerged as a critical factor in both survey responses and expert discussions. Human factors engineering principles, encompassing aspects such as seating position, visibility, and control accessibility, were highlighted as crucial for enhancing the overall user experience. It is a critical factor in automotive design, encompassing seating arrangements, cargo capacity, and other functional aspects that impact the user experience. Designers must prioritize the comfort and usability of vehicles.

Survey participants emphasized the importance of ergonomic considerations in designing controls, interfaces, and seating arrangements. The integration of human-centric design principles aims to create vehicles that minimize driver fatigue, enhance safety, and provide a comfortable and intuitive driving experience (Jaafarnia, 2019).

Aesthetic Considerations:

Aesthetics play a pivotal role in influencing consumer preferences and perceptions of a vehicle. Survey results indicate that a significant majority of respondents rank aesthetic considerations, such as exterior design, interior styling, and overall visual appeal, as highly important in the design process. Industry experts, during subjective discussions, emphasized the significance of creating visually striking and distinctive designs to captivate consumers in a competitive market (Estrela, 2023).

Designers often strive to strike a balance between innovation and maintaining brand identity, ensuring that the aesthetic appeal aligns with the target market's tastes. Aesthetic considerations extend beyond visual appeal, encompassing elements like colour choices, material selection, and design coherence throughout the vehicle. The design of vehicles must balance aesthetics and functionality, considering factors such as aerodynamics, safety, and the overall appearance of the vehicle (Liamadis & Tsinikas, 2013).

Environmental Sustainability:

Environmental sustainability emerged as a notable factor influencing contemporary automobile design. Survey participants expressed a growing awareness of environmental concerns, with a significant proportion indicating that factors such as fuel efficiency, emissions reduction, and the use of eco-friendly materials are important considerations in the design process. The modern automobile design must incorporate requirements for pollution-control components, reflecting the industry's commitment to environmental sustainability (Wellbrock et al., 2020).

Experts discussed the increasing emphasis on sustainability in the automotive industry, with a focus on developing eco-friendly vehicles, exploring alternative propulsion systems, and adopting sustainable manufacturing practices. The integration of environmental sustainability considerations reflects a broader societal shift towards greener and more responsible design practices.

Automotive design is shaped by a multitude of factors, including consumer preferences, regulatory requirements, technological advancements, and historical influences. Designers must skilfully navigate these considerations to develop vehicles that are visually appealing, safe, functional, and compliant with industry standards (Duragappa & Sheshadri, 2020). The design process is a complex interplay of these elements, collectively determining the form, functionality, and user experience of a vehicle. This section delves into the key factors influencing automobile design, integrating insights from quantitative survey data and qualitative discussions with industry experts.

Study of various models

Examining case studies provides a practical lens through which to understand how user experience (UX) design principles have been applied in the development of automobiles. The following case studies illustrate successful implementations of UX design in the automotive industry, showcasing the integration of user-centric considerations in the design process.

Tesla Model 3: Elevating User Experience through Simplicity and Innovation:

The Tesla Model 3, an all-electric sedan, exemplifies a user-centric approach to automobile design. Tesla's commitment to innovation, coupled with a focus on simplicity and user-friendly interfaces, sets the Model 3 apart in the automotive market. The Tesla Model 3 is widely regarded as one of the best cars in terms of user experience due to its remarkable blend of simplicity and innovation (Bluestone, 2021). The car's minimalist design approach, which eliminates traditional physical controls and relies heavily on a single large touchscreen, creates a seamless and intuitive interface that empowers drivers. The Model 3's advanced technology, including AI-driven features and over-the-air updates, ensures that the user experience is constantly evolving and improving. Additionally, the car's focus on simplicity and ease of use makes it accessible to a wide range of users, from those new to electric vehicles to seasoned tech-savvy drivers (Miccio, 2020). Overall, the Tesla Model 3's innovative design and user-centric approach have set a new standard for the automotive industry, making it a benchmark for other manufacturers to follow. Below figure2 the image wallpaper of Tesla Model 3.

Figure 2. Tesla Model 3

Key UX Design Features:

Minimalist Interior: The Model 3's interior is characterized by a minimalist design, featuring a large central touchscreen as the primary interface. This design choice eliminates physical buttons and switches, creating a clean and uncluttered dashboard.

Intuitive Controls: The touchscreen interface consolidates controls for navigation, entertainment, climate, and vehicle settings, providing users with an intuitive and centralized control hub. Voice commands further enhance accessibility.

Over-the-Air Updates: Tesla's unique capability to deliver software updates over-the-air enables continuous improvement of features, addressing user feedback and introducing new functionalities without requiring a physical visit to a service centre.

Impact and Results: The Model 3's user-friendly interface and continuous software updates contribute to a positive and evolving user experience.

The emphasis on simplicity aligns with the preferences of modern consumers, and the streamlined design has become a hallmark of Tesla's UX philosophy. Tesla's UX philosophy is rooted in a forward-thinking approach that emphasizes simplicity, innovation, and user-centric design. From its early years, Tesla has prioritized creating an intuitive and seamless user experience, integrating cutting-edge technology with a minimalist aesthetic. Central to this philosophy is the belief that the car should be an extension of the driver's digital life, offering a seamless interface that is both functional and elegant. Tesla's continuous software updates and over-the-air enhancements reflect a commitment to evolving and improving the user experience, ensuring that each vehicle becomes better over time. The large touchscreen interface, advanced driver assistance systems, and focus on automation and connectivity illustrate Tesla's dedication to redefining how users interact with their vehicles, setting a new standard for automotive UX in the industry.

Volvo XC40 Recharge: Prioritizing Safety and Sustainability in UX Design:

Volvo, renowned for its commitment to safety, has extended its principles to the XC40 Recharge, an electric SUV. The XC40 Recharge integrates user experience design with a strong emphasis on safety and sustainability. The Volvo XC40 Recharge stands out as one of the best cars in terms of prioritizing safety and sustainability in UX design. Volvo's commitment to safety is deeply ingrained in the XC40 Recharge, evident through its advanced safety features and robust construction that prioritize the well-being of both passengers and pedestrians (D'souza & Overdrive.In, 2022). Additionally, the car's sustainability focus is showcased through its electric powertrain, emphasizing Volvo's dedication to reducing environmental impact. In terms of user experience design, the XC40 Recharge seamlessly integrates safety and sustainability features into its user interface, ensuring that drivers not only enjoy a luxurious and comfortable ride but also feel secure and environmentally conscious while driving. This holistic approach to safety, sustainability, and user experience design positions the Volvo XC40 Recharge as a standout choice for those seeking a vehicle that excels in all these crucial aspects (Volvo SUVs: The Perfect Blend of Luxury, Safety, and Sustainability, n.d.). Below figure 3 and 4 show the wallpaper of Volvo XC40 Recharge of interior and exterior.

Figure 3. Volvo XC40 Recharge interior

Figure 4. Volvo XC40 Recharge exterior

Key UX Design Features:
Safety-Centric Design: Volvo's City Safety features, including collision avoidance systems and pedestrian detection, prioritize user safety. The interior design incorporates features like run-off road protection and whiplash protection.

Seamless Charging Experience: The XC40 Recharge focuses on simplifying the electric vehicle (EV) charging experience. The infotainment system provides information on charging station locations, charging times, and remaining battery range.
Sustainable Materials: The interior of the XC40 Recharge uses sustainable materials, contributing to Volvo's commitment to environmentally conscious design.
Impact and Results: The integration of safety features aligns with Volvo's brand identity, appealing to consumers who prioritize safety in their vehicle choices.

The UX design considerations for electric vehicle charging contribute to a more accessible and convenient experience for users adopting electric mobility.

BMW iX: Merging Luxury with Sustainable Innovation in UX Design:
The BMW iX represents BMW's foray into sustainable luxury with an emphasis on electric mobility. This case study highlights the integration of user experience design principles in creating a futuristic and environmentally conscious vehicle. The BMW iX stands out as one of the best cars in terms of merging luxury with sustainable innovation in UX design. The iX's interior showcases a stunning new design language that replaces traditional plastics with high-quality materials like crystal, wood, and fabrics (10 Best Interiors & UX Winner: BMW iX, 2024). This commitment to sustainability extends to the use of recycled materials throughout the cabin, including Econyl from recycled fishing nets and olive leaf-tanned leather (BMW iX Named a 2022 Wards 10 Best Interiors and UX Winner | Uncategorized, 2024).At the same time, the iX's interior exudes a sense of luxury and craftsmanship, with elegant aesthetics, warm colors, and innovative design elements. The minimalist dashboard is dominated by the BMW Curved Display, a sweeping glass panel that houses the 12.3-inch digital instrument cluster and 14.9-inch infotainment screen (Salem, 2022). This seamless integration of technology and premium materials creates a calming, lounge-like atmosphere that prioritizes the user experience. The iX's advanced features, such as the intelligent personal assistant and smart fabrics, are discreetly integrated into the design, allowing the driver to focus on the joy of driving (Banks, 2021). By striking a balance between sustainability, luxury, and cutting-edge technology, the BMW iX sets a new standard for the future of automotive design and user experience. Below figure 5 and 6 show the wallpaper of BMW iX of interior and exterior.

Figure 5. BMW iX interior

Figure 6. BMW iX exterior

Key UX Design Features:

Cohesive Digital Cockpit: The iX features a digital cockpit with a large curved display, incorporating controls for navigation, entertainment, and vehicle settings. The interface is designed for intuitive interaction, minimizing distractions for the driver.

Augmented Reality Head-Up Display: BMW's Head-Up Display integrates augmented reality elements, providing navigation instructions, safety alerts, and other information directly in the driver's line of sight.

Eco-Friendly Materials: The iX incorporates sustainable materials in its interior, reflecting BMW's commitment to reducing the environmental impact of its vehicles.

Impact and Results: The cohesive digital cockpit enhances the overall user experience, offering a blend of advanced technology and user-friendly interfaces.

BMW's focus on sustainability in materials aligns with the growing consumer demand for eco-friendly choices in luxury vehicles.

The case studies of leading automotive manufacturers exemplify how they leverage UX design principles to prioritize user needs, safety, sustainability, and innovation in their vehicles. By integrating these crucial considerations into their design processes, these companies have not only elevated the user experience but also established new benchmarks for the industry's evolution. Through a focus on user-centric design, safety features, sustainable materials, and cutting-edge technology, these manufacturers have redefined what it means to create a truly exceptional driving experience. By placing the user at the centre of their design philosophy and incorporating the latest advancements in safety and sustainability, these companies have not only met but exceeded consumer expectations, setting a high standard for the automotive industry as it progresses into the future.

Result

Here is a table 1 summarizing the key user experience design factors that impact automobile design, based on the survey and case studies results:

Table1: UX Design Factors thst impaxr Automobile Design

UX Design Factor	Impact on Automobile Design
Safety	- Designers must ensure vehicles meet safety standards and regulatory requirements
	- Safety features and advanced driver-assist technologies are integrated to enhance occupant protection
Functionality	- Users prefer functions related to functionality, especially safety and assistance in driving
	- Functionality is prioritized over entertainment to achieve a high level of user experience
Ergonomics	- Designers must prioritize user comfort, convenience, and safety by focusing on seating arrangements, controls placement, and overall user experience
Aesthetics	- Aesthetic considerations influence the visual appeal and brand identity of vehicles
	- Designers must balance aesthetics with functionality to create visually appealing and distinctive designs
Sustainability	- Eco-friendly materials and lightweight construction techniques are used to reduce environmental impact
	- Seamless charging experience and energy-efficient technologies are integrated for electric vehicles
Connectivity	- Advanced infotainment systems, digital cockpits, and augmented reality features provide a seamless and immersive driving experience
Ease of Use	- Intuitive controls and minimalist interior design enhance the ease of use and user experience
Accessibility	- Designers must ensure that vehicles are accessible to users with diverse needs and abilities
Responsiveness	- The vehicle's systems and interfaces should respond promptly to user inputs and commands
Navigation	- Clear and intuitive navigation systems help users easily find their way and access desired features

The key user experience design factors that directly impact automobile design include safety, functionality, ergonomics, aesthetics, sustainability, connectivity, ease of use, accessibility, responsiveness, and navigation. Designers must ensure vehicles meet safety standards and regulatory requirements, prioritize user comfort and convenience, and balance aesthetics with functionality to create visually appealing and distinctive designs. Additionally, eco-friendly materials and lightweight construction techniques are used to reduce environmental impact, while advanced infotainment systems and digital cockpits provide a seamless and immersive driving experience. Intuitive controls and minimalist interior design enhance ease of use, while accessibility ensures that vehicles cater to users with diverse needs and abilities. Responsiveness and navigation are also crucial, with the vehicle's systems and interfaces responding promptly to user inputs and providing clear and intuitive navigation systems.

Conclusion

The evolution of automobile design is intricately linked to the dynamic interplay of technological advancements, changing consumer expectations, and the integration of user experience (UX) design principles. This research has delved into the multifaceted landscape of automobile design, exploring factors that influence the process, the role of UX design in new product development, insights from industry experts, and recommendations for future design processes.

The comprehensive analysis of factors influencing automobile design revealed the significance of safety, functionality, ergonomics, aesthetics, sustainability, connectivity, ease of use, accessibility, responsiveness, and navigation. User experience design emerged as a pivotal factor, shaping the contours of contemporary vehicle designs to meet the expectations and preferences of an increasingly sophisticated consumer base.

Insights from industry experts provided valuable perspectives on design priorities, challenges, and future directions. The emphasis on user-centricity, the challenges posed by technological advancements, and the potential for innovation through interdisciplinary collaboration were recurring themes. The case studies illustrated successful applications of UX design principles in real-world scenarios, showcasing how leading manufacturers prioritize simplicity, safety, sustainability, and innovation.

As the automotive industry continues to undergo transformative shifts, the implications for future automobile design are profound. The integration of UX design principles will be paramount in creating vehicles that not only meet functional requirements but also resonate with users on emotional and experiential levels. The recommendations put forth emphasize the need for a holistic and collaborative approach, leveraging emerging technologies and continuous user feedback to drive innovation.

The future of automobile design is poised for a paradigm shift, marked by a convergence of technology, sustainability, and user-centric innovation. Vehicles are evolving beyond mere modes of transportation, becoming personalized, connected, and sustainable extensions of users' lifestyles. Designers are tasked with

navigating a landscape where the traditional boundaries between automotive and tech industries blur, creating opportunities for ground breaking advancements in user experience and mobility solutions.

The integration of artificial intelligence, augmented reality, and sustainable materials will play pivotal roles in shaping the future of automobile design. As the industry embraces these advancements, a delicate balance between functionality and aesthetics, safety and innovation, and environmental responsibility will be crucial in creating vehicles that stand at the forefront of technological and experiential excellence. The journey through the intricacies of automobile design reveals a vibrant landscape where innovation, user experience, and sustainability converge.

Abstract

To simulate the astrophysical scenarios at the scale of laboratory astrophysics, the interaction of high-power lasers with plasmas is increasingly being used. So, in this perspective, a nonlinear wave-wave interaction between right-hand circularly polarised wave (R-mode wave) and electron plasma wave (EPW) is proposed to understand the localization of the pump R-mode wave and associated magnetic turbulence at electron scale in magnetized plasma relevant to laboratory astrophysics. The ponderomotive force and relativistic variation of electron mass are accountable for this nonlinear wave-wave interaction model. For this nonlinear dynamics, coupled model equations for EPW and R-mode wave are developed and solved by laboratory simulations utilizing finite difference and pseudo-spectral methods. The observed simulation findings, like the nonlinear evolution of the pump wave, typical scale size of the formed localized structures, and electron scale turbulent spectra associated with the coherent structures resemble various laboratory and space plasma scenarios. A semi-analytical model in the paraxial limits is also developed to understand the physics behind the localization process of the pump wave inside the plasma medium.

1. Introduction

The invention of high-intensity lasers opened new areas of research at the scale of laboratory astrophysics concerning a wide range of magnetized plasma systems from space to astrophysical phenomena [1–3]. In various theoretical and experimental investigations of intense laser-plasma interactions in magnetized plasma, numerous features of space and astrophysical situations, such as turbulence generation, magnetic field enhancement, filamentary structure formation, particle acceleration, laser wakefield acceleration [4, 5], and so on, have been observed at the scale of laboratory astrophysics [6–14]. One of the most vital features of magnetized plasma systems is turbulence generation at electron and ion scale, which has been seen in a wide range of systems like solar wind, supernovae remnants, interstellar circumstances, galaxy evolutions, cluster merger events, and astrophysical laboratory studies. Turbulence generation assists the energy cascades from large to small scales, which eventually causes the energization or heating of the charged particles in laboratory and astrophysical plasmas [15–18]. The enhancement of the magnetic field and turbulence generation have been reported by the interaction of plasma flows generated by intense laser at the scale of laboratory astrophysics relevant to galaxy collisions, clumpy media, cluster merger events, etc [12, 13, 19]. The filamentary structure formation, magnetic field enhancement, turbulent spectra at electron and ion scale, acceleration of the charged particles, etc, have been observed in magnetized plasma generated by intense laser at the scale of laboratory astrophysics relevant to the interstellar medium, supernovae remnants, etc [11, 14, 20].

In a high-intensity laser-plasma interaction investigation conducted by Mondal *et al* [11], electron scale turbulent spectra with power-law scaling of $\sim k^{-2.0}$ (where k is the wavenumber) was recorded. The filamentary structure formations and magnetic field amplification of the order of mega gauss was also seen. This investigation is governed by electrons, and Wiebel instability is anticipated for this electron-dominated dynamics for early timescales up to the first few picoseconds. The intense laser-plasma interaction investigation

© 2024 IOP Publishing Ltd

performed by Chatterjee *et al* [20] reported the transition from the electron to the ion-dominated regions at later timescales. Also, two different spectral indices were observed in this investigation, separated by a spectral kink (the breakpoint at $k\rho_i \sim 1$, where k is the wave vector of the pump wave and ρ_i is the ion cyclotron length) in the turbulent spectra. The Weibel instability failed to explain the nonlinear dynamics and observations reported by Chatterjee *et al* [20] at later timescales due to the saturation of the Weibel instability. It was anticipated that after the saturation of Weibel instability, an unknown instability may be responsible for this nonlinear energy cascade at later timescales. Therefore, different mechanisms are needed to know about this unknown instability. A model based on the nonlinear wave-wave interaction considering ponderomotive and relativistic non linearity is proposed in this investigation, which could be one of the possible mechanisms.

Several investigations have attempted to replicate numerous space and astrophysical situations at the laboratory scale using the nonlinear wave-wave interaction model incorporating the ponderomotive effect [10, 21, 22]. The formation of filamentary structures, amplification of magnetic field, acceleration of charged particles, turbulent spectra at electron scale as well as at ion scales, and many other astrophysical situations have been observed within the magnetized plasma by utilizing the nonlinear interaction of the plasma waves model [23]. Singh *et al* [24] performed an investigation based on a nonlinear wave-wave coupling model and observed turbulent magnetic field amplification relevant to the cluster merger events. Singh *et al* [23] proposed a model based on the nonlinear wave-wave interaction between an elliptically polarized high-frequency pump wave and an electrostatic electron wave propagating perpendicular to the magnetic field to replicate the observations of electron-dominated dynamics performed by Mondal *et al* [11] in intense laser-plasma interaction experiments. In that investigation, enhancement of the magnetic field, scale size of the filamentary structures, and electron scale turbulence generation with the power-law scaling $\sim k^{-1.5}$ have been observed from the simulation findings. Some simulation results are quite close to the experimental results observed from the Mondal *et al* [11] intense laser-plasma interaction investigation. Still, there is a difference in the scaling of the turbulent spectra at the electron scale. Therefore, there is need for further investigation in this direction especially to look at electron-scale magnetic turbulent spectra. Hence, in this context, a model based on the nonlinear interaction of a circularly polarized pump wave with a parallel propagating electron plasma wave is proposed in this investigation.

This paper presents an investigation of a nonlinear wave-wave coupling of the right circularly polarized wave (R-mode wave) with the electron plasma wave (EPW) propagating parallel to the background magnetic field. The primary focus of this investigation is the electron scale turbulence generation associated with the coherent structure formation in the laser-produced magnetized plasma. In this context, model coupled equations for R-mode wave and EPW are developed, taking relativistic electron mass variation and nonlinear ponderomotive force into account. The equation of motion and all four of Maxwell's equations are employed to develop the model coupled equations. The laboratory simulations are used to solve the developed coupled equations utilizing pseudo-spectral and finite difference methods. This study also presents a simplified model considering the paraxial limit to look deep into the insights of the filamentary structure formation in the magnetized plasma.

The study is organized as follows. The model equations of R-mode wave and EPW are formulated in section 2; the normalized coupled model equations, details of the laboratory simulations, and used parameters are given in Section 3; the observed results from the numerical simulation and simplified model are discussed in Section 4; Results obtained from the simplified model are discussed in Section 5 and 6 provides the summary of this study.

2. Formulation of model equations

2.1. Basic model equations

The basic equations utilized for the mathematical formulation of nonlinear interaction between R-mode wave and EPW considering background magnetic field along z-direction ($\vec{B} = B_0\hat{z}$) are given in this section, which is as follows:

$$\nabla \times \vec{E} = -\frac{1}{c}\frac{\partial \vec{B}}{\partial t} \text{ (Faraday's law)} \tag{1}$$

$$\nabla \times \vec{B} = \frac{4\pi}{c}\vec{J} + \frac{1}{c}\frac{\partial \vec{E}}{\partial t} \text{ (Ampere's law)} \tag{2}$$

$$\nabla \cdot \vec{E} = -4\pi e n_e \text{ (Poisson's equation)} \tag{3}$$

$$\frac{\partial n_e}{\partial t} + \nabla \cdot (n_e \vec{v}_e) = 0 \text{ (Equation of continuity)} \tag{4}$$

$$\frac{\partial m_e \vec{v}_e}{\partial t} + m_e(\vec{v}_e \cdot \nabla)\vec{v}_e = -e\left(\vec{E} + \frac{(\vec{v}_e \times \vec{B})}{c}\right) \text{(Equation of motion)} \tag{5}$$

Where e, v_e, n_e, c and m_e are the electronic charge, the velocity of electrons, the number density of electrons, the speed of light in free space, and the electron mass, respectively.

2.2. Model equation for r-mode wave

Considering the laser beam propagating parallel to the background magnetic field ($\vec{B} = B_0\hat{z}$) with frequency ω_0 in the magnetized plasma. By combining equations (1) and (2), one may get the following wave equation:

$$\nabla^2\vec{E} - \nabla(\nabla \cdot \vec{E}) = \frac{1}{c^2}\frac{\partial^2\vec{D}}{\partial t^2} \tag{6}$$

Where $\vec{D}$ is the electric displacement vector and is defined as $\vec{D} = \bar{\bar{\varepsilon}} \cdot \vec{E}$, $\bar{\bar{\varepsilon}}$ denotes the plasma dielectric tensor [25] and $\vec{E}$ denotes electric field of the laser and it's varying rapidly. It is quite helpful to segregate the rapidly moving Electric field of the laser by writing $\vec{E}$ in the following way in order to adopt the slowly varying amplitude approximation [26, 27]:

$$\vec{E}(x, y, z, t) = E_0(x, y, z, t)e^{-i\omega_0 t} \tag{7}$$

Where the slowly varying amplitude of the laser pulse is denoted by E_0. Breaking equation (6) in x and y components, one can obtain the following equations:

$$\frac{\partial^2 E_x}{\partial y^2} + \frac{\partial^2 E_x}{\partial y^2} - \frac{\partial}{\partial x}\left(\frac{\partial E_y}{\partial y} + \frac{\partial E_z}{\partial z}\right) = -\frac{\omega_0^2}{c^2}(\bar{\bar{\varepsilon}} \cdot \vec{E})_x \tag{8}$$

$$\frac{\partial^2 E_y}{\partial x^2} + \frac{\partial^2 E_y}{\partial z^2} - \frac{\partial}{\partial y}\left(\frac{\partial E_x}{\partial x} + \frac{\partial E_z}{\partial z}\right) = -\frac{\omega_0^2}{c^2}(\bar{\bar{\varepsilon}} \cdot \vec{E})_y \tag{9}$$

Now, the component of equation (6) along the z-direction utilizing $\nabla \cdot \vec{D} = 0$ can be written as the following:

$$\frac{\partial E_z}{\partial z} \approx -\frac{1}{\varepsilon_{zz}}\left(\varepsilon_{xx}\frac{\partial E_x}{\partial x} + \varepsilon_{xy}\frac{\partial E_y}{\partial x} + \varepsilon_{yx}\frac{\partial E_x}{\partial y} + \varepsilon_{yy}\frac{\partial E_y}{\partial y}\right) \tag{10}$$

Where $\varepsilon_{zz} = 1 - (\omega_{pe}^2/\omega_0^2)$ It is assumed that $E_+ = E_x + iE_y$ and $E_- = E_x - iE_y$ represents two modes of propagation of pump wave, namely L-mode (left circularly polarized) and R-mode (right circularly polarized) respectively. For the R-mode wave, the electric field vector rotates in a clockwise direction, and for the L-mode wave, the electric field vector rotates in a counter-clockwise direction. Now, multiplying the equation (9) by $\pm i$ and adding it to equation (8) and then Substituting the value of $\partial E_z/\partial z$ from equation (10), the equations for the two coupled modes (R-mode and L-mode) can be written as follows:

$$\begin{aligned}&\frac{\partial^2 E_+}{\partial z^2} + \frac{1}{2}\left(1 + \frac{\varepsilon_+}{\varepsilon_{zz}}\right)\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}\right)E_+ + \frac{1}{2}\left(-1 + \frac{\varepsilon_-}{\varepsilon_{zz}}\right)\left(\frac{\partial^2}{\partial x^2} - \frac{\partial^2}{\partial y^2}\right)E_- \\ &- i\left(1 - \frac{\varepsilon_-}{\varepsilon_{zz}}\right)\frac{\partial^2 E_-}{\partial x \partial y} + \frac{\omega_0^2}{c^2}(\varepsilon_+)E_- = 0\end{aligned} \tag{11}$$

$$\begin{aligned}&\frac{\partial^2 E_-}{\partial z^2} + \frac{1}{2}\left(1 + \frac{\varepsilon_-}{\varepsilon_{zz}}\right)\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}\right)E_- + \frac{1}{2}\left(-1 + \frac{\varepsilon_+}{\varepsilon_{zz}}\right)\left(\frac{\partial^2}{\partial x^2} - \frac{\partial^2}{\partial y^2}\right)E_+ \\ &+ i\left(1 - \frac{\varepsilon_+}{\varepsilon_{zz}}\right)\frac{\partial^2 E_+}{\partial x \partial y} + \frac{\omega_0^2}{c^2}(\varepsilon_-)E_- = 0\end{aligned} \tag{12}$$

Where $\varepsilon_- = \varepsilon_{xx} + i\varepsilon_{xy} = 1 - \frac{\omega_{pe}^2/\omega_0^2}{1 - \omega_{ce}/\omega_0}$, $\varepsilon_+ = \varepsilon_{xx} - i\varepsilon_{xy} = 1 - \frac{\omega_{pe}^2/\omega_0^2}{1 + \omega_{ce}/\omega_0}$. E_+ and E_- are two loosely coupled modes. It is challenging to solve the simultaneous propagation of E_+ and E_- hence assuming E_+ to be zero [27] (by considering $E_- = 0$, an analogous equation can also be derived for E_+), the equation for R-mode wave can be written as:

$$\frac{\partial^2}{\partial z^2} + \delta_-\left(\frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}\right)E_- + \frac{\omega_0^2}{c^2}(\varepsilon_-)E_- = 0 \tag{13}$$

Here, $\delta_- = 1/2(1 + (\varepsilon_-/\varepsilon_{zz}))$, $\omega_{pe}^2 = 4\pi n_e e^2/m_e$ (here $n_e = n_0 + n_1$, where n_0 is the unperturbed background electron number density and n_1 is the perturbed electron number density) is the plasma frequency and $\omega_{ce} = \frac{eB_0}{m_e c}$ is the electron cyclotron frequency. Now the solution of equation (13) can be written as (Because there is symmetry in x and y direction hence for simplification here only one direction is considered)

$$E_- = E_{0-}(x,\ z,\ t)e^{(-i(\omega_0 t - k_- z))} \tag{14}$$

Here $k_- = \omega_0/c(\varepsilon_-)^{\frac{1}{2}}$ is the propagation constant of the R-mode wave in the plasma having a background magnetic field. Now, substituting equation (14) in equation (13) and then applying slowly varying envelop approximation $\left(\frac{\partial^2 E_{0-}}{\partial t^2} \ll \omega_0 \frac{\partial E_{0-}}{\partial t}\right)$ and using the relativistic mass variation effect, we get the following equation:

$$2ik_-\frac{\partial E_{0-}}{\partial z} + \frac{\partial^2 E_{0-}}{\partial z^2} - k_-^2 E_{0-} + \delta_-\frac{\partial^2 E_{0-}}{\partial x^2} + 2i\omega_0\frac{\varepsilon_-}{c^2}\frac{\partial E_{0-}}{\partial t} + \frac{1}{c^2}\left(1 - \frac{\frac{\omega_p^2}{\gamma\omega_0^2}}{1 - \frac{\omega_{ce}}{\gamma\omega_0}}\right)\omega_0^2 E_{0-} = 0 \tag{15}$$

Where γ is the Lorentz factor and is given as $\gamma = (1 - v_0^2/c^2)^{-1/2}$, here $v_0^2 = v_{0x}^2 + v_{0y}^2$ where v_{0x} and v_{oy} are the velocity components of the pump wave and are calculated by using the equation of motion (equation (5)) and are given as:

$$v_{0x} = \frac{e}{m_e\omega_0}\left(-iE_x - \frac{\omega_{ce}}{\omega_0}E_y\right)\left(1 - \frac{\omega_{ce}^2}{\omega_0^2}\right)^{-1} \tag{16}$$

$$v_{0y} = \frac{e}{m_e\omega_0}\left(-iE_y + \frac{\omega_{ce}}{\omega_0}E_x\right)\left(1 - \frac{\omega_{ce}^2}{\omega_0^2}\right)^{-1} \tag{17}$$

Using these velocity components γ comes out to be $1 + \alpha\ |E_{0-}|^2$ where $|E_{0-}|^2 = E_x^2 + E_y^2$ and $\alpha = \frac{1}{2c^2}\left(\frac{e}{m_e\omega_0}\right)^2\left[\frac{(1+\omega_{ce}^2/\omega_0^2)}{(1-\omega_{ce}^2/\omega_0^2)^2}\right]$. By utilizing the Lorentz factor ($\gamma = 1 + \alpha\ |E_{0-}|^2$) and density perturbation ($n_e = n_0 + n_1$) in equation (15), one can easily get the following expression:

$$\left(2ik_-\frac{\partial}{\partial z} + \frac{\partial^2}{\partial z^2} + \delta_-\frac{\partial^2}{\partial x^2} + 2i\omega_0\frac{\varepsilon_-}{c^2}\frac{\partial}{\partial t}\right)E_{0-} = \left(\frac{\omega_{pe}^2}{c^2(1 - \omega_{ce}/\omega_0)}\left(\frac{n_1}{n_0} - \alpha\ |E_{0-}|^2\right)\right)E_{0-} \tag{18}$$

The above equation (18) represents the dynamical coupled equation for the pump right-circularly polarized (R-mode) wave.

2.3. Model equation for electron plasma wave (EPW)

In magnetized plasma, considering propagation of the EPW parallel to the laser propagation direction. EPW is the electrostatic wave and its electric field vector in the propagation direction; hence, the electric field expression of the electron plasma wave can be written as follows:

$$\vec{E}_1 = E_{1z}\exp\left(i(k_1 z - \omega_1 t)\right)\hat{z} \tag{19}$$

where ω_1 and k_1 are the oscillation frequency and the propagation constant for the EPW, respectively. Now, considering the thermal effects and ponderomotive force equation (5) can be written as:

$$m_e\frac{\partial\vec{v}_{1e}}{\partial t} = -e\vec{E}_1 - \frac{e}{c}(\vec{v}_{1e} \times B_0\hat{z}) - \frac{K_B T_e \nabla n_1}{n_0} + \vec{F}_0 \tag{20}$$

Where $\vec{v}_{1e}$ is the velocity of electrons in the electron plasma wave and $\vec{F}_0$ is the ponderomotive force that is exerted by the pump wave on the electron plasma wave inside the plasma and the expression for the ponderomotive force is given as:-

$$\vec{F}_0 = -\frac{1}{2}\left\{m_e(\vec{v}_0 \cdot \nabla)\vec{v}_0 + \frac{e}{c}(\vec{v}_0 \times \vec{B}_p)\right\} \tag{21}$$

Here, $\vec{B}_p$ is the magnetic field of the pump wave whose propagation direction can be decided using Faraday's law (equation (1). Taking the time derivative of the equation of continuity (equation (4)) and applying the procedure of linearization [28] we get the following equation:

$$\frac{\partial^2 n_1}{\partial t^2} + n_0\nabla \cdot \frac{\partial\vec{v}_{1e}}{\partial t} = 0 \tag{22}$$

Calculating $\partial\vec{v}_{1e}/\partial t$ from equation (20), substituting it in equation (22), and taking the z-component of the obtained equation, we get the following equation:

$$\frac{\partial^2 n_1}{\partial t} - \frac{n_0 e\nabla_z E_{1z}}{m_e} - \frac{n_0}{m_e}\frac{K_B T_e}{n_0}\frac{\partial^2 n_1}{\partial z^2} + \frac{n_0 F_{0z}}{m_e} = 0 \tag{23}$$

The z-component of the ponderomotive force can be calculated by equation (21), and using the velocity components of the pump wave given by equations (16) and (17), the expression for the ponderomotive force is given as:

$$F_{0z} = \frac{k_0 e^2 |E_{0-}|^2}{2i\omega_0^2 m_e (1 - \omega_{ce}^2/\omega_0^2)} \tag{24}$$

Using Poisson's equation (equation (3)) and equation (24) in equation (23) and rearranging the obtained equation, we get the following equation:

$$\left(\frac{\partial^2}{\partial t^2} + \omega_{pe}^2 - v_{th}^2 \frac{\partial^2}{\partial z^2}\right) n_1 = \left(\frac{\omega_{pe}^2}{8\pi m_e(\omega_0^2 - \omega_{ce}^2)} \frac{\partial^2}{\partial z^2}\right) |E_{0-}|^2 \tag{25}$$

The above equation (25) represents the model coupled equation for electrostatic electron plasma wave (EPW).

3. Normalised equations and parameters used

Numerical simulation has been used in this section to investigate the dynamics associated with the interaction of R-mode waves and Plasma waves. The coupled system of equations (18) and (25) in the dimensionless form can be expressed as:-

$$\left(i\frac{\partial}{\partial t'} + ic_1 \frac{\partial}{\partial z'} + \frac{\partial^2}{\partial z'^2} + \frac{\partial^2}{\partial x'^2}\right) E_{0-}{}' = (c_4 n'_1 - c_2 |E_{0-}{}'|^2) E_{0-}{}' \tag{26}$$

$$\left(i\frac{\partial^2}{\partial t'^2} + c_6 - c_3 \frac{\partial^2}{\partial z'^2}\right) n'_1 = c_5 \frac{\partial^2}{\partial z'^2} |E_{0-}{}'|^2 \tag{27}$$

Where $E_{0-}{}'$, $n_1{}'$ is normalized using E_n and n_n respectively and $c_1 = \frac{k_- t_n c^2}{\omega_0 \varepsilon_- z_n}$, $c_2 = \frac{\alpha c^2 t_n E_n^2}{2\omega_0 \varepsilon_-}$, $c_3 = \frac{v_{th}^2 t_n^2}{z_n^2}$, are the normalizing constants and the normalizing quantities are $x_n = \sqrt{\frac{\delta_- c^2 t_n}{2\omega_0 \varepsilon_-}}$, $z_n = \sqrt{\frac{c^2 t_n}{2\omega_0 \varepsilon_-}}$ $t_n = 5\omega_{pe}^{-1}$, $E_n = \sqrt{\frac{8\pi m_e(\omega_0^2 - \omega_{ce}^2) z_n^2 n_n}{t_n^2 \omega_{pe}^2}}$, $v_{th} = \sqrt{\frac{K_B T_e}{m_e}}$. The coupled equations represented by equations (28) and (29) are solved for the electric field, and then equation (1) can be utilized to transform the electric field into the magnetic field. With a step size of 10^{-5}, the finite difference technique for temporal integration is used along with the predictor-corrector approach, and for the space integration, a pseudo-spectral scheme in the x-z plane has been employed. The coupled system of dimensionless equations (26) and (27) are solved by computational simulations in this study. A well-known nonlinear Schrodinger equation (NLS) is used to check the accuracy of the algorithm that we have used for our computation simulations. Up to the accuracy of 10^{-5}, the Plasmon number was preserved during the simulation. The algorithm was altered to solve the dimensionless nonlinear coupled equations. The following initial conditions are used for the computational simulation:

$$E_{m-}(x, z, 0) = |E_{m0-}| \{1 + p \cos(\alpha_x x)\} \{1 + p \cos(\alpha_z z)\} \tag{28}$$

$$n_1(x, z) = \sum_m |E_{m-}(x, z, 0)|^2 \tag{29}$$

Where E_{m0-} and p denote the initial amplitude of the laser and the perturbation amplitude, respectively. Numerical simulations using the above given initial conditions are implemented to solve the coupled system of equations (26) and (27) in the 2-dimensional periodic spatial domain. $\frac{2\pi}{\alpha_x} \times \frac{2\pi}{\alpha_z}$ is the size of the periodic spatial domain with 512×512 grid points, and $\alpha_x = \alpha_z = 0.1$ is the wavenumbers of perturbation that are normalized by x_n^{-1}, z_n^{-1} respectively. The parameters used for the numerical simulation are $T_e = 8$ keV, $B_0 = 0.1$ MG, $n_0 = 5.75 \times 10^{17}$ cm^{-3}, $\omega_0 = 2.25 \times 10^{14}$ rad/s, $\omega_{ce} = 1.75 \times 10^{12}$ rad/s, $\omega_{pe} = 4.27 \times 10^{13}$ rad/s and the values of the normalizing parameters are $n_n \approx 0.01 n_0$, $t_n = 0.12ps = 5\omega_{pe}^{-1}$, $x_n \approx 5\mu m \approx 0.7\lambda_e$, $z_n \approx 5\mu m \approx 0.7\lambda_e$(where $\lambda_e = \frac{c}{\omega_{pe}}$ is the electron skin depth) and $E_n = 2.85 \times 10^5$ statV/cm. Condition for normalization is such that the time is normalized with plasma frequency and space coordinates are normalized with electron skin depth. This study aims to understand the physics behind the magnetic turbulence generation at the electron scale associated with the localized structure formation reported by Mondal *et al* [11] in experimental investigations of intense laser-plasma interaction. In this context, numerical simulation is performed in the present investigation utilizing the parameters from the experimental investigation, considering our simulation constraints.

4. Results and discussion

The numerical simulations are carried out to solve the dimensionless coupled equations (26) and (27), and the observed results are discussed in this section. A ponderomotive force is exerted on the plasma wave during the propagation of the R-mode wave inside the plasma medium that causes perturbations in the background

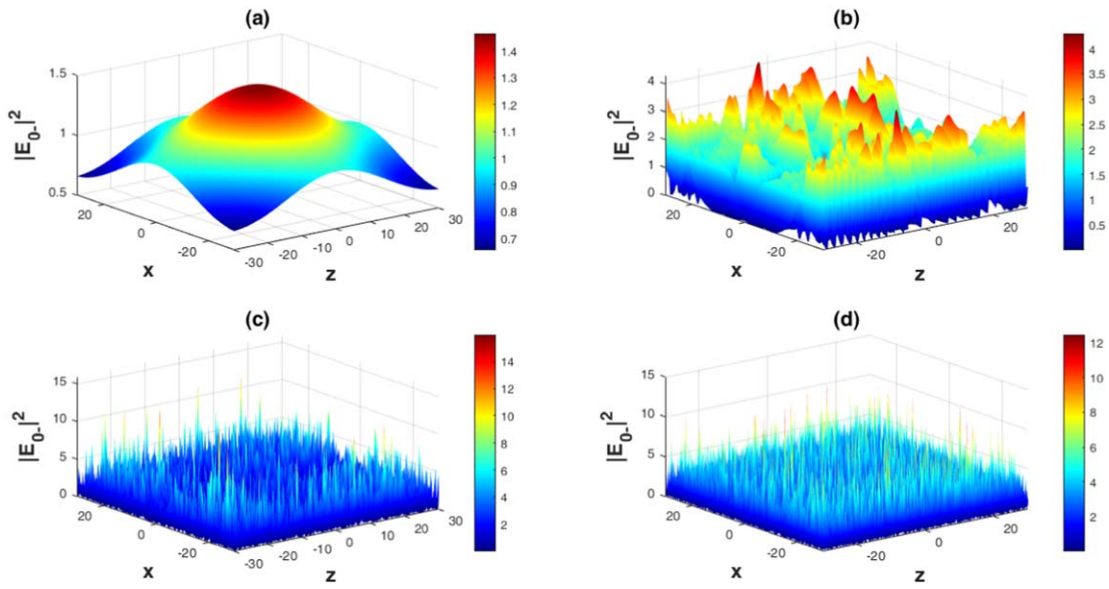

Figure 1. For different normalized times (a) 0, (b) 15, (c) 20, and (d) 30, the Normalized intensity of the R-mode wave in the x-z plane.

density, resulting in the emergence of density cavities and humps. When the R-mode wave further propagates in the modified background density, breaking of the R-mode wave in the filamentary (localized) structures takes place, and these structures become chaotic with time evolution, indicating the turbulence generation. It has been observed from the simulation results that the initiation time of the filamentary structures is approximately 1.1 picoseconds, and these structures become localized at around 1.7 picoseconds.

The localization initiating time in the experimental results reported by Mondal *et al* [11] was mentioned around 0.3 picosecond, which is quite close to our simulation observations. The localization profiles of the R-mode wave at different normalized times in the *x*-*z* plane are illustrated in figure 1. Figures 1(a) and (b) show the initial profile (at normalized time t = 0) of the pump wave and early stage of the localized structures (at normalized time t = 15) respectively inside the plasma medium. Figures 1(c)–(d) illustrate the chaotic localized structures at normalized times t = 20 and t = 30 of the R-mode wave inside the plasma medium, indicating the turbulence generation. The energy exchange between the R-mode wave and the plasma wave is shown by the evolution of the localized structures.

Figures 2(a)–(b) shows density variation in an *x*-*z* plane at a normalized time t = 24 and t = 30, respectively. This depiction portrays the humps and depletion of the density in various locations in the x-z plane.

Figure 3 complements the understanding by presenting the localization plots of the field and density cavitation. Mondal *et al* [11] show a filament size of ∼4 μm, and the result obtained in this study shows a thickness of about ∼6 μm at an early time, which is close to the results obtained by Mondal *et al* [11]. The resolution of the system is∼ 0.6 μm, and hence, the results obtained in this paper are adequate to resolve the filamentary structures satisfactorily. Thickness of the localized structures at the later time is around ∼2 μm, which is also resolvable by the system. The localization of the pump wave takes place inside the magnetic plasma medium, and the pump energy transports to the small scale from the large scale, which can be indicated by the power spectrum. For the long spatial scale length, the magnetic field power spectrum (electron dominated) of the R-mode wave versus *k* has been plotted. Figure 4. shows the ensemble-averaged power spectrum, which is averaged over the normalized time from t = 20 and t = 30 comprising ten spectra. To confirm the turbulent scaling, a reference red solid line is given in the power spectrum of the order of $\sim k^{-1.9}$. This power law scaling is quite close to that observed by Mondal *et al* [11] ($\sim k^{-2.0}$). In the magnetic field profile, the emergence of chaotic structures is an indication of turbulence generation.

To understand the evolution of the density harmonics/modes for different points in time, the fluctuation of the modes of density $|n_m|$ versus k_x (when $k_z = 0$) has been studied. At different times, the fluctuation of the density modes with k_x is shown in figures 5(a)–(b). At $k_x = \alpha_x, 2\alpha_x, 3\alpha_x$, up to $256\alpha_x$ the spectral density modes are generated, and these modes exhibit variation over time. It can be made clear from equation (27) that the nonlinear ponderomotive force {last term of equation (27)} is the cause of the origin of density harmonics for the different instants of time.For $k_z = 0$, at a given normalized time (t), the generation of the modes of density is provided by $n_1'(x, z) = \{1 + p \cos(\alpha_x x)\}^2$

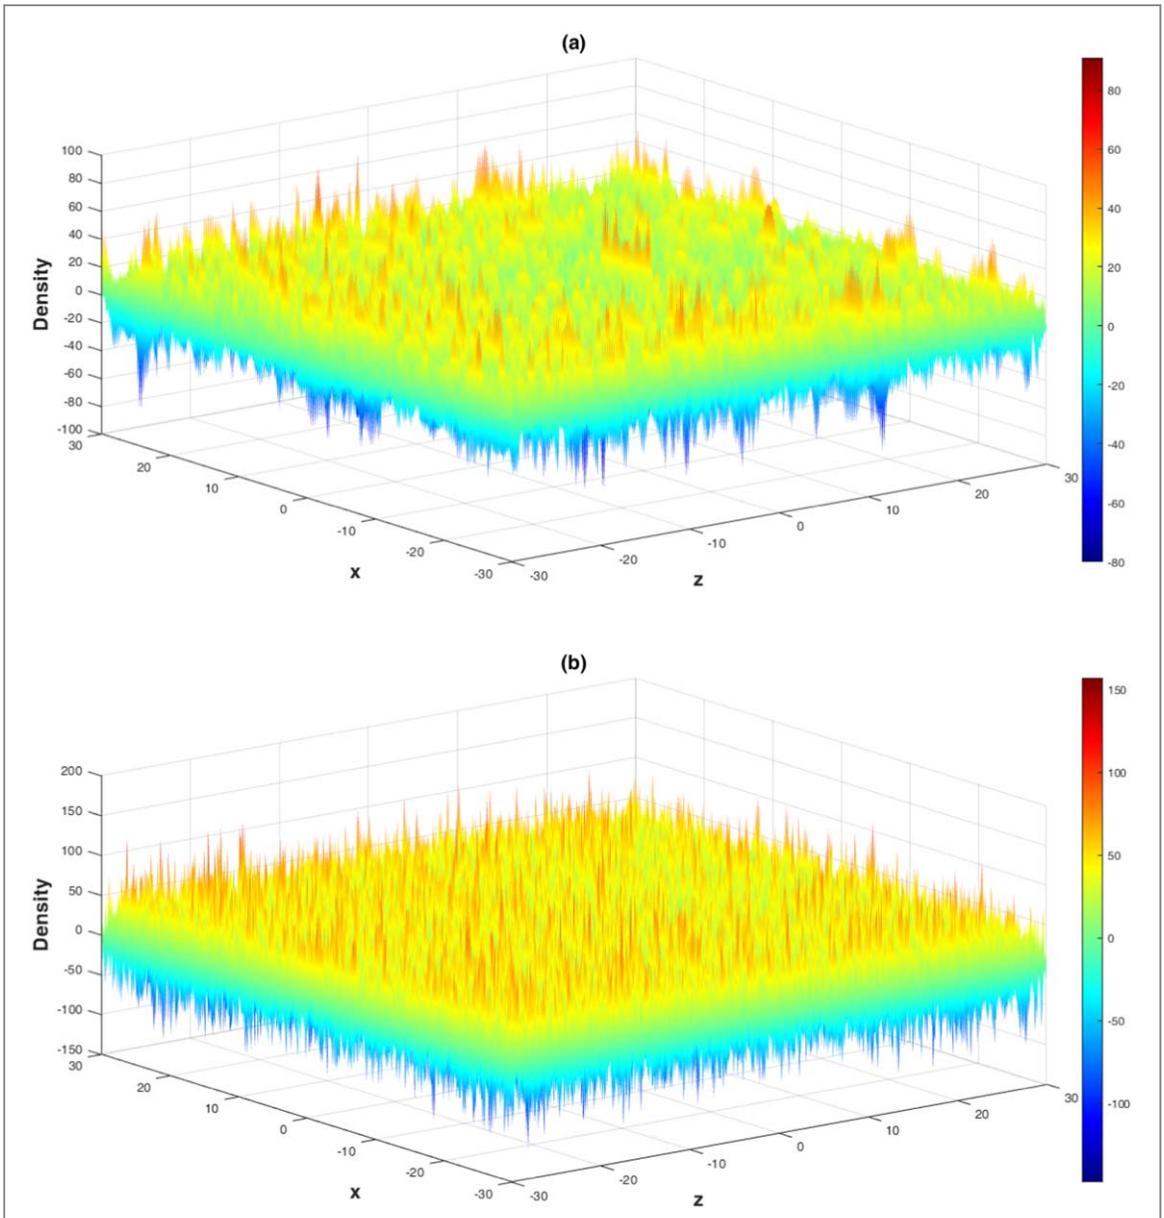

Figure 2. For normalized time (a) t = 24 and (b) t = 30 profile of the normalized density in the x-z plane.

$$n_1'(x, z) = \{1 + p^2 \cos(\alpha_x x)^2 + 2p \cos(\alpha_x x)\} \tag{30}$$

Equation (30) shows the generation of mode occurs at α_x and 2 α_x. Using equation (30), the coupling term $n_1'E_{0-}'$ of equation (26) can be expressed as

$$n_1'E_{0-}' = \{1 + p^2 \cos(\alpha_x x)^2 + 2p \cos(\alpha_x x)\}\{1 + p \cos(\alpha_x x)\} \tag{31}$$

The higher modes will be generated in E_{0-}' at α_x, $2\alpha_x$, and $3\alpha_x$ it can be seen from equation (31). The phenomenon of generation of higher density modes will persist until k_x becomes equal to $256\alpha_x$ in the spectrum.

5. Simplified model

A semi-analytical approach is also provided in this investigation to explore the evolution of pump wave. However, turbulence generation observation is not possible in this model due to the consideration of paraxial limits. Still, the nonlinear evolution of the pump wave inside the magnetized plasma is also an important phenomenon. Therefore, the exact comparison of the results obtained by this model and simulation results is not possible.

After neglecting the time variation from the equation (18), the equation for the R-mode wave can be written as follows:

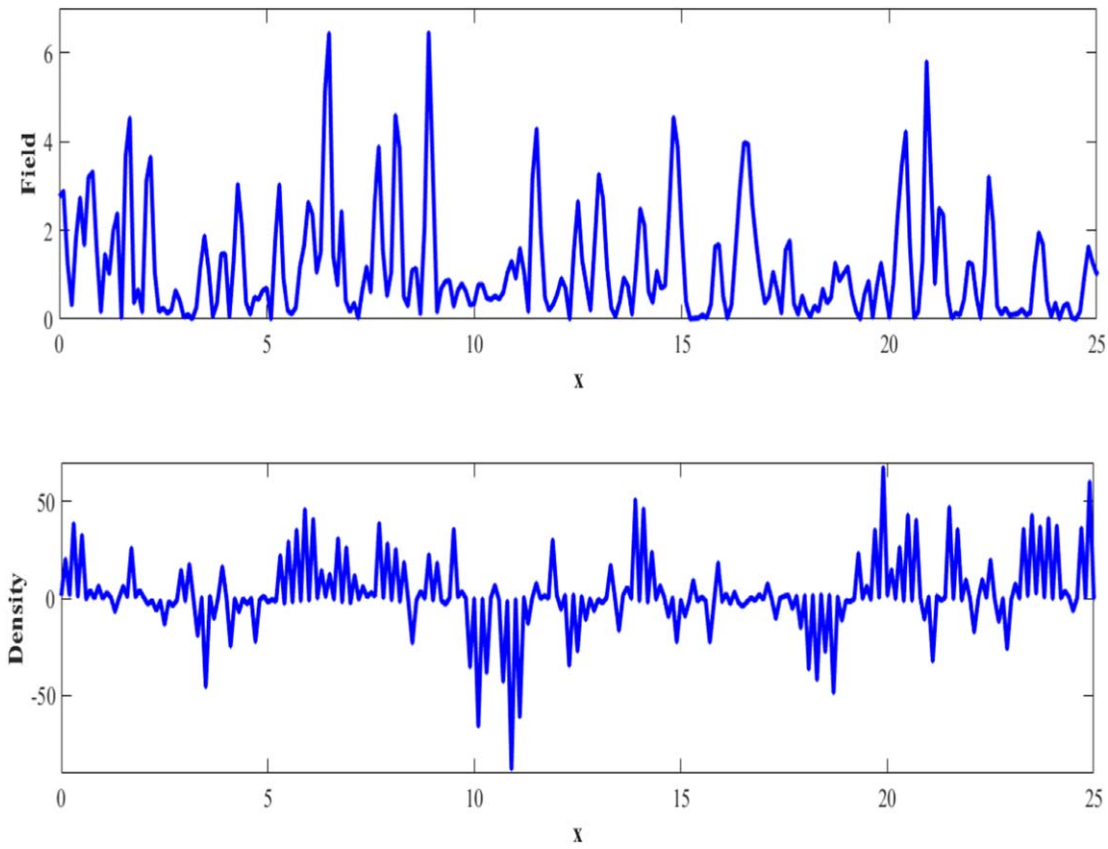

Figure 3. At normalized time t = 26, the profile of localization of field and density cavitation for R-mode wave.

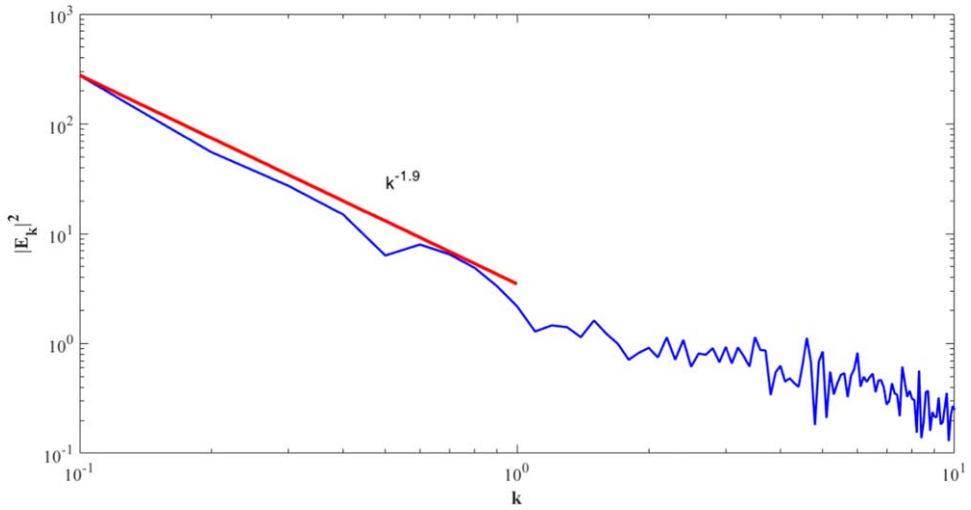

Figure 4. The magnetic power spectrum that is ensemble-averaged over the normalized time between t = 20 and t = 30.

$$2ik_{-}\frac{\partial E_{0-}}{\partial z}+\delta_{-}\frac{\partial^2 E_{0-}}{\partial x^2}+2i\omega_0\frac{\varepsilon_{-}}{c^2}\frac{\partial E_{0-}}{\partial t}-\phi\left(\frac{n_1}{n_0}-\alpha\left|E_{0-}\right|^2\right)E_{0-}=0 \tag{32}$$

Here $\phi=\frac{\omega_{pe}^2}{c^2(1-\omega_{ce}/\omega_0)}$ and the term (n_1/n_0) is time-dependent and can be written as:

$$\frac{n_1}{n_0}=N+\sum_{m=1}^{256}n_m\{\cos(m\alpha_x x)\}=N+\sum_{m=1}^{256}n_m\left(1-\frac{(m\alpha_x x)^2}{2}+\ldots\right) \tag{33}$$

n_m Represents number density modes evaluated by simulations for $m=1-256$, N denotes the Plasmon number in equation (33), and. Now, using the eikonal, the solution of equation (33) is assumed as follows [29]:

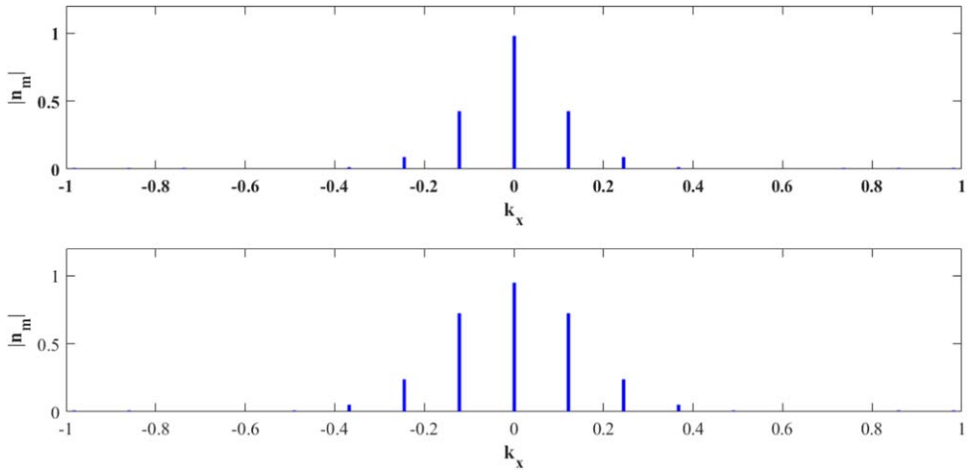

Figure 5. At normalized times (a) 10 & (b) 15 and at fixed k_z, fluctuation of density ($|n_m|$) versus k_x.

$$E_{0-} = A_0(x, z)\exp(ik_s(x, z)) \tag{34}$$

Now, substituting equations (34) and (33) in equation (32) and isolating the imaginary and real components, the following equations are obtained:

$$2k_^2 A_0\frac{\partial s}{\partial z} - \delta_\frac{\partial^2 A_0}{\partial x^2} + k_^2\delta_A_0\left(\frac{\partial s}{\partial x}\right)^2 + \phi\left\{N + \sum_{m=1}^{256} n_m\left(1 - \frac{(m\alpha_x x)^2}{2} + ...\right) - \alpha\,|A_0|^2\right\}A_0 = 0 \tag{35}$$

$$2\frac{\partial A_0}{\partial z} + 2\delta_\frac{\partial A_0}{\partial x}\frac{\partial s}{\partial x} + \delta_A_0\frac{\partial^2 s}{\partial x^2} = 0 \tag{36}$$

Now, with the initial beam width r_0 defining the amplitude of the beam and eikonal as:

$$A_0 = \frac{E_{00}}{\sqrt{f}}\exp\left(-\frac{x^2}{2r_0^2 f^2}\right) \tag{37}$$

And

$$s = \frac{x^2}{2f\delta_}\frac{\partial f}{\partial z} \tag{38}$$

Here, r_0, f, and E_{00} denote the transverse scale size, beam width parameter which is dimensionless, and initial field of the laser beam, respectively. The dynamical equation for the beam width parameter can be obtained by putting equations (37) and (38) in equation (36) and comparing the x^2 coefficients, which is given by the following equations:

$$\frac{d^2 f}{d\xi^2} = \frac{\delta_^2}{f^3\varepsilon_} - \frac{\phi E_{00}^2\delta_r_0^2}{E_n^2 f^2\varepsilon_} + \frac{\phi f\delta_r_0^4\alpha_x^2}{2\varepsilon_}\sum_{m=1}^{256} n_m m^2 \tag{39}$$

Here $\xi\left(=\frac{c}{\omega_0 r_0^2}\right)z$. Equation (39) describe the beam width parameter's behaviour as the laser travel through the plasma. In equation (39) the natural diffraction term is represented by the first term this term is responsible for the divergence of laser beam, the nonlinear term due to ponderomotive force and nonlinear term due to variations in background density with time is represented by second term and the third term respectively and the second and the third terms are responsible for the focusing of laser beam inside plasma. To solve equation (39) with numerical simulation parameters, the Runge–Kutta method of fourth order is utilized using initial conditions $f|_{x=0}$ and $\frac{df}{d\xi}\Big|_{x=0}$. The transient development of the R-mode wave is attributed to the inclusion of the time-varying background density variations in the third term of equation (39). Wave can undergo without convergence or divergence in the plasma when there is a balance between the nonlinear term (second and third terms) and the diffraction term (first term). It can be made clear from equation (39) that the self-focusing and defocusing of the laser beam is due to the competition between the diffraction term and the nonlinear term. Hence, one can say that filamentary structures are formed due to the nonlinearity exerted by the R-mode wave on the plasma wave. Self-focusing of the laser beam inside the plasma occurs when the nonlinear terms predominate the diffraction term, and at this point, the beam width parameter gets its minimum value. At the minimum value of beam width parameter (f), the intensity of the laser beam becomes maximum inside the plasma medium. Figure 6 illustrates the profile of the normalized intensity of the R-mode wave versus the

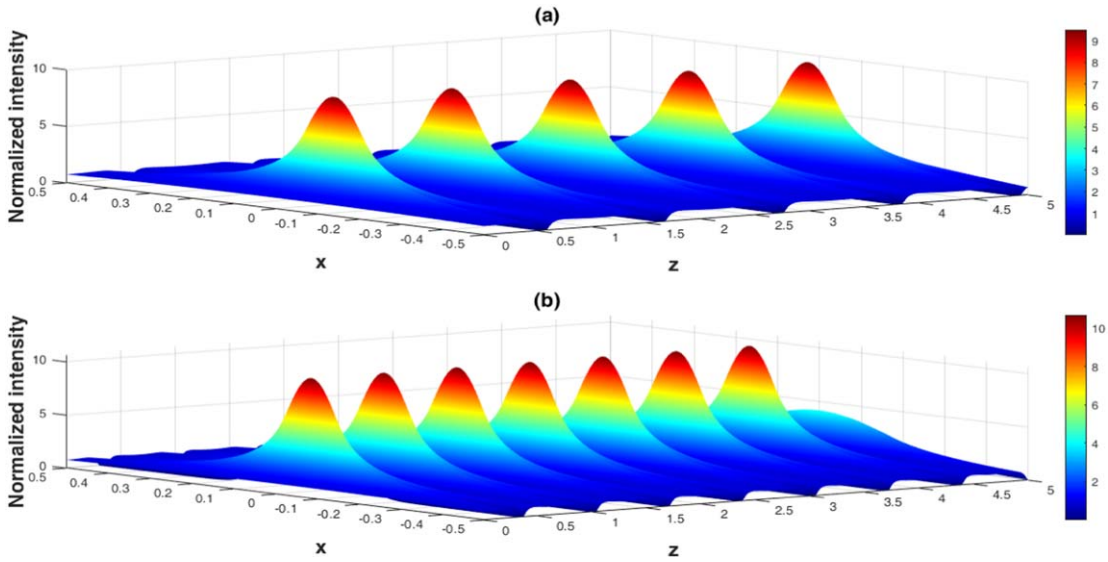

Figure 6. At various normalized times (a) t = 10 (b) t = 15, normalized intensity profiles.

dimensionless propagation distance ξ at two different normalized times. It can be noticed from figure 6 that the variations in the normalized intensity of the R-mode wave inside the plasma medium occur over time with density harmonics variations. This model helps in understanding the localization process, which is the main motive behind semi-analytical study.

6. Summary and conclusion

Numerical techniques and computer simulations are used to solve the nonlinear coupled system of R-mode wave (pump wave) and electron plasma wave. The ponderomotive and relativistic nonlinearities are responsible for the nonlinear coupling of the R-mode and EPW, as result the nonlinear evolution of the R-mode wave have been observed inside the plasma medium. As time proceeds, the pump wave localization becomes more chaotic leading to the turbulence generation. Moreover, the density modifications in the form of cavitation and humps have been observed, which corresponds to the electron plasma waves. The generation of magnetic turbulence associated with the localization of the R-mode wave inside the plasma medium and energy cascading in plasma can be inferred. From the numerical simulations, the ensemble-averaged power spectrum was also obtained for this investigation with the power-law scaling $\sim k^{-1.9}$. The some of the simulation findings observed from the present investigation, like nonlinear evolution (filamentation) of the pump wave, initiation time of the localized structures and their typical scale sizes, and scaling of the turbulent spectra at electron scale quite resemble the experimental outcomes reported by Mondal *et al* [11] experimental investigations of intense laser-plasma interaction. Thus, the model based on the nonlinear interaction of plasma modes could be essential to get insight into the physics of the magnetized plasma associated with the laboratory, space, and astrophysical scenarios.

#LetsTalk: Understanding Social Media Usage of Self-Harm Users in India

Garima Chhikara[1,2], **Abhijnan Chakraborty**[1]

[1] Indian Institute of Technology Delhi, India
[2] Delhi Technological University, India

Abstract

Mental health concerns, such as depression, pose significant challenges for support systems in effectively identifying affected individuals. On the other hand, people suffering from depression often find it easier to discuss on social media rather than in face-to-face interactions. Additionally, the development of distressing conditions typically arises from a multitude of factors accumulated over time rather than a singular event. To gain a fine-grained understanding of these facets, in this work, we perform a longitudinal analysis of the tweeting behaviour of Indian users who post content related to self-harm. We categorise users based on their posting frequency and examine various aspects including their social network, bio descriptions, tweeting preferences, temporal variations and cognitive indicators. By elucidating these nuances, we aim to contribute insights that could aid in the early detection of mental health issues and prompt timely intervention from support networks.

Introduction

Today, a large number of people around the world suffer from mental health issues like depression and anxiety. Mental health support systems are in place to help people who are struggling with mental health problems. However, these systems often face the challenge of identifying people who need immediate help. This is because people who are depressed may not always seek help, or they may not be able to identify that they need help. Worryingly, unless attended to in early stages, many individuals resort to deliberate self-injury to cope with their acute feelings. In fact, self-harm is reported to be one of the main causes of death at a young age (Rane and Nadkarni 2014). Since 2005, the percentage of teenagers and young adults who experience major psychiatric distress, including suicidal ideation and suicide attempts, has climbed by 71% (Twenge et al. 2019). In India, around 85% of the total lives lost due to self-harm between 2015 and 2019 belonged to the age group 15 to 49 (Rane and Nadkarni 2014).

Besides identification, mental health support systems face another challenge – people suffering from depression find it hard to express their feelings because they are ashamed and have a constant fear of being judged (Wasserman et al. 2012). Social media platforms like Facebook, Instagram, X (Twitter) provide space for users to connect with others, build communities, share personal life events, spread awareness, and overcome fear and stigma (Ernala et al. 2018). Almost 60% of the Indian population are active on social media (Basuroy 2022a). Apart from entertainment, social media has evolved as a significant resource of information on mental health. Researchers have leveraged social media platforms for analysis and detection of self-harm content (Chancellor, Baumer, and De Choudhury 2019; Aldhyani et al. 2022; Ophir et al. 2020). Social media like X allows users to be pseudo-anonymous (disguised under imaginary profile names), allowing people to reach out to others for help without revealing their actual identity (Coppersmith et al. 2018; Robinson et al. 2015; De Choudhury et al. 2021). This also helps to mitigate the bias present in surveys and self-reported data (Yuan et al. 2023).

While there have been multiple studies on mental health issues observed from the prism of social media (Aldhyani et al. 2022; Ophir et al. 2020), we believe that such studies need to be undertaken in a particular geopolitical and cultural context and in this work, we focus our attention on India. Every nation possesses its own set of challenges, and India is no exception. With a growing economy and the dubious distinction of being the most populous nation with 1.43 billion people, India has been witnessing numerous highs and lows over the last few years (Mozumder 2023; Chatterjee 2023), ranging from the crises of unavailability of hospital beds and medical oxygen during the height of COVID-19 pandemic in May 2021 (Ghoshal 2021), the plight of the migrant workers during nationwide lockdown (Varma 2019) highlighting societal inequalities, to farmers' protest against three agricultural laws.[1] Moreover, often *Dalits* and religious minorities[2] have faced the problem of identity, security, social discrimination, communal tensions and riots (Insights 2022; LotusArise 2022; Nations 2021). Such socio-political activities have great implications on person's men-

[1]The farmers' protest took a toll on the agitating farmers' mental health leading to three suicides (BBC 2021).

[2]In December 2019, the Indian Parliament passed Citizenship Amendment Act (CAA) to provide a route to citizenship to members of six religious communities from Pakistan, Bangladesh and Afghanistan but not for Muslims, which led to nationwide protests spearheaded by Indian Muslims (BBC 2019).

Issues	Post
Covid Oxygen	My friends father was on the way to hospital and said pls see that I come back home, I dont want to die gasping on the want of oxygen. And on day 3 we get a call that he is no more. These stories will keep on going in our head with pain.
Labour Rights	Here in India - Migrant workers have died and are dying. Poor are dying. Children are suffering. Speak up India. Speak up. #SpeakUpIndia #DeathsofMigrantWorkers #MigrantLaboursDying #SocialRevolution #WorkersUnite #EndHunger #GiveJobs #EqualPay #ConstitutionalRights
Farmer Protest	How do we account for the harms caused to so many farmers and their families during the period preceding the withdrawal? How culpable is the union government and what should be the appropriate reparation? #FarmLawsRepealed #FarmersProtest"
Minority	#Minority communities could not avail govt benefits due to lack of documentation and fear of discrimination. #Muslims fear approaching state institutions for any kind of redressal for the fear of discrimination. No families received scheme benefits in 4%-34% of 53 Muslim areas.
Dalits	Dalit student other than me from our batch was attacked with so many questions in school. And we both had only each other to share these everyday 'casteism' we had to face from school.
CAA	SOS - I am currently being detained at Nagpada Police Station. The police is targeting me now for exercising my fundamental right to peacefully protest against CAA/ NRC. @MumbaiPolice I have not violated any laws. I will take this further to the courts if need be.

Table 1: Tweets highlighting major challenges faced by Indians over past few years (author info omitted for privacy).

tal health. Table 1 shows some example tweets about the major issues that have been surfacing in India over past years.

Earlier works on mental health of Indian social media users (Di Cara et al. 2023; Roy et al. 2021; Lathabhavan 2020; Thippaiah, Nanjappa, and Math 2019; Kumar and Nayar 2021; Barkur, Vibha, and Kamath 2020; Khasawneh et al. 2020) have looked at a binary categorisation: one either has mental health issues or not. However, in reality, people gradually transition from the initial stage of anxiety to depression, leading to extreme steps like suicide (Ageitos et al. 2021). Identification of this transition in the early phase can help in preventing cases of self-harm. Furthermore, changing social, political and personal elements can have an additive effect on a person's mental discomfort. Depression and anxiety level keeps on changing with external factors and thus there is a need to comprehend the change in users behaviour over time. Towards this, in this work, we undertake a longitudinal analysis of Indian social media users, categorising them into three categories based on the posting frequency of afflicting content – low, moderate and high frequency users.

Collecting extensive longitudinal data from X between 2017 and 2021 for all three user categories, we try to answer the following research questions in this paper: How engagement and activity levels vary across user categories? How users across different categories describe themselves? How tweeting preferences, temporal characteristics, and cognitive traits evolve over time for various user categories?

According to our analysis, users who post self-harm content more frequently follow many individuals but have fewer people following them. As we transition from high to low frequency users, the trend seems to reverse. The largest number of followers and lowest number of following are among low frequency users. Most high frequency users connect their identity with their hobbies and passions, while a larger proportion of low and moderate frequency users associate themselves with personal attributes and are vocal about their concerns. We also examine the reactions of other users to tweets posted by self-harm users. In contrast to tweets from low and moderate frequency users, tweets by high frequency users receive more comments. Additionally, self-harm content posted by high frequency users receive more attention as compared to non self-harm content posted by the same user set. High frequency users use mentions to spread the word about their issues, and they are often seen addressing similar topics in their original tweets, retweets, and comments.

Overall, our work helps in uncovering different categories of users undergoing mental health issues and how their social media usage evolves with time. We hope that this work will lead to follow-up efforts to identify early onset of mental health issues and enable support systems to act accordingly.

Related Work

Social media has become a crucial tool for analysing mental health as it is easily accessible (Kosinski et al. 2015), overcoming a number of difficulties in cutting-edge clinical mental health evaluation techniques that depend on subjectivity and retrospective recall bias (Lazer et al. 2009). Considerable work is done in identifying and predicting depression among social media users (Coppersmith et al. 2018; De Choudhury, Counts, and Horvitz 2013; De Choudhury et al. 2021); implication of anonymous nature of platform on self-disclosure (Andalibi et al. 2016; Ernala et al. 2017); comparing the online and offline mental health behaviours (Saha et al. 2017); comprehending social support measures to encourage positive mental health (Andalibi, Ozturk, and Forte 2017; De Choudhury and Kiciman 2017); identifying the norms and practices of community (Chancellor et al. 2016); and how social platforms can be leveraged to provide support (Inkster et al. 2016). Previous studies (Eichstaedt et al. 2018; Owen et al. 2023; Schemer et al. 2020; A. et al. 2022) have conducted longitudinal analysis to predict depression using social media data. However, our research

hang myself	hate myself	am lonely
self injury	take my life	want death
self harm	end my life	kill myself
want to die	been suicidal	cut myself
suicidal thoughts	commit suicide	have no one

Table 2: Keyphrases used for collecting self-harm posts.

specifically targets Indian users, offering a more comprehensive examination of posting behaviors and user traits. To the best of our knowledge, this is the first work that performs longitudinal analysis of self-harm users in India based on the users posting frequency.

Dataset Gathered

Our dataset curation went through the following stages: (i) collect tweets with several keyphrases, (ii) manually annotate them to identify true instance of self-harm and get rid of false positives, (iii) collect timeline of self-harm users, (iv) gather a collection of random tweets, and (v) build and apply a binary classifier to label timeline posts as self-harm or non self-harm. Figure 1 shows various stages of data collection.

Collecting Self-Harm Tweets

We collected all public tweets with geolocation India between 2017 to 2022 which included any of the keyphrases mentioned in Table 2, using the (now defunct) Twitter API with academic research access. These key phrases were curated using the phrases mentioned in prior literature (Coppersmith, Dredze, and Harman 2014; Coppersmith, Harman, and Dredze 2014). Through this data collection process, we obtained 3,759 posts from 3,026 unique users. However, the mere presence of these keyphrases does not necessarily indicate intention of self-harm. Table 3 shows example instances where the presence of a keyphrase can denote both presence and absence of self-harm intent. While there are tweets depicting real cases of anxiety, depression and self-harm; there are also tweets on disappointment with government rules and policies, political and economic situation, death of a famous celebrity, criminal offence or suicide in neighbourhood, suicide awareness and prevention, dialogue from a movie or drama, complaints about customer services etc.

To separate the true instances from false positives, we manually annotated 3,759 posts as valid (true case) or invalid (false case). We employed three annotators, and disagreements were resolved by a majority vote.[3] We find 1,147 posts from 939 users depicting actual instances of mental affliction. Since these 939 users have posted at least one mentally alarming post between 2017 and 2022, we refer to them as the *Focus Group*. We concentrate on this focus group for further analyses.

Compiling X Timelines of the Focus Group

Longitudinal studies have proven to be useful in explaining how people behave in various situations. We analyse the focus group over time from 2017 to 2022. Towards this, we attempted to collect the X timelines of all 939 users from the focus group. We found 49 accounts to be deleted or suspended, and gathered the timeline data for the remaining 890 users. The Twitter API generates an error message 'user not found' or 'user has been suspended' for unavailable accounts, we utilise this information to monitor deleted and suspended accounts. Overall, we obtained 1,385,535 tweets posted by the 890 users of the focus group.

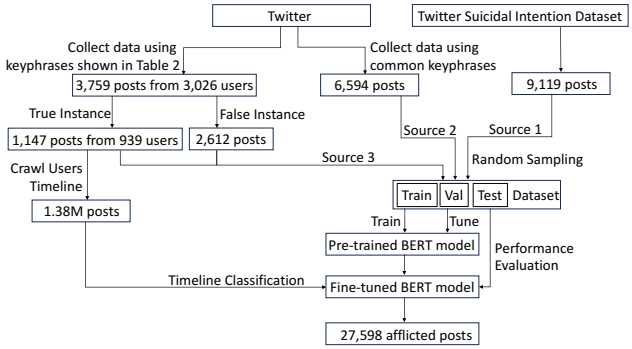

Figure 1: Steps followed for collecting data from users timeline. Transformer based BERT model is fine-tuned using data from three different sources. Model reported F1-score of 0.91 on test dataset. Fine-tuned model classified 27,598 posts as mentally alarming.

Classifier for Automated Labelling

For further analyses, we need to identify how many among these 1.38M tweets are related to self-harm. Since manual annotation of 1.38M tweets is challenging, we use the state-of-the-art transformer based BERT model (Devlin, Chang, and Lee 2019) for the classification task. Previous research has indicated BERT's efficacy in binary classification tasks in the realm of mental health (Owen et al. 2023). For our task, we fine-tune the BERT base model to classify a post as self-harm or non self-harm.[4]

Data for fine-tuning. The data for fine-tuning and testing is collated from three different sources: (i) *Twitter suicidal intention dataset* [5] with 9,119 tweets, amongst which 3,998 posts are labelled as suicidal intention and 5,121 are labelled as non suicidal intention; (ii) we additionally collect 6,594 tweets from X using keywords like 'shopping', 'travel' and 'happy'. Rationale behind this is that timeline posts can deal with routine activities and may not depict self-harm content always, hence such data is necessary for training the classifier;[6] and (iii) the initial manually annotated dataset with 1,147 self-harm tweets and 2,612 non self-harm tweets.

[3]The annotators are aware of the Indian context and have a good understanding of self-harm and non self-harm text.

[4]The classifier code is available at https://github.com/garimachhikara128/MentalHealth/

[5]The dataset is available at https://github.com/laxmimerit/twitter-suicidal-intention-dataset/

[6]We assume that since these tweets are obtained through keywords denoting happy state of mind, they are non self-harm posts.

Self-Harm Intent Present
I've decided to by myself take psychiatric help to give myself one last chance. If I see no improvement then I may just **end my life**.
My life at the current stage is making me to want to **end my life**. I'm slowly losing all purposes that have kept me alive to this day. I don't know how much longer before I can no longer take it and finally **end my life**.
Today's very very bad day, Anniversary of my parents, I'm the very unlucky daughter, I **hate myself** and my worst fate.
Yesterday and for many months before that, I've had intense stages of **self harm**. And these happen late, usually around and after 12 AM. And there's no suicide prevention helpline available. I called up one yesterday because I had self harmed and they asked me to try Savasana ???
Self-Harm Intent Absent
It would have **been suicidal** for congress to let priyanka fight from Varanasi. She is just entering political arena and would have surely lost big from Varanasi. A safe seat like Wayanad is required for her..!
After doing all household chores, I am loving to spend my time on Instagram, YouTube and WhatsApp more these days. I am not much on Facebook because I want to **cut myself** from all the food pics.
It's end of the crossroads now, wanna **end my life** long relationship with @Airtel_Presence, wanna port my SIM into @JioCare, Please let me know the process!
Today at 12:25AM, I have spent more than 45 mins in total waiting and searching for a ride at @Uber_India. I almost **hate myself** for being in situations like these where I need to rely on your service despite of the certainty of your services.

Table 3: Example instances showcasing presence and absence of self-harm intent.

Data	**Original**			**Sampling**			**Train + Validation**			**Test**		
	Class 0	Class 1	Total	Class 0	Class 1	Total	Class 0	Class 1	Total	Class 0	Class 1	Total
D1	5121	3998	9119	2000	3998	5998	1600	3198	4798	400	800	1200
D2	6594	0	6594	2000	0	2000	1600	0	1600	400	0	400
D3	2612	1147	3759	1140	1142	2282	912	913	1825	228	229	457
							4112	4111	**8223**	1028	1029	**2057**

Table 4: Table showcasing equal distribution of training, validation and test data from each data source. *Original* indicates the actual data collected through existing repository and through X API. Random *Sampling* is done to guarantee equal proportionality from both classes. 80% of the sampled data is used for training and rest 20% is used for testing. Amongst training data, 80% is used for fine-tuning the model and other 20% is used for validation. Test data is employed to evaluate the model's performance.

Then, we randomly sample the dataset to ensure an equal number of tweets from both classes, resulting in 8,223 tweets in the training+validation dataset and 2,057 tweets in the test dataset. Table 4 shows the detailed breakup of posts used for training, validation and testing. We observe that the final fine-tuned BERT model exhibits good performance on the test dataset with an accuracy of 91%. After applying this classifier to 1.38M posts collected from different users timelines, 27,598 tweets are classified as self-harm and the remaining tweets are classified as non self-harm.

Categorising Users in the Focus Group

Based on the frequency of self-harm posts over the years, we categorise the users from the focus group into three categories – **low frequency users**, **moderate frequency users**, and **high frequency users**. Figure 2 shows the frequency of self-harm posts between 2017 and 2022 posted by all users. We define low frequency as those who posted less than 50 self-harm posts, moderate frequency who posted more than 50 but less than 150 tweets, and high frequency who posted more than 150 tweets. Details about the user distribution across these categories are shown in Table 5. We observe that 1%, 3% and 8% of tweets posted by low, moderate and high frequency users respectively reveal the presence of mental discomfort. This suggests that when compared to low and moderate frequency users, high frequency users not only post more self-harm content but also a bigger percentage of their posts are distressing.

Characterising Different User Categories

In this section, we examine the long-term trends among different user categories based on social media neighbourhood, bio description, tweeting preferences and temporal variations. While there have been multiple works focusing on mental health concerns, to the best of our knowledge, this is the first work to consider the longitudinal differences amongst Indian users based on the posting frequency.

Social Media Neighbourhood

The number of followers and followees of a user reveal their attempt at socialising as well as the willingness to consume outside information. Earlier works have shown that power law best fits the in-degree distribution (followers), whereas log-normal best fits the out-degree distribution (followees) (Myers et al. 2014; Lerman, Yan, and Wu 2016). Interestingly, in our case (as shown in fig. 3), we observe that

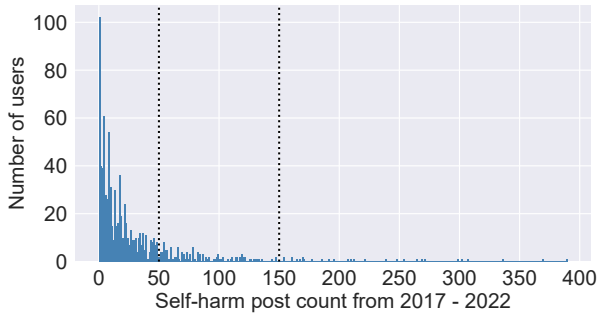

Figure 2: Total number of self-harm posts made by 890 users of the focus group from 2017 - 2022. We select 50 and 150 as threshold for low, moderate and high frquency users. Users with less than 50 self-harm posts are low frequency users, users with self-harm post count between 50 and 150 are moderate frequency users, and users with self-harm post count greater than 150 are high frequency users.

Category	No. of Users	No. of Posts	No. of SH Posts	Fraction of SH Posts
low	739	1023919	10892	0.011
moderate	122	286042	10086	0.035
high	29	75574	6620	0.088

Table 5: Distribution of self-harm (SH) users and posts across various categories.

both follower and followee counts obey log-normal distribution for all three user categories in the focus group. Table 6 shows the value of exponent α for power law and value of mean and standard deviation i.e., μ and σ for log-normal distribution. Moderate frequency users are reported to have the highest mean μ across both the measures of followers and following and it is interesting to observe that the standard deviation σ is the lowest across medium frequency users, indicating that most of the followers and following of moderate frequency users are clustered around the mean, whereas for low and high frequency users the spread is relatively higher as compared to moderate frequency users.

Engagement. To assess levels of engagement across three user categories, we establish three measures based on the volume of users followers, following and tweets (Wang et al. 2017). We characterise the level of engagement of category c in terms of measure m as follows:

$$Engagement(c, m) = \frac{\sum_{u=1}^{n} \#m_u}{n} \quad (1)$$

where $c \in \{Low, Moderate, High\}$ and $m \in \{Followers, Following, Tweets\}$, n are the number of users in category c and $\#m_u$ denotes the count of measure m for user $u \in c$.

Table 7 lists the statistics for social engagement. Low frequency users show the maximum engagement for #followers and high frequency users exhibit the maximum engagement

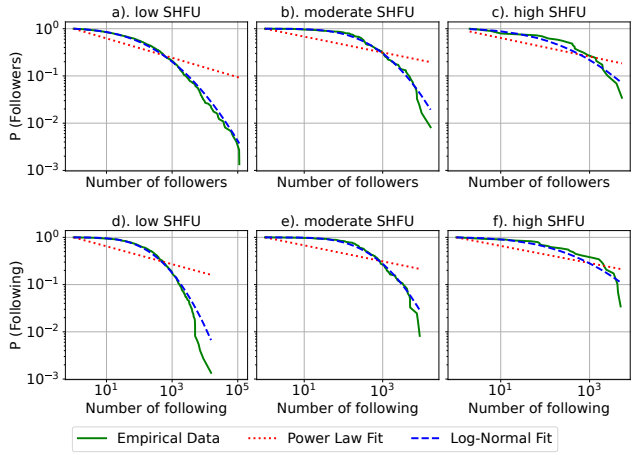

Figure 3: Complementary cumulative distribution function (CCDF) for count of followers and following. Red and blue curves denote fitted power law and lognormal distributions across low, moderate and high self harm frequency users.

Measure	Category	Power Law α	Log-normal μ	Log-normal σ
Followers	low	1.205	4.661	2.589
	moderate	1.168	**5.955**	**1.820**
	high	1.197	4.948	2.456
Following	low	1.189	5.272	1.766
	moderate	1.169	**5.903**	**1.673**
	high	1.181	5.415	2.521

Table 6: Statistics for distribution of followers and following. The parameter α assumes $P(x) \sim x^{-\alpha}$ for degree x (power law). The μ and σ parameters assume $P(x) \sim \frac{1}{x}\exp[\frac{(\ln x-\mu)^2}{2\sigma^2}]$ (log-normal).

for #following and #tweets. One might argue that it was implied for high frequency users to receive the maximum engagement on #tweets since this itself was the categorisation approach, but note that our method of categorisation is exclusively based on the number of **self-harm posts** regardless of the total number of posts. In addition to posting more instances of self-harm, high frequency users have the highest #tweets across all user types. Earlier works have reported the shrinkage of networks as a useful indicator of impending behavioural changes (De Choudhury, Counts, and Horvitz 2013). In contrast to low frequency users, who have a bigger network of #followers, high frequency users have less individuals following them. This suggests that users who publish more distressing content are less likely to be followed by other users. High frequency users have highest #following, which indicate they are more intrigued about others as compared to low and moderate frequency users. Kolmogorov-Smirnov (KS) test (Lilliefors 1967) revealed the results to be statistically significant with $p < 0.05$.

Activity. We investigate which user category is most active on Twitter. We quantify activity as the average number

Measure	Low	Moderate	High
Engagement			
#Followers	**1749.51**	1372.76	817.07
#Following	643.84	1035.57	**1203.97**
#Tweets	1385.55	2344.61	**2606.00**
Activity			
#Followers/day	0.65	**0.72**	0.37
#Following/day	0.61	0.65	**0.94**
#Tweets/day	1.05	3.06	**11.1**

Table 7: Social Media Neighbourhood: Statistics for Engagement and Activity across various user categories.

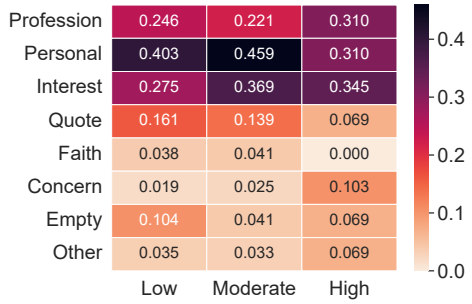

Figure 4: Normalised score for labels across three different user categories.

of followers, following and tweets per day.

$$Activity(c, m) = \frac{\sum_{u=1}^{n} \left(\frac{\#m_u}{d_u} \right)}{n} \quad (2)$$

where d_u is the number of days between – user u joining X and his last post. Higher activity levels indicate higher expressiveness (Ernala et al. 2017; Saha, Weber, and De Choudhury 2018; De Choudhury et al. 2021; Yuan et al. 2023). Moderate frequency users have active #Followers/-day whereas #Followers are not the highest for them, this indicate users with moderate frequency are engaged for a shorter amount of time on Twitter.

Bio Description

Users embark on significant communicative and identity disclose properties when they create their unique accounts, e.g., by filling up the bio sections, as opposed to being confined solely to the content that gets posted thereafter (Greene and Brownstone 2023; Chakraborty et al. 2017). We analyse bio description of the 890 users from the focus group and label them as 'profession', 'personal', 'interest', 'quote', 'faith', 'concern', 'empty', and 'other'.

Profession: where a user describes something about their profession, e.g., *"Associate Director"*, *"Practicing Gynaecologist"*, *"Assistant Professor(Pharmacology)"*, *"Fitness Coach"*.

Personal: information regarding age, gender, birthday, education, location, religion, qualities and relations, e.g., *"she/her 24"*, *"Astrophysics Scholar"*, *"Believe in Secularism — Peace — Love"*, *"A proud Resident of Bihar"*, *"Proud Father"*.

Interest: where users highlight interests or hobbies, e.g., *"BTS : Justin"*, *"Interest in Photography & Documentary Making"*, *"a singer and baker by hobby"*.

Quote: users use well known quotes or dialogue from movies or pen down their thoughts in bio description, e.g., *"Emptiness is better than something temporary"*, *"When life gives you lemons, make lemonade of it"*.

Faith: user mention about religion and God, e.g.,*"God Protect Me"*, *"Jai Shree Ram"*, *"Inservice to Lord Krishna"*, *"Burn the evil spirits and demons now and forever. Amen omshanthi Allah"*.

Concern: user raises concern regarding personal or societal issues, e.g., *"#cancel 12th board exam"*, *"Alone boy. Need adoption or family"*, *"Dream IIT but no money and guidance. Please help me for higher education."*, *"My life Dedicated towards Saving & Serving Innocent Speechless Souls (Animals)..In real,trying to be humane"*.

Empty: user prefers to leave their bio description unfilled.

Other: bio description is not significant enough to convey meaning, e.g., *'#'*, *'eh.'*, *'...'*, *'anyway,,,'*.

People use bio to express their *self-identification*, and individuals can opt to do so from a variety of perspectives, hence a bio description can be tied to several labels. Figure 4 shows the normalised count of labels across different user categories. 40.3% of low frequency and 45.9% of high frequency users mention about their *personal* lives in their bio descriptions, followed by *profession* and *interest*. Majority of the low and moderate frequency users discuss their personal traits on social media, on the contrary only 31% of high frequency users mention personal elements, which suggests fewer high frequency users prefer to divulge their personal identities on social media. The biggest percentage of high frequency users (34.5%) mention their amateur interest, suggesting that they possess or at least identify themselves with some leisure pursuits. An equal percentage (31%) of high frequency users mention about *profession* and *personal* elements, among high frequency users *identification* is nearly equally distributed across *profession*, *personal* and *interest*. Faith is mentioned in 3.8% and 4.1% of user bios from low and moderate frequency users respectively, on the contrary none of high frequency users referred to or exhibited trust in God in their bio descriptions. Low and moderate frequency users have only 1.9% and 2.5% bio descriptions tied to *concern*, whereas, among high frequency users 10.3% of tweets address critical issues, suggesting high frequency users are relatively more vocal about venting concerns.

Tweeting Preference

We analyse how users from the focus group engage with one another – interaction with posts and publishing of posts (Wang et al. 2017).

Post Interaction. We consider three measures for interaction with post - replies, likes and mentions. Figure 5 shows average number of replies, likes and mentions received on ***all set*** and ***self-harm set*** for different user categories.

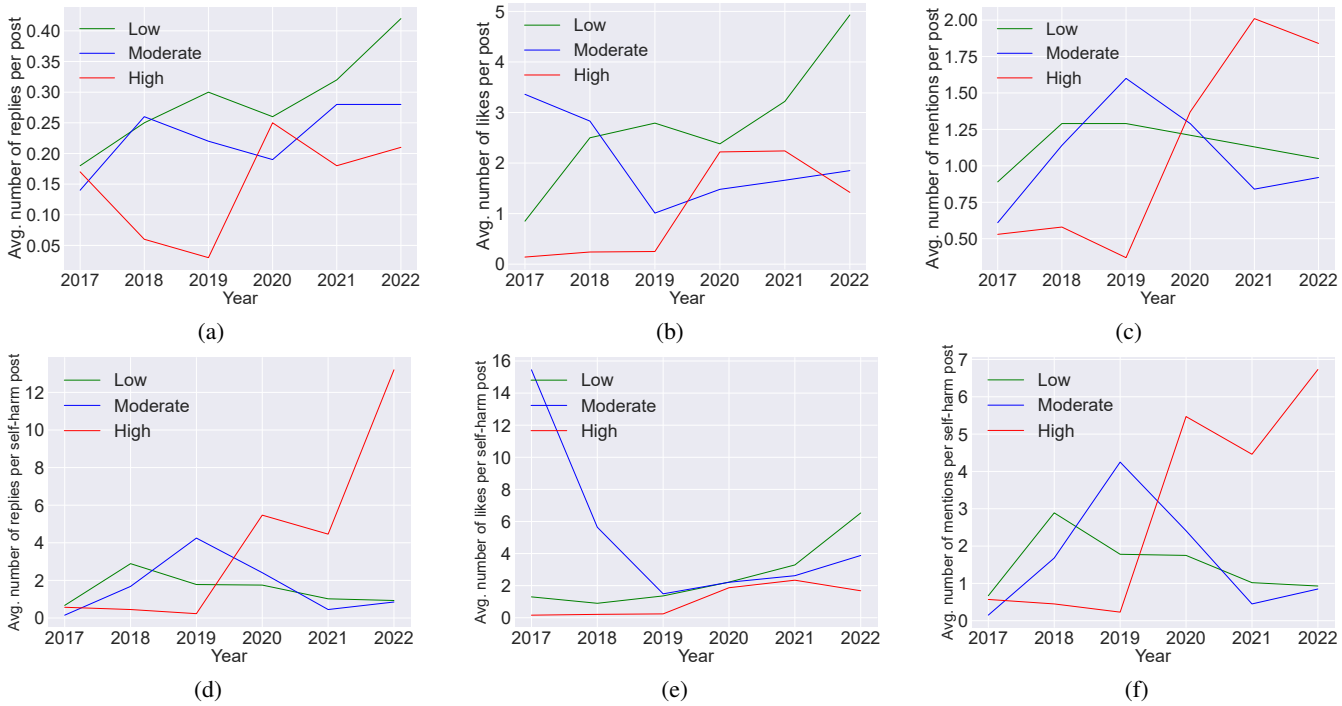

Figure 5: Post Interaction from 2017–2022 for various user categories. Average number of (a) replies (b) likes (c) mentions received on all set. Average number of (d) replies (e) likes (f) mentions on self-harm set.

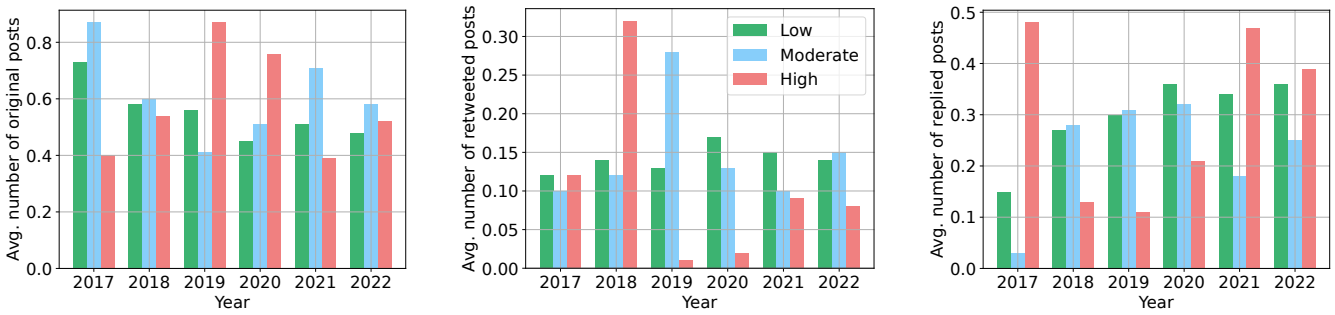
We first compare the measures across all set and self-harm set. All set comprises of the entirety of timeline posts made by users of the focus group, self-harm set refers to mentally afflicting posts from the focus group's timeline. i) Replies for all set vary between [0,0.4] (fig. 5a), whereas for self-harm set replies range between [0,12] (fig. 5d). Self-harm set exert higher interaction – the average number of replies are greater in comparison to all set, people on social media exhibit higher interaction with self-harm posts indicating higher social assistance, some earlier works have shown replies can act as a proxy for social support (De Choudhury and Kiciman 2017). ii) Number of likes for all set varies between [0,5] (fig. 5b), whereas the spread for self-harm set is [0,16] (fig. 5e), however if we consider year 2018 and later, the number of likes drop to range of [0,7], which is sufficiently close to the likes received on all set. If we investigate recent years, we can deduce that all set and self-harm set receive a nearly identical pattern of interaction with regard to likes. iii) Figure 5c and 5f illustrates the mention count on all set to range between [0,2] and self-harm set to range in [0,7] respectively. Self-harm set have a higher count of mentions as compared to other posts, which indicates the intent to disseminate the self-harm post to a broader audience.

Secondly, we compare user categories across various measures. i) Replies. On all set, low frequency users receive highest replies and high frequency users seek minimum replies (fig. 5a), whereas the trend seems to be reversed when we consider the self-harm set – high frequency users gather maximum and low frequency users receive minimum replies (fig. 5d). This reveals that people on social media converse more with low frequency users when they post non self-harm content and people engage more with high frequency users when they post self-harm content. ii) Likes. Over recent years, from 2019 – 2022, the pattern of likes across user categories has been similar for all set and self-harm set (fig. 5b and 5e), low frequency users receive maximum number of likes whereas high frequency users obtain minimum number of likes. This indicates social media users do not prefer interacting with high frequency users through likes. iii) Mentions. Usage of mention implies the want to let the other party know about the problem or anticipate a solution. Mention for high frequency users increased drastically since 2019, high frequency users avail the maximum usage of mentions across all set and self-harm set (fig. 5c and 5f) indicating they want their posts to reach to the maximum audience, and in haste, the users tag all potential helpers. While we observe an increase in mentions for high frequency users since 2019, there is a dip in mentions for low and moderate frequency users across all set and self-harm set. KS test indicates statistical significance for results shown in Figure 5 with $p < 0.001$.

The takeaway is high frequency users garner maximum replies for self-harm posts, whereas for general posts low frequency users attract the most replies. For year 2018 – 2022, statistics for likes and mentions follow similar patterns for various user categories across all set and self-harm set. Likes received by a user on a normal post and on a self-harm post are alike, and likes are not the preferred way of interacting with high frequency users. Self-harm posts comprise higher mentions as compared to general posts.



(a) (b) (c)

Figure 6: Fraction of (a) original (b) retweeted and (c) replied posts in all set from 2017 - 2022 for various user categories.

Post Type	User Category	Distinct Frequent Keywords
original	low	cope, feelings, depressed, stressful, crying, unhappiness, emotionless, mistreatment, crying, attachment, loneliness, distress, longing, grief, stress
	moderate	existence, imprisons, calm, silenced, deprivation, isolate, relativesam, memories, suicide, psychopath, awareness, hide, disappear, paranoia, invisibility
	high	admission, prevention, exams, intervene, discrimination, depression, anxiety, stressed, sufferings, hospitalisation, cbse, exams, pandemic, students, covid
retweet	low	dharmapuri, prayer, spiritual, coping, depressed, treatment, depression, patanjali, psychotherapy, pranayama, ayurveda, meditating, buddha, yoga, depressant
	moderate	meditation, addictive, smoking, overcome, remorse, suicides, mindfulness, therapy, psychiatric, depressed, addict, debilitating, suicidal, craving, medications

	moderate	husbands, disorders, loneliness, marriage, dysfunction, introvert, societal, depression, stigma, divorce, therapy, coping, patriarchal, matrimonial, feminists
	high	castes, student, cbse, delhi, panchayat, conferred, bharat, exam, declared, india, xii, assessment, mandir, examination

Table 8: Distinct high frequency keywords in original posts, retweets and replies.

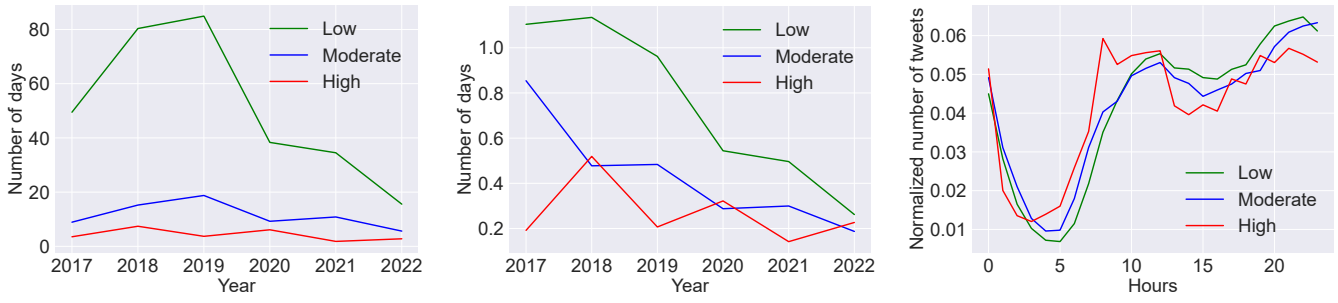
Publishing Posts. Users can publish posts in three ways: original post, retweet, or reply. We analyse the timeline posts of three user categories. Original post initiates a new discussion or thread, retweeted post is the retweet of another post, and replied post is the comment provided on another post.

In 2021 and 2022, all three user categories posted more original content followed by replied and retweeted posts (fig. 6). From 2017 - 2022, retweeted posts are observed to be minimal across all user categories, which indicate retweet is not extensively used by users.

We find the most frequently used words in original posts, retweets and replies across different user categories (table 8). We leverage the use of KeyBERT for keyword extraction, KeyBERT utilises BERT embeddings to generate keyphrases and keywords that are the closest to the given document (Grootendorst 2020). New conversation initiated by a low frequency user mostly talks about depression, stress, anxiety, and grief whereas a moderate frequency user posts about invisibility, isolation, and question their existence. In retweets, users suggest methods for coping with various mental issues through meditation, pranayama which is a breath regulation exercise, yoga, prayer, and medication. In replies, users are more expressive about their personal lives and share their perspectives about society, family, and personal matters like violence, divorce, and stigma. High frequency users, across all the posts, often discuss about exams, studies, students, results, and grades; this section of self-harm users seems to be mostly students and are trying to raise their concerns via new threads, retweets and replies. There is variation in the posts made by low and moderate frequency users across new posts, retweets and replies. Whereas high frequency users seem to be constantly discussing about the same issue across all the posts.

Temporal Variation

We study the relation between user categories and variation with time, we utilise the entire timeline data of 1.38M posts for temporal analysis. Low frequency users report highest average time gap between any two successive self-harm post, followed by moderate and high frequency users (fig. 7a). One might argue, this observation was implied as low frequency users post the least amount of self-harm posts, to



(a) (b) (c)

Figure 7: (a) Average time gap between two successive self-harm post (b) average time gap between any two successive post (c) time of the day when a post is created.

answer this, let us consider an example, a user posts three self-harm posts on day 1, day 4 and day 11 respectively, average time gap between two successive posts is 5 days. On the contrary, if the user posts on day 1, day 7 and day 15, the average time gap will be 7 days. In both cases, user posted three tweets but the average time gap differs, our method of categorisation is solely dependent on the number of self-harm posts. High frequency users tend to post self-harm content more frequently.

Similar statistics are observed for the average time gap between any two successive posts, low frequency users are reported to have the highest time gap (fig. 7b), which however has tremendously decreased over the past years. Low frequency users are less involved towards self-harm and general posts. On the other hand, high frequency users exhibit elevated levels of activity for both self-harm and general posts. If we look at the broader pattern, since 2017, the average time gap on self-harm posts has decreased for all three user categories, indicating people are getting more engaged and responsive to posts. KS test revealed results of fig. 7a and 7b to be statistically significant with $p < 0.001$.

We analyse the time of the day when users post. People with mental health issues may experience insomnia, they might act differently from regular users in terms of their online activities (Lustberg and Reynolds 2000). High frequency users are more engaged as compared to low and moderate frequency users from 3 am to 9 am and are least active from 11 am to 7 pm (fig. 7). Sleep cycle is particularly worse for high frequency users, who appear to be most active in early mornings and less active during the day. Prior work has suggested that disrupted sleep is one of the factors that is closely associated with depressive illnesses (Abdel-Khalek 2004). High frequency users are most prolific during odd hours which raises concerns about their mental health.

Cognitive Attributes

We study cognitive measures such as readability, complexity and repeatability for various user categories in all set.

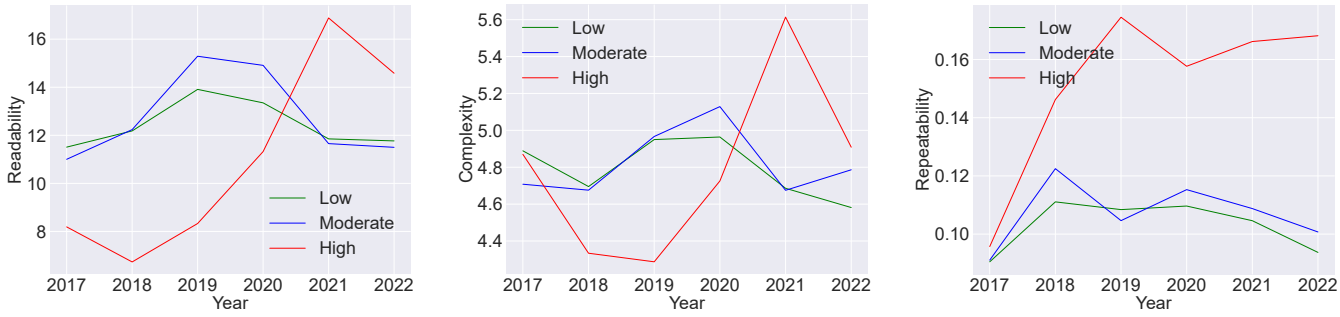
Readability. Readability is a measure to gauge the ease with which readers may understand a certain text (McCallum and Peterson 1982). Readability is an important indicator of people's cognitive behaviour, and earlier research has utilised this metric to comprehend the patterns of conversation in social networks (Ernala et al. 2017; Saha, Weber, and De Choudhury 2018; Saha and Sharma 2020). We employ Coleman-Liau Index (CLI) to calculate readability. CLI is calculated as, $CLI = 0.0588 * L - 0.296 * S - 15.8$, where L is the average number of letters per 100 words and S is the average number of sentences per 100 words (Pitler and Nenkova 2008).

We analyse the readability index in all set for different user categories (fig. 8a). CLI for low and medium frequency users are observed to be greater than 11 throughout the timeline of six years, depicting that the data is fairly difficult to read. For high frequency users CLI was lower than 8 until year 2019, indicating the text is ideal for average readers, but since then CLI has increased and in recent years is found to be higher than low and moderate frequency users. This indicates, as opposed to earlier years, high frequency users are now expressing their thoughts in fairly complex language.

Complexity. Complexity is the average length of words per sentence (Ernala et al. 2017; Saha and Sharma 2020). Since 2019, there has been an increase in the complexity for high frequency users with a decline in complexity for low and medium frequency users (fig. 8b).

Our analysis reveals that, since 2019, for low and medium frequency users there is a decrease observed in readability and complexity, and there is an increase for high frequency users. Earlier works (Ernala et al. 2017) have shown psychosocial health to have a positive correlation with readability and complexity. Note that, the data set used by (Ernala et al. 2017) is from year 2012 to 2016, which is disjoint with our data set which is from 2017 to 2022. If we base our analysis on the arguments made by (Ernala et al. 2017), from year 2017 to 2019, high frequency users show low scores for readability and complexity, indicating lower well-being. With many new Indian people joining X over the past few years (Basuroy 2022b), posting behaviour has changed substantially, high frequency users form more complex sentences as compared to low and moderate frequency users.

Repeatability. Repeatability is the normalised count of non-unique words, and correlates negatively with psychosocial health (Ernala et al. 2017; Saha, Weber, and De Choud-



(a) (b) (c)

Figure 8: (a) Readability (b) Complexity (c) Repeatability scores for all set across different user categories.

hury 2018). For high frequency users, repeatability is observed to be higher as compared to low and moderate frequency users (fig. 8), and higher repeatability is indicative of low well-being.

Takeaway. Since 2020, high frequency users from India have shown an increase in readability, complexity and repeatability, indicating they form more complex sentences and repeat words as compared to low and moderate users.

Concluding Discussion

We gathered timeline information from 1.38 million posts for 890 self-harm users in India. We opted for an automated transformer-based BERT model to classify 1.38 million tweets as self-harm and non-self-harm. On the basis of the number of self-harm tweets, we suggest a system to categorise self-harm users into three categories: low, moderate, and high. We conducted a number of analysis to learn more about the mental health of users in different categories. According to our findings, high frequency users are the most active; they follow many individuals and, in contrast, obtain fewer followers. High frequency users have highest comment counts, and likes are not the preferred method of communication with them. High frequency users had the worst sleep patterns of all and tend to write long, complicated phrases with repeated words. High frequency users show evidence of poor mental health, this category of users require quick assistance. The results of this study can provide assistance in early healthcare intervention in cases of self-harm.

Implications

Rich literature on mental health has considered two categories of users - one who face anxiety and depression and the other who does not. It is important not to place the users in either of the two axes – positive or negative. People who post mentally afflicting content can have different levels of affliction, motivated via this, we proposed a method to classify self-harm users in different categories based on their posting frequencies. Analysis reveals the psychosocial well-being of users from different categories, and the longitudinal analysis informs about the changing patterns across various measures.

Our work has practical implications for preventing self-harm. We currently assign each user a fixed category, but this work can be modified to allow for dynamic categorisation, where users who appear to change their categories from low to moderate or from moderate to high require immediate attention and users who change their categories from moderate to low or high to moderate can be seen benefiting from social media.

Limitations and Future Work

We acknowledge the limitations of our work, some of which suggest interesting areas for additional investigation. Our analysis is probably affected by selection bias, we collect publicly available data from X, given the stigma associated with mental illness (Corrigan 2004), only a small fraction of people prefer to post their opinions openly on social media. Our dataset encompasses the timeframe from 2017 to 2022, which coincided with the COVID-19 pandemic. This global event profoundly affected individuals' lives, with many experiencing personal losses. As a result, the user behavior depicted in our findings may be influenced by this unique period. It is imperative to recognise that conducting a similar study during a different timeframe could yield varying behavioral outcomes.

While India boasts a rich linguistic diversity, our analysis is confined to English tweets. It's noteworthy that many Indians utilise *code-mixing* (such as, Hinglish) for their social media interactions, suggesting a promising avenue for exploring tweet analysis across diverse Indian languages. Furthermore, our analysis overlooks user demographics. Individuals of varying genders, ages, and locations encounter distinct challenges. Delving into user characteristics at a more granular level, rather than merely at the national level, presents an intriguing opportunity for future research.

Ethics Statement

We utilise publicly available data from Twitter and we commit to safeguard the privacy of individuals. In this paper, we prioritise anonymity by removing all personal identity information and rephrasing the Twitter posts included in this document to prevent identification. Nevertheless, we recognise the potential negative impact of this work. Reporting of user characteristics of different categories may lead to

high anxiety levels among other users who may experience similar pattern. Moreover, there exists a potential for misuse of the findings presented in this paper, particularly in the development of commercial tools aimed at detecting levels of depression. Such tools could be exploited in various domains, including targeted hiring and insurance premium calculation, thereby amplifying existing societal inequities.

Acknowledgements

We would like to express our sincere gratitude to the anonymous reviewers for their valuable feedback which helped in improving the quality of the paper. We also extend our appreciation to our colleagues Kausik Hira and Vijay Kumar Meena for assistance during the early stages of this work.

Checklist

1. For most authors...
   (a) Would answering this research question advance science without violating social contracts, such as violating privacy norms, perpetuating unfair profiling, exacerbating the socio-economic divide, or implying disrespect to societies or cultures? Yes
   (b) Do your main claims in the abstract and introduction accurately reflect the paper's contributions and scope? Yes
   (c) Do you clarify how the proposed methodological approach is appropriate for the claims made? Yes
   (d) Do you clarify what are possible artifacts in the data used, given population-specific distributions? Yes
   (e) Did you describe the limitations of your work? Yes
   (f) Did you discuss any potential negative societal impacts of your work? Yes
   (g) Did you discuss any potential misuse of your work? Yes
   (h) Did you describe steps taken to prevent or mitigate potential negative outcomes of the research, such as data and model documentation, data anonymization, responsible release, access control, and the reproducibility of findings? Yes
   (i) Have you read the ethics review guidelines and ensured that your paper conforms to them? Yes
2. Additionally, if your study involves hypotheses testing...
   (a) Did you clearly state the assumptions underlying all theoretical results? Yes
   (b) Have you provided justifications for all theoretical results? Yes
   (c) Did you discuss competing hypotheses or theories that might challenge or complement your theoretical results? Yes
   (d) Have you considered alternative mechanisms or explanations that might account for the same outcomes observed in your study? Yes
   (e) Did you address potential biases or limitations in your theoretical framework? NA
   (f) Have you related your theoretical results to the existing literature in social science? Yes
   (g) Did you discuss the implications of your theoretical results for policy, practice, or further research in the social science domain? Yes
3. Additionally, if you are including theoretical proofs...
   (a) Did you state the full set of assumptions of all theoretical results? NA
   (b) Did you include complete proofs of all theoretical results? NA
4. Additionally, if you ran machine learning experiments...
   (a) Did you include the code, data, and instructions needed to reproduce the main experimental results (either in the supplemental material or as a URL)? Yes
   (b) Did you specify all the training details (e.g., data splits, hyperparameters, how they were chosen)? Yes
   (c) Did you report error bars (e.g., with respect to the random seed after running experiments multiple times)? NA
   (d) Did you include the total amount of compute and the type of resources used (e.g., type of GPUs, internal cluster, or cloud provider)? NA
   (e) Do you justify how the proposed evaluation is sufficient and appropriate to the claims made? Yes
   (f) Do you discuss what is "the cost" of misclassification and fault (in)tolerance? NA
5. Additionally, if you are using existing assets (e.g., code, data, models) or curating/releasing new assets, **without compromising anonymity**...
   (a) If your work uses existing assets, did you cite the creators? Yes
   (b) Did you mention the license of the assets? NA
   (c) Did you include any new assets in the supplemental material or as a URL? NA
   (d) Did you discuss whether and how consent was obtained from people whose data you're using/curating? Yes
   (e) Did you discuss whether the data you are using/curating contains personally identifiable information or offensive content? Yes
   (f) If you are curating or releasing new datasets, did you discuss how you intend to make your datasets FAIR (see FORCE11 (2020))? NA
   (g) If you are curating or releasing new datasets, did you create a Datasheet for the Dataset (see Gebru et al. (2021))? NA
6. Additionally, if you used crowdsourcing or conducted research with human subjects, **without compromising anonymity**...
   (a) Did you include the full text of instructions given to participants and screenshots? NA, we collected publicly available data from X.
   (b) Did you describe any potential participant risks, with mentions of Institutional Review Board (IRB) approvals? Yes
   (c) Did you include the estimated hourly wage paid to participants and the total amount spent on participant compensation? NA
   (d) Did you discuss how data is stored, shared, and deidentified? NA

***Abstract*—The identification and estimation of exercise poses has been a field of ongoing research in computer vision. Many deep learning architectures have demonstrated impressive performance, and as a result, much progress has been achieved in this area over the years. These developments highlight the enormous potential that exists at the nexus of fitness-related applications and computer vision, which applies to both images and videos. The complex task of workout image classification is addressed here using keypoint based classification, using YOLOv8 and MediaPipe to identify keypoints in the image and using those keypoints for classification. Then rigorous experiments were performed on a custom dataset designed to cover a wide range of poses—including differences in camera viewpoints, angles, and exercises. As part of this research, multiple algorithms were trained, including ensemble learning algorithms in an attempt to differentiate between the model performance of each algorithm. The effectiveness and limitations of different approaches have been measured in correctly identifying and classifying workout poses from 2D images. Analysis using multiple techniques is presented, where LightGBM with MediaPipe shows the best performance, achieving an accuracy of 95.95%.**

Keywords—deep learning, ensemble learning, keypoint detection, computer vision, pose detection

I. INTRODUCTION

Pose identification means determining the way a person positions their body when performing any activity. That position is then associated with that of a particular exercise, given the context learned from the image or video or real-time camera. Accurate identification of exercises is necessary for a variety of use cases, for example, supporting virtual personal trainers in guiding users through exercises with individualized recommendations, allows fitness tracking programs [1] to monitor workout routines and provide real-time feedback on form, and help with rehabilitation monitoring [2]. It also improves gesture detection in fitness games for immersive experiences, makes it easier to analyse athletes' actions for sports performance analysis [3], and can also connect with health monitoring devices to track physical activity levels and offer personalized recommendations.

Many exercise image recognition implementations use deep learning solutions, like CNNs, that is, Convolutional Neural Networks which are well-known for their effectiveness in classification and keypoint identification tasks [4]. However, the efficiency of these hinges significantly on the variety of the dataset. Ensuring that the model can represent the subtleties present in the given setting requires a strong dataset that covers a broad range of exercises, angles, and ambient conditions. Also, exercises are dynamic in nature. Further, many applications of exercise pose recognition may require fast inference and analysis, for example real-time analysis [5]. In such cases, the processing capacity of the underlying hardware is also an important consideration. This is because some people may prefer working out themselves with the help of a mobile application. Or they may be unable to hire a personal trainer. As a result, it is essential to find stability within accuracy of the model and computing resource limits because the application should be efficient for the given context.

In this paper, the process involves 2 approaches for keypoint detection by using cutting-edge methods, YOLOv8 (You Only Look Once) and MediaPipe. Both of these offer robust skeletal frameworks by obtaining keypoints from the images. Then that data is fed as input for training to various machine learning models like Decision Tree, Linear Support Vector Machine, Multi-Layer Perceptron, K-Nearest Neighbors and Gaussian Naive Bayes. Ensemble approaches like XGBoost, Bagging, LightGBM and Random Forest have also been used. Also to work with class imbalance due to some class having minority representation, SMOTE technique is applied. Then comparative evaluation is performed on various metrics with respect to all the models.

II. RELATED WORK

Pose identification and correction using machine learning methods has been extensively researched. It involves either entering exercises manually before performing them or automatically identifying and classifying user motion into an activity. There are studies that have used either images, or videos or both. In paper [6], the authors evaluated the motion quality of the workout performed by a user against the known correct motion. The authors used the HPTE dataset consisting of eight exercises performed by 5 different people from different backgrounds and angles. The proposed approach used PoseNet model in the backend which used two-dimensional data that has confidence linked to the body's important points and produces a heatmap for stance assessment. The system reached an overall accuracy of 80%. The user received feedback upon the completion of the task.

Bhat et al. [7] detected which joints need to be fixed during exercise by finding the overall joint angle distribution of the dataset and detecting poses in which a joint angle is an anomaly. The researchers created skeleton layouts using a variety of datasets based upon Yoga, Kungfu and Pilates. With the Kungfu-7 dataset, the DenseNet+Random Forest classifier delivered the best result, 86% validation accuracy.

Vimala et al. [8] offered an artificial intelligence-based solution to follow patients' physical activity types. Two deep learning techniques were used: a recurrent neural network (RNN) and a deep feed-forward neural network (DNN). Two datasets, one with 14 daily life activities from wrist-worn sensors and the other with 10 activities from hip-worn sensors were used to evaluate model performances among volunteers. The RNN model performed better with 84.89% accuracy. The F1-score was 82.56%. This suggested the model's capacity to accurately understand as well as track the physical activities of patients.

Rangari et al. [9] focused on individual exercise pose recognition using 2D coordinates for body keypoints recorded by an RGB camera. 18 major body joints' coordinates were identified and used as the model's attributes for exercise classification. Human volunteers of various ages and heights were taken to create a benchmark dataset. When tested on that dataset, the model outperformed previous methods with an impressive accuracy of 97.01%, demonstrating the efficacy of their proposed strategy.

Joshi et al. [10] attempted to classify six different sports categories with respect to athlete's body movement. Inception V3 was used for derivation of feature and then neural networks for pose categorization. On comparison with other machine learning classifiers, it validated the framework's efficacy. The suggested method successfully detected and classified a variety of sports data, evident by its remarkable 96.64% average accuracy. Chen et al. [11], utilized computer vision techniques where the suggested system extracted the human body's contour, skeleton, dominating axes, and feature points to examine posture from front and side views. Then, directions for posture rectification were offered so that the posture could be altered.

In an another approach, Yubin et al. (2021) [12] proposed a Mediapipe based computer vision-based technique for rating yoga poses utilizing two datasets: Dataset A, which they took from Kaggle and Dataset B, which the researchers created. Using coarse as well as fine contrastive samples, the method produced the greatest accuracy for Dataset A, 0.8321.

Singh et al. [13] put forth a novel approach to position estimation and identification which did not require wearable technology. To reliably categorize different postures, two pre-trained models' performances were compared with those of a bespoke CNN called DeepPose, which was trained using both image and keypoint datasets. The outcome demonstrated that the suggested model performed better than the image dataset when using the keypoint dataset.

A self-prepared dataset as well as a publicly available one were used to demonstrate the findings of paper [14] for WorkoutNet, a deep learning network for exercise action identification. It surpassed models like as XceptionNet, VGG-19, and DenseNet121, with a validation accuracy of 92.75%. It was verified with F1-measure and confusion matrix to properly classify exercises into 10 groups. Faisal et al. [15] used a deep learning-based model that can recognize five distinct poses with significantly less data. The variability in the dataset is compensated by improving the diversity in the images. They evaluated performance of their model against many image classification models, including ResNet, InceptionResNet, and Xception. With their suggested architecture, each of the image's spatial and depth information is extracted and taken into account for additional calculations. According to the experiments, it attained 94.91% accuracy and 95.61% precision.

III. Proposed Approach

There are several steps in the procedure used for the assigned work. The proposed approach is demonstrated in Fig. **1**.

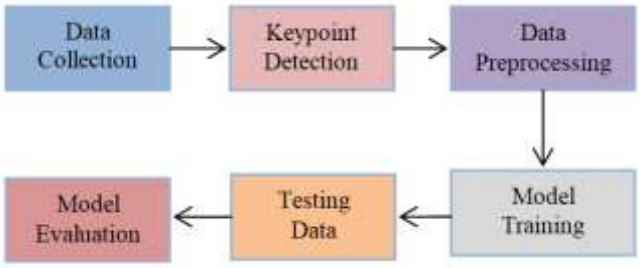

Fig. 1. Proposed Approach

A. Dataset Collection

Popular exercises were selected, and for each exercise, images were manually retrieved using Kaggle [16] as a guide and Google search engine. Consequently, the dataset has 1058 images, divided into 20 classes, each including 55–60 images. The twenty workout categories are as follows: bridges, bench press, bow, crane pose, crunches, cycling, cobra, child's pose, donkey kicks, downdog, deadlift, flutter kicks, pullup, plank, standing toe reach, shoulder press, squat, and triceps pushdown. A variety of stretches, bodyweight exercises, and weight training exercises are included in this set.

Tensorflow is then used to load images with a standard size of 224x224. Every image has a label based on the exercise being performed. Before loading, the dataset is shuffled to prevent imbalanced splits, following which a 80:20 split is made for training and testing respectively.

B. Keypoint Detection

YOLOv8 and MediaPipe algorithms have been used as the keypoint extraction algorithms. For YOLOv8, a grid is created using the input image, which gives cells. Now for each grid cell, bounding boxes and corresponding confidence ratings are predicted as part of a single-stage object recognition approach. The architecture usually comprises of many convolutional layers followed by upsampling and concatenation operations. Anchor boxes are used to increase localization accuracy, while feature fusion and skip connections are used to record spatial relationships.

The second method, MediaPipe extracts keypoints by first preprocessing the input image, then utilizing a convolutional neural network model trained for predicting the location of specific keypoints by detecting and localizing keypoints on the human body, including joints and landmarks. Features are extracted from the image at different scales, followed by regression techniques to predict the coordinates of each keypoint. Post-processing techniques may be applied to refine the results. That extracted keypoints act as the feature for each image. An example of keypoint detection using MediaPipe on a test image taken from the dataset [16] is shown in Fig. **2**.

C. Data Preprocessing

Preprocessing involves augmentations, which are required to increase the dataset's diversity to improve generalization. SMOTE (Synthetic Minority Over-sampling) Technique is a method frequently used in data augmentation to reduce class imbalance. By fabricating synthetic records for the minority class, it mitigates imbalance issues. First, a sample is selected at random from the minority class, and then its k-nearest neighbors are found. After calculating a

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 24,2024 at 04:36:38 UTC from IEEE Xplore. Restrictions apply.

vector between the current data point and chosen neighbor, a random number between 0 and 1 is multiplied. For every image in the dataset, this procedure is repeated. The labels were categorical in

Fig. 2. Keypoint detection in an exercise image

nature. They are encoded into numerical values using LabelEncoder.

D. Model Training

Thereon multiple algorithms have been trained on both the above skeletal data to compare the performance between them. For each algorithm, GridSearchCV was used to find the best hyperparameters. It is a method for systematically tuning hyperparameters of machine learning models. It works by searching through a specified list of parameters and also utilizes cross-validation to evaluate each combination's performance. The following models are used.

GaussianNB: It is a Bayes' theorem based probabilistic classifier, assuming normal distribution of features. It may be used to categorize keypoints according to probability distribution to differentiate between exercise postures.

K-nearest neighbors (KNN): KNN uses majority class voting to classify items using its K nearest neighbors. By calculating the distances between the keypoints of labeled instances, it can determine which class label the new instance most closely resembles [17].

Linear support vector machines: Linear SVM is utilized to effectively discriminate between postures by classifying them into distinct exercise categories based on spatial arrangement.

Decision tree: It is a tree structure with leaf nodes representing class labels and branches are the decision rules. Exercise posture categorization can be facilitated using this technique by generating hierarchical judgments based on the attributes of keypoint [18].

Random forest: Here, multiple decision trees are constructed. These then provide us with classification using the mode of the identifications for each tree. The performance hinges on the quality of the features found.

LightGBM: It uses a leaf-wise splitting technique. It divides the feature values into bins and then creates histograms on it due to which it effectively manages large datasets while reducing processing cost [19].

Bagging: With the help of voting, it combines the results of multiple classifiers which have been previously trained on varying bootstrap samples of the training data.

XGBoost: Based on gradient boosting, it is a boosted ensemble of decision trees for keypoint identification, XGBoost can efficiently capture intricate interactions between keypoints [20].

Multi layer perceptron (MLP): It is a neural network made up of several layers of neurons and has connections between every neuron in layers above and below.

E. Model Evaluation

The test set was used for evaluation of the models. On each model, several techniques were applied for a thorough analysis.

Then their test accuracy, precision and recall were determined.

A comparative analysis was conducted in order to further understand each models' performance with respect to the keypoint detection techniques used. The model that performed the best and had the highest test accuracy was then selected, and its weights were saved.

IV. Experimental Analysis

A. Requirement and Specification

Python version 3.10 was used to conduct the study. Hardware requirements include an Nvidia RTX 3080 GPU, a 4-core Intel i7 processor, 32GB DDR4 RAM, and the use of Google Colab's GPU for faster processing.

B. Experimental Details and Results

YOLOv8 predicted a total of 32 keypoints in this experiment while MediaPipe produced 33. TABLE I listed the best parameters found using Grid Search with respect to each machine learning and ensemble technique upon training on each skeletal data.

According to Table II, classifiers that use MediaPipe keypoints as opposed to YOLOv8 achieved higher accuracies. For instance, Linear SVM with MediaPipe shows accuracy increase from 69.88% to 90.90%, while GaussianNB's accuracy increases from 56.79% to 88.88% as well. LightGBM performed best with MediaPipe with 95.95%. Random forest closely follows it with 94.94%. Other ensemble techniques like Bagging also shows higher accuracy rates. Additionally, Multi-Layer Perceptron shows a notable improvement in accuracy employing MediaPipe keypoints, going from 81.89% to 91.41%.

For YOLOv8, Bagging showed the best performance of 82%. Further, in contrast to MediaPipe, Decision Trees and KNN show comparatively poorer accuracy rates when using YOLOv8. These results highlight how important feature extraction methods are to improving classifier performance.

TABLE I BEST HYPERPARAMETERS FOUND USING GRIDSEARCHCV

Model	Parameter	YOLOv8	MediaPipe
Decision Tree	criterion	entropy	entropy
	max_depth	none	none
	min_samples_split	2	1
	min_samples_leaf	2	2
	splitter	best	best
Linear SVM	c	1	1
	loss	hinge	hinge
	penalty	l1	l2
Multi Layer Perceptron	activation	relu	relu
	alpha	0.0001	0.0001
KNN	n_neighbors	3	3
	weights	distance	distance
	p	2	2
XGBoost	learning_rate	0.001	0.001
	n_estimators	128	100
	max_depth	5	3
	gamma	0.1	0.2

Bagging	n_estimators	128	100
LightGBM	learning_rate	0.003	0.001
	n_estimators	100	100
	max_depth	3	5
Random Forest	n_estimators	128	100
	max_depth	none	5
	min_samples_split	2	5
	min_samples_leaf	1	1

Compared to using just one model, ensemble algorithms integrate several models to get more accurate predictions. They increase strengths and minimize weaknesses by utilizing the diversity of several models. This is reflected in the results with all ensembles showing better performance.

Overall it can be said that the combination of MediaPipe with ensemble algorithms show consistently good performance when compared with other combinations.

TABLE II TEST ACCURACIES OF ALL CLASSIFIERS

Individual classifier	Accuracy (YOLOv8)	Accuracy (MediaPipe)
Decision Trees	50.00%	84.34%
Linear SVM	69.88%	90.90%
Multi-Layer Perceptron	81.89%	91.41%
KNN	66.68%	70.20%
GaussianNB	56.79%	88.88%
XGBoost	73.00%	91.91%
Bagging	**82.00%**	93.43%
LightGBM	80.00%	**95.95%**
Random Forest	78.00%	94.94%

To obtain more fine-grained understanding of the performance, precision, recall and F1 score are shown in Table III. Precision tells us out of all the positively predicted occurrences, what is the percentage of correctly predicted positive instances. Recall gives us the percentage of accurately predicted positive cases among all true positives. It tells us how well the model recognizes positive cases. F1 score gives us a single metric for model evaluation which is defined as the harmonic mean of precision and recall.

TABLE III PRECISION, RECALL AND F1 SCORE FOR MEDIAPIPE METHODS

Algorithm	Precision	Recall	F1 score
Decision Tree	0.83	0.85	0.83
Linear SVM	0.89	0.87	0.88
Multi-Layer Perceptron	0.89	0.90	0.88
KNN	0.67	0.64	0.64
GaussianNB	0.87	0.88	0.87
XGBoost	0.96	0.95	0.95
Bagging	0.97	0.95	0.96
LightGBM	0.97	0.96	0.96
Random Forest	0.95	0.94	0.95

Accurate classification and a reduction in false positives using MediaPipe keypoints is demonstrated by most ensembles, which routinely attain precision and recall above 0.95. When it comes to reliably classifying images based on MediaPipe keypoints, Linear SVM and Multi-Layer Perceptrons also fare well, scoring around 0.89. Lower ratings for KNN, however, point to possible false positives and limitations in its classification. The findings highlight the significance of choosing the right technique with MediaPipe-based features for classification tasks.

The confusion matrix in Fig, provides a breakdown of exercise classifications. The accurate pose predictions are demonstrated via diagonal elements. The regions that are misclassified and hence need improvement are the off-diagonal elements. For every exercise, it displays the wrong class that the model predicts. From the confusion matrix, the system demonstrates 100% accuracy for a number of exercise categories, namely bench press, cobra, child's pose, downdog, deadlift, flutter kicks, leg extensions, lat pulldowns, plank, standing toe reach, shoulder press and triceps pushdown.

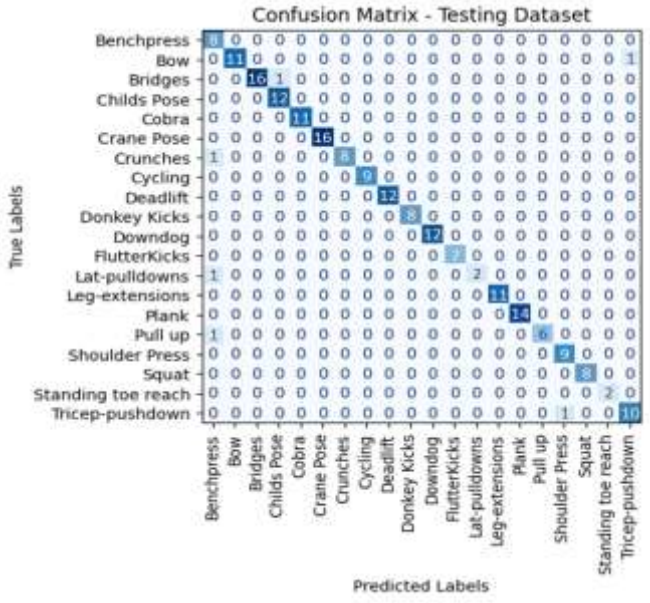

Fig. 3 Confusion matrix of LightGBM model with MediaPipe landmarks

Table IV shows the pose-wise accuracy for MediaPipe+LightGBM model. This is confirmed by its high precision and recall.

TABLE IV ACCURACY OF EACH WORKOUT CLASS FOR LIGHTGBM MODEL (WITH MEDIAPIPE KEYPOINTS)

Pose	Accuracy
Bridges	94.11%
Bench press	100.00%
Bow	91.66%
Cobra	100.00%
Child's pose	100.00%
Crane pose	93.75%
Cycling	88.88%
Crunches	88.88%
Downdog	100.00%
Donkey kicks	87.50%
Deadlift	100.00%
Flutter kicks	100.00%
Leg extensions	100.00%
Lat pulldowns	100.00%
Pullups	85.71%
Plank	100.00%
Squat	87.50%
Standing toe reach	100.00%
Shoulder press	100.0%
Tricep pushdown	100.00%

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 24,2024 at 04:36:38 UTC from IEEE Xplore. Restrictions apply.

Fig. 3 displays the learning curve for the LightGBM model with the number of training instances on the x-axis and the cross-validation score on the y-axis. The cross-validation score is shown by the green line, which initially increases rapidly from around 0.6 to 0.95 as more training samples are added. This indicates that the performance of the model is improving and it is becoming more proficient at extracting features from the data. But after a certain point, the score begins to plateau, as seen from the slow increase in score from 0.95 to 0.96, indicating that the model's performance may not significantly enhance further by adding more training data.

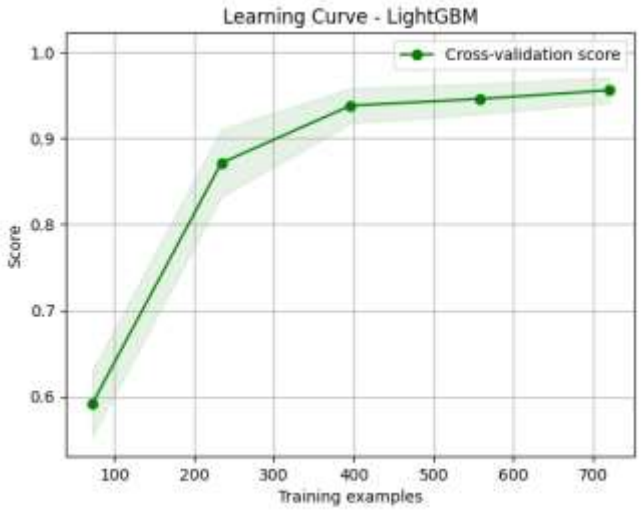

Fig. 3 Cross-validation score vs number of samples

The Fig. 4 shows the AUC-ROC curve for each class in the MediaPipe keypoints based LightGBM model. The ROC curve displays the true positive rate versus the false positive rate. The curve closest to the top-left corner represents the Benchpress class, indicating perfect classification performance. Classes like Bridges, Cobra and many others also have ROC curves hugging the top-left corner, suggesting excellent discrimination ability.

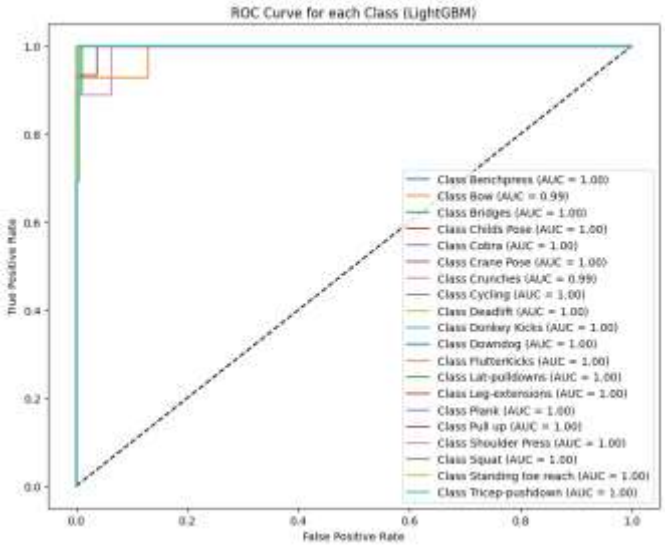

Fig. 4 AUC-ROC curve for each class Mediapipe+LightGBM)

C. Output

In Fig. 5, photos from testing dataset [16] of various exercise positions are taken, and the true and predicted labels are displayed. Also, the predicted keypoints on the poses are also showcased.

V. Conclusion

In this research, the domain of action recognition was explored by utilizing multiple techniques using multiple algorithms, using keypoint detection via YOLOv8 and MediaPipe. During training, data augmentation techniques were used to correct class imbalance and improve resilience. The classification step was carried out after data augmentation and keypoint extraction. MediaPipe with ensemble algorithms consistently showcased impressive performance. However YOLOv8 was found to be inferior to MediaPipe in all the tests, even though the number of keypoints that were found to be nearly the same for both. This also shows the capability of

Fig. 5 True vs Predicted pose of a few test samples

ensemble algorithms in how the different models combine their learned features to improve performance.

A. Future Work

Future work will investigate the use of transformer-based models for vision, namely Vision Transformers which is a new architecture proposed for computer vision tasks. Vision transformers [21] have performed extremely well on a number of computer vision tasks and have also outperformed many state-of-the-art benchmarks previously held by deep convolutional neural networks. Further, this domain can benefit from the inclusion of explainable techniques that give clarity about the output generated. For example, if an exercise was classified incorrectly, then which features caused that misclassification. Incorporating explainability into exercise feedback systems can also provide real-time explanation about the pose performance. This will enable researchers to obtain insights into the model understanding and improve performance for the future applications.

Abstract
In the last decade, data hiding in encrypted image has got a lot of attention within the security and privacy researcher's communities. This attention has led to the development of various reversible data hiding techniques for encrypted images (RDHEI) which enables separable lossless recovery of cover media and extraction of the secret message, at the receiving end. In this paper, a link chain driven (LCD) RDHEI algorithm for providing high embedding capacity, is proposed. The LCD-RDHEI exploits neighbourhood similarity of image pixels and clubs them in variable size link chains. The pixels in each link chain are estimated either by their average or using two quantization values based on the size of link chains. This helps in reserving a big room inside the image which can be used to fill in the secret information. Additionally, the pixels which are not part of any of the link chains are also utilized for embedding the secret information by adaptive multi MSB prediction and Huffman Coding method. Experimental results show that the LCD-RDHEI provides significantly greater embedding capacity than the existing and related modern data hiding method for encrypted images.

Keywords Link chain · Reversible data hiding · Encrypted images · RDHEI · Huffman · AMBTC

1 Introduction

In recent years, there has been an exponential growth in the size of cloud storage as people are using cloud storage for saving their data that is usually in the form of images, audios, videos, documents, etc., Behind the surge in the usage of the cloud storage, it has been the cloud storage's advantage such as usability, accessibility, cost-efficiency, convenience, scalability, etc., over the traditional way of storage, however, at the same time, the cloud storage lacks total control on security and privacy[1]. For this, data hiding appears one of the most promising options in order to obtain the basic goals of security i.e., confidentiality, authentication, and integrity of cloud users [1, 2]. Data hiding makes immersion of secret data in a multimedia cover possible and allows flawless extraction of the same during the process of decoding [3]. That's why, the data hiding (in short DH) finds its applications in domains such as military, medicine, judiciary and mass media where confidentiality of data in transit, are of utmost importance [4, 5].

Reversible data hiding (RDH) is an extension of DH that ensures the rebuilt of multimedia cover in the process of extraction of the immersed secret data which was not guaranteed in the case of traditional data hiding [6]. With the advent of cloud technology and the flow of large amounts of data that is usually in the form of images over the Internet, RDH finds images as the potential covers. Additionally, the images in this context may also be encrypted to create a better level of security. Therefore, to provide the required security, reversible data hiding in encrypted images (in short RDHEI) have been introduced which immerses data in encrypted images [7, 8]. RDHEI allows the data owner to hide their data in a cover image even without knowing the image content. The primary objective of the RDHEI is to achieve a higher embedding capacity and low distortion in the image with high security of data. However, the problem in achieving higher embedding capacity and low distortion at the same time, is their trade-off, in other words, the mechanism of data immersion in an image brings in a distortion in the original image cover. So, the larger the data is immersed the bigger

will be the distortion. In the proposed work, an effort is put to optimize this traditional trade-off for improved performance.

Over the last few years, various methods have evolved in RDHEI [7–30]. These methods take into consideration numerous techniques such as data compression, spatial correlation, histogram frequency and other encryption techniques for creating the room in the image to embed the data. However, as far creating the room inside the image is concerned, there are majorly two categories namely, Vacating room after encryption (VRAE) and Reserved room before encryption (RRBE). The VRAE techniques [7–14] usually create a room for embedding the secret information after the image encryption. In other words, VRAE does not demand the image owner to pre-process his/her original image for creating space for data immersion. VRAE techniques usually have smaller room for data immersion in the multimedia cover as the encrypted image has its level of entropy at maximum and thus leaves minimum spatial correlation. Various VRAE based data hiding works have been discussed, however, most of the work has limited embedding capacity. In contrast, the RRBE technique as its name suggests, reserves room before encryption of image which demands the image owner to have an idea regarding usage of his image as a multimedia cover so that he can leave room for data immersion within the image. Thus, grants a higher amount of secret data to be immersed in them.

Various RRBE based methods have already been proposed in recent years [15–30]. One such and one of earliest as well is discussed by Ma et al. [15] in 2013. In this method, a room is created inside the image using histogram shifting. Here, the shifting of the first three Least significant bits (LSBs) is done from one region to another region. This method does not guarantee a perfect reconstruction of the original image. Moreover, its embedding capacity is very low. Zhang et al. [16] discussed a data hiding method for cipher images obtained after encrypting by public-key cryptosystems with probabilistic and homomorphic properties. They embed the secret information into LSBs of the image which causes very low distortion and in turn allows lossless recovery of the original image. Cao et al. introduced a RDHEI method by borrowing sparse coding from the sparse representation technique. The sparse coding allows the hider to exploit the local correlation and creates a larger room inside the image for embedding the secret information. Yi et al. [18] discussed an RDH method for encrypted images using binary block embedding (BBE). The method introduces the usage of the most significant bits (MSB) planes for embedding the data and provides a significant increase in the data hiding capacity over the erstwhile RDHEI methods. Additionally, a bit level scrambling process is also employed to fully scatter the data inside the image for thwarting brute-force and similar attacks. Puteaux et al. [19] extended the work of MSB based embedding in the RDHEI domain by introducing two hiding methods. The first method basically replaces all the MSB bits with data and obtains an embedding capacity of 1 bpp (bit per pixel) with the resultant image being quite similar to the original image. The second method replaces only suitable MSB bits and to achieve the identical image as the embedded data is a little less than 1 BPP. Puyang et al. [20] extended the work of [19] by exploiting the neighbourhood correlation and making use of two MSBs for data embedding. Chen et al. [21] discussed a high capacity RDHEI method based on extended run-length coding and block-based MSB plane re-ordering. The run-length coding has been used to compact the MSB planes of images for creating large room and in turn obtaining the higher embedding capacity.

Shiu et al. [22] discussed a RDHEI method which make use of two compression techniques i.e., interpolative AMBTC and Huffman coding. It first vacates the room using interpolative AMBTC within a block and generates a code, and then reduces the length of code by Huffman encoding. Thus, a room is created inside the blocks which can be used for embedding the secret information. In 2020, Yin et al. [23] introduced another extension of [19] by multi-MSB prediction and Huffman encoding. The method makes use of prediction strategy for predicting the pixel and compares the original pixel value with the predicted one in bitwise manner. For the error encoding, Huffman method has been used which helps in optimally representing the errors and save the space for creating a large room. Thus, large embedding capacity is achieved. In the prediction domain, another method which is based on parametric binary tree levelling (PBTL), was introduced by Wu et al. [24]. The PBTL method here divides the image into blocks and make use of median edge detector (MED) predictor for prediction. The errors here are encoded using PBTL method. The PBTL method provides good embedding capacity. Xiao et al. [25] use compressive sensing for increasing the data hiding capacity. However, the method does not provide lossless recovery of the cover image but the immersion capacity was very large, moreover high and constant PSNR was achieved. Weng et al. [26] discussed an RRBE-RDHEI method by re-arranging bits of 5 MSB-planes to achieve a highly correlated bitstream. Afterwards, the resulting bitstream is compressed using a group classification encoding and the created space after compression is used for data embedding. Another method to create a larger space inside the encrypted image was introduced by Gao et al. [27]. The introduced method makes use of difference in prediction errors and creates a label map which is then divided into groups. The groups are then encoded to create space for embedding. Thus, the method has been able to achieve more than 2bpp embedding capacity.

In 2023, Li et al. [28] proposed a method predicting the MSB of each pixel, similar to Puteaux et al. [19]. Post MSB prediction, embeddable bits are highlighted on an error map, followed by the division of bit planes, executing a cycle

exclusive OR operation. This intricate process ensures a smooth transition of anticipated bits to the LSB plane while preserving the high-bit plane's integrity. Consequently, the method is constrained to achieve embedding rate (ER) of approximately 1 bpp. Qin et al. [29] devised a method for enhanced ER using grey transformation, compressive sensing (CS), and intra-block difference coding. Initially, grey transformation is employed to prioritize important bits. Then, the matrix is blocked, and CS-based reconstruction is utilized for optimized image data representation. Further refinement is achieved via intra-block difference coding to extract block correlations. Despite achieving high ER, this method also leads to considerable distortion in the reconstructed image. To amplify the EC, Liu et al. [30] put forth a method combining arithmetic and Huffman encoding. The process begins by partitioning the image into bit-planes. Each bit-plane undergoes arithmetic encoding, followed by further compression through Huffman encoding. Additionally, the methodology incorporates scrambling to encrypt overhead, necessitating an extra key. Although the approach ensures lossless recovery of image and data, it lacks separability. Similarly, Gao et al. [31] proposed a hierarchical scheme that categorizes image pixels into multiple linear regressions (MLR) predictable and non-MLR predictable sets. The MLR-predictable pixels generate two label maps using adaptive adjustment of predicted data and multiple bits prediction, while the non-MLR pixels use simple one-bit prediction for a label map. By compressing and embedding these label maps into the encrypted image, ER of 2.99–3.88 bpp is achieved across datasets. Fu et al. [32] presented a new RDHEI method using "L"-shaped block embedding (LBE) and improved binary-block embedding, which fully utilize the Laplacian-like distribution of prediction errors from pixel prediction. This approach adaptively selects embedding methods based on net capacities, therefore significantly enhancing embedding capacity. However, both the methods [31, 32] lack in adaptability of increasing the EC at the cost of quality and vice-versa.

Based on the analysis of the related literature, it has been observed that the high embedding capacity is usually achieved by block wise prediction-based methods as the prediction errors can be encoded to create space which can be later used for embedding. However, due to the fixed size blocks, the complete neighbourhood correlation has not been fully utilized which leads to non-accurate prediction sometimes. Moreover, there is a need of the method which can provide flexible embedding capacity at the cost of PSNR. To address these problem, a new high-capacity data hiding method which tries to exploit the neighbourhood correlation, is proposed. The proposed method basically generates variable size link chains of highly correlated pixels and represents those pixels by one or two values i.e., their average or two quantization levels, respectively, based on the size of link chains. Thus, a large room inside the image is created which is used to embed the secret information. The main contribution of this work is as follows:

- The proposed work introduces a novel high-capacity data hiding method that leverages the similarity between neighboring pixels to create variable-length chains of connected pixels. These chains are then used to create space within the image, which can be utilized to embed secret information.
- The method involves estimating the values of pixels within each chain using either their average value or two quantization values, depending on the size of the chain. This estimation process helps in creating a big room within the image for hiding the secret data.
- The experimental results demonstrate that the proposed LCD-RDHEI method offers greater embedding capacity compared to the existing and related data hiding methods, while ensuring that the original image can be recovered after data extraction.
- The aforementioned capabilities of the proposed LCD-RDHEI method makes it ideal for cloud applications where sensitive data need to be stored within encrypted multimedia files for ensuring end-to-end data confidentiality, integrity while reaping the benefits of the accessibility and the limited cost.

In the next section, review of some of the most closely related data hiding methods in encrypted domain is provided.

2 Review of related work

In this section, review of the working of two most closely related works i.e., Yin et al. [23] and Shiu et al. [22] in the field of RDHEI, is presented. All of these aforementioned works belong to RRBE category and provide good embedding capacity. In the presented review, the complete working process of Adaptive Multi-MSB Prediction and Huffman Coding (AM2PHC) [23] followed by Interpolative Absolute Moment Block Truncation Coding (IAMBTC) based RDHEI methods, is precisely explained as follows.

2.1 Adaptive multi-MSB prediction and Huffman coding (AM2PHC) [23]

Yin et al. introduced a new RRBE method based on adaptive multi-MSB prediction and Huffman coding (AM2PHC) for reversible data hiding in encrypted images (RDHEI). AM2PHC-RDHEI is a completely lossless method which makes use of prediction strategy for reserving the room inside the image and provides high embedding capacity. For this, Yin et al. employs the median edge detector (MED) predictor used in the LOCO-I algorithm of the JPEG-LS

compression for prediction of the pixel values of the original image (I) of size M×N pixels. The pixel located at $(i,\ j)$ is predicted using MED predictor based on three closest causal pixels (i.e., $X = I(i-1,\ j)$, $Y = I(i,\ j-1)$ and $Z = I(i-1,\ j-1)$) as follow:

$$p(i,\ j) = \begin{cases} \max(X,\ Y) & if\ Z \leq min(X,\ Y) \\ \min(X,\ Y) & if\ Z \geq max(X,\ Y) \\ X + Y - Z & otherwise \end{cases} \quad (1)$$

where $2 \leq i \leq M, 2 \leq j \leq N$ and $p(i,\ j)$ is the predicted value of $I(i,\ j)$. Next, both the original and predicted pixel values are converted into 8-bits binary representation and compared in bitwise manner from MSB to LSB until a non-match bit is found. Then, a label that is equal to the number of matching bits (till the first non-matching) is created for the pixel. Therefore, the label value for embeddable pixels can vary from 0 to 8, where 0 represents the first MSB itself is different and 8 represents all the bits are matching, thus, total 9 values. The process of prediction and label generation is repeated for the entire image to get a label map, which contains label (t) for each pixel of the image. This label is used to embed $t + 1$ bits in that pixel. The first pixel, on the other hand, is a reference pixel that cannot be used for data embedding. The generated label map is then encoded using Huffman method which generally results into the following Huffman code i.e., {00, 01, 100, 101, 1100, 1101, 1110, 11110, 11111} for the label map values based on their frequency. Usually, the least frequent value is represented by maximum bits and vice-versa. Thus, an encoded label map (ELM) in the form of binary stream is obtained. Afterwards, the original image (I) is encrypted by performing a bit-wise exclusive-or operation on every bit of the original image using an encryption key. The encryption process is same as the one to be discussed in the proposed work. Next, the ELM is embedded in the encrypted image to generate space inside the image. Before embedding the secret data, Huffman coding rules (HCR), length of ELM and other partial auxiliary information which includes ELM and original reference pixel's values is embedded. This embedding is done in the certain pixels (also knowns as reference pixels) of the first row and the first columns by replacing their values. The partial embedding of auxiliary is done because it is not possible to replace all reference pixels in their original locations due to the size, separability and reversibility constraints. The value of t is used to guide the embedding process which basically enables embedding of $t + 1$ bits from MSB onwards except for the case of $t = 8$, where all the bits of the pixel can be embedded. After embedding of HCR and partial auxiliary information, the embedding of remaining auxiliary information and bits of secret data is done by data hider using the same embedding process defined above and final marked encrypted image is obtained.

The marked encrypted image is obtained by the receiver who can the extract the hidden information and restore the image based on the availability of only data key, only encryption key or both. In all three cases, first the HCR and auxiliary information are extracted. If the data receiver has only the data key, the encrypted data is extracted from the similar position as embedded during hiding, and then decrypted to obtain lossless data. In case the receiver has only encryption key, after extracting the HCR, $LELM$ and reference pixels, the image is decrypted using the same process of encryption. Although, the image reconstruction process is done in raster scan manner and pixel values are predicted using Eq. (1), with the exception of the first row and column. And the appropriate predicted value bits are used to get the original pixel values. Following the completion of this replacement, a lossless image is obtained. In case both hiding and encryption keys are available with the same receiver, the above defined process of extraction and recovery can be executed in a sequential manner to get both hidden data and recovered original image.

2.2 Shiu et al.'s IAMBTC [22]

Shiu et al. [22] discussed an interpolative absolute moment block truncation coding [33] (IAMBTC) based high-payload RDH method for encrypted images. IAMBTC technique is an extended version of Absolute Moment Block Truncation Coding (AMBTC) approach given by Lema et. al. [34] in 1984. Shiu et al.'s method first divides the image into 4×4 blocks into two categories namely hiding and saving based on their variance. If the variance is less than a user-defined threshold then the block is a hiding block, otherwise, it is a saving block. In Fig. 1, block (a) and (k) represents hiding and saving blocks respectively. Next, the saving blocks are marked at the 4th pixel LSB to discriminate them from the hiding block as shown in block (l) and the hiding blocks are encoded using IAMBTC. For this, an average (h) of each hiding block is calculated using Eq. (2).

$$h = \left\lfloor \frac{1}{n} \sum_{i=1}^{n} x_i \right\rfloor \quad (2)$$

where n represents the number of pixels in a block and x_i is the intensity of i^{th} pixel. Next, two quantization values (H^l and H^h) are computed using Eqs. (3) and (4), respectively.

$$H^l = \approx \left[\frac{1}{p} \sum_{i=1}^{n} x_i \right] \quad if\ x_i \leq h \quad (3)$$

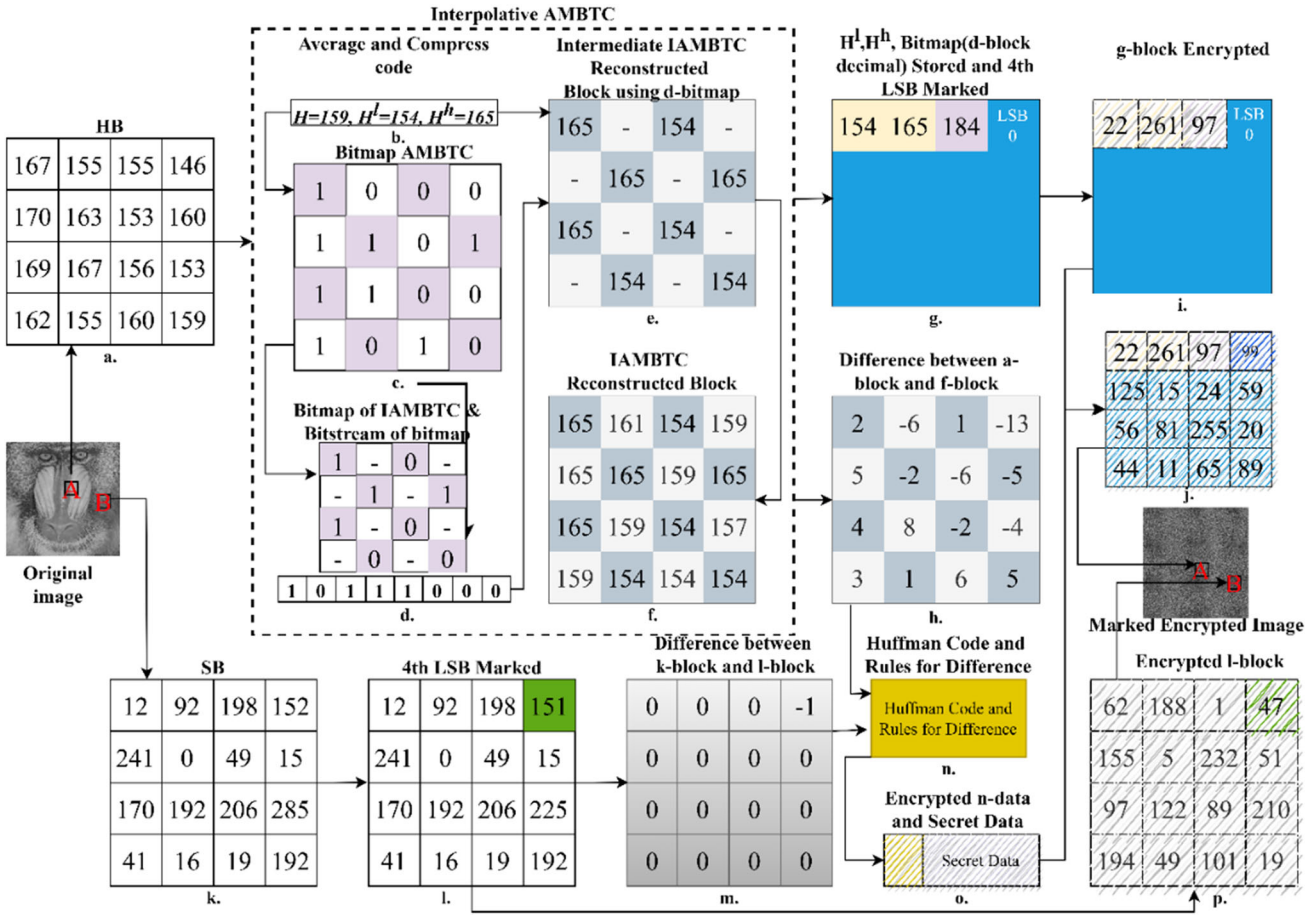

Fig. 1 An example of pre-processing, marking, and data hiding of the IAMBTC-RDHEI method

$$H^h = \approx \left[\frac{1}{n-p} \sum_{i=1}^{n} x_i \right] \quad if x_i > h \tag{4}$$

where p denotes the count of pixels having value less than h and '$=\approx$' represents assignment to the nearest whole number. H^l and H^h represent low and high quantization values, respectively, as shown in block (b) of Fig. 1. Additionally, a bitmap is also created which represents each pixel of the block by a bit which is '1' if the pixel value is greater than h otherwise it is '0', as shown in block (c) of Fig. 1. To further reduce the size, every alternate (even) bit of the bitmap is dropped as shown in block (d) of Fig. 1 to get a partial bitmap $\left(B^M\right)$. Thus, the hiding block is represented by trio i.e., $\left\{H^l,\ H^h,\ B^M\right\}$. To reconstruct the block, odd numbered pixels can be reconstructed using following Eq. (5), as shown in block (e) of Fig. 3.

$$\overline{p_i} = \begin{cases} H^l & if\, B_i^M = 0 \\ H^h & if\, B_i^M = 1 \end{cases} \tag{5}$$

where $\overline{p_i}$ is the decoded intensity of i^{th} pixel of the block. For even numbered pixels, some pre-defined interpolation equations are applied using the reconstructed odd pixel values. Thus, the complete hiding block is estimated as shown in block (f) of Fig. 1. In case of hiding blocks as well, the 4th pixel LSB is also marked to discriminate them from the saving block as shown in block (g). Now, the difference between the original and new blocks is calculated as shown in Fig. 1h and m for the hiding and saving block, respectively. Following that, the Huffman encoding is applied to the differences of all blocks to condense their size, resulting in the Huffman codes and dictionary as shown in Fig. 1n, which are then coupled with the encrypted secret data as depicted in Fig. 1o. On the other end, IAMBTC trios are stored into first three pixels. Afterwards, combined blocks are encrypted using a stream cypher with the assistance of a pseudorandom generator and an encryption key, except first MSB of 4th pixel of each block, as shown in block (i) and block (p) of Fig. 1. Finally, the remaining space of hiding blocks is used for embedding the Huffman code, directory and secret data, and an encrypted image with hidden secret data is obtained which is also known as marked encrypted image.

For image recovery and data extraction, the reverse of embedding process is performed, by the receivers. However, there may be three types of receivers. One who has only a data hiding key, he/she can only extract the Huffman code, Huffman directory and secret data and in case the receiver merely has an encryption key, he/she can distinguish between the hiding and saving blocks. Only the first three pixels are decrypted from the hiding block, which contains the trio $\{H^l,\ H^h,\ B^M\}$. The trio then can be used to predict all the pixels with the help of interpolation formulas defined in [22]. Saving blocks, on the other hand, are directly decrypted and an image is obtained. In case a receiver has both the keys, then he/she can extract the hidden information and can also restore the image using the same process defined above.

Both the works i.e., [22] and [23] are completely lossless and provides decent embedding capacity. Basically, most of the existing works which includes AM2PHC [23] and IAMBTC [22] either use linear prediction strategy or use block compression to exploit spatial correlation and create large room inside the image for embedding the secret information. However, none of the existing works seems to make use of variable size blocks/groups or chains based on the prevalent spatial correlation to make its optimal benefit. So, in this paper, we propose a new reversible data hiding method for encrypted images based on link chain strategy. The proposed method generates different size and shape link chains based on the prevalent spatial correlation and helps the data hider to embed large amount of secret data. In the next section, the proposed LCD-RDHEI method is described in detail.

3 Proposed method

This section presents the proposed method which can be seen with the purviews of content owner, data hider and recipient as follows. In the purview of content owner (3.1), operations such as image pre-processing, encryption of image, and process of supporting information (SI) embedding are done: and in the purview of data hider (3.2), operations such as extraction of PI, extraction of directory of link chain and embedding of the secret data are implemented; and in the purview of the recipient (3.3), operations such as extraction of the data and image decoding either separately or combined subject to the availability of hiding keys are performed. For clear representation of different purviews and operations there-in, Fig. 2 is provided that illustrates the framework of the proposed LCD-RDHEI.

As shown in Fig. 2, the content owner's major work is to encode the original image (I) by first pre-processing the image to create a room inside, for embedding the secret data. In the pre-processing, supporting information (SI) is generated which is embedded inside the image so that subsequent user i.e., data hider can extract to find the created room for embedding. Afterwards, the image is encrypted using an image key (K_e) to get an encrypted image [[I]] which is forwarded by the content owner to data hider, who may be present anywhere in the network. Now, the data hider identifies the pixels from [[I]] for embedding secret information that can be encrypted using a data key (K_d). Thus, a marked encrypted image $\overline{\overline{[[I]]}}$ is obtained which can be forwarded to receivers, who can extract the secret message and recover the image $\overline{\overline{(I)}}$ according to the availability of the keys i.e., K_d and K_e. In the next sub-section, the working process in the content owner's horizon is described in detail.

3.1 In content owner's Horizon

The content owner has three functions which include image pre-processing, encryption of the image and process of supporting information embedding, which are defined as follows:

3.1.1 Image pre-processing

The original image I of size $M \times N$ is scanned in raster scan manner and pixels are marked by their sequence number (S) of scan instead of their coordinates. The sequence number of a pixel $(p_{i,j})$ will be $((i-1)*N+j)$, where i and j represents row and column number. For example, the pixel $(p_{3,2})$ of the 512×512 size image can be represented with its sequence number i.e., $((3-1)*512+2) = 1026$, as (p_{1026}). Next, the content owner processes I to form highly correlated groups of pixels. The groups are hereafter called link chains (l_c) as these are also formed externally by making a link between consecutive pixels of the group. The pixels of the link chain are also called nodes. The first node of the link chain, which is also known as link chain head (h_{lc}), will have the sequence number of the corresponding pixel along with direction to the subsequent node and rest of the nodes only contain direction to their next node. It is to be noted that the link chains can be of any size and shape but will have pixels of very similar intensity or high spatial correlation. Thus, by doing this, a room can be created in the image for embedding the secret information. Next, processing of the untouched pixels which have not been part of any of the aforementioned link chain is done so that the reserved room can further be extended. Thus, the image pre-processing is done in two phases i.e., a) link chain directory generation and b) untouched pixel identification and their prediction which are discussed as follows:

a) **Link chain directory generation:** This phase has three steps which includes i) link chain generation, ii) categorization of link chains, iii) node representation in link

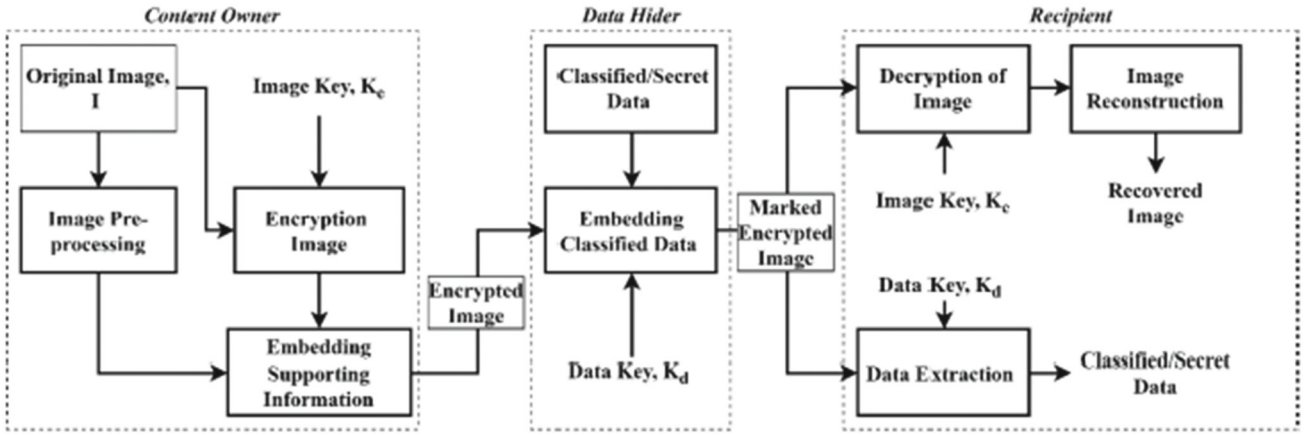

Fig. 2 Framework of the proposed LCD-RDHEI method

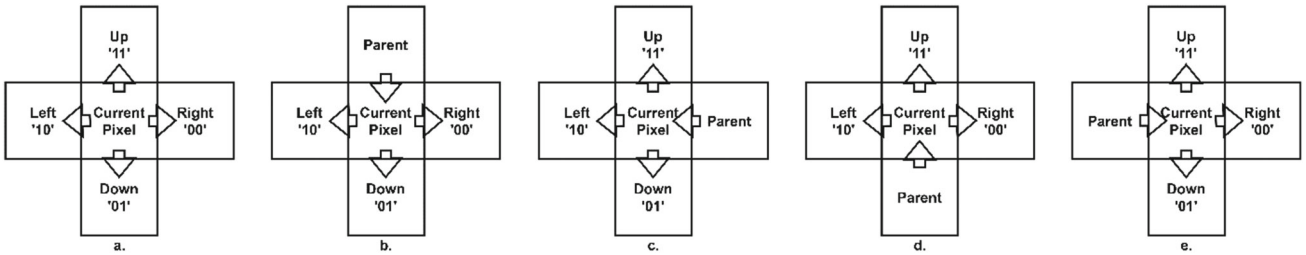

Fig. 3 An example of possible link movement for adjacent pixels (**a**) If the node is link chain head. **b** If the next node is down to the parent move, **c** If the next node is right to the parent move, **d** If the next node is up to the parent move, **e** if next node is left to the parent move

chains, which are introduced below. For more clarity, the algorithm to create the directory of link chains is provided in sub-section iv.

i) *Link chain generation:* For generating the link chains (l_c), first of all, a list (Li) is generated which stores all the pixels of I by their intensity value (val) and sequence number (S) in increasing order of their val (except the pixels reserved for process information (PI), which will be discussed later in Sect. 3.1.3). Now, the first pixel of the list (Li) is chosen as a link chain head (h_{lc}) and then any adjacent pixel from I that can be either right, down, left or up pixel, of the current pixel, is selected for adding the same into l_c, as per the Fig. 3a. The adjacent pixel can only join l_c, if the intensity difference of the h_{lc} and the adjacent pixel is less than a given user-defined threshold (i.e., variability coefficient (V_c)). The variability coefficient (V_c) shows the maximum allowable intensity difference within a l_c. The adding of the adjacent pixel to the current link chain may lead to a situation where multiple l_c are possible at any stage because more than one adjacent pixel i.e., right, down, left or up, can satisfy the variability coefficient condition. Thus, it may lead to a situation similar to the Hamiltonian path problem. Moreover, this problem is non-polynomial time solvable. So, it is not suitable for the content owner to find the maximum length l_c. To avoid the above situation, the proposed l_c generation method follows the greedy approach. The proposed method uses many recursive calls to determine the maximum length (max_len) for any l_c. In the recursive calls, multiple virtual l_c are formed at the step of adding an adjacent pixel, but only one virtual l_c with the maximum length is added as final, and the others are dropped. As a result, a pixel can be a member of many virtual l_c, requiring length calculations multiple times for a single pixel. To avoid the scenario, this method assumes that the first computation of the length of link chain from that pixel is perfect and that itself may be applied to any of the remaining virtual link chains from that pixel. Or, to put it another way, if virtual l_c generation has already been completed for any pixel, and any virtual l_c later reaches that pixel, that pixel is attached to the virtual l_c as the next node, and the already formed l_c is presumed to be the virtual l_c's tail. Although each virtual l_c must be preserved as part of the aforementioned process, as it can be used immediately during an interdicted call. As a result, this method uses two intermediate lists to store the intermediate information for each virtual l_c, where the first list (Len) contains the max_len of the l_c from the current pixel $I(S)$ and another lists (Dir) stores the encoded form of direction of the next possible

attached pixel that can be right (00), down (01), left (10) and up (11) obtained from the following Eq. (6).

$$S^c = \begin{cases} S+1 & if\, Dir(S) =' 00' \\ S+N & if\, Dir(S) =' 01' \\ S-1 & if\, Dir(S) =' 10' \\ S-N & if\, Dir(S) =' 11' \end{cases} \tag{7}$$

Function 1 $Max_Len_LC(I, C_s, X, V_c, S, Len^*, Dir^*)$

1.	***if*** $X \le I(S) < (X + V_c)$ $AND\ S \notin C_S$ $AND\ Len^*(S) = 0$	//returns true only if value of the adjacent pixel is within the defined range AND it does not belong to C_s AND the pixel is not already processed
2.	$Temp[1:4] = 0$	//initialize the Temp array of four elements to 0
3.	$Temp(1) = 1 + Max_Len_LC(I, \{C_S \cup S\}, X, V_c, S+1, Len^*, Dir^*)$	//computing max_length for right adjacent pixel
4.	$Temp(2) = 1 + Max_Len_LC(I, \{C_S \cup S\}, X, V_c, S+N, Len^*, Dir^*)$	//computing max_length for down adjacent pixel
5.	$Temp(3) = 1 + Max_Len_LC(I, \{C_S \cup S\}, X, V_c, S-1, Len^*, Dir^*)$	// computing max_length for left adjacent pixel
6.	$Temp(4) = 1 + Max_Len_LC(I, \{C_S \cup S\}, X, V_c, S-N, Len^*, Dir^*)$	// computing max_length for top adjacent pixel
7.	$[Len(S), ind] = MAX(Temp)$	// assigns max_length and index of the max_length adjacent pixel in $Len(S)$, *and* ind, respectively
8.	***if*** $ind = 1$ then $Dir^*(S) = '00'$; ***elseif*** $ind = 2$ then $Dir^*(S) = '01'$ ***elseif*** $ind = 3$ then $Dir^*(S) = '10'$ ***elseif*** $ind = 4$ then $Dir^*(S) = '11'$ ***endif***	//update the next pixel encoded direction in DIR using index of maximum value of Temp
9.	***endif***	
10.	***return*** $Len(S)$	// returns length

$$Dir(S) = \begin{cases} 00\ if\, S^c = S+1 \\ 01\ if\, S^c = S+N \\ 10\ if\, S^c = S-1 \\ 11\ if\, S^c = S-N \end{cases} \tag{6}$$

where S^c is the sequence of the next node of child node to be added in the l_c. Initially, Len and Dir are set null for every new l_c generation to avoid incorrect overlapping with the already generated link chains. Following the determination of a virtual l_c for a pixel, max_len and Dir of the next pixel is updated in Len and Dir, respectively, corresponding to the sequence number S. It can be observed from the *function-1:* $Max_Len_LC()$ that $Len(S)$ is checked from the Len before calculating the virtual l_c for a pixel $I(S)$ as all the intermediate virtual l_c share a common intermediate list. Additionally, pixels that are part of (any of) the link chains are regarded to be part of a cover set (C_S), which is initially set to null. The pseudocode to determine the maximum length of a link chain for a pixel $I(S)$ is given as function-1 (Max_Len_LC). It can be observed that maximum three recursive calls are possible in the above function Max_Len_LC for a pixel since one of the directions always points towards parent i.e., already a part of C_S, as illustrated in Fig. 3b–e. At last, the l_c is extracted from the intermediate lists as follows: first, a link chain head (h_{lc}) is constructed for the current pixel with sequence S, which also contains two bits of $Dir(S)$. The $Dir(S)$ gives the sequence number (S^c) of the next node (also called as child node) of the link chain as per the following Eq. (7).

Next, same process of adding the next node in the link list by considering S^c as the sequence number of the current pixel, is continued until the $Dir(S)$ is Null, which represents the last pixel of link chain. Finally, in the last node of the link chain, the encoded direction to the penultimate node is updated using Eq. (8) which is denoted by $S^p_{direction}$ whereas parent node is denoted as S^p.

$$S^p_{direction} = \begin{cases} 10\ if\, S^c = S+1 \\ 11\ if\, S^c = S+N \\ 00\ if\, S^c = S-1 \\ 01\ if\, S^c = S-N \end{cases} \tag{8}$$

Thus processing, all the link chains from the image can be extracted. In the next sub-section, categorization of the extracted link chains is discussed.

ii) *Categorization of Link chains:* The generated link chains are now categorized in three categories jump, small and large link chain, for the sake of achieving high embedding capacity and low distortion. Two user-defined thresholds i.e., T^1 and T^2 are used to separate them into the above suggested categories. More specifically, if the length (max_len) of any l_c is less than the first threshold (T^1) then it can be considered as a jump l_c, which can be represented by l_{cj} and if the length is greater than or equal to T^1 and less than T^2, it is considered small l_c which can be represented by l_{cs}, otherwise, large l_c which can be represented by l_{cl}. Note that, the T^1 and T^2 are fixed, i.e., $T^1 = 3$ and $T^2 = 16$ (for the sake of simplicity) in this paper. The proposed method does not mark the entries for jump link chains (l_{cj}) in

the cover set (C_s) so that those pixels can be utilized for other link chains (if possible). Therefore, there are only small (l_{cs}) and large (l_{cl}) link chains, effectively. All the generated link chains are sorted in increasing order based on their head node's sequence number.

iii) *Node representation in link chains:* For reserving bigger room, the pixel values of link chains are estimated either by their average values or by two quantization levels along with a bitmap based on the type of link chain. More specifically, the pixels of small link chains are estimated by their average (H) using Eq. 2, and pixels of large link chains are estimated by two quantization levels and bitmap using IAMBTC as defined in II-B. The process of IAMBTC has been adjusted for employing on link chains in place of image blocks. Firstly, H^l and H^h are calculated using Eqs. (2) and (3) for l_{cl}. Next, to represent every node of l_{cl} is generated using the process defined in II-B and every alternate (in other words, even-positioned) pixel representation in the bitmap is dropped, to get the partial bitmap $\left(B^M\right)$. Moreover, the proposed method stores the difference value $\left(D^{hl}\right)$ calculated as $D^{hl} = H^h - H^l$ in place of H^h to further reduce the required number of bits to represent the trio of H^l, H^h and B^M, for representing the nodes of the l_{cl}. Since the D^{hl} can range between 0 to $V_c - 1$, so fixed Huffman codes are derived to represent D^{hl}. However, it should be noticed that if $V_c = 1$, then every l_{cl} is treated like l_{cs}, because all of the pixels have the same intensity in the l_{cl} and their average will also be the same, so producing H^l, H^h and B^M will be pointless and waste a lot of space. The derived Huffman codes are provided in Table II which can be used by content owner, data hider and recipients. Further, binary representation of H for l_{cs} and H^l, D^{hl} & B^M for l_{cl}, are stored as a sequence of bits (H_{bs}) in the same order as the h_{lc}

b) Untouched pixel identification and their prediction: The pixels, which have not been covered in any of the link chains (or PI, which will be discussed later Sect. 3.1.3), are called untouched pixels $\left(ut_p\right)$. In the proposed work, untouched pixels are also being used for embedding the secret information in order to increase the embedding capacity of an image. For this, AM2PHC [23] (which has already been discussed in Sect. 2.1) have been employed. Prediction for remaining pixels and generation of Huffman code and rules, on the other hand, are done in the same way as in AM2PHC [23].

3.1.2 Encryption of the image

For encrypting the image contents, the content owner uses stream cipher to encrypt original image I. For this, initially, a matrix (m_e) of size M × N and list (l_e) of size $\lceil len(H_{bs})/8 \rceil$ are populated using a pseudo-random number generator considering image key (K_e) as the seed. Then, the image is encrypted using Eq. (9) and link chains are encrypted using Eq. (10), as follows.

$$[\![\mathrm{I}(i,\ j)]\!] = I(i,\ j) \oplus m_e(i,\ j) \quad \forall i,\ j \tag{9}$$

where $1 \le i \le M$, $1 \le j \le N$ and $[\![\mathrm{I}(i,\ j)]\!]$ is an encrypted pixel at coordinates $i,\ j$. After turning the l_e in a bit stream 8 bit for each integer, H_{bs} is encrypted as follows:

$$\overline{H}_{bs}(i) = H_{bs}(i) \oplus l_e(i) \tag{10}$$

where $\overline{H}_{bs}$ represents encrypted bit stream and $1 \le i \le size\ of\ H_{bs}$. Although, m_e and l_e can also be populated using a chaotic generator or AES algorithm in output feedback mode.

3.1.3 *Process of supporting information (SI) embedding*

Supporting Information (SI) is an additional information required by the receivers to extract the hidden secret data and decrypt the image. This information must be embedded in the image for the sake of hiding and extraction of secret data and decoding of the image. The details regarding supporting information and its embedding algorithm are presented in the following two subsections:

a) Details of supporting information (SI): *SI* basically, consists of following information components:

- **Variability coefficient (V_c):** The variability coefficient shows the maximum intensity difference (possible) within a l_c. Since the pixel values in a grayscale image, ranges from 0–255, the maximum possible absolute difference between any two pixels can be 255 which can be represented by 8 binary bits. Therefore, 8 bits are fixed for storing the value of V_c in the present work.
- **Location of the first link chain head $\left(d_l^1\right)$:** The location of the first link chain head which is denoted by d_l^1, is represented in $\lceil log_2(M \times N) \rceil$ bits.
- **Greatest location difference $\left(d_l^{max}\right)$and location difference sequence** (dl_{bs}): As mentioned in the preceding sub-Sect. 3.1.1, the link chains are sorted based on the location sequence number of their head nodes in a directory of link chains (DL_c). To get the greatest location difference between any two consecutive link chains, the location difference $\left(d_l^{k+1}\right)$ between every two consecutive heads i.e., h_{lc}^k and h_{lc}^{k+1}, is calculated using following Eq. (11).

$$d_l^{k+1} = \left(h_{lc}^{k+1}.S - h_{lc}^k.S\right) \tag{11}$$

where $h_{lc}^{k}.S$ and $h_{lc}^{k+1}.S$ represents the sequence number of head nodes of k^{th} and $(k+1)^{th}$ link chains. From the calculated difference sequences, the greatest location difference $\left(d_l^{max}\right)$ is identified and all the difference sequences are converted into $\lceil log_2\left(d_l^{max}\right)\rceil$ bit binary and stored in dl_{bs}.

- Huffman code rules (HCR): In the proposed work, multi-MSB matching [23] based data hiding scheme has been used for embedding in the untouched pixels $\left(ut_p\right)$ as described in II-B. In the scheme, a label map is generated which can have 9 different values. For optimally storing the label map, Huffman encoding has been used as described in [23]. For the Huffman encoding, some rules have been devised as in [23] which can be represented in 32 bits.
- **Encrypted link chain representation information $\left(\overline{H_{bs}}\right)$:** In Sect. 3.1.1, a bitstream of link chain representation information (H_{bs}) that contains average (H) for small link chains, low quantization $\left(H^l\right)$, quantization difference $\left(D^{hl}\right)$, and bit map $\left(B^M\right)$ for large link chains is generated. Afterwards, the bitstream H_{bs} is encrypted in Sect. 3.1.2 to get the encrypted bitstream of link chain representation information.
- **Encoded label map (ELM):** ELM is obtained form Sect. 3.1.1 for identification of untouched pixels and their prediction.
- **Encrypted MSBs of starting pixels ($EMSP$):** Six (6) MSBs of starting $\left(\left\lceil\frac{3\times log_2(M\times N)+11}{6}\right\rceil\right)$ pixels of image $[\![\mathrm{I}]\!]$ which are not part of any of the link chains are stored in $EMSP$. This information is required for recovering the image by the decoder and therefore needs to be recorded.

All of the above defined information components (if concatenated together) represents SI.

b) ***SI embedding algorithm:*** As discussed in the preceding subsection, the SI consists of several information components. However, these information components have been grouped in two different sets namely Process information (PI) and Auxiliary information (AI) based on their requirement and for the sake of simplicity to employ the proposed method. The AI is majorly required by the hider for embedding of the secret data and by the receivers as well during their process. In contrast, PI is required to initiate any of the phases such as hiding, decoding and/or extraction. More specifically, AI consists of concatenation of $dl_{bs}\left(\text{of size } number\ of\ n * \lceil log_2\left(d_l^{max}\right)\rceil \text{ bits}\right)$, HCR (of size 32 bits), ELM, $EMSP$ and $\overline{H}_{bs}$, in the given order. The size of ELM, $EMSP$ and $\overline{H}_{bs}$ are dependent on multiple parameters such as number of untouched pixels, PI, and number of link chains and their type etc. As far as PI is concerned, It is a concatenation of d_l^{max} (of size $\lceil log_2(M\times N)\rceil$ bits), d_l^1 (of size $\lceil log_2(M\times N)\rceil$ bits), V_c(of 8 bits), and LAI (o size $\lceil log_2(M\times N)\rceil$ bits) in the given order, where LAI represents length of AI. Thus, the total size of PI is $(3\times\lceil log_2(M\times N)\rceil+11)$ bits. The PI is basically embedded in the starting pixels of the encrypted image I in raster scan manner by replacing 6 MSBs of each pixel with the PI bitstream. These pixels can be called *PI enabled pixels* and their total count (NP_{PI}) is $\left(\left\lceil\frac{3\times log_2(M\times N)+11}{6}\right\rceil\right)$. Next, AI is embedded in the 6 MSBs of each pixels, which are part of link chains. The algorithm-2 to embed SI which includes both AI and PI, is provided as follows:

3.2 In the purview of data hider

Data hider is a person who basically embeds the secret information inside a cover media. Here, the cover media is an encrypted image with SI i.e., $\overline{[\![\mathrm{I}]\!]}$. Before starting the embedding of secret information, the data hider first needs to extract PI, link chains, and encoded label map (ELM), respectively as defined in the following subsections. Subsequently, he/she performs the embedding of secret data in the image using the process discussed in sub-Sect. 3.2.4.

3.2.1 Extraction of PI

For extraction of the PI, reading of 6 most significant bits (MSBs) in raster scan is started from the very first pixel of $\overline{[\![\mathrm{I}]\!]}$ and first of all, $\lceil log_2(M\times N)\rceil$ bits i.e., 19 bits in case 512×512 pixels image are extracted from the first four pixels to get greatest location difference $\left(d_l^{max}\right)$ by their decimal value. Then, next $\lceil log_2(M\times N)\rceil$ bits are extracted which are used to determine d_l^1 and subsequent 8 bits to get V_c. And lastly, next $\lceil log_2(M\times N)\rceil$ bits are used to determine the length of auxiliary information, which is represented by LAI. Thus, a total of $3\times\lceil log_2(M\times N)\rceil+11$ bits are read.

3.2.2 Extraction of link chains and embedding of secret data in link chain

The link chain extraction process is somewhat similar to the link chain generation process. Here, the data hider first reaches to the head of the first link chain using d_l^1, which is the pixel $[\![\bar{\mathrm{I}}(S)]\!]$ and reads 6 MSBs of the pixel (except the PI enabled ones) for EI (which is same as AI in the encoding/hiding phase, but being denoted differently for avoiding any confusion) extraction and two LSBs for direction to its next (or child) pixel of the link chain. Next, read again the 6MSBs of the next pixel and 2 LSBs for the direction to its child node using Eq. 7. This process is continued until complete auxiliary information is not retrieved. In case, the direction of the next (or child) points to its parent, which in turn signifies the end of the k^{th} link chain $\left(l_c^k\right)$, the next link chain $\left(l_c^{k+1}\right)$ needs to be picked. To get the next link chain head node location, the hider reads bits

$\beta+1\ to\ \beta+\lceil log_2(d_l^{max})\rceil$ and converts them into decimal to get d_l^{k+1}, where $\beta=(k-1)*\lceil log_2(d_l^{max})\rceil$. Next, d_l^{k+1} is added to the current link chain head node location to get the sequence number of $(k+1)^{\text{th}}$ link chain head. As soon as, all the bits of EI are extracted, the same process is repeated for embedding the bits of secret data by just substituting the process of reading the 6MSBs of the pixels by the replacing 6MSBs with the bits of secret data. The complete process is reiterated until we get $d_l^{k+1}=0$ which signifies that there is no more link chain in the image.

3.2.3 Embedding of secret data in remaining pixels

To embed the secret data in the untouched pixels, firstly dl_{bs}, HCR, ELM, $EMSP$ and $\overline{H}_{bs}$ are extracted from the EI. Next, the image is scanned in raster scan manner by skipping the PI enabled pixels and the pixels corresponding to the link chains for identifying the untouched pixels. Afterwards, information is embedded in each of the untouched pixels (ut_p) based on the corresponding label map information using AM2PHC [23] which is also reviewed in the Sect. 2.1.

Thus, all the pixels of the image are utilized for embedding the secret information. In the next subsection, the algorithm-3: for embedding of secret data is presented in step-wise manner.

3.3 In the purview of recipient

Since the proposed method is a separable RDHEI method, there can be two different receivers namely decoder and extractor. The decoder is the person who hold the image key (K_e), and can get back the contents of the original image whereas the extractor holds the extracting key (K_d) to get the hidden contents. It should be emphasised that the decoder and extractor can be the same person if they possess both of the aforementioned keys. In the following subsection, data extraction is defined first, followed by image decoding in the subsequent subsection.

3.3.1 Data extraction

The data extraction process is basically similar to the hiding process (described in Sect. 3.2). Here, the extractor first needs to extract the PI, link chain and AI like the hider and then reads the six bits from each pixel instead of replacing them as in the case of data hiding to get the encoded secret information from the link chain pixels. Next, the untouched pixels (ut_p) are processed using the label map to get back the hidden data. Finally, the extractor decodes the extracted information using the key (K_d) to get back the hidden information.

3.3.2 Image decoding

As discussed earlier, the image decoding process is performed by the decoder who holds the decoding key (K_e). In the image decoding process, first of all, PI, directory of link chains (DL_c), label map (LM) and AI is extracted on the similar lines of the hider (described in Sect. 3.2). Afterwards, dl_{bs}, HCR, ELM, $EMSP$ and $\overline{H}_{bs}$ are extracted as per the steps 7, 8 and 10 defined in the decoding algorithm. Next, the secret data is then extracted from the untouched pixels with the help of AI and PI. Afterwards, a pseudo-random number list $\tilde{l}_e$ is created using key using K_e with the help of a pseudo-random number generator and $\overline{H}_{bs}$ is decrypted using Eq. (12), as follows.

$$H_{bs}(i)=\overline{H}_{bs}(i)\oplus\tilde{l}_e(i) \tag{12}$$

where, $1\le i\le size\ of\ \overline{H}_{bs}$. Additionally, image decryption is done according to Eq. (13) by first creating a pseudo-random number matrix $\tilde{m}_e$ of size M × N size with the help of key (K_e) using a pseudo-random number generator.

$$\bar{\bar{\mathrm{I}}}(i,\ j)=\overline{\overline{[[\mathrm{I}]]}}(i,\ j)\oplus\tilde{m}_e(i,\ j)\forall i,\ j \tag{13}$$

where $1\le i\le M$ and $1\le j\le N$. Now to restore the image, all l_c of DL_c are processed in their order as follows: If the l_c is small then 8 bits are removed from H_{bs} and converted into decimal to get average (H). Afterwards, a list for recovered intensity (R) of size $max_len(l_c^k)$ is generated where each element of R is assigned average (H) value. In case the l_c is large then 8 bits are removed the from H_{bs} and converted into decimal which represents low quantization (H^l). Next, D^{hl} bits are removed from H_{bs} and decoded using Table II. Afterwards, high quantization (H^h) is computed as $H^h=H^l+D^{hl}$ and partial bitmap (B^M) is obtained by extracting $\max_len(l_c^k)/2$ bits from H_{bs}. The complete bitmap (B_c^M) is estimated using following Eq. (14)

$$B_c^M(x)=\begin{cases}B^M\left(\lceil\frac{x}{2}\rceil\right) & if\ x\%2=1,\\ -1 & if\ x\%2=0.\end{cases} \tag{14}$$

where x is a positive integer (1, 2, 3, ..., $\max_len(l_c)$). Thus, odd locations are filled by the values of the partial bitmap and '− 1' is set to the even locations of the bitmap. Next, a list (R) to recover intensity values of the pixels is constructed using Eq. (15) as follows:

$$R(x)=\begin{cases}H^l & if\ B_C^M(x)=0\\ H^h & if\ B_C^M(x)=1\\ R_avg & if\ B_C^M(x)=-1\ and\ x<\max_len(l_C)\\ R(x-1) & if\ B_C^M(x)=-1\ and\ x=\max_len(l_C)\end{cases} \tag{15}$$

where, $R_avg = \left\lfloor \frac{1}{2}(R(x-1) + R(x+1)) \right\rfloor$. All the pixels of $\bar{\bar{\mathrm{I}}}$ corresponding to l_c are then replaced by a corresponding value of recovered intensity (R). Thus, the pixels corresponding to the link chains are recovered. Next, the untouched (ut_p) pixels are reconstructed using AM2PHC [23] as described in II-A. Thus, the complete image is recovered and secret data is extracted.

4 Experimental results and discussion

This section elaborates upon experimental results and their analysis in order to compare and evaluate the performance of the proposed (LCD-RDHEI) method with respect to the existing and related RDHEI methods. The discussion and analysis of the experimental results has been done in four parts which are discussed in four sub-sections as follows. The first sub-section presents a detailed explanation of the LCD-RDHEI considering image 'Lena' as a use case, the second sub-section discusses performance analysis on different test images and datasets such as BOSSBase [35], BOWS-2 [36] and UCID [37], the third sub-section provides discussion around security of the method under consideration, and final sub-section presents a comparative analysis of the LCD-RDHEI with respect to the state of art methods. The main focus is on increasing the embedding capacity or embedding rate, illustrating how much data can be incorporated either in an entire image or per pixel. Additionally, PSNR, which is a logarithmic metric devised to measure the variations between an original image and its reconstructed version, is also explored. Infinite PSNR implies absolute reversibility, whereas superior to 30 dB is regarded as satisfactory reversibility.

4.1 A detailed explanation of the LCD-RDHEI considering image Lena as a use case

The trade-off of ER and PSNR i.e., if V_c increases the ER increases but PSNR decreases has been depicted in Table III, where ER and PSNR are dependent on the variability coefficient V_c. The proposed LCD-RDHEI method is applicable for $V_c = 1$ to 256, but for sake of simplicity and for comparative ease, $V_c = 1 - 18$ or PSNR $> 40dB$ has been taken into consideration in the presented experiments. However, the content owner can decide the value of V_c according to his/her application needs.

A test image 'Lena' is chosen to experimentally study different aspects such as pixel distribution of original and reconstructed image, representation of original, encrypted and reconstructed images etc., as provided in Fig. 4 for $V_c = 12$. In Fig. 4a, the original image of Lena of 512×512 size is shown and its pixel distribution using a histogram is

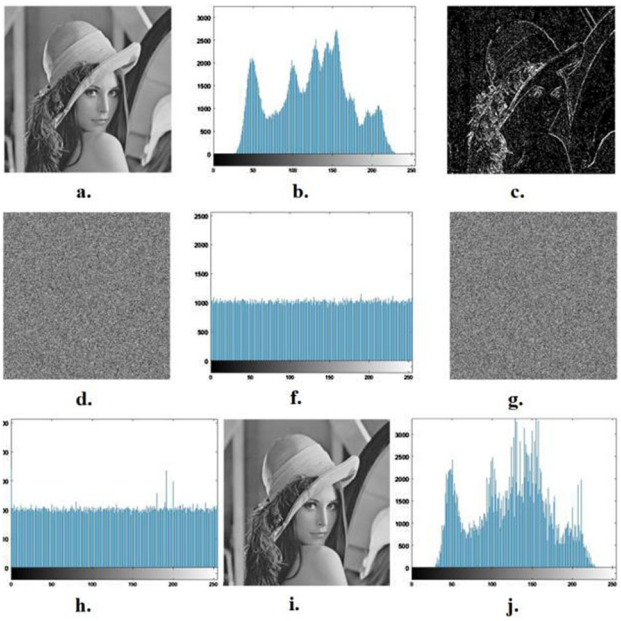

Fig. 4 Experimentation on image 'Lena' considering $V_c = 12$ (**a**) Test image; **b** Histogram of the test image (**c**) Coverage of Link Chains (**d**) Encrypted image (**e**) Histogram of encrypted image (**f**) Marked image (**g**) Histogram of Marked image (**h**) Reconstructed image (**i**) Histogram of the reconstructed image

presented in Fig. 4b. Since the proposed method starts its process with link chain (l_c) generation as discussed above, the coverage of pixels by link chains in the Lena image is also presented in Fig. 4c. The black colour in the Fig. 4c represents the pixel covered by the link chains. However, the LCD-RDHEI method generates a total of 13,585 l_c out of which 2666 are large l_c and remaining 10,919 are small l_c, where the maximum size of l_c thus formed is 1553 pixels whose initial location is at coordinate (233, 475) or sequence number (119,259). In addition to this, a total of 223,119 pixels have been covered in the link chain which includes 149,619 pixels of large l_c. Two bits are reserved for direction, therefore the preceding l_c can reserve six bits per pixel, or a total of 1,338,714 bits. Following that, other room in the image is reserved using AM2PHC on the remaining 39,025 pixels, and a label map of 158,814 bits is generated for a total room of 246,001 bits.

The total supporting information includes 85 bits of PI (that includes 18 bits for d_f^l size identification, 9 bits for d_f^l, 8 bits for V_c, 32 bits for Huffman code [23], 18 bits for (E^f)), 236,925 bits for all d_f^l, H, H^l and D^{hl} for all l_c, 74,807 bits for bitmap and 158,814 bits of label map, which will embed after encryption. In Fig. 4d, the encrypted image which has been encrypted by considering $K_d = 143$, is shown. The histogram of the encrypted image is presented in Fig. 4e, which clearly shows that pixels are equally distributed after encryption and there is no similarity left between the original

image i.e., Fig. 4a and encrypted image i.e., Fig. 4d. Then, 470,631 bits SI are embedded in total reserved room, which is the sum of the 1,338,714 bits generated by l_c's and the 246,001 bits generated by AM2PHC. Next, the data hider can embed secret data at a rate of 4.2498bpp in the aforesaid SI-enabled encrypted image. Figure 4f displays the marked encrypted image containing 1,114,084 bits of secret data. The pixel distribution of the marked encrypted image has been provided in Fig. 4g. This distribution is closer to the encrypted version provided in Fig. 4e which implies that the marked encrypted image also does not have any clue about the original image. Finally, the recovered image is shown in Fig. 4h after error-free extraction of the hidden data. The PSNR between the original image, shown in Fig. 4a, and the reconstructed image, shown in Fig. 4h, is 40.2966 dB. The histogram of the recovered image, which is substantially identical to the original image, is shown in Fig. 4i.

4.2 Performance analysis on different test images and datasets

In order to analyse the efficiency of the proposed LCD-RDHEI technique, the 8 standard test images namely Lena, Man, Baboon, Peppers, Airplane, Boat, Barbara and Crowd, each of size 512 $\times$ 512 pixels, have been taken into consideration. The experimental results in terms of ER (in bpp) and PSNR (in dB) by setting $V_c = 1$ to 16, have been presented in Table III. At $V_c = 1$, PSNR is infinite as the receiver can losslessly get the original image after extraction of the secret data. However, as the value of V_c increases, the PSNR decreases but embedding capacity increases and vice-versa is also true, which represents the traditional trade-off between the ER and PSNR. It can be observed from the Table III that the smother images such as Airplane, Lena provide more ER as compared to the rough images such as Baboon. In other words, the maximum ER i.e., 3.0789 is achieved in case of smoothest image i.e., Airplane and in contrast, minimum ER i.e., 1.0923 is provided by the most complex image i.e., Baboon with infinite PSNR. This suggests that the LCD-RDHEI method efficiently utilizes the spatial correlation. As a result, around half of the bits (i.e., 4 bits) in a smother image are easily utilized for embedding while keeping the PSNR over 40 dB. It can be observed that the in few cases, ER at $V_c = 2$ is lower than that of at $V_c = 1$ because LCD-RDHEI, at $V_c = 2$ and onwards, employs IAMBTC to represent the pixels of link chain by trio of H^l, D^{hl} and bitmap, which results in more overhead instead of one average value (in case of $V_c = 1$).

The performance of the LCD-RDHEI is also analysed on three data sets at $V_c = 1$ and 10. For this, the results of embedded capacity of each data set and corresponding PSNR are provided in Table 1. At $V_c = 10$, the ER for 500 randomly selected images from the BOSSBase [35], BOWS-2 [36], and UCID [37] are 4.2325, 4.0012, and 3.8497 respectively, while the PSNR values are 42.8769, 40.9913, and 41.0458. Conversely, at $V_c = 1$, the proposed method attains infinity PSNR for the similarly selected 500 images, delivering ER values of 3.2348, 3.0415, and 2.704 bpp for the BOSSBase, BOWS-2, and UCID databases respectively.

Table 1 Embedding Rate (bpp) and PSNR (dB) of the recovered images with $V_c = 1$ and $V_c = 10$ for three datasets

		BOSS Base	BOWS-2	UCID
V_c=1	ER	3.2348	3.0415	2.704
	PSNR	$+\infty$	$+\infty$	$+\infty$
V_c=10	ER	4.2325	4.0012	3.8497
	PSNR	42.8769	40.9913	41.0458

4.3 Comparison with State of Art methods

To comprehensively evaluate the performance of the proposed LCD-RDHEI method against some of the notable and recently developed existing methods such as the works of Fu et al. [32], Gao et al. [31], Liu et al.[30], Qin et al.[29], Li et al. [28], Gao et al. [27], Wang et al. [26], Xiao et al. [25], Yin et al. [23], Shiu et al. [22], Puteaux et al. [11], Cao et al. [9], Zang et al. [8] and Ma et al. [7], have been comparatively analysed. The aforementioned state-of-the art methods belong to both VRAE and RRBE. Figure 5 graphically represents the comparative analysis between the SOTA and the proposed method, focusing particularly on PSNR and ER as the pivotal performance metrics. The comparative analysis is given using four different characteristics test images Lena, Man, Baboon, and Airplane. As inferred from Fig. 5, the ability to embed a substantial payload is feasible in every case while maintaining an acceptable level of PSNR.

More specifically, the proposed method, in case of Lena and Man images which are moderately smooth images, surpasses all of the existing works in terms of the maximum ER but at the cost of PSNR. Further, the performance of the proposed method is at peak for highly smooth i.e., Airplane and highly complex image i.e., Baboon as evident from the Fig. 5c and d, respectively. For these images, the method seems to either beat all of the existing works or provide comparable results even at infinity PSNR. This has been made possible because of the method's effectiveness in exploiting the neighbourhood correlation. Overall.

Overall, the illustrative insights from Fig. 5 reveal that the Proposed LCD-RDHEI method achieves the highest ER, with negligible distortion. Moreover, its pivotal to highlight that, unlike the existing works which are usually constrained to a fixed embedding capacity, the proposed method offers enhanced flexibility. This adaptability allows for increased

capacity through manageable increments in distortion, providing a versatile solution that can be tuned for optimal performance.

5 Conclusion

In this research article, a high embedding capacity link chain driven RDHEI method based on pixel correlations, was proposed. The proposed LCD-RDHEI method collects the highly correlated pixels in terms of link chains which are of variable sizes and shapes. This collection of correlated pixels based on a variability co-efficient, helps in creating a big room before encryption which in turn helps in embedding the large amount of secret data. It is to be noted that the proposed method works as completely reversible data hiding method in encrypted domain if the variability co-efficient is zero, in other words, when all the pixels have the same intensity value within a link chain, which results into minimal embedding capacity. At larger embedding capacities where the values in a link chain are subject to a user-defined range based on the variability co-efficient, some of the contents of the cover media might be lost at the time data extraction and image restoration. To our knowledge, this is the first method that suggests the usage of variable size and shape of groups so that highly correlated groups can be formed. Experimentally, the proposed LCD-RDHEI method provides significantly greater embedding capacity than the existing and related data hiding methods. In future work, the focus

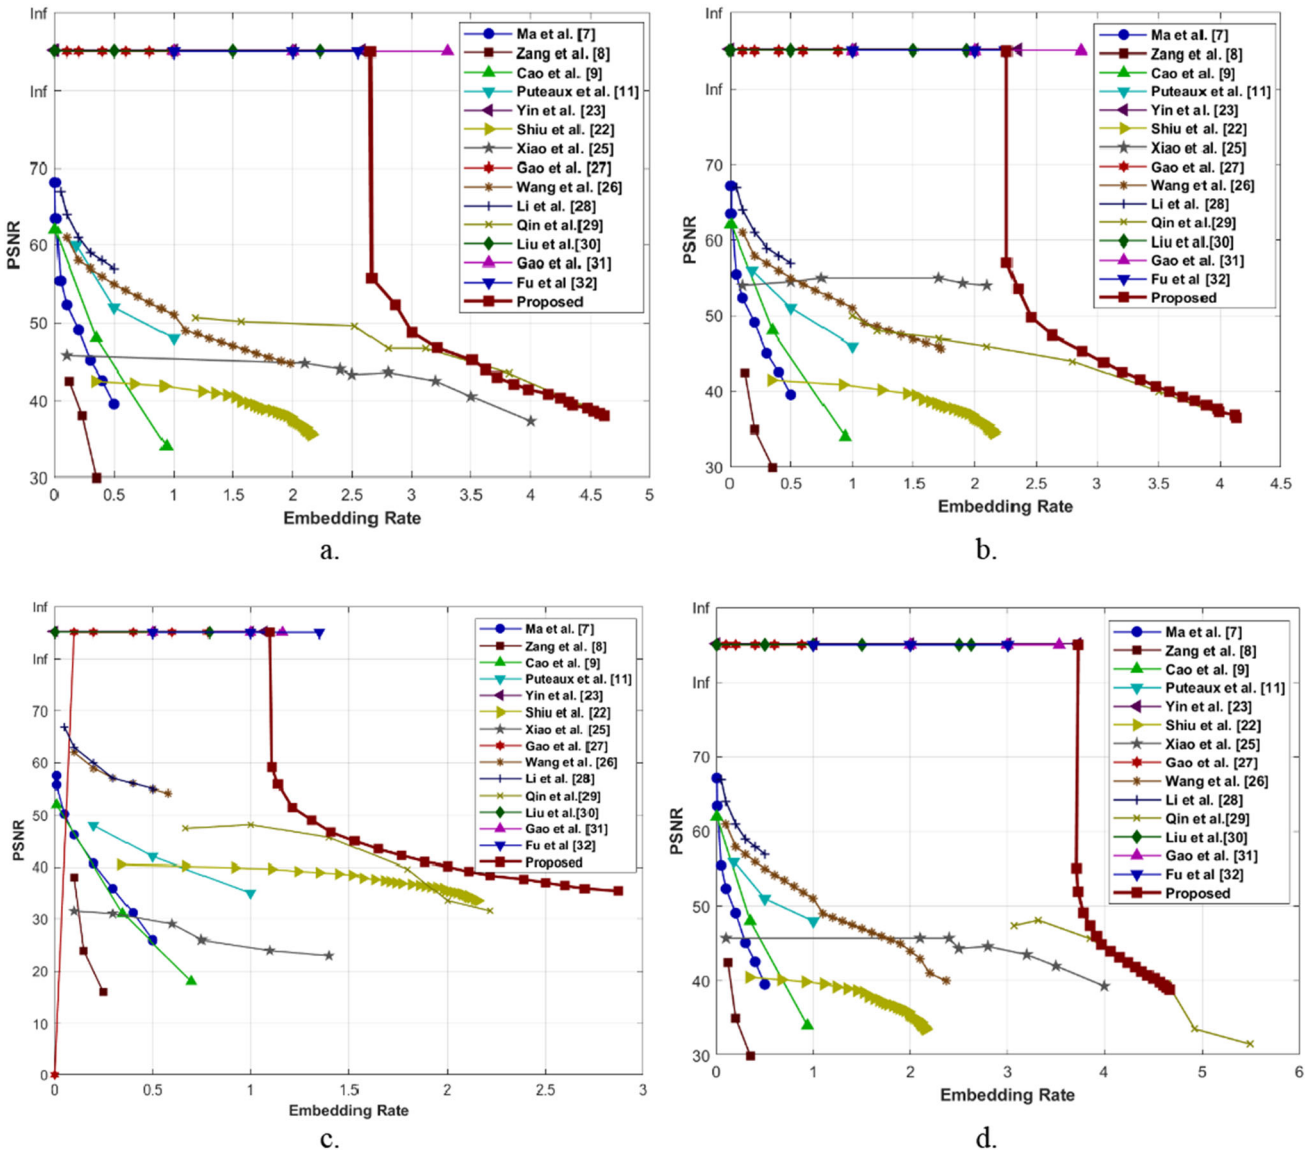

Fig. 5 Comparative analysis of proposed method w.r.t. SOTA methods for four test images of: **a**. Lena, **b**. Man, **c**. Baboon and **d**. Airplane

will be on reducing the distortion in case of long chains. Further, efforts will be made to reduce the overhead generated for identifying the next link chain.

Supplementary Information The online version contains supplementary material available at https://doi.org/10.1007/s11760-024-03275-1.

Author contributions Ankur and R.K. wrote the main manuscript text and conceptualized the idea. AKS reviewed the manuscript and provided supervision.

Data availability The data can made available on request to the first author.

Abstract One of the most remarkable techniques recently introduced into the field of bioprocess engineering is machine learning. Bioprocess engineering has drawn much attention due to its vast application in different domains like biopharmaceuticals, fossil fuel alternatives, environmental remediation, and food and beverage industry, etc. However, due to their unpredictable mechanisms, they are very often challenging to optimize. Furthermore, biological systems are extremely complicated; hence, machine learning algorithms could potentially be utilized to improve and build new biotechnological processes. Gaining insight into the fundamental mathematical understanding of commonly used machine learning algorithms, including Support Vector Machine, Principal Component Analysis, Partial Least Squares and Reinforcement Learning, the present study aims to discuss various case studies related to the application of machine learning in bioprocess engineering. Recent advancements as well as challenges posed in this area along with their potential solutions are also presented.

Introduction

Bioprocess engineering is a multidisciplinary field with applications ranging from the synthesis of medicinal proteins, polysaccharides, vaccines, and antibiotics to products that can regulate harmful

Published online: 21 June 2024

wastes (Mowbray et al. 2021a, b). Current research focuses on developing mathematical models in subfields of this discipline (Esfandyari et al. 2017). These unique and dynamic mathematical concepts are used to optimize different kinetic models and further compute fluid dynamics for bioreactor and fermentation scale-up. Although a high amount of research has been done related to the development of complex mathematical theories, the research community still lacks efficient and robust modelling methods to accurately compute advanced biochemical engineering domain knowledge in terms of mathematical concepts (Ab Azar et al. 2020). Complex biochemical processes are often modelled with the help of physical, chemical, and biological principles, although we are slowly moving towards hybrid modelling, which encompasses statistical, machine learning (ML), and data-driven approaches to solve complex biochemical processes (Bhange et al. 2023; Cutajar et al. 2019; Vega-Ramon et al. 2021). With the help of data-driven and ML techniques, complicated correlations in the data can be uncovered (Khanal et al. 2023).

Biochemical processes, "one of the most complicated processes," have attracted scientists from different domains to work and contribute towards this research community (Dürrenmatt and Gujer 2011). There are different factors which determine the ambiguity of biochemical processes, such as biological cell materials, temperature, pH, control algorithms, sensor development, and the multiphasic nature of bioreactors, etc. These factors are often considered as a form of input for ML models, including Support Vector Machine (SVM), Artificial Neural Network (ANN), Multivariate Statistical Analysis (MSA), and Reinforcement Learning (RL), etc. ML can be used to optimize bioprocesses by modelling nonlinear relationships between operating parameters, for example, in biofuel production, optimization of inoculation proportion, bioreactor optimization, etc. (Kell 2006).

In the recent advancements of ML in biochemical and bioprocess engineering, diverse research studies have showcased the transformative impact of computational approaches on optimizing complex biological systems (Lee et al. 2018). The fermentation of blueberry juice, as explored in one study, utilized a unique combination of strains and intricate mathematical tools such as sequential simplex lattice mixture design, regression modelling, and genetic algorithm optimization (Liao et al. 2023). The ML-driven approach for predicting glucose responses from Kraft waste-based pretreatments exemplifies the seamless integration of artificial intelligence (AI) into bioprocess optimization, with high R^2 scores and robust validation metrics indicating the efficacy of the developed models (David et al. 2023). The exploration of pharmaceutical bioprocesses within the quality by design (QbD) framework employs the statistical design of experiments (DoE) as a robust tool, emphasizing the advantages of leveraging DoE and design space methodologies (Kasemiire et al. 2021; Lutnick et al. 2023). The study not only underscores the necessity for a reliable and efficient methodology to monitor and control various factors involved in optimizing bioprocesses but also demonstrates the shifting paradigm from traditional quality-by-testing (QbT) approaches to the more efficient QbD methodologies facilitated by ML techniques (Helmy et al. 2023). Furthermore, the study on improving Computational Fluid Dynamics (CFD) modelling in cell culture bioreactors introduces an ANN-based ML model (Cantarero-Rivera et al. 2024). This novel approach effectively corrects coarse-mesh-induced errors in CFD modelling, showcasing the potential of ML to enhance computational efficiency in understanding fluid dynamics within bioprocess systems. The study on monoclonal antibody (mAb) manufacturing in the pharmaceutical field explores the early stages of ML support for QbD-based development (Khuat et al. 2024). ML-based models, replacing conventional multivariate data analysis methods, are highlighted for their potential in contributing to reducing production times without compromising product quality, a critical aspect in the biopharmaceutical industry (Ge et al. 2017; Xu et al. 2014). Additionally, the study on biohydrogen production using dark fermentation introduces ML algorithms such as SVM, random forest (RF), ANN, and genetic algorithm (GA) to optimize and control this complex biological process (Nagata and Chu 2003; Pandey et al. 2023). The application of ML in predicting the growth kinetics of acetic acid-producing bacteria isolated from fruit waste further underscores the versatility of these techniques in various bioprocess applications (Upadhyay et al. 2024).

The present study aims to provide a fundamental mathematical understanding of commonly used ML and deep learning algorithms in the field of biochemical engineering, such as MSA, SVM, ANN, and RL.

Here, we present various case studies associated with the use of ML in bioprocess engineering. The impact of ML and the difficulties encountered are discussed in detail.

Machine learning techniques

ML algorithms employed in the field of biochemical engineering predominantly include MSA, SVM, ANN, and RL. To apply them to the field of biochemical engineering, a basic mathematical understanding of these algorithms is imperative.

Multivariate statistical analysis (MSA) or multivariate analysis (MVA)

"Multivariate Statistical Analysis (MSA)," which emerged in the 1990s, is a methodical approach for examining data comprising diverse measurements or observations. It involves the simultaneous examination of multiple dependent variables alongside other relevant factors. In the realm of mathematical theory, MSA relies on intricate computations to arrive at accurate conclusions (van Heel 1991). It is a versatile tool for handling situations where a multitude of factors impact the variability of dependent variables, contributing to more realistic and accurate outcomes. Examples of specific techniques within MSA include Multiple Regression Analysis, Conjoint Analysis, and Multiple Discriminant Analysis. Multiple Regression extends the principles of simple linear regression to predict a variable based on multiple predictor variables. Conjoint Analysis, often employed in market research, utilizes surveys to gauge the relative importance of various attributes of a product or service to consumers. Multiple Discriminant Analysis aids in classifying samples into groups based on predictor variables, with the goal of creating a model that minimizes misclassification.

MSA plays a pivotal role in supporting various crucial activities in bioprocessing, such as process characterization, scale-up, monitoring, fault diagnosis, and root cause analysis (Li et al. 2020). Rathore and Singh (2015) highlighted the utility of MSA as a diagnostic tool for identifying scale-up discrepancies and parameter interactions that adversely affect cell culture process performance. Through multivariate data analysis and modeling utilizing data from "small-scale (2 L), pilot-scale (2,000 L), and commercial-scale (15,000 L) batches", the root cause was successfully pinpointed, and experimental conditions were tailored to showcase and rectify it. The parameters under scrutiny in the investigation encompassed bioreactor p_{CO_2}, glucose, ammonium, lactate, raw materials, and seed inoculum, while the outcome parameters included product titer, attributes, cell viability, viable osmolality, and density.

MSA uses a broad variety of statistical techniques, including principal component analysis (PCA), partial least squares (PLS), and polynomial regression. Traditional MSAs are often regarded as "old" statistical procedures but have a wide range of uses in the bioprocessing sector. PCA and PLS help to minimize the number of dimensions in a high-dimensional dataset.

Principal component analysis (PCA)

PCA emerges as a critical tool to address the challenges posed by the "curse of dimensionality," particularly in the realm of high-dimensional datasets. The curse of dimensionality is characterized by issues such as overfitting, prolonged computation time, and diminished accuracy in ML models as the number of features or dimensions increases exponentially. Due to the expansion of dimensionality, the computational complexity and cost escalate, making tasks like clustering and classification challenging (Lever et al. 2017). Feature engineering techniques, including feature selection and feature extraction, aim to mitigate these challenges. PCA tackles dimensionality reduction by transforming a set of correlated variables into a set of uncorrelated variables.

PCA operates on the premise that while mapping data from a higher-dimensional space to a lower-dimensional space, the variance of the data in the latter should be maximized. This statistical procedure involves several key steps, starting with the standardization of the dataset to ensure a mean of 0 and a standard deviation of 1. Subsequently, the covariance matrix is computed to measure the joint variability between variables. The eigenvalues and eigenvectors of the covariance matrix are then calculated to identify the principal components. The essence of PCA lies in its linear transformation, which preserves the most variance in the data with the least number of

dimensions. This involves projecting the data onto selected principal components, thereby achieving dimensionality reduction. Practical implementation entails steps such as standardizing the dataset, computing the covariance matrix, determining eigenvalues and eigenvectors, sorting them in descending order, calculating explained variance, and selecting the number of principal components based on desired variance retention. Ultimately, the data is mapped onto the principal components, effectively reducing its dimensionality.

In PCA, the n-dimensional dataset is converted to m-dimensional feature space, where the dimensions are orthogonal. This algorithm works on a concept called the "Eigenvalue Decomposition" of a covariance matrix, which is calculated using a specific dataset. Figure 1 shows the steps involved in the PCA algorithm.

According to PCA, for each dataset, $y_{i\in N} = \left(y_{i^1}, \ldots y_{ij}\right)^T$ there are y different variables. The objective of this algorithm is to formulate $K<J$ new variables $X_{i\in N} = \left(x_{i1}, \ldots, x_{iK}\right)^T$ that satisfy the following conditions:

$$x_{ik} = a_{k_1} y_{i_1} + \cdots + a_{k_y} y_{i_j}, \tag{1}$$

where y_{ij} represents the original variable with y_j in the ith data point, and x_{ik} refers to the latent variable x_k in the ith data point.

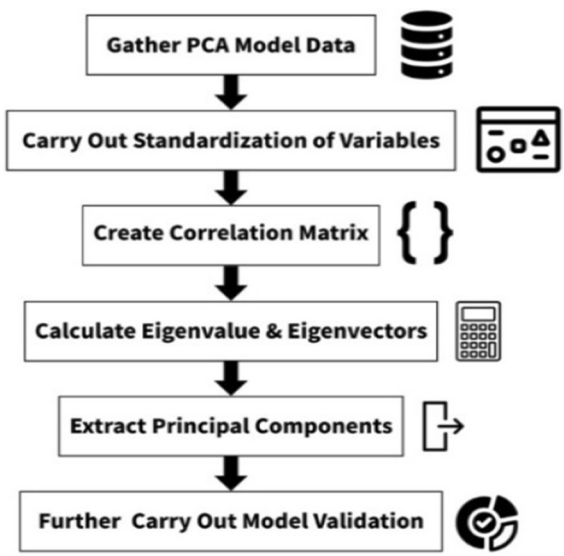

Fig. 1 Working of principal component analysis (PCA)

For the application of PCA in the field of biochemical engineering, the original variable y_j represents a particular variable with significance in a biochemical process. It may represent a bioprocess factor in the bioreactor dataset or an estimation at a specific wavelength in the spectroscopic dataset. These engineering parameters can include pH, temperature, flow rate, fluid velocity, shear stress, and mass transfer, etc.

The vector $a_k = (a_{kl}, a_{k2},....,a_{kJ})$ is obtained by increasing the correlation variable variance (y_k), as given in the following equations:

$$\sum_{i=1}^{N} \left(y_i k\right)^2 = y_{1k}^2 + \cdots + y_{ik}^2, \tag{2}$$

$$a_{k1}^2 + \cdots + a_{kJ}^2 = 1, \tag{3}$$

$$a_k a_m^T = 0, \quad m = 1,2, \ldots, k-1. \tag{4}$$

The purpose of PCA is to generate new variables by using different combinations of original dataset values, and this newly generated data is called the principal component. In most cases, maximum variations are mapped by PC1 (principal component 1) and PC2 (principal component 2). Hence, the data should be segregated into their PC sets (1st PC, 2nd PC) and mapped out to find possible connections (Abdi and Williams 2010).

PCA has been used in Raman Spectroscopy data analysis to uncover hidden relationships between various reactor operating variables in the case of biogas and biofuel production and is also used to identify process irregularities in large-scale cell culture systems (Goodacre 2003; Sharma et al. 2023).

Partial least squares (PLS)

PLS, also known as "projection to latent structure," emerges as a potent predictive modeling approach, particularly when conventional techniques like ordinary least squares (OLS) regression, canonical correlation, or structural equation modeling encounter difficulties arising from highly correlated predictor variables or an imbalance between predictors and cases (Boulesteix and Strimmer 2006). PLS methodology integrates components from PCA and multiple regression. In its operation, PLS begins by extracting a set of latent factors, aiming to capture the maximum

covariance between independent and dependent variables. This latent factor extraction proves pivotal in situations where traditional methods struggle due to multicollinearity or a surplus of predictors relative to observations. Subsequently, PLS employs a regression step to forecast the dependent variables' values using the decomposition of the independent variables (Wold et al. 2001).

Unlike traditional linear regression, PLS regression involves projecting both the predicted and observable variables into a new space. This unique characteristic categorizes the PLS family of methods as bilinear factor models. Particularly noteworthy is Partial Least Squares Discriminant Analysis (PLS-DA), a variant of PLS used when the dependent variable (Y) is categorical. The primary objective of PLS is to uncover fundamental relationships between two matrices, denoted as X and Y. It adopts a latent variable approach to model the covariance structures in these two spaces. In the X space, PLS endeavours to identify a multidimensional direction that explains the maximum variance in the corresponding multidimensional direction in the Y space. This approach makes PLS regression well-suited for situations where the matrix of predictors has more variables than observations and multicollinearity among X values is prevalent, scenarios in which standard regression may falter unless regularization techniques are applied.

If the original input and output dataset variables are X_i, R^J and Y_i, R^K ($K \in J$), then PLS transforms them into their respective latent variables Z_i, R^p and Q_i, R^l with $p \in J$ and $l \in K$. Furthermore, PLS obtains a correlation between Z_i and Q_i. Equations (2)–(4) are used to calculate Z_i and Q_i.

If there are several output variables to be correlated with input factors, it is usual practice to create multiple independent PLS models concurrently. Figure 2a and b depict the flow and purpose of the PLS algorithm, respectively. Figure 2c shows the working of PCA in association with the procedure of the PLS algorithm.

Since the PLS algorithm can handle missing data values, it has been used for analysing industrial batch data. Data is obtained from multiple batches and covariance is determined between input and output variables; this ability makes it suitable for bioprocess modelling (Patel et al. 2020). PLS is also employed for state estimation and control in bioreactors, as well as monitoring of bioprocesses (Mandenius and Titchener-Hooker 2013). It also serves several purposes in mapping protein–amino acid sequences and discovering connections between reactions and metabolic pathways (Whittle 1952).

Support vector machine (SVM)

Statistical learning theory serves as the cornerstone for the innovative ML method known as SVM. It has become the ML community's research focus due to its higher accuracy. SVM is a powerful ML algorithm that operates on the principle of finding an optimal hyperplane to separate different classes in a feature space. Unlike many ML algorithms, SVM does not rely on explicit equations for class boundaries (Yang 2004). Instead, it focuses on finding the optimal hyperplane that maximizes the margin, which is the distance between the hyperplane and the nearest data points from each class. This is achieved using support vectors, which are the data points closest to the decision boundary. SVM's mathematical elegance lies in its ability to efficiently handle linear and non-linear relationships through the kernel trick without explicitly requiring equations for decision boundaries. The algorithm's strength lies in its geometric interpretation and the optimization of margins, providing a versatile tool for various classification tasks.

Figure 3 provides a clear visual representation of the SVM applied to two-dimensional data. In this illustration, two distinct lines are constructed to separate data points belonging to different classes. These lines, also known as decision boundaries, are strategically placed to maximize the margin between the two classes, ensuring the obtention of the best possible hyperplane. SVM's objective is to find this hyperplane, which not only separates the data but also maximizes the distance between the nearest data points from each class. This approach results in an optimal classification model, making SVM a powerful tool for various applications, including image recognition, text classification, medical diagnosis, and financial forecasting, etc.

Since the late 1990s and early 2000s, SVMs have been used for both classification and regression problems in the field of biochemical engineering. SVMs extract intricate nonlinear correlations frequently exhibited in biological applications. They have been successfully applied to estimate metabolic fluxes,

foresee membrane contamination in bioreactors, and find nucleotides for nanopore sensing. Bioprocess monitoring and control rely heavily on SVM estimates of important state variables, including product and biomass concentrations (Ge et al. 2023). Because of the time-varying nature of complex biochemical processes, researchers often use a learning-prediction approach for the construction of SVM training databases. SVM outperformed a few ANN algorithms (FBNN, RBFN, and RNN) in terms of efficiency and reliability in a study aimed at the estimation of product concentration in industrial penicillin manufacturing (Chen et al. 2015).

The application of SVM in predicting crucial state variables within bioprocesses, including product and biomass concentrations, has demonstrated notable success (Zhang et al. 2017). A rolling learning-prediction procedure designed to address the time-varying nature of the bioprocess has also been reported (Li and Yuan 2006). This method aids in the establishment of a comprehensive training database for the SVM predictor. SVM exhibited remarkable prediction accuracy, achieving an impressive range of 1–3% accuracy for predictions spanning 4–40 h into the future. Notably, this performance surpassed the best results obtained from three distinct ANNs examined.

Although SVM promises great results for the prediction of critical state variables in the realm of bioprocesses, many challenges remain to be resolved. Limitations associated with SVM algorithms are realized when this procedure is applied to large datasets. The reason could be the demand for large memory space by kernel functions. This is computationally expensive, i.e., "memory demands are $O(Y^2)$ and computation demands $O(Y^2 y_x)$ operations," where Y and y_x represent the number of data points and variables, respectively (Widodo and Yang 2007). In addition, SVMs do not always give a probabilistic output in the forecast they are making.

Artificial neural network (ANN)

ANNs are a class of ML models inspired by the structure and functioning of the human brain. ANN comprises interconnected nodes organized into layers: an input layer, hidden layers, and an output layer. Each connection is associated with a weight, and each node has an associated activation function (Lancashire et al. 2008). The mathematical representation involves a series of matrix multiplications and activation function applications during forward and backward propagation. The forward pass computes the predicted output, and the backward pass adjusts the weights using optimization algorithms like gradient descent and backpropagation to minimize the difference between predictions and actual outcomes (Phung 2019). The network learns by iteratively updating weights to enhance its ability to generalize from training data to unseen examples, making ANNs powerful tools for complex pattern recognition and nonlinear function approximation.

Predicting fermentation variables, characterizing amino acid sequences, simulating bioprocesses, biomass concentration estimation and modelling bioremediation of polluted groundwater are few applications of ANN in biochemical engineering (Natarajan et al. 2021). It takes into consideration many factors, like ionic strength and media composition. Thanks to a high number of adjustable parameters, neural networks are very general-purpose and may likely be trained to approximate any function. Parameters are often repeatedly optimized so that the neural network can become more efficient and produce accurate results.

There are different types of ANN, such as Deep Neural Network (DNN), Convolutional Neural Network (CNN), Recurrent Neural Network (RNN), etc. All these types of neural networks have found their application in the field of biochemical engineering (Krishna et al. 2021). CNN has been used for optimization of classification of enzyme tertiary structure in metabolic engineering, algal biofuel production, bioreactor optimization, and prediction of protein structure with incredible precision (Shin et al. 2016). RNNs find applications in genetic engineering for the recognition of promoter sequences, protein engineering for the statistical summarization of amino acid sequences, and biosensor calibration for soft sensors (Rivera and Karim 1992). The discovery that many hidden layers might ease the modelling of exceedingly complicated underlying functions due to the large number of parameters involved led to the creation of DNNs, which was possibly the most significant structural breakthrough. Figure 4 shows

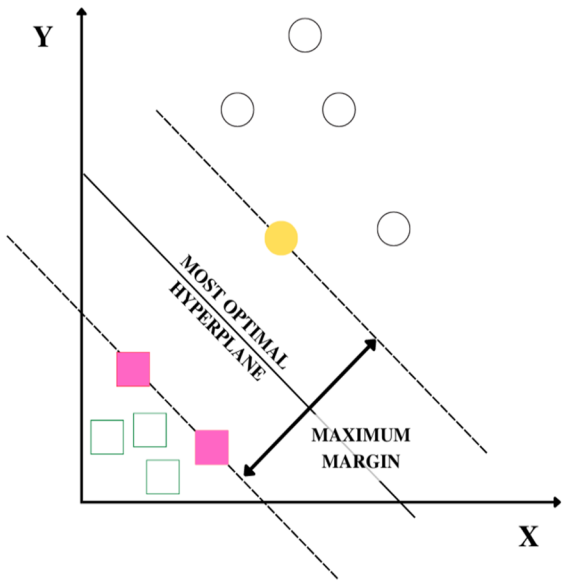

Fig. 3 Representation of support vector machines (SVM)

diagrammatic representations of workflows for ANN, CNN, RNN, and DNN.

Choosing the right number of hidden layers, neurons per hidden layer, and activation function is critical to the effectiveness of neural networks (Ren et al. 2017). Various methodologies have been used, ranging from the simple (such as a random search of hyper-parameters) to the complicated (such as Bayesian optimization) (Brochu et al. 2010). Unfortunately, the importance of hyper-parameter selection in neural network models is commonly underestimated. Choosing suitable hyperparameters is vital in neural network applications for feature selection and dimensionality reduction, like auto-encoders applied in cleaning RNA sequence databases and producing latent representations of genomic data.

Reinforcement learning (RL)

RL is a ML paradigm where an agent learns to make sequential decisions by interacting with an environment to maximize a cumulative reward signal. The learning technique uses a reward and penalty approach for reaching the best optimal result (Abbeel and Ng 2011; Popova et al. 2018). Unlike traditional approaches such as supervised and unsupervised learning, RL utilizes a trial-and-error methodology. The mathematical formulation of RL involves the Markov Decision Process (MDP), characterized by states, actions, transition probabilities, and rewards. The agent learns a policy, denoted as π, which maps states to actions, aiming to optimize the expected cumulative reward (Mahmud et al. 2018). The value function, represented by Q-values or state–action values, quantifies the long-term reward of taking a specific action in each state. The fundamental RL algorithms, such as Q-learning or policy gradient methods, employ mathematical mechanisms like Bellman equations, temporal difference updates, and stochastic gradient descent for learning optimal policies through trial and error. The convergence and effectiveness of RL models heavily rely on these mathematical foundations, enabling applications in the field of biochemical engineering (Petsagkourakis et al. 2020). Figure 5 gives a visual representation of the RL technique.

In the evolving landscape of bioprocess engineering, the integration of RL techniques, both model-based and model-free, represents a paradigm shift in how we approach process optimization and control. While model-based RL offers a structured and model-driven approach, model-free RL thrives in dynamic and uncertain environments (Pan et al. 2021). These methods provide the means to adapt and fine-tune bioprocesses with unprecedented precision and efficiency. Whether it is the production of life-saving pharmaceuticals, sustainable biofuels, or efficient wastewater treatment, the applications of RL are diverse and impactful.

A particular study presents a special RL algorithm called REINFORCE, for the optimization of "continuous control variables," "u" (Petsagkourakis et al. 2022). Often, Value-Based Algorithms are represented by Q-learning. They build the optimal policy by greedily picking the control with the greatest Q(x, u) value, which is learned and optimized directly from the state–action value function (state–action value). Actor–critic techniques are one kind of hybrid algorithm that combine policy optimization with value-based approaches. For instance, in the production of monoclonal antibodies, RL systems can dynamically adjust bioreactor conditions, resulting in a significant increase in yield while maintaining product quality. In bioethanol production, RL optimizes fermentation parameters, leading to higher yields and reduced energy consumption (Petsagkourakis

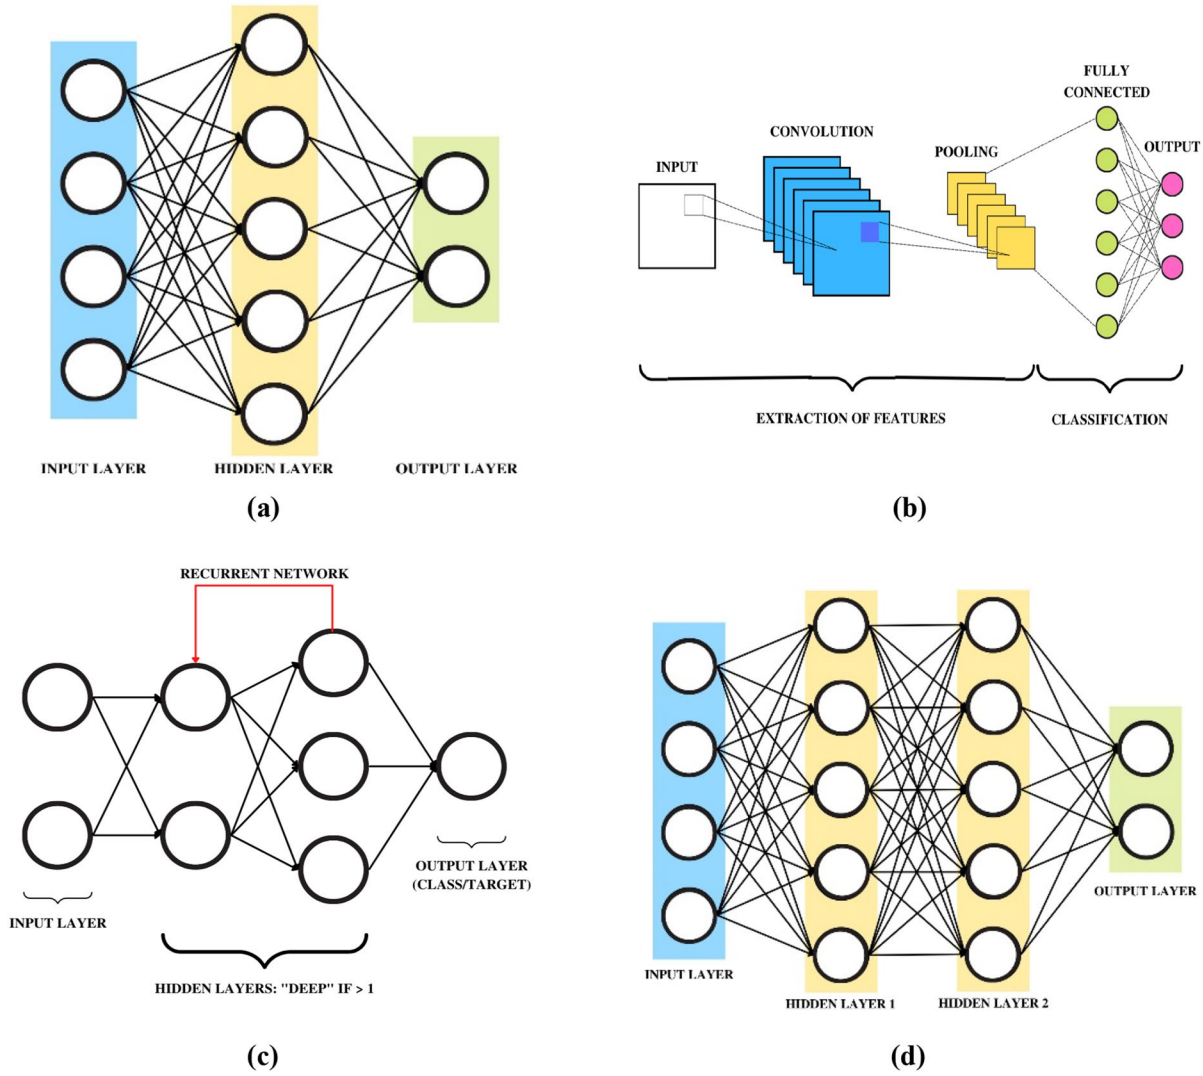

Fig. 4 Diagrammatic representations of workflows **a** Artificial Neural Network (ANN), **b** Convolutional Neural Network (CNN), **c** Recurrent Neural Network (RNN), and **d** Deep Neural Network (DNN)

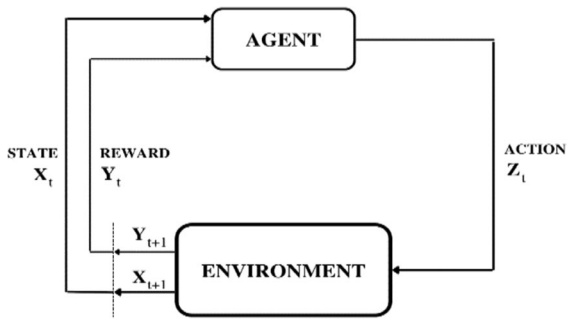

Fig. 5 Workflow of reinforcement learning algorithm

et al. 2022). In wastewater treatment, RL enhances the removal of contaminants and reduces chemical usage while meeting stringent effluent standards. RL is also involved in microbial biotechnology processes to yield more bio-based chemicals with cost-efficient production (Mowbray et al. 2022). Furthermore, for bioreactor control, RL outperforms traditional controllers, achieving precise regulation and minimizing batch-to-batch variability (Duong-Trung et al. 2023). These case studies underscore the transformative impact of RL in the field of biochemical and bioprocess engineering, offering not only operational

efficiency but also sustainability, cost-effectiveness, and the promise of further innovations in the industry (Nian et al. 2020).

Applications of ML algorithms in bioprocess engineering

ML algorithms find application in diverse sub-fields of bioprocess engineering. These include bioreactor optimization, bioreactor control, microbial co-culture optimization, fermentation process optimization, batch bioprocess optimization, metabolic engineering, bioprocess modelling, and bioresources and bioenergy processes, etc.

Bioreactor optimization

Bioprocess development, an integral part of the biopharmaceutical industry, remains a challenging and resource-intensive endeavor (Smiatek et al. 2020). Among its intricacies, optimizing the culture media used for bioprocessing can be particularly time-consuming and labour-intensive. In a study on the generation of therapeutic proteins, researchers explored the application of Bayesian optimization (BO) models (Alcântara 2018). The primary focus of this investigation was the enhancement of the feeding strategy within a pre-existing fed-batch protocol for Chinese Hamster Ovary (CHO) cell lines, specifically those involved in the production of mAb derived proteins. To carry out this ambitious project, BO and its various iterations were put to the test using both *in silico* and experimental models. The researchers initiated the optimization process by employing computer simulations, leveraging an *in silico* model that mirrored a fed-batch process (Cougnon et al. 2011). Notably, one study within this research adopted an approach involving Latin hypercube sampling for initialization and employed expected improvement as an acquisition function. Additionally, local penalization was integrated into the BO methodology (Sampaio and Calado 2019; Viana 2015). This was achieved through a series of systematic experiments to determine the most effective feeding strategy among four different options, ultimately yielding the highest protein titres. The optimization process began with an initialization phase comprising 16 tests, followed by four batches of experiments, each conducted in 50 mL spin tubes. Impressively, this comprehensive study resulted in a remarkable 35% increase in protein titres compared to the baseline method. To further validate the applicability of the scaled-down models, the research extended into 3 L benchtop bioreactors, reaffirming the promising results. Moreover, this study delved into the development and deployment of several ML algorithms, all meticulously implemented using MATLAB functions. Key algorithms such as initialization methods, surrogate models, and acquisition functions were precisely employed, further enhancing the efficiency and accuracy of the optimization process.

The insights garnered from this study open exciting prospects for the optimization of feeding strategies, not only for bioprocesses but also for the formulation of ideal culture media in perfusion cultures. It also underscores the importance of addressing concerns related to medium osmolarity. In a larger context, these findings pave the way for the discovery of optimal operating parameters through the utilization of perfusion scale-down models, promising advancements in bioprocessing efficiency, and the production of therapeutic proteins (Pereira et al. 2018; Zheng et al. 2017).

Bioreactor control

In recent scientific investigations, there has been a growing interest in the application of RL and ANN for the control of complex industrial processes. Traditional inverse model ANN-based control methods exhibit remarkable adaptability to intricate nonlinear systems, even with limited training data, while RL algorithms introduce a distinct approach. They establish an optimal control policy through iterative exploratory operations, albeit at a somewhat slower convergence rate.

Notably, a groundbreaking strategy has emerged to circumvent the need for extensive training data in the context of inverse ANN-based control. This innovative approach, known as Partially Supervised Reinforcement Learning (PSRL), leverages ANNs to acquire an initial control policy. PSRL represents a compelling solution for addressing the significant economic challenges associated with regulating yeast fermentation within a semi-continuous fed-batch

bioreactor (Xu 2019). This control problem is formally framed as a 'Markov Decision Process (MDP)', utilizing a synthesis of RL and PSRL techniques.

The bioreactor control problem can be formulated as MDP with a state space S, an action space A, a transition function T(s, a, s') for all $s \in S$ and $a \in A$, a reward function R(s, a), and a discount factor γ. The goal is to learn a policy $\pi(a|s)$ that maximizes the expected cumulative reward over time. Through comprehensive comparative assessments involving model-based and model-free RL control in practical tests and simulations, PSRL consistently emerges as the superior performer, excelling in a diverse array of performance criteria when juxtaposed with RL and inverse model ANN-based control techniques.

Microbial co-culture optimization

Deep RL techniques have found applications in the control of microbial co-cultures as well, where they are employed to optimize growth conditions, regulate metabolic pathways, and manage community dynamics for various biotechnological purposes, such as biofuel production, bioremediation, and pharmaceutical development. Treloar et al. (2020) harnessed the power of Neural Fitted Q-Learning to control a model representing microbial co-culture. This study demonstrated that RL surpasses traditional industrial control systems, particularly when dealing with extended sample-and-hold intervals. RL is especially advantageous when dealing with situations where data limitations are not a constraint. Furthermore, investigations have shown that RL can efficiently optimize microbial co-cultures in cost-effective bioreactors. This implies that it is possible to optimize the output of a microbial population without the need for a specialized model, relying instead on information about microbial population levels and the pace at which the desired product is generated. The approach introduces a specific optimization methodology employing a chemostat model for a bioreactor. "Auxotrophy" was utilized as a control mechanism, although other control measures such as "independent carbon sources," "induced lysis," or "growth arrest" could also be implemented. Notably, controlling microbial populations can potentially lead to mutations. Therefore, the RL technique utilized in this study involves the continuous updating of the agent's policy, ensuring flexibility to adapt to evolving growth dynamics.

Given the iterative nature of RL, only a few studies have explored techniques that may influence evolutionary changes in growth dynamics. While RL offers a promising avenue, model-based alternatives such as dynamic programming might also contribute to optimal control challenges.

Researchers have underscored the efficacy of deep RL in managing diverse ecosystems. The significance of community engineering is expected to grow in the context of synthetic biology and industrial biotechnology as production processes become increasingly complex (Fisher et al. 2022). As a result, the application of advanced AI techniques to steer intricate biological systems is becoming increasingly valuable (Bain and Sammut 2000).

Fermentation process optimization

Fermentation technology plays a crucial role in various applications, and the ability to optimize fermentation conditions is of paramount importance. A study specifically focused on the enhancement of Iturin A production, employed various approaches, including ANNs and SVMs (Chen et al. 2015). Independent variables such as the concentrations of asparagine, glutamic acid, and proline (mg/L) were meticulously considered, while the dependent variable was the "Iturin A titer" (Tang et al. 2021). Multiple ML models, including SVM, multilayer feed-forward neural networks (MLFNs), and general regression neural networks (GRNNs), were developed and meticulously compared to determine their performance in this context. Notably, MLFNs exhibited higher root-mean-square error, longer training periods, and significant variability with shifts in the number of nodes. In contrast, GRNNs showcased the lowest root-mean-square error and the quickest training period, maintaining consistent performance across various experiments. The SVM model also demonstrated a brief training period and a minimal root-mean-square error. The model findings highlight that the GRNN excels as the preferred choice for establishing fed-batch fermentation conditions aimed at enhancing Iturin A production. Renowned for its robustness and high precision, the GRNN emerges as the top performer. The SVM stands as a viable alternative model with comparable

performance. Both the GRNN and SVM consistently achieve prediction accuracies exceeding 100% within a 30% tolerance margin across independent experiments.

Thus, it can be concluded that the application of ML, particularly through the GRNN and SVM models, provides a potent means to optimize fermentation processes, delivering accuracy and robustness essential to produce compounds like Iturin A.

Batch bioprocess optimization

Many scientists are looking for bioprocesses to replace their use of fossil fuels with more environmentally friendly options. However, they might be difficult to optimize because of their non-stationary operation modes and stochastic behaviour (Duong-Trung et al. 2023). Plant model mismatch is very widespread since biological systems are so complicated. An optimization strategy for batch processes, based on RL, is one option for dealing with the aforementioned problems.

The research work carried out by Petsagkourakis et al. (2019), presents a novel approach for optimizing bioprocesses utilizing RL techniques. By leveraging RL algorithms, particularly the "REINFORCE" algorithm, the study addresses the inherent challenges posed by the stochastic nature of bioprocess dynamics and the discrepancies between plant models and real-world systems. In the first stage of the methodology, an initial control policy is developed offline using an approximate model of the bioprocess system. Through extensive training epochs, the policy network, represented by a RNN, learns to optimize control actions to maximize a predefined reward function, such as the concentration of target products. Subsequently, in the second stage, the control policy undergoes refinement using real plant data in a batch-to-batch framework. This real-world data enables online updates to the policy network, enhancing its accuracy and adaptability to actual bioprocess conditions. The stochastic control policy, implemented through the RNN, dynamically predicts optimal control actions based on current states, past actions, and remaining batch time. By iteratively refining the control policy through a combination of offline training with approximate models and online updates with real plant data, the proposed methodology demonstrates significant advancements in bioprocess optimization under uncertainty. This research offers valuable insights and practical implications for improving the efficiency and reliability of bioproduction systems in various industrial applications.

Consequently, the utilization of RL, specifically the batch-to-batch policy gradient approach, exhibits great potential in the optimization of complex bioprocesses. This approach offers a proactive strategy for addressing the challenges posed by non-stationary modes and system complexities, thereby contributing to the development of sustainable energy solutions.

Metabolic engineering

ML also finds applications in the field of metabolic engineering. Here, two different case studies in the field are discussed.

Predicting metabolic circuit kinetics

Anticipating the kinetics of a metabolic circuit is a common challenge in bioengineering that can be effectively addressed through ML. Pathway dynamics prediction substantially enhances the efficiency of the pathway design process by allowing us to foresee which pathway designs will meet our requirements in advance (Narayanan et al. 2021). Classical kinetic models, with an explicit functional link between substrate/product concentrations and enzymes, have traditionally been employed to estimate the rate of change of specific metabolites. The Michaelis–Menten kinetic model has been the gold standard for investigating enzyme metabolism over time. However, for many processes, the precise functional link between metabolites and enzymes remains elusive, leading to suboptimal predictive ability due to knowledge gaps regarding the underlying mechanisms.

Costello and Martin (2018) introduced an innovative approach to predict metabolite dynamics by utilizing supervised ML, focusing on the limonene/isopentenol ratio. The core methodology involved developing a function based on protein and metabolite concentration data, prioritizing predictive accuracy over an intricate understanding of underlying biochemical processes. To enhance the model's performance, the researchers conscientiously grappled with the challenge of dimensionality, recognizing the

potential benefits of additional data while considering the exponential growth in data requirements, known as the 'curse of dimensionality.' A pivotal aspect of their strategy was the employment of feature selection algorithms, systematically identifying and retaining the most influential input features. This process not only streamlined the model architecture but also addressed issues of redundancy and overfitting. Synthetic features, derived from the original dataset, were introduced intelligently to strike a balance between model simplicity and accuracy. Additionally, dimensionality reduction techniques were judiciously applied to manage the complexity of the dataset while preserving predictive precision. The integration of a tree-based pipeline from scikit-learn ML models brought automation to the feature preprocessing approach, further enhancing efficiency and objectivity. This automated strategy not only expedited the feature selection process but also ensured a systematic and data-driven decision-making process. Hence, their study exemplifies a nuanced integration of ML and feature engineering strategies to optimize predictive accuracy while navigating the challenges posed by high-dimensional datasets.

Enhancing *n*-butanol production pathways

Metabolic pathways serve as intricate networks guiding biochemical transformations, crucial for synthesizing essential molecules and driving cellular functions (Oberhardt et al. 2009). The complexity of metabolic pathways, such as those involved in *n*-butanol production, underscores the need for innovative approaches like ML to unravel intricate relationships and optimize pathway design efficiently. In recent years, statistical techniques like PCA have emerged as invaluable tools for analyzing data derived from engineered organisms, offering insights crucial for guiding subsequent rounds of design. Historically, the complexity of data obtained from proteomics analysis posed challenges in discerning meaningful trends for system understanding and reengineering. However, advancements in techniques such as PCA have revolutionized this landscape by enabling the analysis of small datasets to unveil patterns or trends essential for informing system redesign. As datasets become increasingly abundant and diverse, the necessity for more sophisticated data-analysis tools, including ML algorithms, becomes apparent (Nielsen and Keasling 2016; van Lent et al. 2023).

The study conducted by Karim et al. (2020) provides a compelling demonstration of how ML techniques revolutionized the optimization of *n*-butanol production pathways. Central to the exploration is the elucidation of *in vitro* Prototyping and Rapid Optimization of Biosynthetic Enzymes" (iPROBE) methodology, which involves utilizing cell lysates enriched with biosynthetic enzymes through cell-free protein synthesis. This process allows for the rapid assembly and testing of metabolic pathways, facilitating the assessment of pathway performance *in vitro* (Batista et al. 2021).

Through a series of experiments, the researchers showcased the platform's capability to drastically reduce the time required for pathway construction while enabling the exploration of a vast array of enzyme combinations. By employing cell-free prototyping within the iPROBE framework, they were able to accelerate the design-build-test-learn (DBTL) cycles in metabolic engineering from months to mere days. The results were impressive, with ML-guided pathway designs significantly outperforming traditional base-case pathways, achieving over fourfold improvements in butanol production scores. However, the study also shed light on the challenge posed by the immense number of potential pathway combinations, emphasizing the need for a data-driven approach to pathway design. Through the utilization of DNNs, the researchers effectively navigated this complexity, generating optimized pathway designs that surpassed expert-determined alternatives. The neural network crafted in this case featured "5–15 fully connected hidden layers" and "5–15 nodes per layer." Training the neural network relied on a dataset comprising 120 pathway designs, with genetic algorithms assisting in determining the optimal neural network architecture. Looking ahead, the scalability of ML models in metabolic engineering hinges on the availability of abundant, high-quality, and well-organized data. While challenges such as data scarcity and dimensionality remain, continued advancements in ML techniques offer promising solutions to overcome these obstacles.

In conclusion, this study underscores the transformative potential of ML-guided pathway optimization in bioprocess engineering. By leveraging the power of computational methods within innovative

platforms like iPROBE, researchers can accelerate the development of sustainable bio-based production processes, paving the way for a more efficient and environmentally friendly future in industrial biotechnology. These studies have ushered in a new era of pathway optimization characterized by expeditiousness and have harnessed the cutting-edge capabilities of neural network predictions.

Bioprocess modelling

ML technology has also been put to good use in modelling and optimizing bioprocesses (Fakharudin et al. 2007). Among the various ML techniques, gradient boosting stands out as a unique ensemble learning strategy that combines weak learners to yield enhanced predictions. Despite its significant promise in improving the dynamic modelling and prediction of bioprocesses, gradient boosting remains a relatively understudied avenue.

Some researchers have initiated preliminary investigations into gradient boosting, particularly in its capacity to outperform commonly used ANNs. This exploration arises from the inherent challenge of generating a substantial volume of experimental data for model training in many bioprocesses. Researchers have demonstrated through diverse experimental verifications that gradient boosting surpasses ANNs in predictive modelling for bioprocesses, positioning it as a compelling choice for the future of bioprocess digitalization and optimization.

Moreover, ML models, acting as surrogate models, provide a practical alternative to intricate scale-up models, such as substituting costly simulations in computational fluid dynamics, thereby offering a cost-effective and efficient solution for optimizing bioprocesses. Surrogate models can be built using ML algorithms like ANNs, SVMs, or decision trees. These models can be trained on data from laboratory-scale experiments and utilized to forecast bioprocess performance at larger scales.

Another application of ML in bioprocess modeling involves integrating mechanistic models with data-driven models. Mechanistic models delineate the fundamental physical and chemical processes occurring in a bioprocess, whereas data-driven models utilize statistical techniques to discern patterns in experimental data. By amalgamating these two model types, it becomes feasible to uncover non-traditional scale-up criteria by correlating validated mechanistic models that describe bioprocess performance across laboratory and production scales.

The equations utilized in ML models for bioprocess modeling may vary depending on the specific algorithm employed. For instance, ANNs leverage interconnected nodes to process input data and generate output predictions, with equations based on the activation functions used in the nodes. SVM employs a kernel function to transform input data into a higher-dimensional space, facilitating easier separation into different classes, with equations grounded in the specific kernel function used.

Therefore, ML holds considerable promise in enhancing bioprocess modeling by enabling efficient exploration of extensive design spaces and uncovering non-traditional scale-up criteria. Nonetheless, the existing literature on ML for bioprocess modeling remains limited, necessitating further development in this domain.

Bioresources and bioenergy

The negative environmental impact of fossil fuels has driven research into renewable alternatives, such as biofuels and bioenergy, to ensure a sustainable bioeconomy. Biofuel and bioenergy processes are vital components of this transition, necessitating modelling and optimization (Duong-Trung 2023). ML and deep learning techniques hold significant promise for creating reliable models in biofuel production (Bennamoun 2022). However, modelling operational parameters, such as biofuel extraction rate and operating temperature, poses a challenging task.

As biofuels offer potential benefits, including reduced emissions, decreased fuel consumption, and expanded engine operating ranges, they have become a focus of research in combustion engines. However, assessing engine performance with various biofuel blends is time-consuming and requires engine adjustments. ANNs are emerging as a solution to these challenges, enabling the modelling of biodiesel fuel blends in engines and predictions of performance indicators based on engine speed and biofuel percentage. Extending beyond traditional ANNs, Extreme Learning Machines (ELMs) have been explored to address this issue. ELMs offer faster learning and

improved generalization compared to standard ANNs (Wang et al. 2022). A variant called "Kernel-based Extreme Learning Machine (K-ELM)" has been introduced to predict gasoline engine performance. K-ELM demonstrates comparable or superior accuracy to the least-squares support vector machine (LS-SVM), while significantly reducing training and testing times.

Other applications in the field include predicting biogas and methane production during the anaerobic treatment of wastewater molasses using ANN models. ANN-based models are also employed to forecast the impact of operational factors (temperature, moisture content, and ash content) on hydrogen output in biomass gasification. Decision tree-based classifiers aid in determining optimal operational factors for algal biomass growth and lipid synthesis, with a focus on dividing training data into high and low classes based on specific criteria.

Other recent advancements in bioprocess engineering

In recent years, the field of bioprocess engineering has witnessed significant advancements fuelled by the integration of ML, deep learning, and AI techniques. These innovative technologies, exemplified by tools like chatbot, GPT-4, natural language processing (NLP) have revolutionized various aspects of biochemical and bioprocess engineering, offering novel solutions to complex challenges, and unlocking new opportunities for sustainable development (Heras et al. 2020; Xiao et al. 2023; Yang et al. 2023). As ML continues to evolve, its applications in bioprocess engineering have expanded beyond traditional boundaries, encompassing diverse areas such as metabolic pathway design, renewable energy production, waste management, and pharmaceutical research and development. The integration of generative AI, through the utilization of natural language processing tools like GPT-4, has revolutionized knowledge extraction from synthetic biology journal articles, streamlining information retrieval and empowering advancements in bioprocess engineering. Table 1 presents recent studies on the applications of ML, deep learning, and AI in the different sub-domains of biochemical and bioprocess engineering.

Challenges for the applications of ML in bioprocess engineering

Despite the significant advancements that ML has brought to bioprocess engineering, certain challenges persist, hindering its widespread adoption. Bioprocess engineers carefully select the most suitable ML models by comparing their performance on similar datasets and research problems. Benchmarking has been extensively explored as a method to assess and apply ML techniques to bioprocess datasets (Dhar and Shamir 2021; Takei and Ishida 2022). The utilization of ML techniques in bioprocess engineering holds immense promise for optimizing processes, enhancing efficiency, and driving innovation.

In Table 2, we outline the challenges faced in integrating ML into bioprocess engineering and propose practical solutions to address them. By addressing issues related to reproducibility, data quality, interpretability, and model robustness, the objective is to facilitate the seamless integration of ML into bioprocess engineering workflows. This approach aims to foster advancements in this interdisciplinary field.

Conclusion

In the domain of bioprocess engineering, the utilization of ML techniques is driven by three primary objectives: facilitating information retrieval, predicting dynamic responses, and reducing overall effort. It is imperative to emphasize that, in the context of biochemical engineering studies, the knowledge underpinning the information gleaned from data-driven ML methods holds more significance than the data itself. The effectiveness of an ML model ultimately hinges on the tangible impacts of its predictions when applied to bioprocess data. Our exploration into previously undiscovered molecular pathways has revealed that ML models, in isolation, may not always suffice. The central aim is to provide reliable models for the biochemical engineering community, making comprehensive documentation a critical requirement.

While numerous data-driven modelling methods are employed for bioprocess control, optimization, and monitoring, caution must be exercised in the wholesale adoption of deep learning methodologies without adequate explanation (Fisher et al. 2020;

Table 1 Recent advancements of ML in the field of bioprocess engineering

S. No	Sub-field of the ML-based study	Outcome of the study	References
1	Design of metabolic pathways, accelerating the development of microbial cell factories	• The study aims at evaluating the use of digital strategies, including computer-supported tools and deep learning techniques for pathway prediction and enzyme discovery, which streamline the design process of microbial cell factories, and bolsters the prospects of a bio-based circular economy	Ryu et al. (2023)
2	Optimization of gasification for efficient hydrogen production	• The study fosters green economy and circular energy practices, outlining a path towards a sustainable, pollution-free future	Bin Abu Sofian et al. (2024)
3	Optimization of anaerobic co-digestion (AcoD)	• The study provides a comprehensive understanding of operational parameters • Understanding the challenges of manual monitoring and introduction of AI as an innovative solution for AcoD process optimization, control, prediction, and real-time monitoring	Khan et al. (2023)
4	Natural language processing to review the literature on AI in bioprocessing	• By analysing papers from 2013 to 2022, focusing on keywords related to bioprocessing and AI, the study identifies a significant concentration (50%) on hybrid models, ANN, biopharmaceutical manufacturing, and biorefinery in the last 5 years • The findings highlight the potential of AI, particularly in enhancing design and process engineering strategies within the bioprocessing domain	Yang et al. (2023)
5	Application of generative models in protein design, emphasizing their potential for creating tailored sequences for bioenergy applications and the importance of quality datasets	• The review highlights generative ML models' effectiveness in rapid protein sequence generation for bioenergy, addressing energy production hurdles • Moreover, the study elucidates how these ML-based techniques aid in optimizing strains to maximize bioenergy yields, thus contributing significantly to sustainable energy solutions	Barghout et al. (2023)
6	Proposes integration of a chatbot into domain of bioprocess engineering	• This study proposes a chatbot, designed as a "friend" or colleague, which enhances collaborative learning on digital platforms • The chatbot is embedded in an open-source Educational Virtual Bioprocess Plant, FermProc, providing a supportive and interactive learning environment for researchers in bioprocess technology	Heras et al. (2020)
7	Integration of AI based tools within pharmaceutical R&D	• This study aims at introducing a comprehensive platform for analyzing histopathology data in the context of pharmaceutical R&D • It utilizes cutting-edge AI technology integrated into an open-source image viewing platform, enabling clinicians, to effortlessly utilize pre-trained algorithms	Lutnick et al. (2023)

Table 1 (continued)

S. No	Sub-field of the ML-based study	Outcome of the study	References
		• The system facilitates collaboration across disciplines and supports a range of preclinical research tasks, including tissue segmentation and patient-level prediction • Furthermore, it provides flexibility for deploying and evaluating new models, thus enhancing its applicability within pharmaceutical workflows	
8	Development of an advanced combinatorial ANN design-of-experiment (ANN-DoE) model tailored for optimizing parameters of mRNA-LNP (lipid nanoparticles) vaccines	• This study utilized a definitive screening design and ML algorithms to systematically evaluate key factors like ionizable lipid, N/P ratio, and flow rate ratios • Notably, the ANN-DoE model exhibits superior predictive accuracy compared to independent ML models, showcasing its effectiveness in refining critical vaccine parameters • This comprehensive approach implies a significant stride in mRNA-LNP vaccine development, holding promise for enhanced vaccine efficacy and accelerated optimization processes	Maharjan et al. (2023)

Emmert-Streib et al. 2020). Although ML and deep learning models have demonstrated superior accuracy and performance compared to physical models, these metrics should not be the sole criteria for evaluating their effectiveness, creativity, and relevance in the context of bioprocess engineering (Gupta et al. 2021).

It is crucial to remember two fundamental principles when delving into the regulation and optimization of bioprocesses using ML models. First, it is essential to acknowledge that "all models are flawed, but some are valuable." Second, simplicity often suffices when constructing models, as complexity or scale does not inherently imply strength or value. While these methods can prove highly effective when appropriately applied, we must recognize that they are not infallible solutions. Attempts to enhance the fit of a complex ML model by adjusting or increasing the number of parameters may seem appealing, but they can jeopardize the quality of research and diminish its potential impact. Contrary to the notion of a single optimal approach to ML, it is crucial to recognize that each approach has its own merits and limitations. Therefore, when implementing ML methodologies, a deep understanding of the underlying biochemical processes must be maintained throughout the study.

ML techniques have the potential to address the challenges encountered in mechanistic modelling. The data-driven nature of ML, coupled with robust performance metrics, allows for the extraction of highly accurate results, particularly in the realm of biochemical process engineering. This may manifest as the optimization of pathway designs, the enhancement of scale-up processes, or the improvement of bioreactor control. However, it is imperative to acknowledge the limitations of ML, including the demand for substantial amounts of data and challenges related to the interpretation of complex neural networks like DNNs.

Moreover, ML also finds application in the field of metabolic engineering, although it has received relatively less attention compared to the optimization of bioengineering processes. A few papers have delved into this area, with some studies breaking down the application of ML in metabolic engineering into stages such as "gene annotation and pathway design, pathway optimization, pathway construction, performance testing, and production scale-up." Furthermore, new ML techniques, like transfer learning, are continually emerging, but their specific applications within this field remain relatively unexplored.

Table 2 Major challenges for the applications of ML in various fields of biochemical engineering and their potential solutions

Challenges	Problems	Potential solutions
Reproducibility in ML	• Lack of comprehensive documentation, including code, data, and parameter settings, hampers reproducibility • Difficulty in replicating experiments due to variations in implementation and settings	• Encourage authors to provide detailed documentation, including code, datasets, and parameter settings • Establish repositories for open-access code and data to facilitate reproducibility
Complexity in Biological Systems	• Challenges in reproducing experiments due to variability in living organisms, chemicals, and experimental conditions • Lack of "FAIR (Findable, Accessible, Interoperable, Reusable)" data and difficulties in replicating model fitting strategies	• Develop and utilize robust statistical methods capable of handling variability and uncertainty inherent in biological systems • Techniques such as Bayesian inference and hierarchical modeling can account for data heterogeneity and provide more reliable estimates
Limitations of ML Platforms	• Inability of ML platforms to ensure computational reproducibility • Test results generated from these platforms may not always be trustworthy	• Foster open-source collaboration and peer review within the ML community to address platform limitations and improve computational reproducibility • Shared code repositories, community forums, and collaborative projects can facilitate knowledge sharing and continuous improvement of ML platforms
Data Quality and Quantity	• Bioprocess engineering often deals with heterogeneous, noisy, and sparse data, which can affect the performance of ML models • Insufficient data quantity or poor data quality may lead to biased or unreliable predictions	• Employ data augmentation techniques such as varying fermentation conditions, altering nutrient composition, adjusting pH levels, and changing agitation rates to increase the quantity and diversity of training data for bioprocess models, enhancing their robustness and predictive capabilities • Additionally, invest in robust data preprocessing pipelines to handle noise, missing values, and outliers, ensuring high-quality input data for ML models
Interpretability and Explainability	• The interpretability of ML models, particularly complex ones like deep learning, remains a challenge • Understanding the reasoning behind model predictions is crucial for trust and adoption, especially in critical applications	• Tree-based ML algorithms, such as random forest and gradient boosting, offer better interpretability compared to deep learning models • Emphasizing the use of interpretable algorithms, such as decision trees, logistic regression, and linear regression, can enhance the trustworthiness of ML-based predictions by providing clear insights into how inputs are being transformed into outputs
Incorporating Biological Data	• Conventional models often overlook the rich biological data regarding microbial communities, leading to incomplete representations of bioprocesses • Integrating biological information into ML models poses a challenge due to the complexity and high dimensionality of biological data	• Develop methodologies to incorporate microbial community data into ML models to provide a more comprehensive understanding of bioprocesses • Techniques like feature engineering and transfer learning can help extract meaningful patterns from complex biological data

Table 2 (continued)

Challenges	Problems	Potential solutions
Model Robustness and Generalization	• Ensuring the robustness and generalization capability of ML models across different experimental setups, environmental conditions, and datasets is challenging • Models trained on specific datasets may struggle to perform well on unseen data or under varying conditions	• Implement regularization techniques such as dropout and L1/L2 regularization to prevent overfitting and improve model generalization • Ensemble learning methods, such as bagging and boosting, can also enhance model robustness by combining multiple models' predictions

By understanding the advantages and limitations of each approach, bioprocess engineers can make informed decisions, harnessing the power of ML to drive innovation and excellence in bioprocess engineering. The future holds exciting possibilities for the synergy of ML and bioprocess engineering, promising greater sustainability, productivity, and reliability in the bioprocessing industry.

Acknowledgements The authors are grateful to the Delhi Technological University, New Delhi, India, for providing an opportunity to conduct this study.

Author contributions All authors contributed to the study conception and design. The first draft of the manuscript was written by Ritika Saha and Ashutosh Chauhan and all authors commented on previous versions of the manuscript. The manuscript was critically reviewed by Smita Rastogi Verma. All authors read and approved the final manuscript.

Funding The authors declare that no funds, grants, or other support were received during the preparation of this manuscript.

Data availability No additional data available.

Consent to publish No human or animal subjects were involved.

Declarations

Conflict of interest There is no conflict of interest. The authors have no relevant financial or non-financial interests to disclose.

Ethical approval No human or animal subjects were involved.

Informed consent No human or animal subjects were involved.

ABSTRACT

Nanoparticle production is nanotechnology's most important feature. In recent years, physical and chemical techniques to nanoparticle synthesis have shown severe flaws, necessitating the creation of an environmentally benign nanoparticle synthesis methodology. As a result, in this paper, we will detail how to synthesise magnesium oxide nanoparticles (MgONPs) from *Rhizophora lamarckii* and secondary chemicals found in the plant's leaf broth. *Rhizophora lamarckii* is being used to produce MgO nanoparticles by varying parameters such as temperature and pH. A UV-Visible spectrophotometer is used to analyse the absorbance spectra of MgONPs throughout the final synthesis process. SEM, and FTIR and XRD were employed to evaluate the biosynthesized nanoparticles. The current study, which employs a plant to produce MgONPs, is an efficient, environmentally friendly, and straightforward method that could have a significant impact on future industrial and commercial metallic nanoparticle production.

Keywords: Nanoparticles, *Rhizophora lamarckii*, UV-Visible spectrophotometer, Biosynthesized

1. INTRODUCTION

Nanotechnology is playing an increasingly important role in biology, medicine, physics, chemistry, and electronics (1). Agriculture, medicine, waste management, catalysis, pollution control, and therapeutic sectors such as antibacterial and anticancer medicines are all potential applications for nanotechnology. Nanoparticles can have many shapes, sizes,

morphologies, and geometries (2). Physical and chemical approaches to nanoparticle production are damaging to both the environment and humans. The chemical synthesis of nanoparticles has a negative influence on the environment and humans since it emits poisonous hazardous compounds such as sodium borohydride and hydrazine (3). Hydrazine produces irritation in the eyes, throat, and nose. In severe situations, it can cause seizures, coma, and damage to the liver and kidneys (4). Chemical techniques such as microemulsion and evaporation/condensation are equally expensive. Physical methods, such pulse laser ablation, microwave-assisted, and pulsed/explosion wire discharge, need more energy, time, and money (5). As a result, synthesising nanoparticles using green technology appears more practical, non-toxic, cost-effective, and environmentally beneficial (6). It is a bottom-up technique in which plant extract, bacteria, or fungi are employed as raw material and redox reactions occur (7).

Medicinal plants are often used as reducing agents in green nanoparticle synthesis, and they create a wide spectrum of nanoparticles such as copper, silver, gold, zinc, and iron (8). Biologically generated metal nanoparticles have enormous possibilities as cytotoxic agents against cancer cells, antioxidant powder, antibacterial and anticoagulant agents (9). NPs, which are made from a rich pool of secondary metabolites, contain alkaloids and flavonoids. Magnesium nanoparticles offer a wide range of essential uses, particularly in the biological domain, among other metal nanoparticles (10). Magnesium oxide nanoparticles are employed in a variety of applications, including large magnetic resistant materials, sensors, catalysts, optical, electrical, gas sensors, superconductors, solar energy conversion, and the production of organic-inorganic nanostructure composites (11) (12).

The notion of synthesising MgONPs from mangrove plants originated in this setting. Mangrove plants have been used in traditional medicine to cure many ailments. This study suggests a straightforward and efficient methodology for producing MgONPs. Its leaves are useful for treating eye issues and headaches. There is insufficient qualitative and quantitative data to establish the quality and purity of leaves. In this study, magnesium oxide nanoparticles are synthesised using a leaf extract of *Rhizophora lamarckii*. UV-Vis, FTIR, SEM, and XRD techniques are used to characterise the MgONPs that have been synthesised. The plant-mediated synthesis of MgONPs, as mediated by various characterisation approaches, provides substantial insights into the many characteristics that exist today.

MATERIALS AND METHODS

Collection of plant sample

Rhizophora lamarckii leaves were obtained from a forest reserve near Hauz Khas, Delhi. The leaves were thoroughly cleaned with distilled water before being dried on blotting paper. Then, they were sun dried for one day to remove moisture before being pounded into fine powder with a mortar and pestle. This powder was simmered in MilliQ water for 5-10 minutes. Extract obtained after dissolution was used to synthesise MgO nanoparticles.

Preparation of leaf extract

Leaf extract was prepared by weighing 4g of leaf powder and adding it to a reaction beaker containing 100ml MilliQ. The solution was boiled on the heating mantle at 80 degrees for around 10 minutes. After the solution cooled to room temperature, filtration was carried out through Whatman filter paper to produce filtrate. The residue was discarded, and the finished extract was kept at 4°C.

Synthesizing CuO Nanoparticles

All of the chemicals were AR Grade and obtained from reliable providers. MgO nanoparticles were produced using a green technique. Filtered leaf broth was added drop by drop to a 90ml stirring solution containing 10mM magnesium nitrate until the colour changed from yellow to yellowish brown. The liquid was centrifuged at 6000 rpm for 15 minutes. Resulting mixture was left to stir for an hour. It was kept at room temperature overnight and wrapped in aluminium foil before being tested with a range of spectrophotometer techniques.

Characterization

All reagents were acquired from Fisher Scientific Chemicals. The unique properties of nanoparticles were investigated by recording their absorption spectra with an Eppendorf spectrometer. The FTIR spectrum was obtained using a Perkin Elmer instrument and FTIR accessories from PCI analytics, with the synthesised NPs recorded as KBr pellets in the 4000-400 cm^{-1} range (13). The morphological characteristics of the resulting nanoparticles were measured with the SEM ZEISS Instrument EVO 18 Special Edition. SEM images of the synthesised nanoparticles may provide proof of newly generated MgONPs. To assess the stability of synthesised NPs, their size was measured using a Zetasizer and pH was assessed using a HACH device (14). XPERT-PRO X-Ray Diffractometer was used to analyse the results of XRD.

2. RESULTS AND DISCUSSION

Nanoparticles can be created utilising biological agents such as plant extracts, which offers substantial advantages over conventional approaches. It also eliminates the need to monitor cell cultures during large-scale manufacturing. (15). An aqueous leaf extract of *Rhizophora lamarckii* is the most cost-effective method for nucleating nanoparticles. In the current study, MgO NPs were combined with an extricated arrangement of *Rhizophora lamarckii* leaf extract to serve as a dissolvable rather than natural solvent. MgONPs creation can be confirmed using a variety of analytical techniques that provide precise information about nanoparticle synthesis.

UV–Visible Analysis

The nanoparticles were characterised using UV-Vis absorption spectroscopy on an Eppendorf Biospectrometer. Figure 1 depicts the UV-visible spectrum of MgO NPs generated by *Rhizophora lamarckii*. A significant absorption band was detected in the 290-300 nm range, indicating the existence of MgONPs. The absorption spectra alter as the extract composition increases, resulting in production of MgO nanoparticles. As a result, as the content of plant

extract grows, so does the absorption spectrum, with maximum absorption occurring at approximately 300 nm. The observed spectra result from the production of MgO NPs. Even after extended storage, the absorption spectra remained consistent. The collected spectra revealed that the synthesised nanoparticles were symmetrical and spherical in shape.

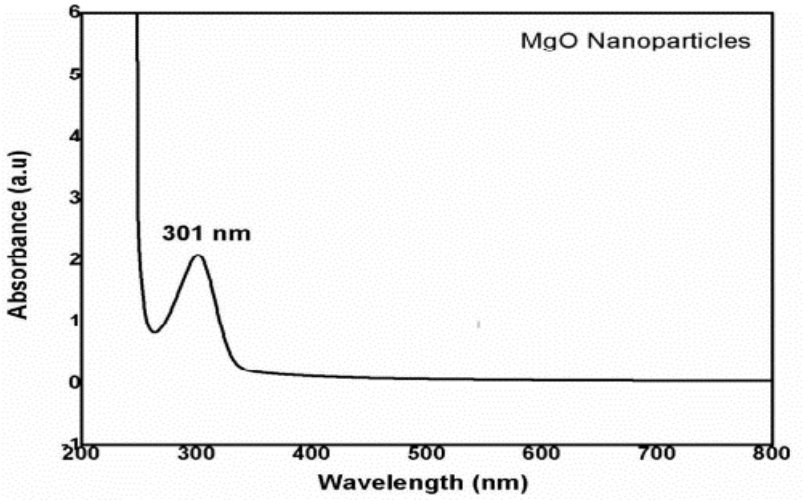

Figure 1: UV-Vis Spectra

Photocatalytic activity

The photocatalytic activity of synthesised MgO nanoparticles was assessed in sunlight using methylene blue dye degradation. Figure 2 displays absorption spectra at different time intervals of irradiation after MgONPs were exposed to sunlight with dye solution and monitored using UV spectra. The greatest absorption spectra in the UV-visible spectrum occur at 660nm. As depicted in the illustration, absorption spectra gradually diminish after irradiation, and the dye disappears within 240 minutes. MgO nanoparticles react with dye to produce electrons and holes, resulting in super oxide radicals. When these hydroxyl radicals reacted with electrons, they destroyed the colour molecules.

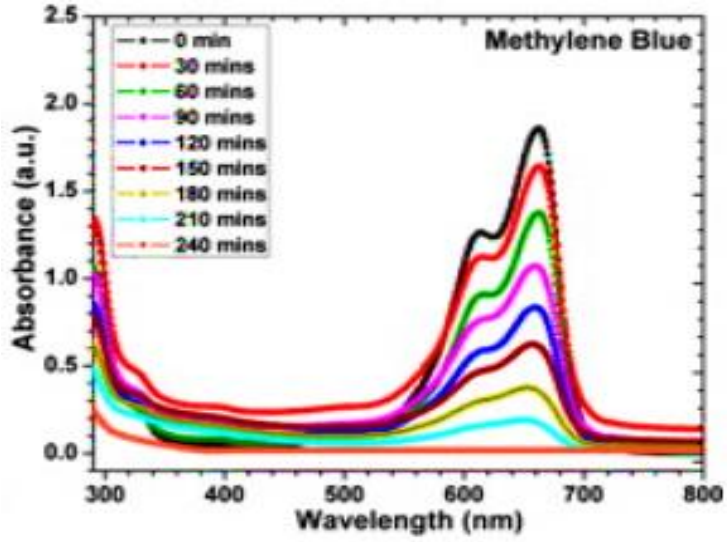

Figure 2: Photocatalytic activity of MgO NPs

XRD Analysis

The resultant nanoparticles were examined with an X-ray diffraction analyzer (Bruker D8, MA, USA). Prior to the XRD investigation, the materials were lyophilized by freezing them in a vial of liquid nitrogen and then subjected to a lyophilizer for 24 hours (FreeZone Freeze dryers, MO, USA) (16). X-ray diffraction could be used to study crystal structure of lyophilized molecules. Figure 3 shows the XRD patterns produced by MgONPs. The XRD analysis may reveal varied diffraction peaks at different intensities for MgO, with the highest at 200. The weak diffraction peaks appeared initially, followed by the greatest peak intensity. The results confirmed previously observed diffraction peaks for MgONPs.

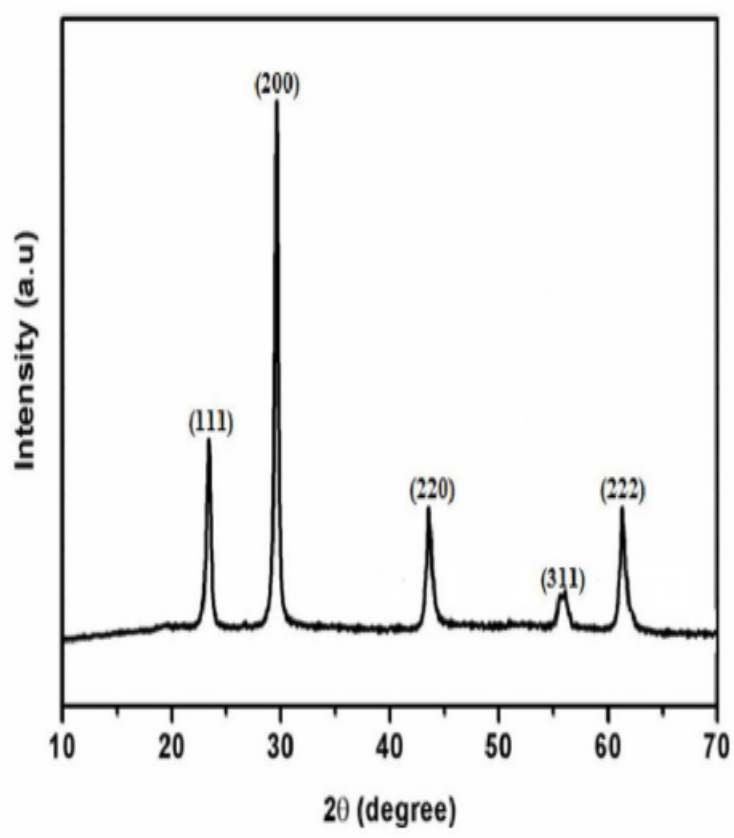

Figure 3: XRD Analysis of MgONPs

FTIR Analysis

FTIR was used to identify biomolecules that decrease and encapsulate MgONPs. Figure 5 shows the FTIR spectra of MgONPs isolated from *R. lamarckii* leaf extract. The spectra have bands at 3405, 2925, 1626, 1402, 1260, and 1035 cm^{-1}, with misplaced peaks at 3395, 2921, 1644, 1450, 1232, and 1077 cm^{-1}. Peaks at 3405 cm^{-1} (shifted to 3395 cm^{-1}) and 1626 cm^{-1} (shifted to 1644 cm^{-1}) show stretching of the N-H amine group. Stretching of the C-H alkane group is shown by absorption maxima shifting from 2925 cm^{-1} to 2921 cm^{-1} and 1402 cm^{-1} to 1450 cm^{-1}. The amine and alkane functional groups of *R. lamarkii* are most likely involved in reducing and capping newly synthesised MgONPs.

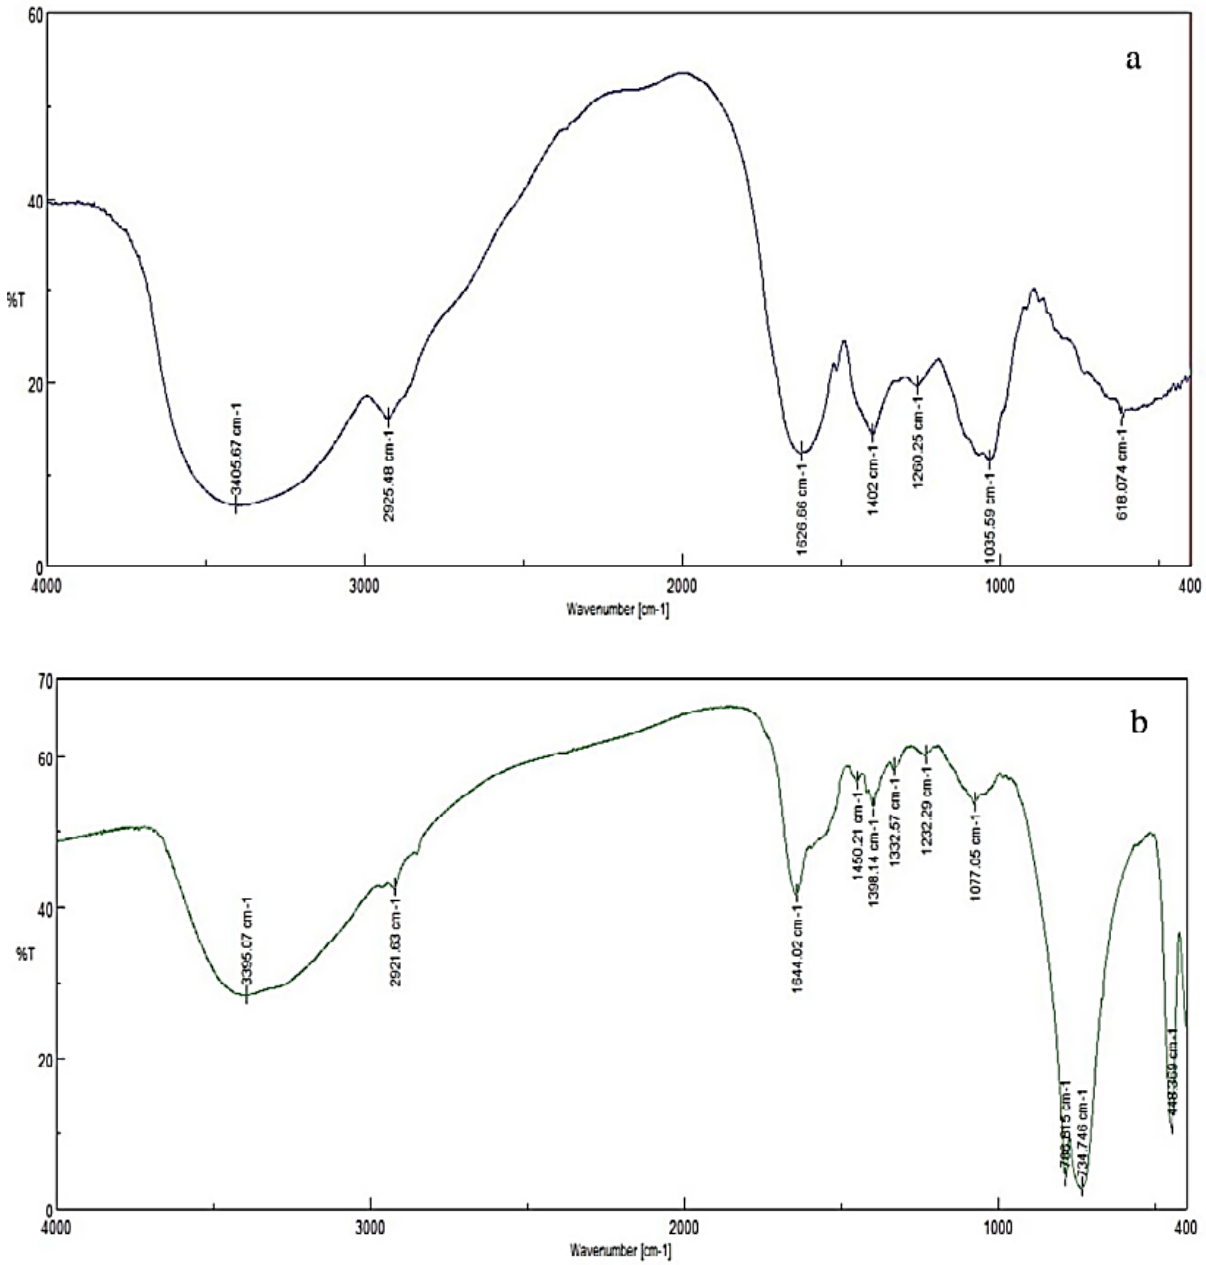

Figure 4: FTIR Analysis of MgONPs: (a) extract of *R. lamarckii* and (b) MgONPs synthesized with *R. lamarckii*

SEM analysis

It is critical to understand the morphological features of the formed nanoparticles by analysing size and shape of the created copper nanoparticles. Scanning electron microscopy was used to analyse the morphological shape and structure of the MgONPs that were created (17). Figure 5 depicts the image produced for SEM investigation of MgONPs. The resultant nanoparticles are generally rod and sphere shaped.

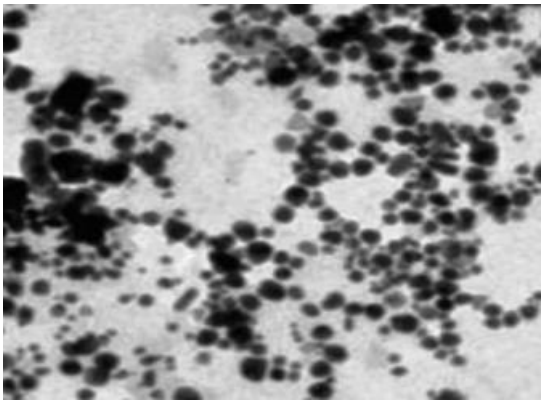

Figure 5: SEM analysis of MgONPs

3. CONCLUSION

Nanoparticle agglomeration can be achieved with a variety of regularly used synthetic substances and techniques. In this study, the amalgamation of copper oxide nanoparticles was explored utilising an environmentally friendly process involving *Rhizophora lamarckii* leaf extracts. Finally, we created a skilled, simple, and successful approach for green amalgamation of MgONPs that employs *Rhizophora lamarckii* leaf extract as a reducing and balancing agent. In compared to the intended MgO NPs, the plant-based MgO nanoparticles were found to be more stable and ejected less particles. Furthermore, whereas hydrodynamic size and accumulation grew over time, plant-blended MgO NPs were smaller and had a lower overall expansion than designed NPs. The proposed MgO NPs were more soluble than plant-interacted MgO NPs, and their particle discharge rate outperformed plant nanoparticles. Plant-incorporated CuO nanoparticles have been demonstrated to be more stable than manufactured nanoparticles. Plant-incorporated MgO NPs were found to be less hazardous than manufactured MgO NPs, making it a better way for releasing more nanoparticles into the environment for a variety of purposes. However, it is uncertain whether the detrimental effects of plant and produced magnesium oxide are caused by particle disintegration or by MgONPs and their interactions with the environment. SEM, XRD, and UV-visible examinations reveal that the MgONPs produced have potential environmental benefits.

Meta-Learning-Based Physics-Informed Neural Network: Numerical Simulations of Initial Value Problems of Nonlinear Dynamical Systems Without Labeled Data and Correlation Analyses

Worrawat Duanyai[1], Weon Keun Song[2,†], Thanadol Chitthamlerd[3] and Girish Kumar[4]

Abstract There are several main challenges in solving nonlinear differential equations with artificial neural networks (ANNs), such as a nonlinear system's sensitivity to its initial values, discretization, and strategies for incorporating physics-based information into ANNs. As for the first issue, this paper addresses the initial value problems of nonlinear dynamical systems (a Duffing oscillator and a Burger's equation), which cause large global truncation errors in sub-domains with a significant reduction in the influence of initial constraints, using meta-learning-based physics-informed neural networks (MPINNs). The MPINNs with dual learners outperform physics-informed neural networks with a single learner (no fine reinitialization capability). As a result, the former approach improves solution convergence by 98.83% in the sub-time domain (III) of a Duffing oscillator, and by 85.89% at $t = 45$ in a Burger's equation problem, compared to the latter one. Model accuracy is highly dependent on the adaptability of the initial parameters in the first hidden layers of the meta-models. From correlation analyses, it is obvious that the parameters become less (the Duffing oscillator) or more (the Burger's equation) correlated during fine reinitialization, as the update manner differs or is similar to the one used in pre-initialization. In the first example, the MPINN achieves both the mitigation of model sensitivity to its output and the improvement of model accuracy. Conversely, the second example shows that the proposed approach is not enough to solve both issues simultaneously, as increased model sensitivity to its output leads to higher model accuracy. The application of transfer learning reduces the number of iterative pre-meta-trainings.

Nomenclature

Symbol	Definition
$\boldsymbol{a}^{[l]}$, $a_n^{[l]}$	Output vector of the l-th hidden layer and the n-th component of $\boldsymbol{a}^{[l]}$
$\boldsymbol{b}^{[l]}$	Bias vector of the l-th hidden layer
c	Constant parameter
cn, dn, sn	Jacobi elliptic functions
d	Constant parameter
$\boldsymbol{d}_k$	Search direction vector at the k-th iteration
$\boldsymbol{D}_{qu}^{(i)}$, $\boldsymbol{D}_{su}^{(i)}$	Query and support datasets, respectively, for the i-th query task and the i-th support one.
$\boldsymbol{D}_{te}, \boldsymbol{D}_{tr}$	Test and training datasets, respectively
f	Constant parameter
$f(\boldsymbol{u})$	Function value at $\boldsymbol{u}$
$f_{\boldsymbol{\theta}}(\boldsymbol{x})$	PINN
$f_{\boldsymbol{\theta}}^m(\boldsymbol{x})$	MPINN
$f_{\boldsymbol{\theta}^{(i)}}^m(\boldsymbol{x}_{su}^{(i)})$	A model for the i-th support task (it is regarded as the i-th support task)
$f_{\boldsymbol{\theta}^{(i)},'}^m(\boldsymbol{x}_{qu}^{(i)})$	A model for the i-th query task (it is regarded as the i-th query task)
$f_{\boldsymbol{\theta}^*}^m(\boldsymbol{x}_{te})$	MPINN evaluated on $\boldsymbol{D}_{te}$
$\boldsymbol{g}_k$	Gradient difference vector at the k-th iteration
$\boldsymbol{H}^{(I)}$, $\boldsymbol{H}_k$	Initial Hessian matrix and Hessian matrix at the k-th iteration
$iter$, $iter^m$	Iterative numbers, respectively, for the PINN (or each inner learner of the MPINN) and the outer learner of the MPINN
$iter^{MAX}$, $iter^{mMAX}$	Maximum iterative numbers, respectively, for the PINN (or each inner learner of the MPINN) and the outer learner of the MPINN.
k	Constant parameter
$L(\boldsymbol{\theta},\ \boldsymbol{D}_{tr})$	Total PINN loss
$L^{(i)}(\boldsymbol{\theta}^{(i)}, \boldsymbol{D}_{su}^{(i)})$, $L^{(i)}(\boldsymbol{\theta}^{(i),'}, \boldsymbol{D}_{qu}^{(i)})$	Support and query losses, respectively, for the i-th task
$\|\|\nabla L(\boldsymbol{\theta}, \boldsymbol{D}_{tr})\|\|$	Norm of the projected gradient of $L(\boldsymbol{\theta}, \boldsymbol{D}_{tr})$
m	Constant parameter
MSE_f, MSE_I, MSE_B, MSE_d	Losses, respectively, of residual, initial constraint, boundary constraint, and labeled data
N_d, N_B, N_f, N_I	Number of labeled data for MSE_d and number of training samples, respectively, for MSE_B, MSE_f and MSE_I
NT	Number of test samples
NQ, NS	Numbers, respectively, of query and support tasks
t, $\triangle t$	Time coordinate and time increment
u, u_n	A single output of $f_{\boldsymbol{\theta}}(\boldsymbol{x})$ and a discrete solution of u at the n-th sampling point
$\boldsymbol{u}$	Output vector of $f_{\boldsymbol{\theta}}(\boldsymbol{x})$
$\bar{u}$, $\bar{u}_n$	Analytical (exact) solution and a discrete solution of $\bar{u}$ at the n-th sampling point
$\boldsymbol{u}_{su}^{(i)}$, $\boldsymbol{u}_{qu}^{(i),'}$, $\boldsymbol{u}_{te}$	Output vectors, respectively, evaluated by $f_{\boldsymbol{\theta}^{(i)}}^m(\boldsymbol{x}_{su}^{(i)})$, $f_{\boldsymbol{\theta}^{(i)},'}^m(\boldsymbol{x}_{qu}^{(i)})$, and $f_{\boldsymbol{\theta}^*}^m(\boldsymbol{x}_{te})$
$\bar{\boldsymbol{u}}_{su}^{(i)}$, $\bar{\boldsymbol{u}}_{qu}^{(i)}$, $\bar{\boldsymbol{u}}_{te}$	Actual output vectors, respectively, for $\boldsymbol{D}_{su}^{(i)}$, $\boldsymbol{D}_{qu}^{(i)}$, and $\boldsymbol{D}_{te}$ ($\bar{\boldsymbol{u}}_{su}^{(i)}$ and $\bar{\boldsymbol{u}}_{qu}^{(i)}$ require no labeled data)
D_{te}^n, ∂_x^n, ∂_t^n	n-th order differential operators
x	Space coordinate
$\boldsymbol{x}$	Input vector

Nomenclature

Symbol	Definition
$\boldsymbol{x}_{su}^{(i)}$, $\boldsymbol{x}_{qu}^{(i)}$, $\boldsymbol{x}_{te}$	Input vectors, respectively, for $\boldsymbol{D}_{su}^{(i)}$, $\boldsymbol{D}_{qu}^{(i)}$, and $\boldsymbol{D}_{te}$
$\boldsymbol{z}^{[l]}$, $z_n^{[l]}$	Output vector of the l-th hidden layer before taking an activation and the n-th component of $\boldsymbol{z}^{[l]}$.
α	Scalar
α_k	Iterative step size
β	Learnable parameter for swish
ε, ε^m, ε^H	Convergence tolerances, respectively, for the PINN (or each inner learner of the MPINN), the outer learner of the MPINN, and loss reduction tolerance
$\boldsymbol{\theta}$	Parameter matrix of the PINN and MPINN
$\boldsymbol{\theta}_k$, $\boldsymbol{\theta}_{mk}^{(i),\prime}$	Parameter matrices updated, respectively, at the k-th iteration by the PINN (or each inner learner of the MPINN) and at the mk-th meta-iteration by the outer learner of the MPINN
$\boldsymbol{\theta}^{(I)}$	Initial parameter matrix
$\boldsymbol{\theta}^{(i)}$	Parameter matrix trained on $\boldsymbol{D}_{su}^{(i)}$
$\boldsymbol{\theta}^{(i),\prime}$	Parameter matrix trained on $\boldsymbol{D}_{qu}^{(i)}$
$\boldsymbol{\theta}^{[l-1]}$	Parameter matrix that maps from $\boldsymbol{a}^{[l-1]}$ to $\boldsymbol{z}^{[l]}$
$\theta_{j,i}^{[l-1]}$	Parameter that controls a function mapping from $a_i^{[l-1]}$ to $z_j^{[l]}$
$\boldsymbol{\theta}^*$	Optimal parameter matrix achieved by the meta-training for a meta-test phase
λ_f, λ_I, λ_B, λ_d	Parameters, respectively, for MSE_f, MSE_I, MSE_B, and MSE_d
ω	Constant parameter
μ	Constant parameter
$\boldsymbol{\sigma}^{[l]}$	Activation of the l-th hidden layer

1. Introduction

Physical phenomena of dynamical systems are modeled by governing differential equations, and the analysis of their solutions provides insight into them. That is why it is critical to find precise solutions in science and engineering. Due to the absence of analytical solutions in many practical cases, numerical approaches such as finite difference, finite volume, and finite element methods have dominated over the last seven decades. Nonetheless, classical solvers have disadvantages that require a lot of computational efforts, especially for multi-scale or multi-physics-based nonlinear systems. Researchers continue to face challenges in numerical solver design with the balance between accuracy and robustness. Recently, various artificial neural network (ANN)-based solvers among many alternatives have gained large attention because of the prospect of replacing classical solvers. The advantages of ANNs for solving governing differential equations are as follows: (i) powerful modeling for interdisciplinary problems; (ii) simple modeling for strong nonlinear relationships; (iii) efficient forward evaluation of a trained model for real-time applications; (iv) automatic gradient-based optimization due to analytically differentiable modeling; (v) meshless modeling for discretization. ANNs have been applied to solve dynamical systems governed by not only ordinary differential equations (ODEs) [1–5] but partial differential equations (PDEs) [2, 6–19]. Consistent challenges [20–22] were reported for performance improvement during 1990 – 2000, but there was no significant progress. Raissi et al. [7] proposed a new conceptual neural network known as a physics-informed neural network (PINN) in 2019. They developed a physics-informed fully connected neural network (PIFCNN) with high

model accuracy, where a PDE residual loss was incorporated into data-driven functional representation as one of constraint conditions, in small data regimes. Their success in the research has led many researchers to explore PINNs. There are several types of neural networks in modeling PINNs, and these two are among them: a PIFCNN [2, 3, 5–11, 13, 15–17, 19, 23] and a physics-informed convolutional neural network (PICNN) [4, 8, 12, 14]. Several studies have revealed that PIFCNNs perform well with small data [4, 7, 11] or even in the absence of data [8, 9, 12]. A literature review by us supports the claim that PINNs have addressed various problems in engineering, science, and mathematics: structural dynamics [1], nonlinear dynamical systems in applied mathematics [2, 3, 6, 10, 12–14, 23], seismic response [4], quantum mechanics, reaction-diffusion, and propagation of water wave [7], flow [7–9, 11, 16], thermal-transfer related problems [15, 18], composite material [17]. Studies on differential equations have been mostly engaged in boundary value problems (BVPs) [2, 8, 13–15] and initial boundary value problems (IBVPs) [2, 3, 6, 7, 9–12, 16–19]. When selecting a research subject, the complexity of boundary conditions can motivate researchers to choose it as a highly challenging topic. However, in many cases, solution convergence with some degree of accuracy or even higher accuracy can be achieved by adding intricate boundary constraints without labeled data. While initial value problems (IVPs) [3, 5, 23] have received less attention despite their poor solution convergence in sub-domains with a sharp decline in the influence of initial constraints. To address this fundamental issue, several studies introduced noticeable but limited approaches. Meng et al. [3] proposed a parallel PINN to decompose a long-time domain into multiple independent sub-domains with shorter time interval. This strategy resulted in faster convergence and reasonable solution predictions. However, the optimal number of sub-domains to be applied, depending on the characteristics of dynamic systems, was not discussed. The study by Florio et al. [5] highlighted the combination of a shallow PINN and the theory of functional connections and an extreme learning process. They succeeded in solving the stiff systems of ODEs by the proposed approach without reducing the stiffness of the problems. Nonetheless, the use of labeled data was exposed as a crucial limitation because of expensive data generation. Robinson et al. [23] used the injection of partially known physical information at an intermediate layer in a PINN during training for solving benchmark problems in the literature including oscillations. Despite the focus, the relationship between the injection and the nature of models has remained inconclusive. This implies that discovering a universal method for diverse dynamical systems is a huge challenging task. This study represents the first application of both meta-learning and transfer learning, which involve the fine initialization of parameters, to PINNs for solving the IVPs of a nonlinear Duffing oscillator and a nonlinear Burger's equation without labeled data. A Duffing oscillator is a type of nonlinear second-order ODE that describes the behavior of a damped-driven harmonic oscillator. It is a type of dynamical system that exhibits complex behavior, including chaos, resonance, and bifurcations due to its nonlinear nature. Applications include electronic circuits, mechanical systems, and biological systems, while Burgers' equation is a fundamental nonlinear PDE that governs fluid flow. It is used in various areas of fluid dynamics, including the study of turbulence, shock waves, and nonlinear wave propagation. Additionally, it has applications in other fields, such as traffic flow modeling and nonlinear acoustics. In a broad sense, meta-learning may be extended to include the selection of a suitable algorithm by taking into consideration the features of

input datasets, exploring the topology of neural network architectures, and tuning a set of hyperparameters. In a narrow sense, it is the algorithm to fine-tune a set of model parameters. Our current study is limited to the latter, but we will extend it to the former. A meta-learning strategy for a new task was proposed by Peng et al. [24] who were one of the pioneers to discover a suitable learning algorithm. A typical strategy involves training existing models on a new target dataset and then selecting the model that performs best on it. Such a strategy needs big datasets to achieve adequate model accuracy. However, in many real circumstances, a lack of data would limit the ineffective traditional method to laboratory experiments. A new requirement in machine learning is to discover new algorithms to imitate how humans learn new tasks based on their prior knowledge. As humans learn new similar tasks based on it, a set of fine meta-tuned initial parameters is similar in function to it. This means that meta-learning-based algorithms can learn new analogous features rapidly and precisely with fewer data. Therefore, meta-learning is one of the strategies for how an ANN acquires useful prior knowledge by adjusting initial parameters. Learning rules of meta-learning were proposed by a series of studies in 1991 [25] and 1997 [26]. Hochreiter et al. [27] and Younger et al. [28] marked a turning point in gradient descent-based deep meta-learning that belongs to one of the three categories: metric-based, model-based, and optimization (gradient)-based techniques. Many trials by the third method update a meta-model using a bi-level optimization process with multi-inner learners for tuning support models and a single outer learner for meta-learning. Model-agnostic meta-learning (MAML), proposed by Finn et al. [29], showed the feasibility of an application of the dual learners to few-shot problems for classification, regression, and reinforcement learning using gradient-based backpropagation. Their application was successful in adapting a meta-model to new tasks. Several ideas [30–33] on meta-learning have been proposed to improve the training efficiency of PINNs. This paper discusses the model accuracy of classical PINNs and meta-learning-based PINNs (MPINNs) for the IVPs of both examples. Non-uniform random sampling (NURS) is applied to both in training. Evaluations on the convergence of the solutions to the problems are made across entire domains. Experimental data show that the MPINNs outperform the PINNs in tracking their solutions in all domains as well as in the sub-time domain (III) of the Duffing oscillator and at $t = 45$ in the Burger's equation problem. The meta-learning with the dual learners makes a large contribution to improving the solution convergence of the MPINNs, as it mostly updates the initial values of the first hidden layers of the meta-models. Correlation analyses assist us in gaining a deeper comprehension of how the initial parameters become adaptable to inputs and responsive to outputs throughout the meta-training, depending on the nature of the dynamical systems. The Duffing oscillator achieves both the mitigation of the MPINN's sensitivity to its output and the enhancement of the model accuracy, but regarding the Burger's equation, the proposed model is insufficient to address both issues simultaneously, as the model's sensitivity to its output increases during the meta-tuning. This means that it could be less robust. In the MPINN algorithm, the application of transfer learning to support tasks minimizes the number of iterative pre-meta-tunings.

2. Problem statement and examples

Using PINNs for solving IVPs may result in significant truncation errors due to their limited capacity to accurately adjust initial parameters. Figure 3 and 4 show two of the cases. This paper employs the MPINNs to tackle the issue at hand for two case studies regarding the nonlinear Duffing oscillator and the nonlinear Burger's equation. The IVPs and the BVPs (or the IBVPs) are both treated to examine the characteristics of the examples. When dealing with IVPs, the complexity of initial conditions can cause an initial constraint effect to persist throughout an entire domain. This can lead to insufficient global truncation error occurrence and poor observation of the reduction of the error. Additionally, as neural network modeling becomes more intricate, there can be more factors that influence model accuracy. To avoid these potential factors and any ambiguity in identifying the sources of errors, this study employs the simple examples and concentrates on the analysis of the impact of initial parameters on the solution accuracy of the MPINNs. In addition, it focuses on the correlation analysis between them before and after the fine reinitialization. For the IVPs, the initial condition of the Duffing oscillator is two-point, whereas in the Burger's equation case, it is one-dimensional. Duffing oscillators governed by a second-order nonlinear ODE can capture the relationship between the input and the output of nonlinear dynamical systems under various conditions such as steady-state, transient, and other dynamic scenarios. The behaviour of the exact solution to Eq.(2.1), including amplitude and phase, depends on the parameter value, $1/4$ of $cn(2t, 1/4)$. As it deviates from zero, the function deviates from a simple cosine wave, and the shape and characteristics of the periodic oscillation change accordingly. In other words, the modulus can range from 0 to 1, with values being close to 0 corresponding to simple cosine-like oscillations, and values being close to 1 corresponding to more complex and highly nonlinear oscillations. Figure 3 demonstrates the phenomena mentioned above well.

$$\begin{aligned} &m \cdot D_t^2 \bar{u} + c \cdot D_t \bar{u} + k \cdot \bar{u} + f \cdot \bar{u}^3 = d \cdot \cos(\omega t),\ \forall t \in [0, 9] \\ &\text{with } \bar{u}(0) = 1 \text{ and } D_t \bar{u}(0) = 0. \end{aligned} \tag{2.1}$$

A Burger's equation (see Eq.(2.2)) is a nonlinear PDE governing the behaviour of traffic, liquid, and gas flow as well as the flow of materials during material processing operations such as casting and forging. It has numerous applications in physics, engineering, and applied mathematics.

$$\begin{aligned} &\partial_t \bar{u} + \bar{u} \cdot \partial_x \bar{u} = \mu \cdot \partial_x^2 \bar{u},\ \forall (t, x) \in [0, 90] \times [-4, 4] \\ &\text{with } \bar{u}(0, x) = 2x, \end{aligned} \tag{2.2}$$

here, $m = 1$, $c = 0$, $k = f = 2$, $d = 0$, $\omega = 0$ and $\mu = 1$. Eq.(2.1) has the exact solution of $\bar{u}(t) = cn(2t, \frac{1}{4})$. The exact solution to Eq.(2.2) is $\bar{u}(t, x) = \frac{2x}{1+2t}$. For the BVP of the Duffing oscillator, the boundary conditions are enforced to Eq.(2.1) instead of the given initial conditions: $\bar{u}(0) = 1$ and $D_t \bar{u}(0) = 0$, and $\bar{u}(9) = cn(18, \frac{1}{4})$ and $D_t \bar{u}(9) = -2dn(18, \frac{1}{4})\ sn(18, \frac{1}{4})$. For the IBVP of the Burger's equation, the boundary condition of $\bar{u}(90, x) = \frac{2x}{181}$ is enforced additionally to Eq.(2.2).

3. PINN

This section introduces a model representation of a classical PINN (see Figure 1) and discusses the outputs from the IVPs and the BVP (or the IBVP) including the limitation in applying the PINN model to the IVPs.

3.1. PINN representation

A PINN is a form of multi-layer perceptron that is interpreted as a functional approximator. It can be defined by

$$\bar{\boldsymbol{u}} = f_\theta(\boldsymbol{x}) \tag{3.1}$$

for the Duffing oscillator,

$$\boldsymbol{x} = \{t\} \text{ and } \boldsymbol{u} = \{u\} \tag{3.2}$$

and in the case of the Burger's equation,

$$\boldsymbol{x} = \begin{Bmatrix} t \\ x \end{Bmatrix} \text{ and } \bar{\boldsymbol{u}} = \{u\}. \tag{3.3}$$

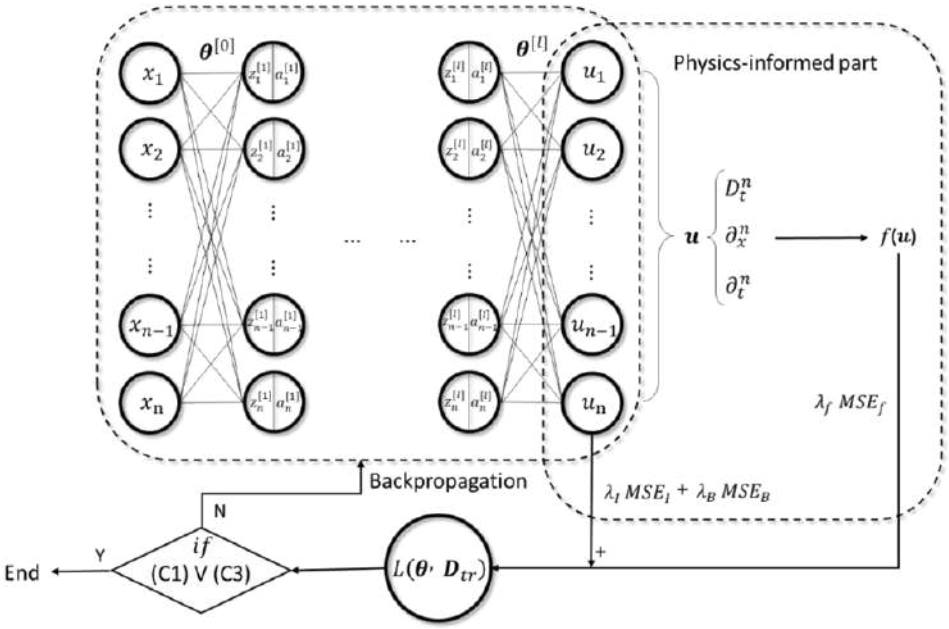

Figure 1. A schematic algorithm of a classical PINN.

An input vector for the first hidden layer is $\boldsymbol{x}$ (see Eq.(3.2) and(3.3)) and each hidden layer's output is represented in a forward propagation phase by

$$\begin{aligned}
\boldsymbol{a}^{[0]} &= \boldsymbol{x}, \\
\boldsymbol{z}^{[1]} &= \boldsymbol{\theta}^{[0]} \cdot \boldsymbol{a}^{[0]} + \boldsymbol{b}^{[1]}, \\
\boldsymbol{a}^{[1]} &= \boldsymbol{\sigma}^{[1]}(\boldsymbol{z}^{[1]}), \\
&\vdots \\
\boldsymbol{z}^{[l]} &= \boldsymbol{\theta}^{[l-1]} \cdot \boldsymbol{a}^{[l-1]} + \boldsymbol{b}^{[l]}, \\
\boldsymbol{a}^{[l]} &= \boldsymbol{\sigma}^{[l]}(\boldsymbol{z}^{[l]}), \\
\boldsymbol{u} &= \boldsymbol{\theta}^{[l]} \cdot \boldsymbol{a}^{[l]} + \boldsymbol{b}^{[l+1]}.
\end{aligned} \tag{3.4}$$

The PINN has a single input layer, a single output one, and l hidden ones. In this study, a Broyden–Fletcher–Goldfarb–Shanno (BFGS) algorithm is used for optimization. It is in the family of Quasi-Newton methods that update an approximate $\boldsymbol{H}_k$ based on $\boldsymbol{g}_k$ across iterations. The optimizer has three different stopping criteria which are listed below, and it stops when one of those is met: (C1) $iter = iter^{MAX}$; (C2) $L(\boldsymbol{\theta}, \boldsymbol{D}_{tr}) < \varepsilon$; (C3) $||\nabla L(\boldsymbol{\theta}, \boldsymbol{D}_{tr})|| < \varepsilon^H$. Here, $iter$, $iter^{MAX}$ and ε are replaced, respectively, with $iter^m$, $iter^{mMax}$, and $\varepsilon^m$for the meta-training. $L(\boldsymbol{\theta}, \boldsymbol{D}_{tr})$ is also switched with $L^{(i)}(\boldsymbol{\theta}^{(i)}, \boldsymbol{D}_{su}^{(i)})$ and $\sum_{i=1}^{NQ} L^{(i)}(\boldsymbol{\theta}^{(i),'}, \boldsymbol{D}_{qu}^{(i)})$, respectively, for each inner learner and the outer learner of the MPINN. The losses are defined by the same combination of the individual losses of Eq.(3.5). (C2) is applied only to the outer learner, not to each inner learner and the PINN with a single learner. The simulations in the study use the options: $iter^{mMax}$ is 5,000; $iter^{mMax}$ is 50; ε^m is 8.0×10^{-6}; ε^H is 2.22×10^{-9}; the maximum number of line search steps per iteration is 50. The PINN updates $\boldsymbol{\theta}$ by minimizing Eq.(3.5) that includes four individual losses presented below. $\bar{u}_s$ can be acquired through measurements or physical laws. In this research, the MSE_d is not considered.

$$L(\boldsymbol{\theta}, \boldsymbol{D}_{tr}) = \lambda_f MSE_f + \lambda_I MSE_I + \lambda_B MSE_B + \lambda_d MSE_d, \tag{3.5}$$

where $\lambda_f = \lambda_I = \lambda_B = \lambda_d = 1$ and

$$MSE_f = \frac{1}{N_f} \sum_{p=1}^{N_f} [f(u_p)]^2, \tag{3.6a}$$

$$MSE_I = \frac{1}{N_I} \sum_{q=1}^{N_I} [u_q - \bar{u}_q]^2, \tag{3.6b}$$

$$MSE_B = \frac{1}{N_B} \sum_{r=1}^{N_B} [u_r - \bar{u}_r]^2, \tag{3.6c}$$

$$MSE_d = \frac{1}{N_d} \sum_{s=1}^{N_d} [u_s - \bar{u}_s]^2. \tag{3.6d}$$

3.2. Experiments for the performance evaluation of the PINN

In this section, the PINNs with different architectures are used to solve the IVPs and the BVP (or the IBVP), and the examination of the convergence of their solutions is included. The PINN for modelling the Duffing oscillator has six hidden layers, and each has 64 nodes with batch normalization and dropout (dropout rate = 0.5). Initialization is achieved by a variance scaling (VS) initializer and activations are swish with $\beta = 1.0$. For the Burger's equation, it has five hidden layers with 128 nodes per layer. Batch normalization is applied to every single hidden layer. A combination of a normal Xavier initializer and tanh activations is used. Figure 2 and tables 1–2 illustrate the evidence of the use of the NURS to the sub-domains across the entire domains in training the PINNs. The entire domain of the Duffing oscillator is divided into three sub-domains (see Figure 2(a) and Figure 2(b)), while the one of the Burger's equation has four sub-domains (see Figure 2(c) and 2(d)). It functions well on imposing samples in a more concentrated manner neighboring the left end or both ones of the entire domains depending on the nature of the problems. Regarding the Duffing oscillator, the IVP uses only two samples to the MSE_I. Each of (I), (II), and (III) has 84.99%, 10%, and 5% of 7,001 samples, respectively, for the MSE_f. The BVP uses each two samples at t=0 and t=9 for the MSE_B, and each sub-domain uses 42.83%, 14.28%, and 42.83% of 7,004 ones, respectively, for the MSE_f. In the case of the Burger's equation, the MSE_I uses 10,000 samples for the IVP. Each of (I), (II), (III), and (IV) has 38.82%, 1.18%, 0.59%, and 0.59% of 17,000 samples, respectively, for the MSE_f. Whereas the MSE_I only uses 1,000 samples for the IBVP, and it must be much less in comparison to the 10,000 samples of the IVP case. Each of the sub-domains has 81.20%, 1.25%, 1.25%, and 3.75% of 8,005 samples, respectively, for the MSE_f. Each of the intersections (90, -4), (90, -2), (90, 0), (90, 2), and (90, 4) imposed along the right end boundary has a single sample for the MSE_B. It turns out that the IBVP needs much fewer samples than 17,000 ones of the IVP for the highly accurate solution. The Duffing oscillator is tested using 1,000 uniformly distributed samples throughout the domain, and the Burger's equation is sampled specifically along the dashed lines shown in (c) or (d) of Figure 2.

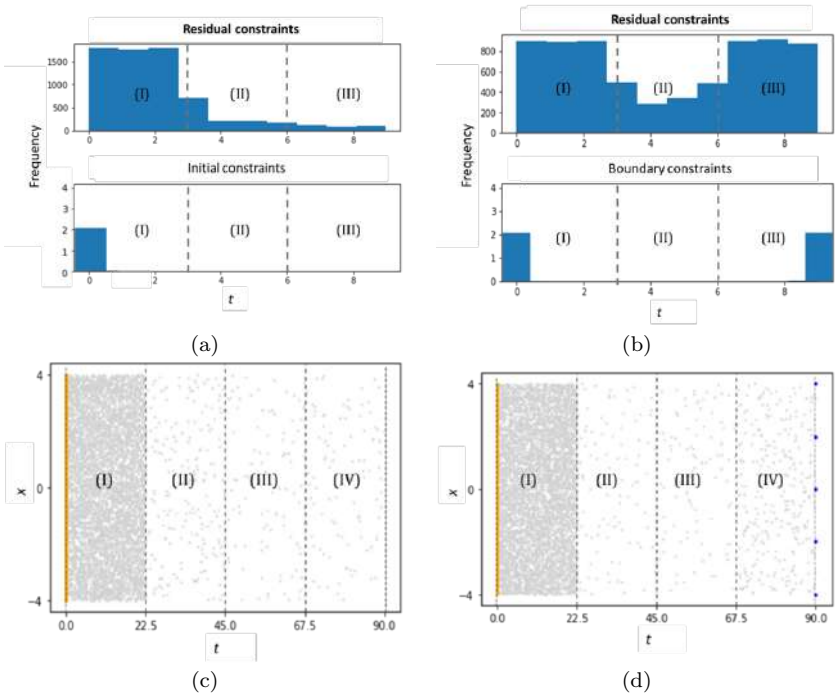

Figure 2. Distributions of samples across the sub-domains. (a) and (b) are, respectively, for the IVP and BVP of the Duffing oscillator; (c) and (d) are, respectively, for the IVP and IBVP of the Burger's equation. In Figure (c) and (d), orange and gray indicate samples, respectively, for MSE_I and MSE_f, and blue displays samples for MSE_B.

Table 1. Number of samples for the Duffing oscillator

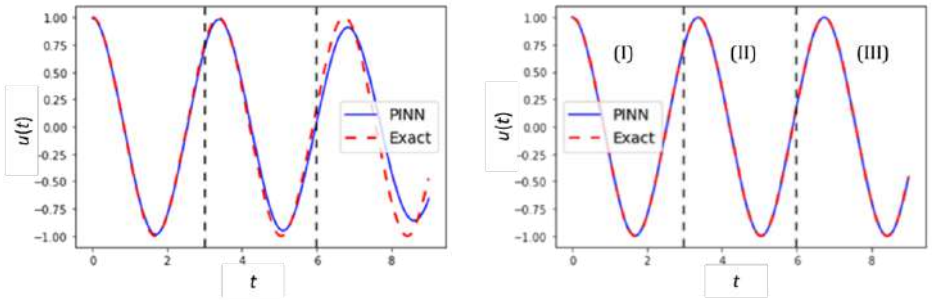
Problem type	MSE_I	MSE_f				MSE_B	Total
		(I)	(II)	(III)	Sub-total		
IVP	2	5,950	700	350	7,000	–	7,001
BVP	–	3,000	1,000	3,000	7,000	4	7,004

Table 2. Number of samples for the Burger's equation

Problem type	MSE_I	MSE_f					MSE_B	Total
		(I)	(II)	(III)	(IV)	Sub-total		
IVP	10,000	6,600	200	100	100	7,000	–	17,000
BVP	1,000	6,500	100	100	300	7,000	5	8,005

To discuss the solution accuracy of the MPINNs as well as the PINNs, we quantify the global truncation errors using the root mean square error (RMSE) presented below:

$$RMSE = \sqrt{\frac{1}{NT}\sum_{n=1}^{NT}(u_n - \bar{u}_n)^2}. \tag{3.7}$$



(a) (b)

Figure 3. Convergence of the solutions to the Duffing oscillator. (a) Comparison of the solution by the PINN and the exact one to the IVP. (b) Comparison of the solution by the PINN and the exact one to the BVP.

Table 3. Comparison of the RMSEs of the Duffing oscillator

Problem	RMSE(m)			
type	(I)	(II)	(III)	Overall
IVP	1.673×10^{-2}	5.967×10^{-2}	1.697×10^{-1}	1.043×10^{-1}
BVP	7.443×10^{-4}	1.307×10^{-3}	6.192×10^{-4}	9.391×10^{-4}

Figure 3 and Table 3 indicate that the RMSEs of the IVP increase with t, and (III) is the critical sub-domain. Unlike the IVP, the largest RSME occurs in (II) for the BVP, but it is relatively very small. The overall RMSE of the IVP increase by 11,006.4 %, and the local RMSE in (III) rises by 27,306.3 % in comparison to the BVP. As shown in Figure 4 and Table 4, the sub-domains at $t = 45$ and $t = 67.5$ are critical for the IVP of the Burger's equation. The IBVP finds the critical sub-domain in the middle, but it is also relatively small. The overall RMSE of the IVP increases by 659.69 %, and the local RMSE at $t = 45$ rises by 475.87 % compared to the IBVP. When it comes to the IVPs, it is obvious from the findings that the PINNs tend to increase the local RMSEs over t. This trend is more pronounced in the case of the Duffing oscillator. In the case of the Burger's equation, the local RMSEs start to increase rapidly after $t = 45$ and decrease somewhat around $t = 90$, but the decrement is not significant. This phenomenon appears to be mainly caused by a reduction in the influence of the initial constraints. In contrast, the boundary constraints play an imperative role in the high-quality convergence of the solutions for the BVP and the IBVP, especially in the critical sub-domains. One of the driving forces behind this study is the IVP issue. In section 4, we propose an alternative strategy to address it for the examples.

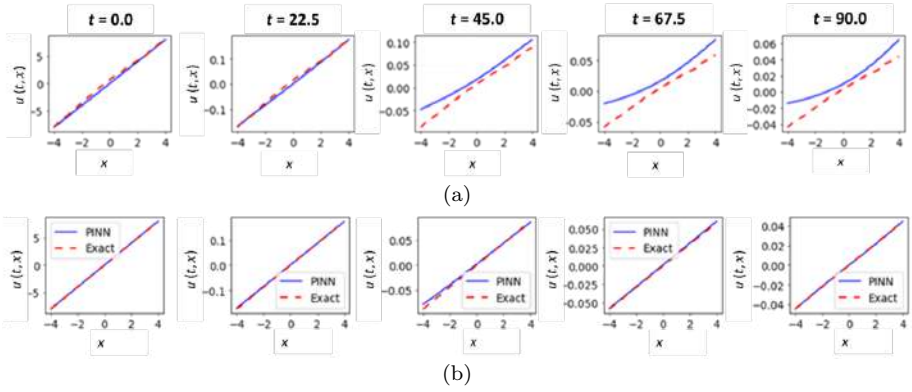


Figure 4. Convergence of the solutions to the Burger's equation. (a) Comparison of the solution by the PINN and the exact one to the IVP. (b) Comparison of the solution by the PINN and the exact one to the IBVP.

Table 4. Comparison of the RMSEs of the Burger's equation

Problem	RMSE(m/s)					
type	$t = 0$	$t = 22.5$	$t = 45$	$t = 67.5$	$t = 90$	Overall
IVP	1.057×10^{-3}	2.198×10^{-3}	2.277×10^{-2}	2.247×10^{-2}	1.616×10^{-2}	1.293×10^{-2}
IBVP	7.837×10^{-4}	2.101×10^{-3}	3.954×10^{-3}	1.271×10^{-3}	3.973×10^{-4}	1.702×10^{-3}

4. MPINN

In machine learning, there are several strategies for better adaptation of parameters to new inputs by learning from prior models. In this regard, various meta-learning techniques have been introduced in the literature [34]. This section discusses the MPINN based on the MAML that fine-reinitializes $\boldsymbol{\theta}$ using bi-level optimization. Comparative evaluations on the convergence of the solutions to the IVPs by the PINNs and MPINNs are implemented.

4.1. Meta-learning based on the MAML

An ANN is a typical nonlinear system, and its solution is highly dependent on its initial parameter values, as is well known. A meta-learning process is designed to improve the adaptability of the initial values of $\boldsymbol{\theta}$ that leads to better solution convergence. To achieve this, bi-level optimization is required. The outer learner, which reinitializes a meta-model for each inner learner in every single meta-iteration, enables each inner one to learn more adaptable features to a new task than a single learner. As a result, bi-level optimization can improve model accuracy as $\boldsymbol{\theta}$ alters its direction and magnitude of increments in a different update manner (see Figure 5), but to improve it, $\boldsymbol{\theta}$ can also be updated in a similar manner, as discussed in section 5 for the Burger's equation. Figure 5 summarizes (a) of Figure 6. Figure 5 and 6 display that first, training on $\boldsymbol{D}_{su}^{(i)}$ updates $\boldsymbol{\theta}$ to $\boldsymbol{\theta}^{(i)}$ by adapting $\boldsymbol{\theta}$ to $\boldsymbol{x}_{su}^{(i)}$. $\boldsymbol{\theta}^{(i)}$ takes a next forward step and achieves $\boldsymbol{\theta}^{(i),'}$ when $\sum_{i=1}^{NQ} L^{(i)}(\boldsymbol{\theta}^{(i),'}, \boldsymbol{D}_{qu}^{(i)})$ minimizes. Therefore, $\boldsymbol{\theta}$ reaches $\boldsymbol{\theta}^{(i),'}$ through $\boldsymbol{\theta}^{(i)}$. $\boldsymbol{\theta}^*$ is more adjustable to a new task when

$\boldsymbol{D}_{su}^{(i)}$ and $\boldsymbol{D}_{qu}^{(i)}$ are more similar in characteristics to $\boldsymbol{D}_{te}$.

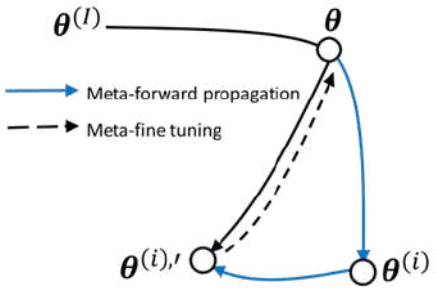

Figure 5. The key concept of the MAML for a single new task.

In the meta-training, the BFGS optimizer is also used. The first step begins with both $\boldsymbol{\theta}^{(I)}$ and $\boldsymbol{H}^{(I)}$, and a procedure with the steps of 1 - 6 for each of $f^m_{\boldsymbol{\theta}^{(i)}}(\boldsymbol{x}^{(i)}_{su})$ is repeated until one of the criteria stops the optimizer. The BFGS keeps $\boldsymbol{H}_k$ positive definite for updating formulations:

$$\text{Step 1: find } \boldsymbol{d}_k \text{ by solving } \boldsymbol{H}_k\boldsymbol{d}_k = -\nabla L(\boldsymbol{\theta}_k, \boldsymbol{D}_{tr}). \tag{4.1a}$$

$$\text{Step 2: perform a line search in } \boldsymbol{d}_k \text{ for computing } \alpha_k = \alpha \text{ by minimize } L(\boldsymbol{\theta}_k + \alpha\boldsymbol{d}_k, \boldsymbol{D}_{tr}). \tag{4.1b}$$

$$\text{Step 3: set } \boldsymbol{s}_k = \alpha_k\boldsymbol{d}_k \text{ and update } \boldsymbol{\theta}_{k+1} = \boldsymbol{\theta}_k + \boldsymbol{s}_k. \tag{4.1c}$$

$$\text{Step 4: compute } \boldsymbol{g}_k = \nabla L(\boldsymbol{\theta}_{k+1}, \boldsymbol{D}_{tr}) - \nabla L(\boldsymbol{\theta}_k, \boldsymbol{D}_{tr}). \tag{4.1d}$$

$$\text{Step 5: update } \boldsymbol{H}_{k+1} = \boldsymbol{H}_k + \frac{\boldsymbol{g}_k\boldsymbol{g}_k{}^T}{\boldsymbol{g}_k{}^T\boldsymbol{s}_k} - \frac{\boldsymbol{H}_k\boldsymbol{s}_k\boldsymbol{s}_k{}^T\boldsymbol{H}_k{}^T}{\boldsymbol{s}_k{}^T\boldsymbol{H}_k\boldsymbol{s}_k}. \tag{4.1e}$$

Step 6: return to step 1.

In (a) of Figure 6, $f^m_{\boldsymbol{\theta}^{(i)}}(\boldsymbol{x}^{(i)}_{su})$ is deployable and NS is nine for both examples, and NQ becomes automatically equal to NS. $\boldsymbol{\theta}$ is updated to $\boldsymbol{\theta}^{(i)}$ by each inner learner when the update of $\boldsymbol{\theta}_k$ in Eq.(4.1c) on $\boldsymbol{D}^{(i)}_{su}$ is completed for $f^m_{\boldsymbol{\theta}^{(i)}}(\boldsymbol{x}^{(i)}_{su})$. Each inner learner follows the learning rule of the PINN. The outer learner updates $\boldsymbol{\theta}$ to $\boldsymbol{\theta}^{(i),\prime}$ ($\boldsymbol{\theta}^{(i),\prime}$ means $\boldsymbol{\theta}^*$ in the test phase) in substance through $\boldsymbol{\theta}^{(i)}$. It is also achieved by Eq.(4.1c) when Eq.(4.2) instead of $L(\boldsymbol{\theta}_k, \boldsymbol{D}_{tr})$ is applied to Eq.(4.1a). Eq.(4.2) indicates the total of individual query losses.

$$\sum_{i=1}^{NQ} L^{(i)}(\boldsymbol{\theta}^{(i),\prime}_{mk}, \boldsymbol{D}^{(i)}_{qu}). \tag{4.2}$$

The optimizer stops the outer learner by (C3) when each $iter^m$ reaches 17 and 40, respectively, for the Duffing oscillator and the Burger's equation. The transfer of the parameters (see (b) of Figure 6) significantly drops the number of the iterative pre-meta-tunings. For the Duffing oscillator, $f^m_{\boldsymbol{\theta}^{(1)}}(\boldsymbol{x}^{(1)}_{su})$ undergoes 1,077 iterations for the training, but $f^m_{\boldsymbol{\theta}^{(6)}}(\boldsymbol{x}^{(6)}_{su})$ needs five iterations only, and the rest necessitate a significantly smaller number of iterations too. For the Burger's equation, $f^m_{\boldsymbol{\theta}^{(1)}}(\boldsymbol{x}^{(1)}_{su})$

undergoes 140 iterations, while each of $f^m_{\boldsymbol{\theta}^{(i)}}(\boldsymbol{x}^{(i)}_{su})$ for i = 2, 4, 5, 8, and 9 requires only one. An automatic evaluation of $f^m_{\boldsymbol{\theta}^*}(\boldsymbol{x}_{te})$ on $\boldsymbol{D}_{te}$ follows the meta-training for computing the RMSE of the MPINNs.

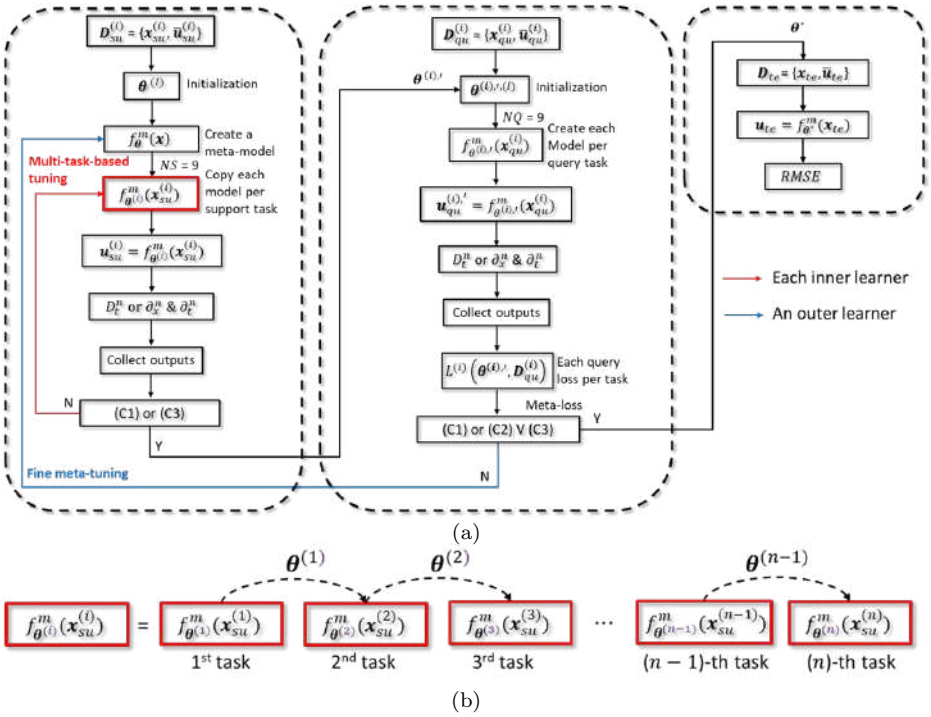

Figure 6. Schematic MPINN algorithm with the dual learners based on the MAML. (a) The meta-tuning and meta-test phases for the MPINN. (b) The application of the transfer learning to $f^m_{\boldsymbol{\theta}^{(i)}}(\boldsymbol{x}^{(i)}_{su})$.

4.2. Experiments for the comparative performance evaluation of the PINNs and the MPINNs

In this section, the experimental results of the IVPs by the PINNs and the MPINNs are discussed. Figure 7 and Table 5 show that the MPINN decreases the overall RMSE and the local RMSE in (III) of the Duffing oscillator problem, respectively, by 98.84 % and 98.83 % relative to the PINN. The former reduces the overall RMSE and the local RMSE at t = 45, respectively, by 79.81% and 85.89 % for the Burger's equation, as shown in Figure 8 and Table 6, relative to the latter. The meta-training samples both examples in the same manner shown in (a) and (c) of Figure 2.

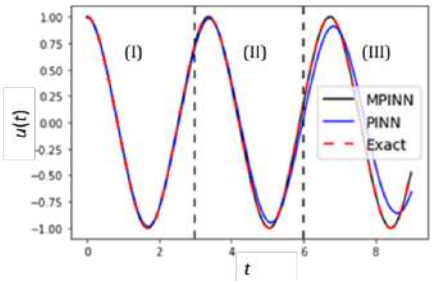

Figure 7. Comparison of the convergence of the solutions to the IVP of the Duffing oscillator.

Table 5. Comparison of the RMSEs of the IVP of the Duffing oscillator

Solver	RMSE			
	(I)	(II)	(III)	Overall
PINN	1.673×10^{-2}	5.967×10^{-2}	1.697×10^{-1}	1.043×10^{-1}
MPINN	1.854×10^{-4}	7.842×10^{-4}	1.979×10^{-3}	1.212×10^{-3}

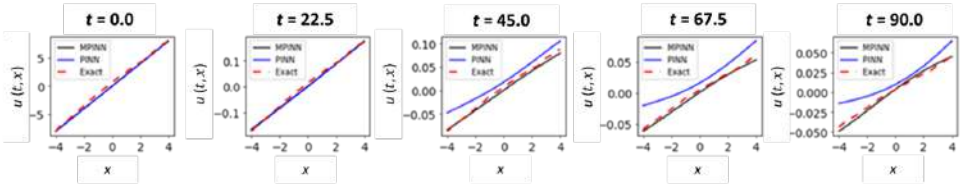

Figure 8. Comparison of the convergence of the solutions to the IVP of the Burger's equation.

Table 6. Comparison of the RMSEs of the IVP of the Burger's equation

Solver	RMSE					
	$t = 0$	$t = 22.5$	$t = 45$	$t = 67.5$	$t = 90$	Overall
PINN	1.057×10^{-3}	2.198×10^{-3}	2.277×10^{-2}	2.247×10^{-2}	1.616×10^{-2}	1.293×10^{-2}
MPINN	5.937×10^{-4}	3.651×10^{-3}	3.213×10^{-3}	1.993×10^{-3}	3.605×10^{-3}	2.611×10^{-3}

Based on the experimental data, we conclude that the MPINNs with reinitialization capability effectively solves the IVPs presented in the examples, whereas the PINNs with no fine adjustment function struggle to solve them.

5. Adaptability and correlation analyses

To showcase the adaptability of initial parameters, we first examine the evolution of the initial values of $\boldsymbol{\theta}^{[l]}$ of $f_{\boldsymbol{\theta}}^{m}(\boldsymbol{x})$ before (either the VS or the normal Xavier is implemented for pre-meta-training) and after the fine reinitialization by the meta-training and then sort out hidden layers that play a key role in the reinitialization

and adaptation (see Figure 9 and 10). From the data, there is no doubt that $\boldsymbol{\theta}^{(0)}$ initiates it for both IVP problems.

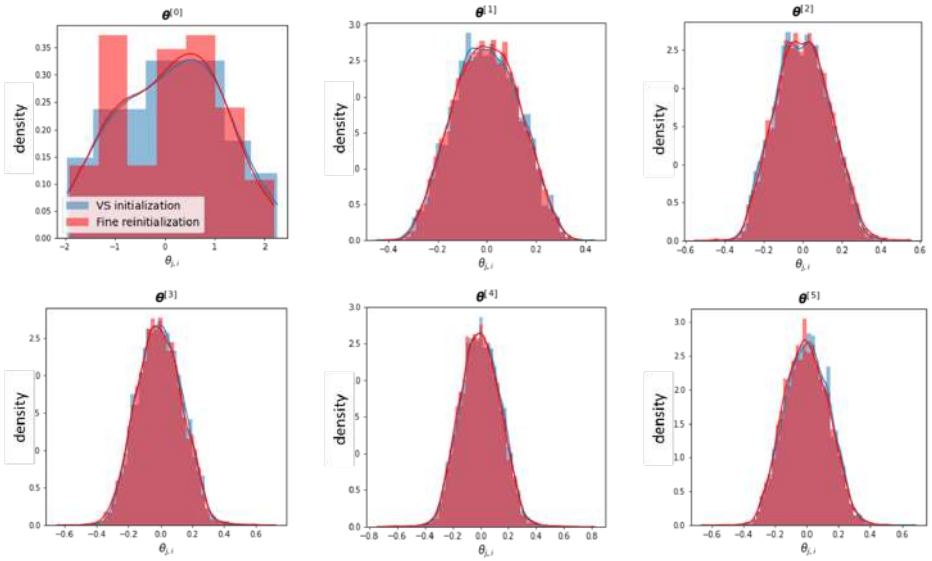

Figure 9. Evolution of the distribution of the initial values of $\boldsymbol{\theta}^{[l]}$ of the Duffing oscillator.

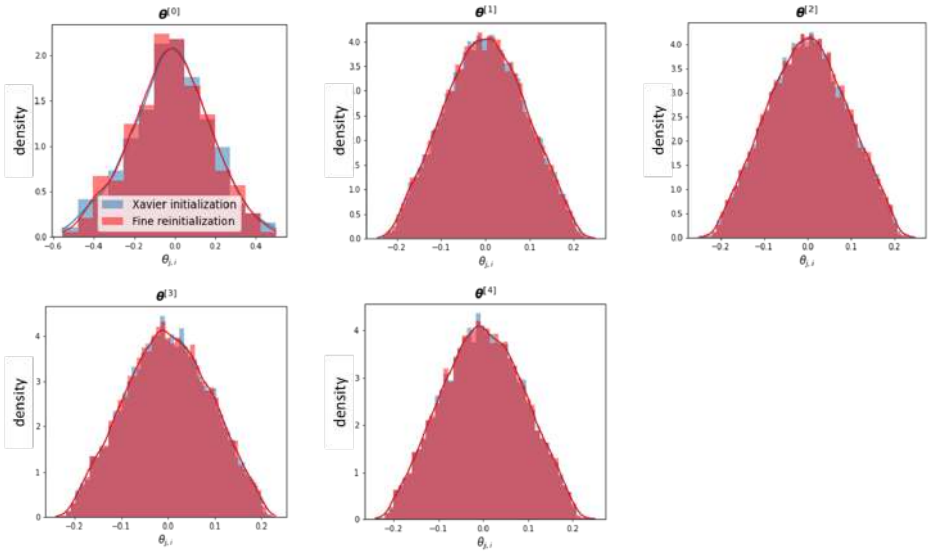

Figure 10. Evolution of the distribution of the initial values of $\boldsymbol{\theta}^{[l]}$ of the Burger's equation.

This section investigates how the initial values of $\boldsymbol{\theta}^{[0]}$s are related to the outputs of the examples. Additionally, as a supplementary to Figure 5, changes in the initial values of $\boldsymbol{\theta}^{[0]}$s before and after the application of the meta-learning are highlighted. As for the issues, correlation analyses are conducted using Kendall's

rank-order correlation coefficient. To make heatmaps for the analyses more readable, in addition to different colors, a square factor with different sizes is added to them. The size of a square in a correlation matrix generally corresponds to the strength of the correlation, with a larger size indicating a stronger correlation. The color of the square indicates the sign of the correlation, with blue and red typically representing positive and negative correlations, respectively. The depth of the color, either darker blue or darker red, represents the strength of the correlation with the square size.

Figure 11 displays the sampling of input coordinates for $u(t,x)$ that is used for correlation analysis between $\theta_{j,i}^{[0]}$ and $u(t,x)$. 256 samples are collected at random. In Figures 12-15, an x-axis or y-axis is graduated from left to right or top to bottom, respectively, and the graduations are labeled with $\theta_{j,i}^{[0]}$ values where necessary. To label them, the Duffing oscillator begins with $i=1$, then selects $j=1,2,\ldots,64$. The Burger's equation begins with $i=1$, then selects $j=1,2,\ldots,128$, and this process repeats for $i=2$. For the first example, Figure 12.(a) and 12.(b) show the heatmaps of the correlation between $\boldsymbol{\theta}^{[0]}$ initialized, respectively, by the VS (before the use of the meta-learning) and the re-initializer (it means the whole meta-learning process) and the output, $u(t)$. The comparative analysis of both heatmaps demonstrates that they become less correlated during the meta-learning. The PINN with the two-point initial condition is sensitive to the initial value of $\boldsymbol{\theta}^{[0]}$, and the mitigation of the sensitivity, as inferred from the lower correlation between the initial value of $\boldsymbol{\theta}^{[0]}$ and $u(t)$, improves the model accuracy. This suggests that the meta-learning effectively finds the optimal initial parameters, which leads to the improved solution accuracy in the presence of the less sensitivity to $u(t)$, as the elements of $\boldsymbol{\theta}^{[0]}$ are updated individually. It can be explained by comparing Figure 14.(a) with 14.(b) which depict the correlations between $\boldsymbol{\theta}^{[0]}$s before and after the fine reinitialization. In the case of the Burger's equation (see Figure 13.(a) and 13.(b)), unlike the Duffing oscillator, the initial value of $\boldsymbol{\theta}^{[0]}$ and the output, $u(t,x)$ become more correlated during the meta-learning. This increased sensitivity leads to the improved model accuracy, as the model captures more complex relationships between x and $u(t,x)$. It seems that the increase in the model accuracy due to the application of the meta-learning comes at the cost of the decreased robustness. The reason for this appears to be the integration of relatively intricate geometric domain information into the initial condition with a large number of samples used for discretization, making it difficult to decrease the sensitivity. However, it is imperative to be cautious, as this could lead to a less robust model that is vulnerable to the risk of overfitting and noise or inaccuracies in new input data, before finding an acceptable trade-off between robustness and model accuracy.

Figure 14 and 15 show the heatmaps of the correlation between $\boldsymbol{\theta}^{[0]}$s initialized, respectively, by the VS and the Xavier initializers (before the use of the meta-learning) and the re-initializer for both examples. The Duffing oscillator (see Figure 14.(a) and 14.(b)) demonstrates that the correlation becomes less during the meta-learning. From the data, it is clear that the re-initializer updates the elements of $\boldsymbol{\theta}^{[0]}$ independently in different directions and with different increments compared to the VS used in the pre-meta-learning. The observation supports Figure 5 well. For the case of the Burger's equation, in contrast to the former, $\boldsymbol{\theta}^{[0]}$s become more correlated as shown in Figure 15.(a) and 15.(b) which suggests that the elements of $\boldsymbol{\theta}^{[0]}$ are updated in an interdependent manner in the application of the re-initializer.

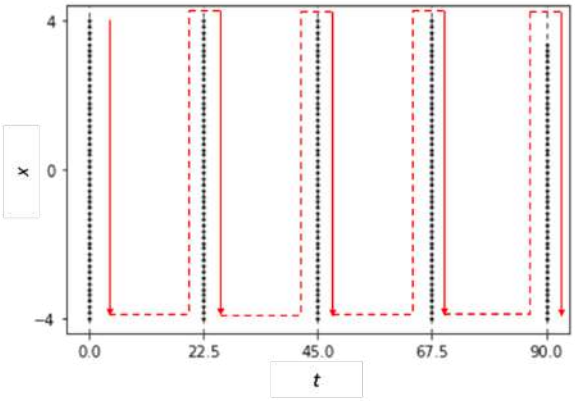

Figure 11. 256 samples for labeling the y-axis of Figure 13.(a) and 13.(b) with (t, x) top to bottom: first select $t = 0$, then select x between 4 and -4, and repeat this for t on the dashed lines (see the direction of arrows).

6. Conclusion

IVPs, which have significant importance in science and engineering and are associated with various real-world challenges, need for their accurate numerical solution as an essential task. In this study, we deal with the examples that are very simple but reflect the characteristics of IVPs well. The case studies are devised to encompass both scenarios: one where the output repeats itself or other similar patterns (the Duffing oscillator) and another where there is substantial variation in the gradient of the output with t (the Burger's equation). Through the scenarios, in addition to the precise numerical solutions of the IVPs, it is possible to observe a distinct dissimilarity in the relation between the solutions with high accuracy and the model's sensitivity to them when the fine reinitialization is implemented.

The PINNs with a single learner struggle to find accurate solutions to the IVPs. As evidence of this, the experimental data demonstrate the large RMSEs. It implies

that the use of PINNs in science and engineering is limited because, unlike BVP and IBVP, IVPs may necessitate fine reinitialization. In response to the limitation, we propose the MPINN with the dual learners based on the MAML. The collaboration of the multiple number of inner learners and the outer learner overcomes the limitation of the PINNs with no fine re-initializer, as it enables the optimal reinitialization of $\boldsymbol{\theta}$ and gives the solutions with higher precision. In this process, $\boldsymbol{\theta}^{[0]}$ initiates the fine reinitialization for both IVPs. The findings show how closely the solution convergence of the IVPs is coupled to the initial values of $\boldsymbol{\theta}^{[0]}$s.

For the Duffing oscillator, the meta-learning decreases the sensitivity of the initial value of $\boldsymbol{\theta}^{[0]}$ to $u(t)$ by updating its components in the different manner, leading to the highly accurate solution. On the contrary, in the case of the Burger's equation, updating the components of $\boldsymbol{\theta}^{[0]}$ in the interdependent manner increases the sensitivity of the meta-model to $u(t, x)$. The findings from the correlation analyses hint that the application of the meta-learning process alone for solving the PDE may be insufficient to optimize both issues at the same time, despite the improvement in the model accuracy. Applying joint optimization to the MPINN, which may reset the correlation between the initial parameters and the output, could provide a double-purpose solution. Regarding savings in computation cost, the use of the transfer learning between $f^m_{\boldsymbol{\theta}^{(i)}}(\boldsymbol{x}^{(i)}_{su})$ contributes to the reduction of the number of iterations required for the pre-meta-training of each inner learner.

7. Future works

A lot of progress has been made in self-tuning neural networks through joint optimization involving neural network architecture search and hyperparameters. It could be imperative to apply the optimization method to the MPINN for achieving both higher model accuracy and robustness. To realize it, our upcoming study will develop a hypergradient descent-based MPINN. The optimal trade-off between higher model accuracy and lower sensitivity using an event-triggered mechanism to activate a hypergradient descent process could be achieved.

Abstract
Modern smart cities rely on Vehicular Ad-hoc Networks (VANETs) for real-time traffic safety warnings and collision avoidance. However, high mobility, variable driving patterns, and urban contexts in VANET require optimal clustering and stable Cluster Head (CH) selection for reliable communication. Problem statement: Due to dynamic mobility in VANET, maintaining the CH stability and reliable communication is still a challenge. In high-density urban environments, the risk of communication disruptions increases due to the presence of a large number of vehicles competing for limited communication resources. Traditional graph-based suboptimal clusters lead to suboptimal communication reliability and disruptions compared to hypergraph based VANET. Such a modelling leads to reduced overhead and increased packet delay. Proposed Methodology: To overcome these issues of varying mobility in VANET and unstable CH selection, a new CH selection framework with an Adaptive Neighboring Behavior-Incentivization (ANB-I) process for stable and reliable CH selection is introduced. The selection of the CH based on Multi-criteria Multi-decision (MCMD) making of three metrics: Adaptive Neighborhood Degree, Adaptive Link Lifetime (Adaptive -LLT), and Adaptive Relative Average Speed. Results: The suggested approach prioritizes CHs with normal behaviours and longer link lifetimes to balance stability and reliability. The proposed model is tested on MATLAB software and SUMO simulations of 100 (sparse) and 1000 (dense) vehicle densities. The proposed model achieves a 75% CH stability with three optimal numbers of clusters, outperforming previous works by 4.17% improvement. Conclusion: A key aspect of the proposed CH selection is the incorporation of dynamic behaviour of driver's estimation based on the concept of incentive process. By prioritizing CHs with longer link lifetimes and stable driving patterns, the proposed model seeks to mitigate disruptions and enhance the throughput (overhead) of the VANET network.

1 Introduction

1.1 Overview

Communication between the vehicles is done with the help of a VANET, a modified form of a Mobile Ad-hoc Network (MANET). It is a significant part of the intelligent transportation system, in which vehicles have different communication modes such as vehicle to structure, vehicle to vehicle, and anything that comes in contact [1]. The standards for the communication that are used are set by the IEEE 802.11p for short-range communication and wireless access in vehicular environments. The functionality of VANET relies on network nodes, which experience frequent changes in position due to the high mobility of vehicles. This results in significant network instability and scalability issues, as depicted in Fig. 1. The node latency in VANET is greater than in MANET, leading to a loss in communication quality and causing delays in timely packet delivery [1].

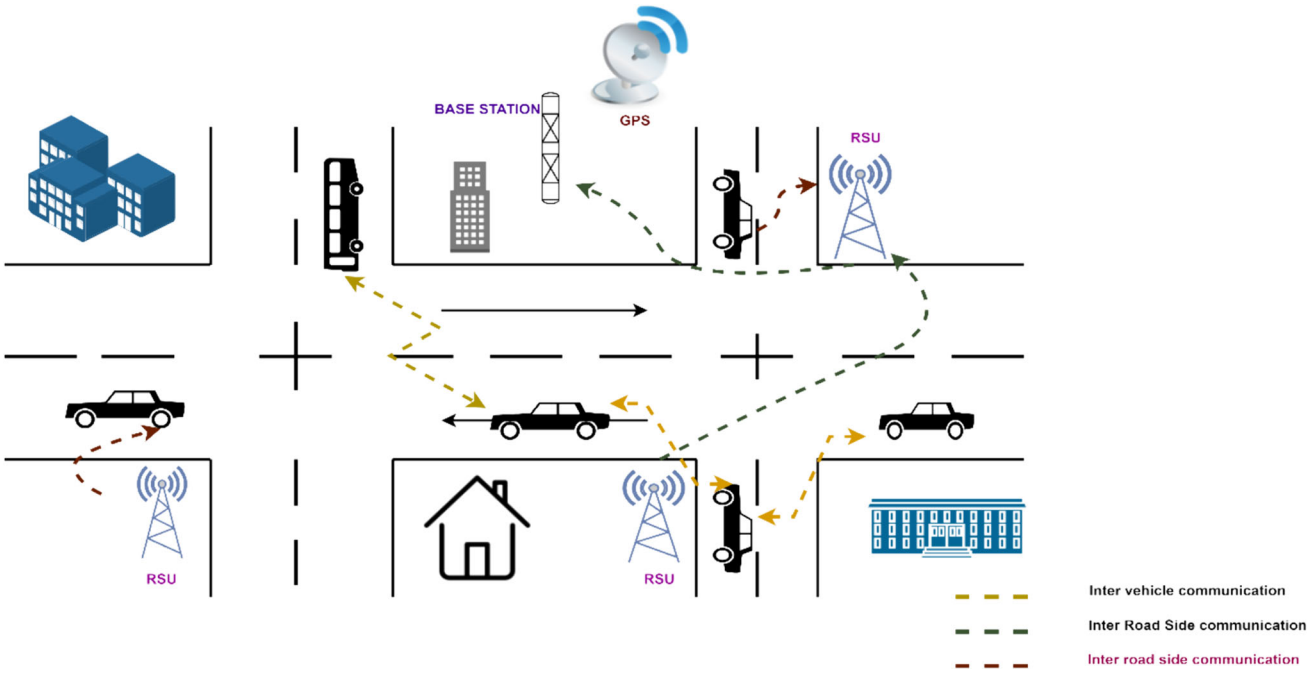

Fig. 1 Basic diagram showing VANET architecture

Within the domain of VANETs, the network exhibits a highly dynamic nature, characterized by the unpredictable and unusual movement of nodes (vehicles), resulting in frequent alterations to the network structure. The constant change and variability present in this situation create difficulties in maintaining stable communication and achieving efficient transmission [3, 4]. More precisely, the frequent rebuilding of the network leads to unreliable connections among vehicles and neighboring vehicles, thereby reducing the overall effectiveness of transmitting information in VANETs [3]. Hence, it is crucial to address the issues of preserving connection quality and reducing the frequency of group reorganization to advance the development of VANETs. To address these issues, researchers have developed algorithms based on the concept of clustering [5]. Most of the clustering methods efficiently classify vehicles into several clusters by utilizing characteristics such as inter-vehicle distance and relative speed. Each cluster consists of a CH and Cluster Members (CMs) that are deliberately chosen. Clustering of vehicles in VANET enhances the development of controllable and expandable VANET clusters, promoting a more equitable allocation of network burden.

The formation of a dynamic virtual backbone by CH plays a pivotal role in handling essential functions like routing and channel allocation. Particularly, in the case of transferring an ongoing vehicle data session from one Roadside Unit (RSU) to another, known as handover, challenges arise, especially for fast-moving vehicle groups. The conventional approach of individual vehicle handovers results in significant signalling overhead between vehicles and RSUs, leading to suboptimal performance. Conventional clustering techniques, such as K-means, have difficulties in effectively managing the changing characteristics of evolving VANETs. Whereas, another method of clustering, spectral clustering prioritizes data connectedness above geometric proximity, offering a semi-convex method that is better suited for the changing graph dynamics of VANETs [10, 13–15]. However, in this study, a hypergraph-based mTTM (Modified Tensor Trace Matrix) model is implemented for clustering. Whereas, the stability of a cluster is contingent on the frequency change in CM and in turn frequency of CH reselection, both of which are essential parameters in CH selection mechanisms. Connecting the stability to the space headway and connectivity by [20], the vehicle stability within a lane is intricately tied to its degree of connectivity in that lane. Higher connectivity implies greater stability, a concept intuitively linked to vehicle density and space headway [20]. Considering this concept, unlike traditional CH metrics, the concepts of dynamic behaviour and relativity are introduced in this study for a novel CH selection metric.

In the presented study, the concept of relativity plays a crucial role in the CH selection mechanism, particularly through the innovative Relative Neighboring Behavior-Incentivization process. In this study, relativity is introduced for the adjustment of CH metrics based on the dynamic behaviour and context of vehicles within the vehicular clusters inspired by [4, 7, 9]. The need for relativity arises from the diverse and dynamic nature of driving

patterns exhibited by vehicles in different scenarios [20], which can significantly impact the stability and reliability of the chosen CH. Relativity, therefore, serves as a dynamic mechanism to align the CH selection parameters with the real-time behaviour of vehicles. It allows the incentivization process to adapt to the varying conditions and driving styles observed in the vehicular network.

1.2 Challenges

There is a recent advancement in utilizing spectral clustering for VANET clustering [13–15] CoVEG (cluster-based VANET-oriented evolving graph) [23, 27]. For CH selection in VANET, most of the studies highlight the importance of considering factors such as trust [3, 11, 15, 22], relative speed [15, 22, 23, 27] and such. However, there is a need for research on prioritising the selection of CH. The identified problems in the recent research are,

- With high mobility, in areas like Connaught in Delhi [22], it becomes challenging to prioritize the selection of CH which shows usual behaviour or aggression as explained in [4, 7, 9] and maintains the longer link lifetimes. Hence, there is a need to consider adaptive and responsive CH selection mechanisms.
- Most of the studies concentrate on VANET analysis in sparse contexts like roadways. However, the transportation network functions differently in an urban setting due to the high vehicle density. The network becomes increasingly challenging as more connections and disconnections occur simultaneously. A super network is what is used when more than two cars are connected at once. The dependence of a vehicle on all of its Neighbors is not considered by traditional network mapping as a two-node graph [22].
- In traditional spectral clustering, the adjacency matrix is a key component used to capture the relationships or similarities between vehicles. However, traditional spectral clustering may result in less detailed community structures within the generated clusters. There is a need for transformation that allows for the determination of the dependency of the vehicle's feature matrix on social connectivity [29].

1.3 Contributions of the paper

Motivated by these challenges, the proposed method for CH selection metrics is introduced with the concept of relativity and incentivized dynamic behaviour to select a stable CH. The main contributions of the paper are,

- The paper introduces an innovative approach to representing VANETs as hypergraphs. It leverages Eigen Heuristics as a means to determine the optimal number of clusters before initiating the clustering process.
- A dynamic driving behaviour assessment mechanism for CH selection based on incentives is proposed. It considers the dynamic driving patterns of vehicles within clusters, distinguishing between usual and unusual patterns of velocity.
- The paper employs three key metrics, namely Adaptive Neighborhood Degree, Adaptive Link Lifetime, and Adaptive Relative Average Speed, to initiate the CH selection process. By incorporating an adaptive thresholding approach (Eq. 3), termed Relative Neighboring Behavior-Incentivization (ANB-I), the metrics are dynamically adjusted based on the relative behaviour of vehicles, fostering a more responsive and context-aware CH selection.
- The proposed model is simulated for CH stability over varying optimal clusters and network parameters for varying vehicle densities (100 and 1000). The metrics proposed with ANB-I is evaluated with the simple metrics over varying vehicles.

The following is the outline of this paper: The conceptualization of the problem is discussed in Sect. 3, which outlines a hypergraph approach to system modelling by making use of the Modularity Matrix and stable and secure CH selection. In Sect. 4, an overview of the proposed methodology is presented, which includes modifications to Spectral Clustering as well as parameters for selecting secure and stable CH. Finally, results and conclusion are detailed in Sect. 5 and 6 respectively.

2 Literature

2.1 Overview

The selection of stable and secure CHs in VANETs can be significantly influenced by the actions of the drivers themselves. It is difficult to select appropriate CHs due to noise and unpredictability introduced into the network connectivity by the dynamics of drivers, such as their speed, direction, and communication patterns, as will be explored in more detail below. In the following section, the challenges faced by current approaches and shedding light on the areas are discussed. The Section is divided into two parts, first discussing on the impact of driving behaviour on CH selection and other is the related works (spectral and non-eigen based clustering).

2.2 Dynamic behavior of drivers and its impact on CH selection

The dynamic behaviour of drivers plays a pivotal role in the selection of CH within vehicular networks, influencing the overall effectiveness of existing methods [20]. In this section, various approaches and their impact on CH selection are discussed. This emphasises the need for dynamic solutions that address the complexities associated with driver behaviour of a vehicle in the cluster to be elected as a CH.

The approach presented in [4] is distributed and thus more effective than existing methods for detecting aggressive driving. Intentionally aggressive driving behaviour can be uncovered through third-party observations. Although RSSI (Received Signal Strength Indicator) measurements may not be able to pick up on every instance of aggressive driving, they do give a framework for the rapid identification and alerting of nearby motorists. This gives other drivers time to respond and avoid dangerous situations. This work introduces a distributed approach for detecting aggressive driving behaviors, which can impact CH selection by influencing the dynamic behavior of vehicles within clusters. Johnson and Trivedi [5], proposed a novel system that utilizes Dynamic Time Warping (DTW) and smartphone-based sensor-fusion (gyroscope, accelerometer, video, GPS, magnetometer) to identify, recognize, and record such actions without external processing to raise awareness and promote driver safety. By combining inter-axial data from numerous sensors into a single classifier, the system offers a novel take on the field of driving pattern identification. Further aiding classification is an Euler representation of device attitude (also derived from fused data). Everything is processed entirely within the mobile device [5]. Hence, understanding driving styles and patterns can aid in selecting CHs that cater to the preferences and behavior of drivers within clusters.

Paper [7] introduced a new weighted evidence-combining strategy to fuse the contradictory information by analyzing the driving behaviour recognition parameter data. The proposed combination technique not only keeps Dempster's combination rule's great mathematical features but also takes into account all the interdependencies and effects of the evidence's body. The level of disagreement between the evidence is first quantified using a novel dissimilarity metric. In addition, uncertainty measurement and internal conflict are employed to assign relative importance to the various pieces of evidence. Reasonable aggregate results are obtained using a weighted averaging combination approach and the experimental results show that the suggested method outperforms the state-of-the-art approaches, making it a viable option for evaluating drivers' actions. Hence, by considering multiple sources of evidence, the method enhances the reliability of CH selection based on driver behavior. To strengthen the backbone of cooperative driving, Hu and Lee proposed a better vehicle clustering in [10]. The work's primary contribution is an innovative method for increasing vehicle reliability by maximizing the clustering of vehicle lifetime problems based on their related node representations, achieved with the help of the GNN model. As a result, it concludes that a GNN-based grouping algorithm that makes use of both features and graph structure outperforms the conventional approaches [10]. Kaur et al. propose that, despite the inherent instability of VANETs, these networks can provide crucial safety features during critical situations. Future guidelines for such important criteria as selecting CMs, CHs, and cluster management are the primary focus of the research. As it is possible to implant all of the managers for each intersection despite the lack of in structure and therefore cover the entire area, they concluded that the plethora of protocols used to connect VANETs just adds to the difficulty of doing so [14].

In order to foresee and prevent car accidents, Kalaivani advocated using vehicular communication technology to provide urgent alerts. This study's key contribution is that advancements in ITS technology have allowed for enhanced network safety, convenience, and longevity. As a result, the paper concludes that, in a smart transportation system, mobile communication technology is utilized to transmit urgent signals to alert vehicles in order to anticipate and prevent car accidents [12]. Hence, CH selection based on network safety considerations can benefit from advancements in ITS technology.

The paper by Hu et al. presents a method for determining the network architectures using Dirichlet processing of a Gaussian mixture model with spectral segmentation. As the study's central focus, a method for identifying community structures and applying it to the examination of many networks is presented. A novel method based on spectral clustering and DPGMM for studying community networks with no overlap is investigated. So, it can be concluded from many studies that this method works effectively in a wide range of settings. Modularity and other assessment indices are extremely useful for both synthetic networks built by computers and other types of networks in the real world. The suggested approach was evaluated against state-of-the-art techniques [16] on both real-world and simulated networks. By exploring community detection techniques, this work provides insights into network structure, which can aid in optimizing CH selection based on community structures. The author, Arkian et al., described a new three-step methodology for predicting traffic on a road segment based on the actual number of wirelessly connected vehicles. As a result, it can be said that the hybrid approach is a scalable

system that makes the most of the number of enabled vehicles travelling along a given road segment to provide an accurate estimate of the traffic flow. As a result, a novel clustering method, a clustered chain methodology, and a traffic-control approach are proposed in [17]. In the work by Miyajima et al., they suggested a model that mimics the accelerator pedal's behaviour under normal driving conditions. The key contribution of this work is a model that can learn the behaviour of the driver's pedal pattern and use it to distinguish between their driving styles. This paper concludes that driver simulations were evaluated in driver recognition trials [18] by using driving signals collected from a real car as well as a driving simulation. This study focuses on modeling and recognizing driver behaviour, which is crucial for understanding the dynamic behavior of vehicles within clusters. Driver behavior can affect vehicle dynamics and communication patterns within VANETs, influencing CH selection strategies. By modelling and recognizing driver behaviour, this work provides valuable insights into the interactions between drivers and vehicles, which can inform CH selection based on driver behavior characteristics.

Sharma et al., proposed an incentive-based reputation scheme, where nodes are first grouped according to their social features. The weighted social tie is determined to represent the strength of their social connections, and finally, the weighted social tie is updated based on any rewards or punishments that have been assigned to the nodes. If there is a tradeoff between residual energy and packet delay, or if packet latency is penalized, then the incentive is offered. To do this, IRU-mDANMF (Deep autoencoder-based non-negative matrix factorization) is created which ism DANMF, a new modularized that uses social features to determine a node's reputation (incentivized reputation update by modularized DANMF). Experiments in a variety of settings have shown that the approach outperforms the best existing options by a wide margin [19]. The incentive-based reputation scheme proposed in this work aims to enhance the reliability and trustworthiness of vehicles within the network. In VANETs, selecting reliable CHs is essential for maintaining network stability and ensuring secure communication. Inspired by this work, by incentivizing desirable behavior and penalizing undesirable behavior, this approach contributes to selecting CHs capable of effectively managing network resources and maintaining communication reliability. Zepeda et al. introduced a dynamic clustering-based driving styles classification and profile approach in their study [20], in which groups shift in reaction to external stimuli. A position-dependent dynamic clustering structure was designed in which a driver is assigned to a cluster sequence rather than a single cluster to better capture dynamic driving patterns and comprehend the driving style transition behaviours and more complex driving patterns. Zhou et al. conducted a study on the intrinsic characteristics of network traffic by examining real-world traffic trace data, and their findings show that traffic possesses the characteristics of temporal stability and geographical affinity. They model TM as multi-Gaussian distributions, which more precisely describe the actual network traffic, based on the spatial features of the traffic. To further estimate the missing traffic data, a novel matrix completion method using multi-Gaussian models was developed in [21].

Vashishth et al. presented GMMR (Gaussian Mixture Models) as a method for routing in OppIot networks in paper [25]. For the soft clustering of the network's nodes, GMMR uses Gaussian Mixture Models. The model was trained on device characteristics such as destination count, distance from the destination, device buffer occupancy, and number of successful message delivery by a device. To implement controlled message flooding, this trained model was utilized to group devices with comparable configurations. GMMR model outperforms other state-of-art models in terms of average hop count, a number of message drops, delivery probability, and overhead ratio. However, GMMR's training phase is tedious and may need to be repeated if significant changes are made to the network. In [24], Law et al. suggest a new way of learning metrics for deep supervised clustering by formulating a novel loss function. An easily calculable closed-form expression for the gradient is derived by us; its computation complexity scales linearly with the size of the training mini-batch and quadratically with the dimensionality of the representation.

From the detection of aggressive driving behaviours [4, 5] to the recognition of driving styles [18] and the prediction of traffic patterns [17, 21], these approaches demonstrate the multifaceted nature of driving behaviour based challenges faced in vehicular networks. Furthermore, innovative techniques such as community detection [16], dynamic clustering [20], and Gaussian Mixture Models for routing optimization [25] offer promising avenues for improving VANET performance and scalability. The overarching theme that emerges from this literature review is the necessity for adaptive and context-aware solutions that can effectively accommodate the dynamic nature of vehicular environments. The insights gleaned from the discussed studies lay the groundwork for further exploration and analysis of clustering methodologies within vehicular networks, underscoring the importance of dynamic and adaptive solutions in addressing the evolving challenges of vehicular communication and cooperative driving.

2.3 Related approaches for clustering in VANET

The related works discussed here are divided as spectral clustering based and non-eigen based.

2.3.1 Non-Eigen clustering based studies

The Grasshopper Optimization Algorithm (GOA) for VANETs has been used for efficient CH selection in paper [1]. However, greater node density had a detrimental effect on other state-of-art models in [1], similar to the proposed model, it addresses the challenge of optimizing cluster formation in dynamic environments. while the proposed GOA was lowering the number of clusters to achieve higher network density. To solve the problem of inefficient data delivery in urban vehicle areas, Kwon et al. [2] suggest a neighbor stability-based VANET clustering (NSVC). In addition to expediting cluster formation and reducing the frequency of CH elections, NSVC also ensures that critical information will arrive reliably in the event of an emergency. The simulation results indicate that NSVC outperforms conventional methods in terms of network performance [2]. NSVC aims to expedite cluster formation and reduce the frequency of CH elections while ensuring reliable data delivery. In paper [3], a novel clustering protocol with a new weighted formula was utilized for selecting CH; this protocol relies on trust, distance, and velocity as its three primary parameters. Clustering and selection of CH varied depending on the values of the parameters. possible that new weighted parameters could be added to an existing weighted formula for selecting CH to achieve optimal results. This protocol incorporates trust, distance, and velocity as primary parameters for CH selection, demonstrating the significance of multi-criteria decision-making in clustering algorithms. Cheng et al. [6] presented a stable clustering approach for VANETs on highways that makes use of the direction vector, the centres of vehicle density areas, and intersections to group fewer but more stable clusters. A unique CH selection algorithm and cluster maintenance algorithm were suggested, which use the relative mobility metric to mitigate the effects of vehicle distance, velocity, and maximum acceleration, thereby mitigating the effects of vehicle type and drivers' driving habits. This approach utilizes relative mobility metrics to form stable clusters, addressing challenges posed by varying vehicle distances, velocities, and driving habits. It complements our study's emphasis on stable CH selection in dynamic VANET environments.

In this paper, Iswarya and Radha proposed a secure and stable routing methodology that helps in establishing robust clustering and reduces the changing frequency between the two vehicles. The primary result of the work was the selection of a state-of-the-art CH for improving network safety and mitigating the effects of dynamic vehicle motion. The purpose of this research was to offer a secure routing algorithm for selecting a novel CH to reduce the impact of a collision between two cars. The study indicates that the proposed work outperforms the existing scheme in terms of reliability, end-to-end delivery, delivery ratio, and future work of this kind [8]. Liu et al. have presented a method for predicting driving behavior using the Navie Bayes classifier and several unrelated variables that he calls NBP. In this case, driving behavior is predicted using the Naive Bayes classifier. The primary result of this work was the proposal of a machine learning method for forecasting using Navir Bayes, based on an analysis of the driving behaviour of the two opposing groups. Therefore, it concludes that cars can be divided into two groups according to their drivers' attitudes on speeding and passing [9]. Although not directly related to clustering, it highlights the importance of considering dynamic driving patterns in CH selection, which resonates with our study's approach. To select reliable cluster leaders, Oubabas et al. introduced a new method that combines stability and trust characteristics. The key contribution is a description of a new clustering technique that takes into account safety and reliability problems. It underscores the significance of secure CH selection, which aligns with our study's focus on incentivizing stable CH selection. Because CH perform such an important role, the election of a malicious or compromised node as a CH can have far-reaching consequences that pose a danger to the network's security and resiliency. A reliable means of communication and reliable data storage are crucial to safety. The proposed method is broken down into its two main phases, which are outlined in [11]. The one proposed by Kamakshi and Sriram selects the next individuals to get safety warnings by forming stable communities of cars while taking irrelative mobility into account. The fundamental contribution of this work is the realization that clustering algorithms, a method for categorizing people based on their degree of similarity, are widely employed in a variety of online communities. A community detection technique to cluster automobiles with shared characteristics has been implemented. Numerical simulations support the findings that stable communities, reduced packet impact ratios, packet loss ratios, and end-to-end delays, and improved performance and accessibility can be achieved by giving the degree of cohesiveness 30% of the weight and the degree of flexibility 70% of the weight [13].

2.3.2 Spectral clustering based studies

A novel two-pronged strategy for long-term CH selection was proposed by Jabbar and Trabelsi. The first part of the proposed method treats the automotive connection as a one-to-many connection network, which is somewhat close to reality. The work centers on the suggestion that TTM can be used to practically and advantageously break up the hypergraph. This paper provides a thorough analysis of the most crucial considerations for selecting appropriate

clustering parameters, thereby revealing fresh perspectives and new lines of inquiry. A linear timeline offers all the benefits but almost no repercussions. All these internal network nodes serve primarily as communication hubs in this paper. This results in a nearly sparse adjacency matrix, which in turn greatly reduces the overall complexity of the procedure. Thus, it concludes that the number of clusters produced over time affects computing efficiency. When compared to the roads, urban areas offer easier mobility options. CH is also more stable in metropolitan settings, where there are more vehicles per square mile but less freedom of movement [15]. VANET is represented as a hypergraph network clustered using tensor trace maximization with the modularity matrix [29] as the feed in the article [22], which provides a unique modularized hypergraph clustering scheme. Based on four vehicle criteria, including vehicle speed relative to neighbors, consensus trust score, link duration, and connectivity level, CH is selected from each cluster. All parameters are transformed into Eigenvalues before the final CH is chosen. Based on a set of four criteria, the fuzzy decision-making scheme chooses the optimal CH for all vehicles in that cluster. Using cutting-edge techniques, the suggested algorithm for identifying the stable CH for enhanced network performance has also been validated and greatly enhanced. The use of a modularity matrix enhances tensor trace maximization for calculating Eigenvalues, and CH stability increases by 17.64% as compared to no modularity matrix. This motivates the author to create four metrics for vehicles: link longevity, consensus trust score, vehicle connectivity, and relative speed. These vehicle metrics provide a weighted adjacency matrix and a sub-hypergraph for each car that corresponds to an adjacent car. These measurements were improved using the modularity matrix idea, leading to modularized metrics. Fuzzy decision-making is employed to determine which vehicle index within a cluster should be designated as the CH [22].

In order to increase the dependability of vehicular communications, paper [23] proposes a unique cluster-based VANET oriented evolving graph (CVoEG) model by extending the existing VoEG model. Cluster members (CMs) and CH (CHs) are chosen based on network reliability. The suggested CVoEG model separates VANET nodes (vehicles) into an optimal number of clusters (ONC) using the Eigengap heuristic. In terms of packet delivery ratio (PDR), end-to-end delay (E2E), dependability, reliable routing request (RRR), and throughput, the suggested method greatly exceeds the existing schemes. This model proposes a unique approach for cluster formation based on network reliability. Our proposed model extends this by incorporating Modified Tensor Trace Matrix (mTTM) clustering and incentivized CH selection parameters for enhanced network performance. Moreover, for more reliable data distribution and less end-to-end delay in VANET, a novel method called Deep Learning Ruzicka Spectral Clustering-based Oppositional Dragonfly Optimized Routing (DLRSC-ODOR) is introduced by Radhika and Bhuvaneswari in [26]. A deep learning idea is utilised by the DLRSC-ODOR method, which consists of an input layer, two hidden layers, and an output layer. Vehicle nodes are clustered using Ruzicka similarity-based spectral clustering according to several mobility metrics such as vehicle density, movement direction, distance, and velocity. To identify the best possible CH across all criteria, the Multi-attribute Oppositional Dragonfly Optimization method is employed. The output layer then determines the best path between the source and the destination. Results demonstrated that compared to state-of-the-art approaches, DLRSC-ODOR significantly improves reliability, throughput, end-to-end delay, and packet drop rate [26]. This method utilizes deep learning and spectral clustering for efficient routing in VANETs. Our model complements this by introducing Modified Spectral Clustering and incentivized CH selection parameters, enhancing network reliability and performance. A novel approach to recasting the clustering problem as a cutting graph problem is presented by Liu et al. in a paper [27]. Combining the Spectral Clustering algorithm with the enhanced force-directed algorithm, a new, innovative clustering technique has been developed. To improve overall system stability, it uses the mean lifetime of all clusters as an optimization target. The Simulation of Urban Mobility (SUMO) creates several plausible hypothetical situations. The numerical findings show that the method excels at preserving cluster-wide stability. Hypergraph Clustering (HGC), a heuristic clustering based on the hypergraph theory that seeks to optimize the energy of sensor nodes, was proposed in [28] by Gbadouissa et al. theoretical analysis revealed that the clustering process required minimal energy during the cluster formation phase and the determination of the CH. Our proposed model extends this by introducing a dynamic behaviour assessment mechanism for CH selection, ensuring stable and reliable CHs in VANETs.

2.4 Research gap

The examination of various clustering and CH selection methodologies in VANETs can be categorized as spectral clustering-based and non-eigen clustering-based. It also represents a diverse landscape of approaches aimed at improving network performance, reliability, and safety.

- Papers such as [1–3, 6] introduce innovative techniques like the GOA, NSVC, and weighted clustering protocols (non-eigen-based), each addressing high mobility and stability-based challenges within vehicular environments.

- Moreover, research efforts such as those in [8, 9, 11, 13] focus on enhancing network safety and reliability through secure routing methodologies, prediction of driving behaviour, and the selection of reliable CH.
- Most studies highlight the importance of considering factors such as [3, 11, 15, 22], relative speed [15, 22, 23, 27] for selection of CH. However, considering dynamic driving patterns like those shown in [8, 9, 11, 13] in CH selection and clustering algorithms is still need to adopted in CH selection in VANET.
- Furthermore, novel strategies like the spectral clustering-based approach proposed in [15] and the hypergraph-based clustering method described in [22] offer unique perspectives on addressing clustering challenges in VANETs. These methodologies leverage advanced techniques such as tensor trace maximization and modularity matrix calculations to optimize CH selection and cluster formation. However, as the vehicle's density increases, the information stored in adjacency-based matrices becomes less content. Hence, there is a need to improve the spectral clustering-based model

However, despite the advancements made in clustering and CH selection techniques, there remains a research gap in the development of a comprehensive and incentivized CH selection mechanism tailored for vehicular networks. The proposed model here adopts an adaptive CH selection process that incentivizes vehicles based on their adherence to usual driving patterns and behaviours. Hence, the study is motivated by this opportunity for further research to explore the integration of dynamic driving behaviour profiling for reliable CH selection for VANET communication.

2.4.1 Distinguishing features: contrasting our approach with existing models

- Existing methods lack a definitive approach to deciding the optimal number of clusters in VANETs [15, 22, 26], leading to inefficiencies in resource allocation. Here the eigen heuristic approach is employed in the proposed model, which accurately determines the optimal number of clusters with uniform loading, addressing resource allocation challenges effectively.
- Non-spectral clustering approaches struggle with sparse networks and dynamic environments [2–9], limiting their practicality. While hypergraph representations offer promise [15, 22], they often rely on simplistic clustering algorithms like k-means. Here to overcome this, the hypergraph representation using a modified tensor trace maximization approach coupled with GMM clustering instead of k-means is proposed. This allows for probabilistic modelling and better adaptation to the distribution of vehicles in the network, making it more suitable for real-world VANET scenarios.
- While factors like relative speed are commonly considered in CH selection, dynamic driving patterns are often overlooked. Existing models often use a weighted sum approach for CH selection criteria, where weights are arbitrarily assigned by the operator, leading to subjective decision-making. By integrating dynamic driving patterns into our CH selection and clustering algorithms, inspired by the findings of previous studies [8, 9, 11, 13], our model ensures a more adaptive and context-aware approach to CH selection in VANETs.

3 Problem conception

3.1 A Hypergraph approach for system modeling based on modularity matrix

The cluster generation in VANET is not a novel concept but yet to be addressed. Where graph representation is used by many scholars, it is only applicable in sparse areas, where mobility is less. Hence, it is possible to mathematically represent a hypergraph as a set of nodes and hyperedges as shown in Fig. 2. The nodes in a VANET are the cars or other entities involved in communication, whereas the hyperedges are the connections between the nodes as seen in Fig. 2 Let V be the vertex of set of nodes (vehicles and other communication entities) in the hypergraph, and E be the set of hyperedges [22]. In this work the Hypergraph for vehicles is formulated as,

The vertex of a vehicle $V = \{v_1, v_2, v_3, v_4, \ldots\ldots\ldots v_n\}$ of hypergraph the distance metric for another vehicle in the reach is node $E = e_1, e_2, e_3, e_4, \ldots\ldots\ldots e_n$ and w is the weight as mentioned in Table 1. Then the weighted hypergraph is mathematically given as, $H = (E, V, w)$. It is possible to express the connections between nodes in a graph or hypergraph using an adjacency matrix. The adjacency matrix A of a VANET, when represented as a hypergraph, is a $|V|$ x $|V|$ matrix. The element A_{ij} in the matrix is equal to 1 if there is a direct communication link between nodes i and j, and 0 otherwise. The communication links between nodes in a VANET must be defined before an adjacency matrix can be constructed for the network. Consider a VANET with five vehicles, v_1, v_2, v_3, v_4, and v_5. Assuming v_1 and v_2 communicate with one another directly, likewise v_2 and v_3, and v_3 and v_4. Furthermore, v_4 and v_5 vehicles are able to exchange information with one another. Using this information, the adjacency matrix A_{ij} is constructed as follows: $A = [0100010100010100010100010]$. For example, $a_{12} =$

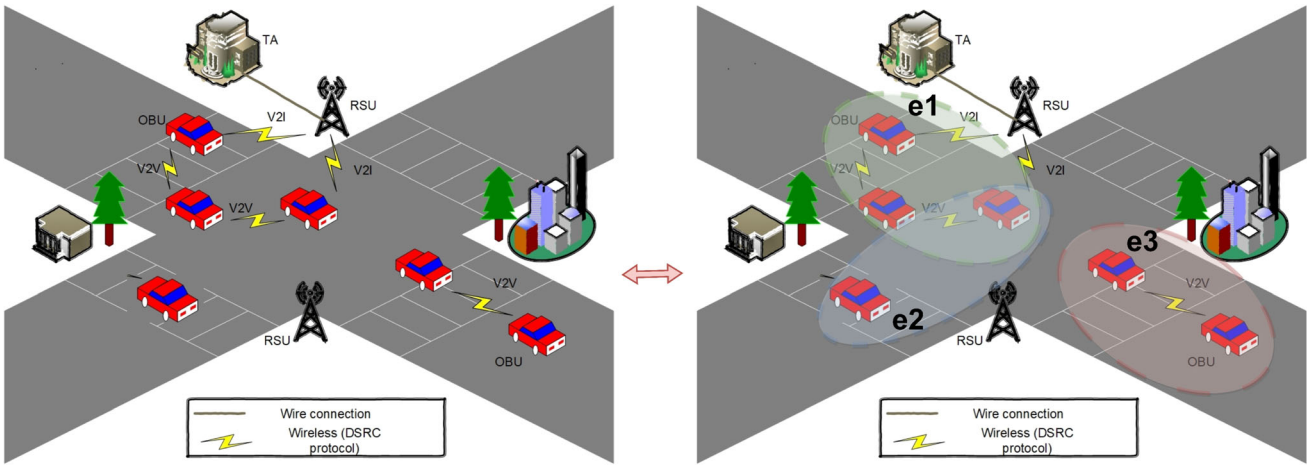

Fig. 2 VANET as hypergraph

1 because there is a direct communication link between nodes v_1 and v_2. Instead of an adjacency matrix, which is typically used to describe a VANET as a hypergraph, the modularity matrix given in [29] is taken into consideration in this research. The modularity matrix is represented as Q. The quality of the partition of the network into communities can be represented by the modularity matrix, which is a $|V|$ x $|V|$ matrix [29] defined as:

$$Q = A - P \tag{1}$$

where A is the adjacency matrix and P is the expected adjacency matrix. The expected adjacency matrix P is defined as in Eq. 2:

$$P_{ij} = \frac{V_{ki} V_{kj}}{2m} \tag{2}$$

where V_{ki} and V_{kj} are the degrees of nodes i and j, respectively, and m is the total number of edges in the network.

The VANET's hypergraph structure can be represented by the modularity matrix Q once it has been defined. Each node in the network is represented by a row and column in Q, and the matrix components indicate the relative importance of the relationship between vertices i and j, taking into account the network's modularity. Most heavily weighted edges are those that connect nearby vertices, which helps in grouping. Removing the weak edge with the lowest $\boldsymbol{Q_{ij}}$ value divides the hypergraph into smaller units. As a result, the modularity matrix provides a more accurate and nuanced picture of the network structure than the adjacency matrix does because it accounts for the predicted number of connections between nodes based on their degree.

Despite the clustering with hypergraph, these clusters show high velocities typically being associated with aggressive driving styles [20]. Given the challenges associated with disruptive behavior caused by impulsive and aggressive drivers, the study proposes an incentive-based CH selection mechanism. This introduces a dynamic behavior estimation process, where nodes (vehicles) are assessed for their behavior within the cluster. The reward mechanism aims to favor nodes exhibiting usual and stable behaviors, increasing their likelihood of being elected as CH. The selection process involves calculating metrics such as Adaptive Neighborhood Degree, Adaptive Link Lifetime, and Adaptive Relative Average Speed. This is further detailed in Next Section.

4 Proposed methodology

The methodology proposed in this study consists of two distinct phases: Modified Spectral Clustering and Stable and Secure CH selection, as illustrated in Fig. 3. The adopted spectral clustering method in this study is detailed as two primary steps: optimal cluster selection explained in Sect. 4.1.1 and mTTM (Modified Tensor Trace Matrix) clustering is explained in Sect. 4.1.2 which utilizes Gaussian mixture models. During Phase one, the simulation commences by incorporating the highest possible vehicle density, thereby collecting data on the vehicles' locations. The hypergraph is constructed based on the provided information and stored in the form of a Laplacian matrix. The modularity matrix is utilized to modify the construction of this matrix. Based on the available data, the Eigen heuristics method is applied to determine the most suitable number of clusters. In the Phase two, the incentivized CH selection process for stable CH. One of the challenges encountered in clustering, particularly in the context of spectral clustering, pertains to the identification of the optimal number of clusters within a VANET simulation. In VANETs, the precise quantity of clusters cannot be

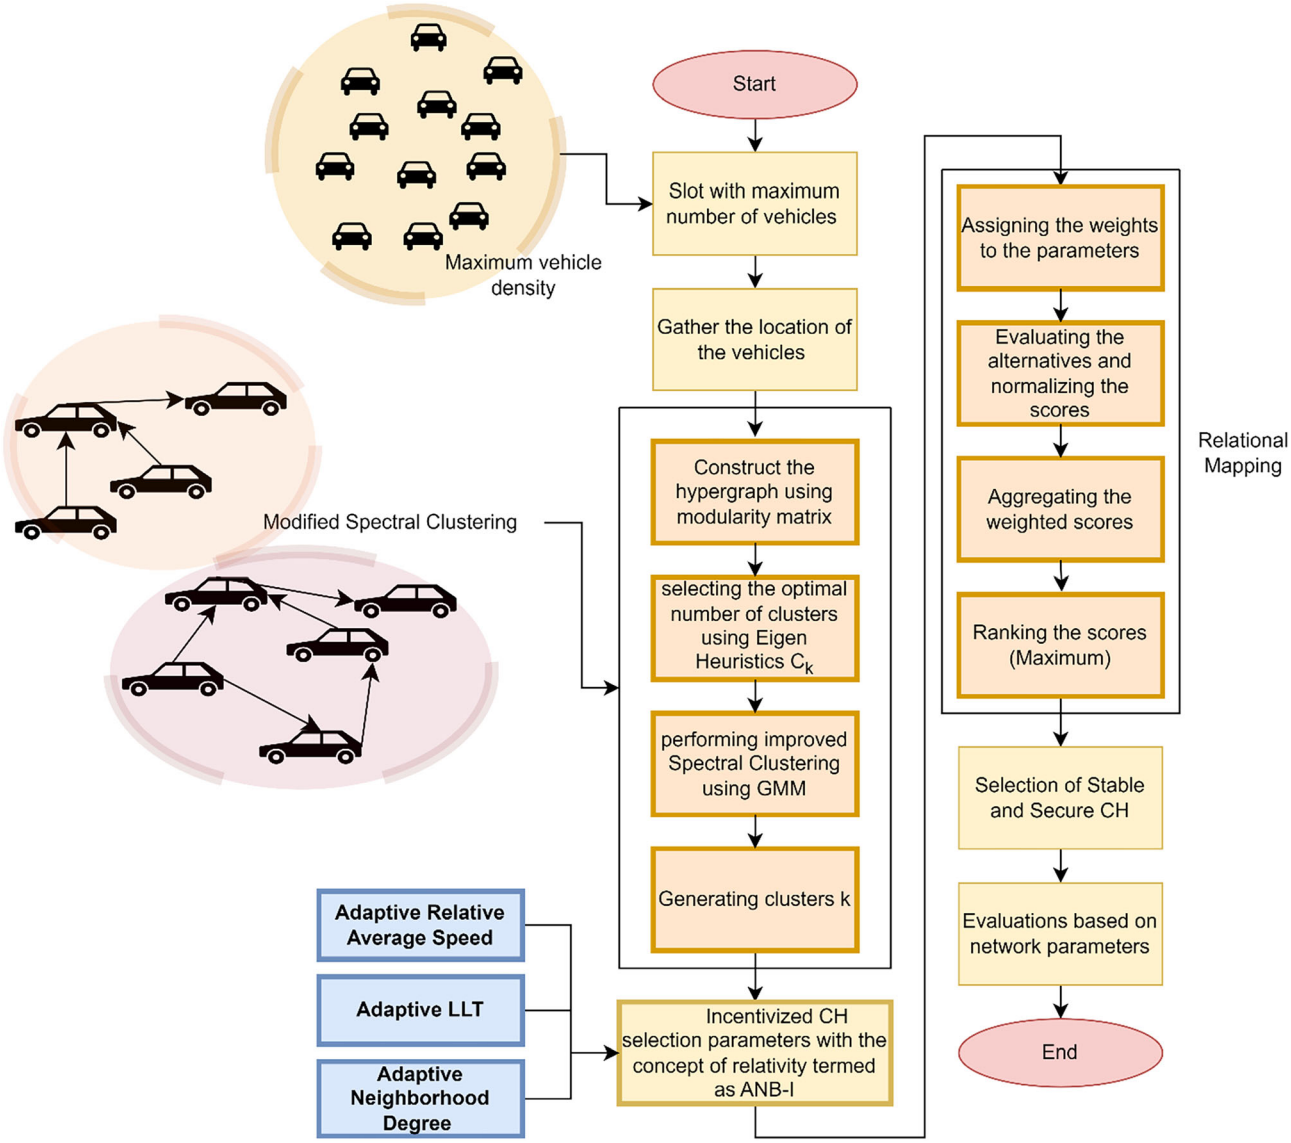

Fig. 3 Detailed proposed framework

predetermined and is subject to fluctuation based on the prevailing network circumstances. Hence, the Eigen Heuristics is employed here for generating an optimal number of clusters.

4.1 Cluster formation

Spectral clustering serves as a fundamental component in the proposed methodology for CH selection in VANETs. Its ability to handle complex data structures and optimize cluster formation contributes to the study's objectives of enhancing network stability, reliability, and responsiveness. Through the incorporation of spectral clustering techniques, the study aims to address the evolving challenges of vehicular communication and cooperative driving in dynamic environments. Here with the help of Eigen heuristics the optimal number of clusters suited for the particular density 100 and 1000 is obtained based on which our mTTM model is implemented for cluster formation in VANET.

4.1.1 Optimized cluster generation

Clustering is an efficient approach to partition the network into smaller, more manageable sections to decrease the excessive burden. A wide range of supervised and unsupervised learning techniques may be found in the literature for classifying networks. For example, K-means [10, 15, 22], machine learning based [9]. The primary limitations of K-means are the requirement to specify the

number of clusters in advance and its inability to accurately categorize vehicles that are not linearly separable in the input space [21]. In the dynamic environment of VANETs, the topology structure undergoes continuous modifications, and it is not guaranteed that the number of clusters will remain constant and K-means is a non-convex optimization problem. In addition to machine learning classifications, other existing clustering techniques [15, 23, 26] employ distinct criteria for cluster creation and CH selection. Determining the optimal number of clusters is a difficult task in all existing clustering methods. Based on the literature [15, 23], having a higher number of clusters can lead to higher hand-off costs, whereas having fewer clusters can result in more frequent link disconnections. The clustering of a developing network relies on the connectedness of nodes at each instant. Therefore, it is preferable to utilize a semi-convex methodology that relies on data connectivity rather than geometrical proximity. In this study, optimal number of clusters is determined using Eigen Heuristics method [23] as shown in Fig. 3. This method analyzes the Eigenvalues of the similarity matrix and identifies the largest gap between consecutive Eigenvalues. The number of clusters is then set to the corresponding number of Eigenvectors.

The Eigen heuristic is calculating the largest difference between successive Laplacian Eigenvalues and then selecting the k value that corresponds to that difference. In this paper, Eigen Heuristics are used to create the best possible value for the Number of clusters. The Eigenvalues of the Laplacian graph L are frequently utilized as input when determining the ideal number of clusters [23]. Input is provided by the Eigenvalues of the Laplacian matrix L, which has a dimension of $n \times n$ (where n is the number of nodes/vehicles). The Eigenvalues of L as $\lambda_1, \lambda_2, \ldots, \lambda_n$ in ascending order, then the Eigen gap heuristic can be used to estimate the number of clusters k as:

$$k = arg\ max(\delta_1, \delta_2, \ldots, \delta_{n-1}) \tag{3}$$

where, $\delta_i = \lambda_{i+1} - \lambda_i$, for i = 1, 2, ..., (n−1) is the difference between successive Eigenvalues, sorted in ascending order. Number of clusters is calculated by using the index returned by the *argmax* operation, which points to the greatest value in the sequence of differences. The Eigen Heuristics method [23] is employed to automatically ascertain the optimal number of clusters without the need for prior knowledge or manual selection. Upon implementation of this methodology, a set of k optimal clusters are obtained, which is subsequently utilized in the application of the modified spectral clustering technique (mTTM). The initial step of this procedure involves the computation of the Laplacian matrix, which is dependent on the interconnections among the vehicles. The use of Eigen Heuristics helps determine the optimal number of clusters, providing a foundation for efficient cluster formation. The spectral clustering method has been enhanced by incorporating the concept of modularity during the computation of the Laplacian matrix. These matrices ensure that the hypergraph captures its essential structure. Furthermore, in this procedure, we have implemented the utilization of GMM as an alternative to k-means for the purpose of assigning vehicles to clusters. The GMM is a probabilistic clustering method that represents the data distribution as a combination of Gaussian components. This approach enables the modeling of diverse cluster shapes and the accommodation of different cluster densities. In this context, k is employed to initiate the clustering process. After the optimal number of cluster is formed, the mTTM clustering is initialized.

4.1.2 mTTM clustering

Spectral clustering involves projecting the data into a lower-dimensional space using the eigenvectors of a matrix. Spectral clustering is a popular unsupervised clustering method used in a variety of fields, including VANETs. In this study, firstly, by traversing the hypergraph that the spectral clustering matrix was based on, a diagonal matrix is generated, it is denoted by *Dig*, the arithmetic sum of which runs over all the vehicle nodes that are next to the node *vi* [22].

$$Dig_{ij} = \sum_{j=1}^{N} Q_{ij} \tag{4}$$

The next step is to calculate the Laplacian matrix L, here the modularity matrix Q is introduced it is given as in Eq. 5.

$$L = Dig^{-1/2} Q Dig^{-1/2} \tag{5}$$

This defines the reminiscent of the clusters that emerge in the simulated road system. To obtain the best cluster configuration for VANET upkeep, these divisions are punned considerably as per the Fig. 3. The modularization of spectral grouping for hyper graphic vehicles is presented in Algorithm 1.

Algorithm 1 Hypergraph based modified TTM clustering with modularity approach

Input: Slot with maximum vehicles: $Vehi_{max}$, Location of each vehicle

1. Select the time slot t when maximum vehicles are present ($Vehi_{max}$)
2. Form a hypergraph $H = (E,V, w)$
3. Calculate the similarity/adjacency matrix based on the distance proximity between the vehicles
4. Calculate the Modularity matrix using Equation 3.1
5. Calculate a diagonal matrix Dig using Equation 4.2
6. Calculate the Laplacian matrix L using Equation 4.3
7. Finding the optimal number of clusters k using Equation 4.1 [23].
8. **For** $i = 1{:}k$:
   a. Cluster assignment for each row is computed using GMM model using $p(x) = \sum_{i=1}^{k} \delta_i N(\mu_i,\Sigma_i)$ where k is number of clusters, δ_i is the probability for point to be in cluster i. $N(\mu_i,\Sigma_i)$ is the normal distribution of mean μ_i and covariance matrix Σ_i. [16].
   b. The clusters $C = \{C_1,C_2,\ldots,C_k,\}$ are generated
9. End For

Output: Cluster Generation $C = \{C_1,C_2,\ldots,C_k,\}$

4.2 Incentivized stable CH selection parameters

In this study, an incentive-based CH selection mechanism is introduced tailored for vehicular networks. A key aspect of this selection is the incorporation of dynamic behaviour of driver's estimation based on the concept of incentive process. Nodes (Vehicles) are assessed for their dynamic behaviour within the cluster, distinguishing between usual and unusual patterns of velocity. The reward mechanism is designed to acknowledge and favour nodes exhibiting usual behaviours, or patterns thereby increasing their likelihood of being elected as CH as elaborated in Fig. 4.

To achieve this, in this study, vehicles initiate the CH selection process by calculating the metrics, Adaptive Neighborhood Degree, Adaptive Link Lifetime (Adaptive-LLT), and Adaptive Relative Average Speed as explained in Fig. 4. The main focus is adopting the concept of dynamic driving patterns and behaviour profiling within vehicular clusters as seen in [20], providing insights into the intricate dynamics and potential driving style switches across different contexts. The authors discuss that high variance in the velocity indicates an aggressive driving style resulting in unusual behaviour and these vehicles will disrupt the communication in clusters making it unreliable. The selection algorithm prioritizes vehicles for CH election based on their Adaptive Relative Average Speed within the cluster and is incentivized.

4.2.1 ANB-I based process for CH selection

To encourage the selection of stable CH, in this study a unique incentivization process incorporating a reward and penalty mechanism based on the dynamic behavior of vehicles termed as ANB-I CH selection parameters. This dynamic behaviour of vehicles aims to align the metrics of neighborhood degree (Adaptive-Nd), Adaptive Relative Average Speed (ADAPTIVE-RAS) and Adaptive-LLT characteristics of vehicles, ensuring a stable and reliable CH.

These metrics ($CH_{metrics\,i}$ for (i = 1 to 3)) are subjected to the relativity and incentive process through the conditions,

$$Adjus_{CH\,metrics\,i} = \begin{cases} Ini_{CH\,metrics\,i} + \delta, (if\ \ diff \leq Thr) \\ Ini_{CH\,metrics\,i} - \delta, (if\ \ diff > Thr) \end{cases} \quad (6)$$

where $\text{Adjus}_{\text{CH}_{\text{metricsi}}}$ is the adjusted CH metric i, $Ini_{CH\,metrics\,i}$ is the initial value of the metric i, δ is the small constant and Thr is threshold value subjected to the difference between the expected and average value of the metric ($diff$). Based on this, the vehicles in clusters at time stamp (t) are rewarded with an incentive or penalized. Adaptive-Nd is defined as the number of corresponding real neighbors of a vehicle whose speed differences are lower than a certain threshold (thr). The RSA of a vehicle is modeled as a random variable following a normal distribution with mean and variance. Similarly, the speed difference as well, so, to determine the threshold is subjected to a dynamic parameter based in standard deviation. It is given as, $Thr = b\sigma$. The description of the metrics for CH selection is given as,

a. Adaptive-RAS: To promote non-aggressive driving and stable speed among the vehicles, an incentivization mechanism for adaptive-RAS is introduced [17]. This process ensures that the vehicles maintain a position close to the average and are rewarded with a chance to be a potential CH. Here, the current speed of the vehicle (X_v) and the average speed of vehicles (X_{avg}) are calculated at the time interval t Whereas in this case, $diff = X_v - X_{avg}$ is subjected in Eq. 3. where the constant is initially set as 0.01 with Adaptive-RAS as 1. This Adaptive mechanism maintains the speed over varying vehicle density compared relative speed. This is shown in Fig. 5.

Compared to the old relative speed parameter for the varying vehicle density the Adaptive-RAS shows less

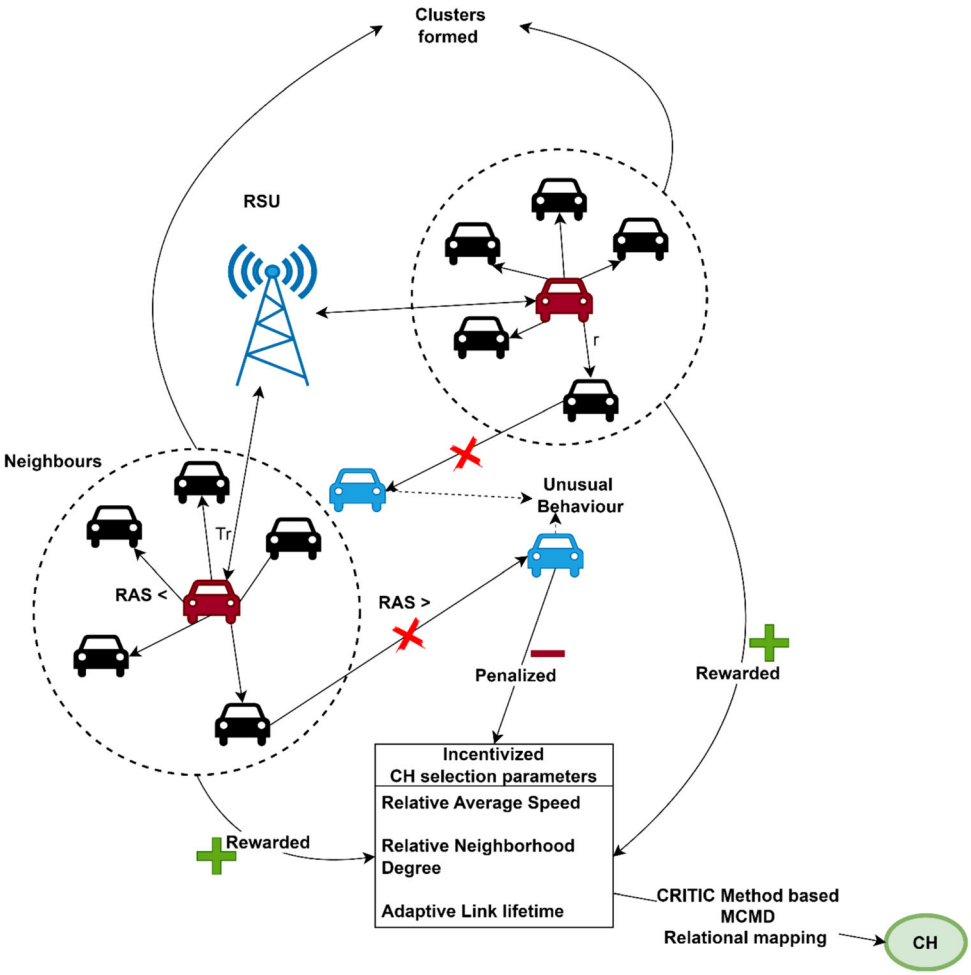

Fig. 4 Incentivized CH selection process

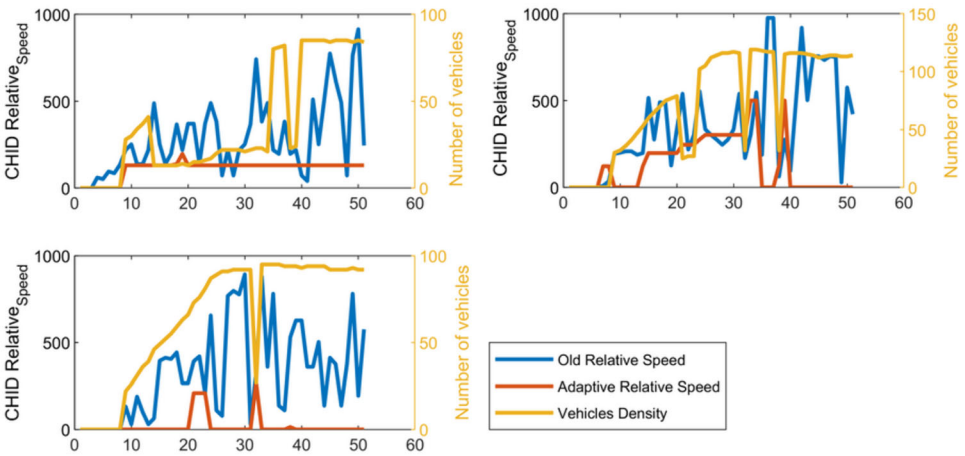

Fig. 5 Evaluation of the proposed incentivized Adaptive-RAS parameter

variation. In the broader context of the driving behavior, where high variance in velocity is associated with aggressive driving styles and potential disruptions in communication within clusters [20], the proposed Adaptive-RAS shows consistency over varying vehicle density contributing towards a stable and reliable selection of CH.

a. Adaptive Nd: During the initial clustering, the vehicles determine the neighbours within the transmission range and the Adaptive-Nd. However, to determine a reliable neighbour, the vehicles showing lower speed variance than the threshold (*Thr*) are rewarded (Eq. 3) and counted as a real neighbour of the vehicle for the given timestamp (t).

$$\begin{cases} RNd(t+1) = RNd(t) + \delta \times 1, \ \ if \ \ diff < thr \\ else, 0 \end{cases} \tag{7}$$

where the neighborhood degree is updated based on the reward mechanism through Eq. 5 and subjected to relativity from Eq. 3, promoting the consideration of vehicles with lower speed variance as reliable neighbors in the clustering process. The proposed method is also evaluated for old Nd and Adaptive-Nd in Fig. 6.

The stability of a CH is contingent on the stability and reliability of its constituent CM. In the CH selection process, the algorithm prioritizes vehicles for CH election based on their relative average speed within the cluster and is incentivized. By incorporating Adaptive-Nd, which rewards vehicles with less speed variance, the selection mechanism further emphasizes the importance of stability and reliability in the chosen CH. This is evident through the simulation results in Fig. 6, that there is less variance with the parameter over the varying vehicles density. This means a consistent and reliable set of neighboring vehicles for each node (vehicle) within the cluster is formed.

b. Adaptive LLT: It ensures a longer duration of link among the vehicles. Consider the vehicles A at position a_i and a_j with speeds v_i and v_j then to sustain communication link it must follow the condition, $-Tr \leq a_i - a_j \leq Tr$ (Tr is communication range). Hence, the LLT_{ij} is given as the ratio of differences in velocities ($D_v = v_i - v_j$) and difference in spatial coordinates ($D_a = a_i - a_j$). In this study, the Adaptive-LLT is given as,

$$\sqrt{(D_a)^2 + (D_v)^2} \cdot \sqrt{(D_v)^2 + \delta} + \frac{Tr}{D_v} \tag{8}$$

The average link lifetime and the individual link lifetime is calculated for the vehicles and the adjustment of the threshold, a small constant δ is added to the standard deviation $\delta\sigma$ to avoid high variation in the number of neighbours as subjected to Eq. 3. If the relative speed is zero, indicating no explicit information, a predefined speed of 40 is considered. This value is based on the predefined speed in the absence of specific relative speed data. The introduction of a constant allows the Adaptive link lifetime metric to handle scenarios with zero relative speed. This adaptive nature in the proposed model is simulated and the evaluation is shown in Fig. 7. It indicates that vehicles within the cluster are maintaining relatively stable links over time without significant fluctuations. Hence, less variation in these metrics aligns with the goal of stability, making vehicles with such characteristics more likely to receive incentives and be elected as CH.

After these metrics are calculated the output is stored as a matrix Y, $Y = [Adaptive - RAS, Adaptive - LLT, Adaptive - Nd]$. K-means is employed with one cluster and the data point in Y, closest to centroid is selected. Then the critic weights are calculated for selection of stable and reliable CH.

4.3 MCMD decision-making process

The weighted approach for the MCMD (Multi-Criteria Decision-Making) method involves assigning weights to the metrics and combining them to make a decision [30]. In this study, metrics stored in Y are normalized and the Pearson correlation is calculated among the normalized metrics. The amount of variation of metrics (σ) is computed for the metrics as well. Further, for each metric in Y, a conflict measure r is calculated by summing the complement of the correlation coefficients. This measure captures the conflict between the jth process indicator and other process indicators. Mathematically, the weights w_i for each of the metric $CH_{metrici}$ in Y is given as,

$$w_i = \frac{\sigma_{CH_{metrici}} \times r_{CH_{metrici}}}{\sum_{j=1}^{n} \sigma_j \times r_j} \tag{9}$$

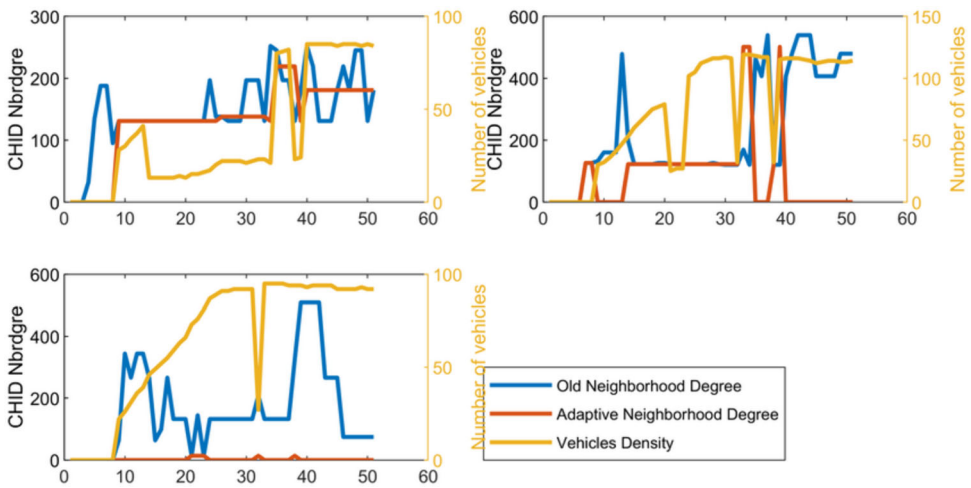

Fig. 6 Evaluation of the proposed incentivized Adaptive-Nd parameter

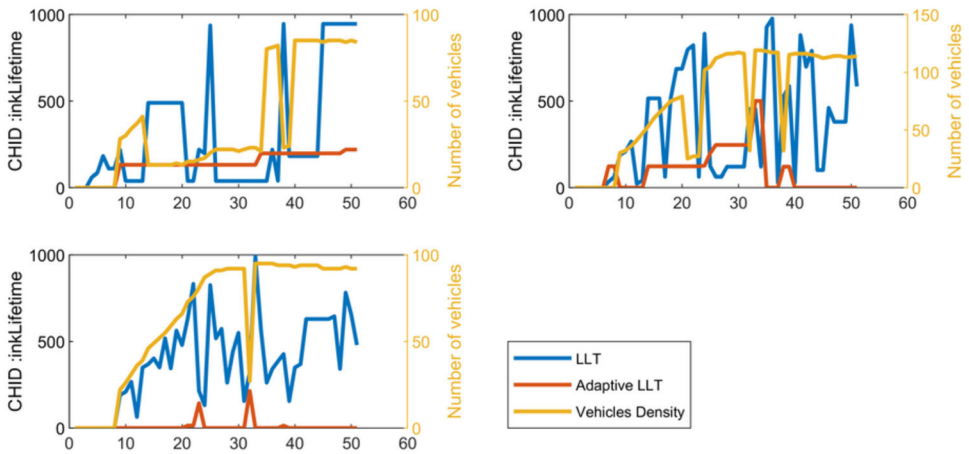

Fig. 7 Evaluation of the proposed incentivized Adaptive-LLT parameter

The final decision is made by considering the sum of metrics with weights multiplied and is given as,

$$W(V_{ID}) = \sum_{i=1}^{CH_{metric\,i}} w_i \times Norm(V_{ID_i}) \tag{10}$$

where, $Norm(V_{ID_i})$ is the normalized value of metric i for the vehicle (V_{ID}). The vehicle with highest weighted sum is considered as CH. It is given as,

$$CH = Max(W(V_{ID})) \tag{11}$$

In this study, weighted approach aims to give more influence to metrics that are both diverse (higher standard deviation) and less correlated with others (higher conflict measure). This aims for a balanced consideration of multiple metrics in the CH selection process. This proposed ANB-I based CH stability improvement model shows consistency over varying vehicle density compared to the individual metrics as seen in Fig. 8. As the process introduces an incentive mechanism that rewards or penalizes vehicles based on their adherence to desirable behavior patterns. By incentivizing vehicles exhibiting usual and stable behaviors, the proposed process encourages the selection of CHs that contribute to a stable and reliable vehicular cluster. This relativity adjustment formulated in Eq. 6, ensures that the CH selection parameters align with real-time behavior, addressing the challenges posed by diverse and dynamic driving patterns observed in different scenarios. Unlike traditional CH metrics that focus on the single aspect of CH metrics, the weighted approach ensures a balanced consideration of diverse metrics, giving more influence to those that are both diverse (higher σ) and less correlated with others (higher r). This leads to a more consistent and balanced decision-making process.

Hence, based on the proposed methodology the simulation is conducted on two varying densities of vehicles 100 and 1000. The discussions and results are given in next Section.

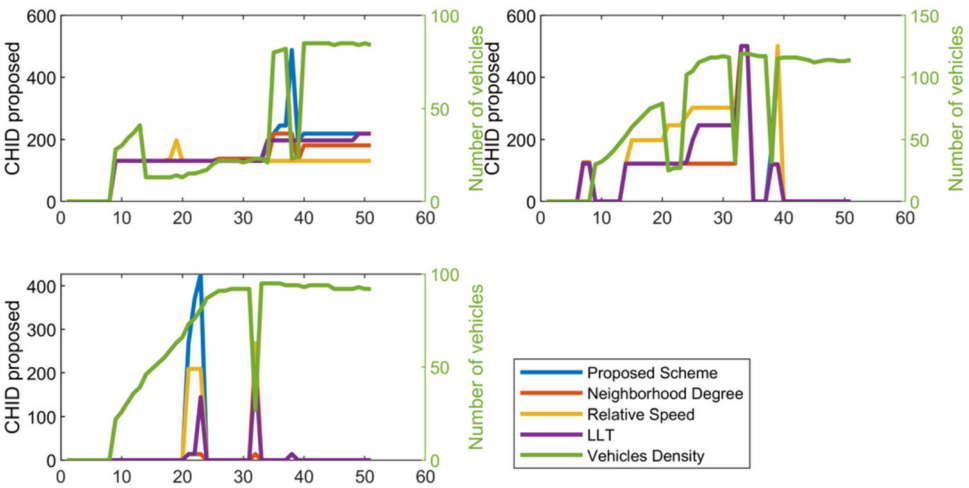

Fig. 8 Evaluation of the proposed incentivized ANB-I model compared to individual metrics

5 Experiments and results

5.1 Simulation parameters

In this Section elaborates the background of the tools employed in this study. The results discussion is considered based on the 2 parts: 1. Network performance (Thr, PD) of the proposed model: this includes the discussion in correlation with CH stability and comparison with state-of-art models. 2. CH stability analysis: this includes the results over packet delay, total distance, throughput and CM frequency over varying vehicle densities.

5.1.1 Tools

The simulation of the proposed model is carried out using the MATLAB (R2023b), SUMO. The complete network model is designed and performance is evaluated through metrics like the throughput and Packet Delay in MATLAB. For the study, the area considered is at 28°39′39″N and 77°13′48″E location in Delhi. SUMO uses Openstreetmap roadways, which have 293 lanes and an average vehicle speed of 10.53 m/s and a maximum speed of 25 m/s, to simulate the traffic conditions at Cannaught Place, Delhi. Delhi Capital of India is a city with huge traffic and is appropriate for an urban setting. The SUMO models traffic flow by utilizing the XML collection of roads and intersections from Openstreet map. The SUMO map of the city considered in this study is shown in Fig. 9.

Three Optimal numbers of clusters are suggested through the proposed Clustering algorithm as seen in Algorithm 1, the clusters in the city are generated and the CH metrics in the matrix Y are recorded for varying vehicle density, i.e., 100 and 1000 vehicles. Through the proposed model 3 clusters were formed and Fig. 10 shows it. Three different colors indicate the clusters and the triangles represent the RSU placed. The simulation parameters used in this study is given by Table 1.

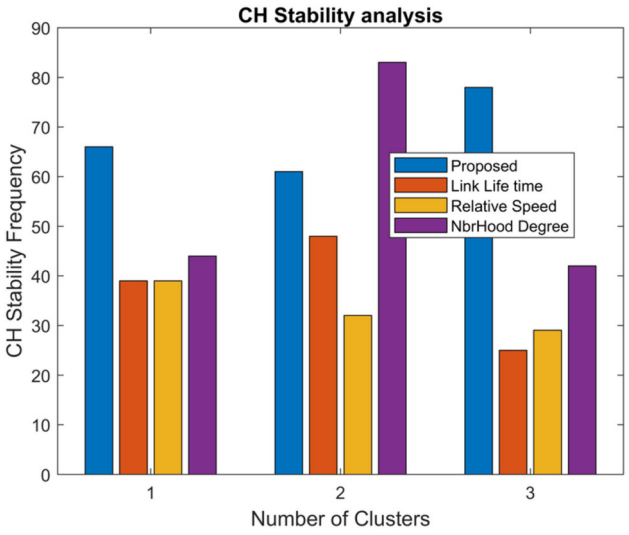

Fig. 10 Cluster-wise evaluation of CH stability for 100 vehicles: Proposed model over individual incentivized CH selection metrics

The communication between cars is achieved through the use of OFDM modulation and the Rayleigh fading channel. The inclusion of the Doppler Effect was necessary to explain the phenomenon of signal degradation resulting from the velocity of a vehicle. The network parameters are obtained from reference [29]. The wireless standard utilized in this study is IEEE 802.11p and the related parameters are noted in Table 2. The standard provides the basis for exchanging data between moving vehicles, mobile nodes, and base stations. Channels with a bandwidth of 10 MHz can be found within the frequency range of 5.9 GHz (specifically, between 5.850 GHz and 5.925 GHz). Due to this progress, receivers will have improved capabilities to handle signal echoes that bounce

off other vehicles or buildings in vehicular communication scenarios.

Message dissemination: The process begins with the generation of random bits representing the data to be transferred between vehicles at a rate of 14 Mbps. These bits undergo subcarrier modulation and FFT analysis using 32 FFT points, preparing them for transmission. A Doppler shift is then applied to account for frequency variations due to relative vehicle velocities. Binary Phase Shift Keying (QPSK) modulation is employed to encode the signal onto the subcarriers. Subsequently, white channel noise and Rayleigh channel noise are added to simulate real-world channel conditions. This comprehensive mechanism ensures the effective encoding, modulation, and transmission of data between vehicles within the VANET, considering the specified network parameters and channel characteristics.Top of Form.

5.2 Evaluation parameters

Compared to clustering in MANET where energy and processing power are the main concerns, in case of VANETs its abundant. But, due to high mobility in VANET cluster stability and CH stability are aimed to be improved by many studies. Thus, most of the studies aim to evaluate the clustering stability by considering optimal clusters and improving the network parameters. In most of the studies, cluster stability is defined and evaluated based on CH stability, cluster member frequency, number of clusters and network parameters, but not limited to these. CH stability is evaluated over frequency of change in CM, total distance and Network parameters in this study. When the frequency of CM in clusters increases, the proposed clustering algorithm should be able to maintain the CH stability as well [15]. Hence, in this study, the proposed model is evaluated for the improvement in CH stability over the number of optimal number of clusters formed and proposed ANB-I CH selection parameters process. Moreover, the stability of the proposed model is evaluated through metrics: Throughput and packet delay. The details of the metrics are as follows:

Throughput (Thr) and Packet Delay (PD): At t, the successful transfer of packets from source to destination vehicles is termed as throughput and it is measured in kbs/s. Whereas, when the packets don't arrive on time due to hop travel distance, noise and network congestion, PD occurs.

5.3 Results and discussion

The proposed model for clustering Hypergraph based Modified TTM is analyzed on the Delhi's map under varying vehicle density that is with 100 and 1000 vehicles. When compared to the rural areas with less traffic, metrics in Y carries less significance compared to urban cities like Delhi. Therefore, enabling the priority to consider stable and CH with less variance in speed is necessary. This study also evaluates the obtained results over the proposed Incentivized CH selection process ANB-I.

The proposed model, outlined in the detailed framework and illustrated in Fig. 3, employs a combination of Modified Spectral Clustering and Stable and Secure CH selection for vehicular networks. The model addresses challenges associated with CH stability, frequency of CM, packet delay, and throughput. CH stability Analysis.

5.3.1 Analysis for 100 vehicles

In this study, the clustering algorithm is applied and CH are obtained through Algorithm 2. To evaluate the performance of the proposed model for frequency change in CH stability when the total distance between the vehicles, Throughput, Packet Delay and Change in CM frequency. This is because the proposed clustering algorithm is able to organize the vehicles into optimal clusters with reduced proximal distance. Hence, from the analysis it can be seen that the proposed model is able reduce the CM frequency, packet delay and improve the throughput of network by maintaining the CH stability.

The proposed model introduces an incentive-based CH selection mechanism (ANB-I). The CH stability analysis for 100 vehicles is analyzed cluster-wise over the proposed model verses the individual CH metrics as seen in Fig. 10. It

helps determine if nodes exhibiting desired behaviors are being prioritized as CHs and the incentive process contributes to CH stability. In the optimal cluster 3, the proposed model shows highest CH stability compared to induvial metrics. Whereas, the Relative speed metric shows lower CH stability over 3 clusters and neighborhood degree when applied with relativity process as explained in Eq. 3 shows high CH stability in the cluster 2. The dynamic nature of the relativity process, with the threshold calculated based on the cluster's standard deviation, allows for adaptability to different clusters with varying dynamics. This adaptability enhances the model's robustness and effectiveness in achieving CH stability across diverse scenarios despite the MCMD process applied for mapping the multiple metrics.

5.3.2 Analysis for 1000 vehicles

Lower packet delay signifies improved communication efficiency and faster data transmission between vehicles. The observed outcomes align with the objectives of the proposed model, demonstrating its scalability and adaptability to larger vehicular networks. Moreover, the concurrent improvements in packet delay and CH stability underline its positive impact on network performance. The proposed model shows promising results compared to individual metrics in high vehicle density over cluster 1 as well as 2. This is seen in results obtained from Fig. 11 when the proposed model is analyzed for 1000 vehicles. It is crucial to consider that the proposed model introduces an incentive-based mechanism, prioritizing nodes with usual behaviors and this is why in cluster 3, proposed Adaptive-Nd shows high CH stability compared to the proposed model. Despite the observed discrepancy in cluster 3, the proposed model's emphasis on incentivized stable CH selection remains beneficial for vehicular networks. Hence, the incentive and penalty mechanism align with the study's focus on distinguishing between usual and unusual driving patterns, promoting the election of stable CHs.

Despite a slight discrepancy in cluster 3 for 1000 vehicles, as shown in Fig. 11, the incentive-based CH selection mechanism contributes to overall CH stability. The proposed ANB-I mechanism, prioritizing nodes with desired behaviors, aligns with the model's focus on stable CH selection. The initial evaluation with 100 vehicles demonstrates the proposed model's capability to effectively manage, packet delay, and CH stability. The clustering algorithm, outlined in Algorithm 4.2, plays a pivotal role in organizing vehicles into optimal clusters, mitigating network congestion, and reducing proximal distances. The adaptive nature of the proposed clustering algorithm is highlighted, allowing for efficient organization even with increased vehicle density (1000 vehicles).

5.3.3 Network parameters evaluation

After the CH stability analysis, the proposed model is evaluated for throughput and packet delay for varying vehicle densities 100 and 1000. When 100 vehicles are subjected for simulation on the proposed model, 3 optimal number of clusters are obtained with varying characteristics. The throughput of the proposed model over 2 and 3 cluster is maintained high compared to the individual metrics employed to the simulation as seen in Fig. 12. However, the Adaptive link lifetime adopted in the simulation shows high throughput in cluster 1.

Despite a slight discrepancy in cluster 3 for 1000 vehicles, as shown in Fig. 11, the incentive-based CH selection mechanism contributes to overall CH stability. The

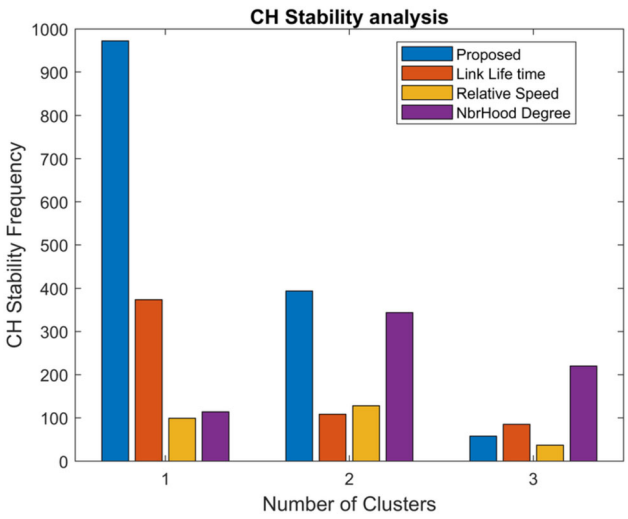

Fig. 11 Cluster-wise evaluation of CH stability for 1000 vehicles: Proposed model over individual incentivized CH selection metrics

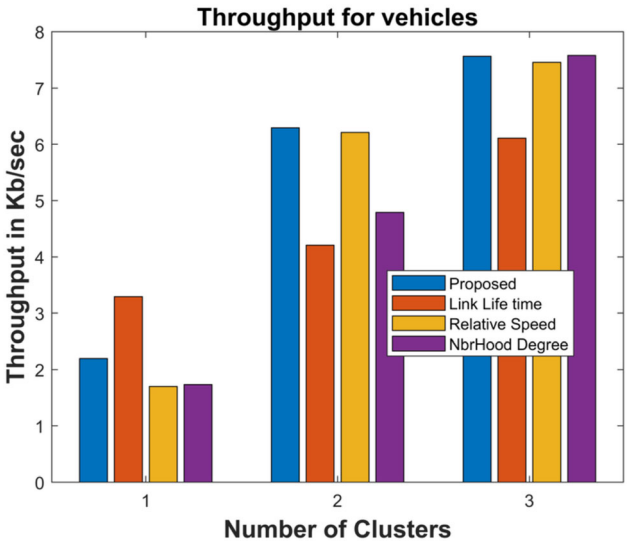

Fig. 12 Cluster-wise evaluation of throughput for 100 vehicles

proposed ANB-I mechanism, prioritizing nodes with desired behaviors, aligns with the model's focus on stable CH selection. The initial evaluation with 100 vehicles demonstrates the proposed model's capability to effectively manage, packet delay, and CH stability. The clustering algorithm, outlined in Algorithm 4.2, plays a pivotal role in organizing vehicles into optimal clusters, mitigating network congestion, and reducing proximal distances. The adaptive nature of the proposed clustering algorithm is highlighted, allowing for efficient organization even with increased vehicle density (1000 vehicles).

5.3.4 Network parameters evaluation

After the CH stability analysis, the proposed model is evaluated for throughput and packet delay for varying vehicle densities 100 and 1000. When 100 vehicles are subjected for simulation on the proposed model, 3 optimal number of clusters are obtained with varying characteristics. The throughput of the proposed model over 2 and 3 cluster is maintained high compared to the individual metrics employed to the simulation as seen in Fig. 12. However, the Adaptive link lifetime adopted in the simulation shows high throughput in cluster 1.

The proposed model's emphasis on incentivized CH selection (ANB-I) introduces a dynamic aspect to cluster formation. The reward and penalty mechanism, based on the dynamic behavior of vehicles, aims to align metrics for stable CH selection as seen in the above discussions in Sect. 5.3.1. This process interacts differently with the CH metrics in clusters, leading to the observed variation in throughput. Whereas, in the case where 1000 vehicles are simulated seen in Fig. 12, shows that the proposed model shows high throughput in all the three cases. This indicates that, at higher vehicle densities, the incentivized CH selection process contributes consistently to throughput enhancement. The dynamic interaction between the reward and penalty mechanism and CH metrics proves effective in diverse scenarios, showcasing the model's potential for enhanced communication stability and efficiency.

It is crucial to have real-time communication in vehicle networks, particularly for safety applications. Timely delivery of vital safety information, such collision alerts, is guaranteed via low packet delay. Congestion and communication issues are more likely to arise when the number of vehicles on the road increases. To determine how well the suggested model scalable to bigger vehicular networks, packet latency and throughput under different densities shows the capability of the proposed clustering and CH selection method.

In case of 100 vehicles for simulation seen in Fig. 13, the proposed model shows low packet delay and Adaptive LLT metric shows highest PD even though high throughput is seen in the Fig. 12. whereas, in the case of 1000 vehicles as seen in Fig. 14, the proposed model shows low packet delay in all the three clusters. In contrast to the variation observed in Fig. 13, the proposed model consistently maintains low packet delay across all three clusters when simulating 1000 vehicles (Fig. 15).

The proposed clustering model, anchored in Hypergraph Modified TTM and featuring an incentivized CH selection mechanism (ANB-I), undergoes a meticulous examination across various vehicular network scenarios, providing valuable insights into its efficacy. In a scenario involving 100 vehicles, the model demonstrates commendable performance in mitigating network congestion, reducing CM frequency, and enhancing CH stability. The clustering algorithm efficiently organizes vehicles into optimal clusters, minimizing proximal distances and fostering improved throughput. A nuanced examination of individual CH metrics reveals dynamic adaptability across clusters, particularly showcased in the cluster-wise analysis (Fig. 10). The incentive-based CH selection process, as seen in Fig. 11, contributes substantially to CH stability, prioritizing vehicles.

The incentivized CH selection process introduces a dynamic aspect to CH selection, leading to varied throughput and PD characteristics over the clusters as well during low mobility simulation (100 vehicles). In contrast, the simulation involving 1000 vehicles (Fig. 14) illustrates the contribution of the incentivized CH selection process to high throughput across all clusters over high mobility. The interplay between the reward and penalty mechanism and CH metrics proves effective, underscoring the model's potential for enhanced communication stability and efficiency. For 100 vehicles (Fig. 13), the model exhibits low packet delay and high throughput, suggesting effective

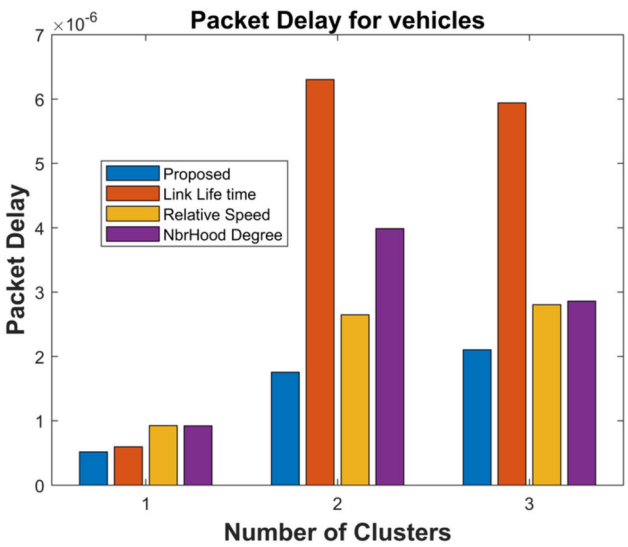

Fig. 13 Cluster-wise evaluation of packet delay for 100 vehicles

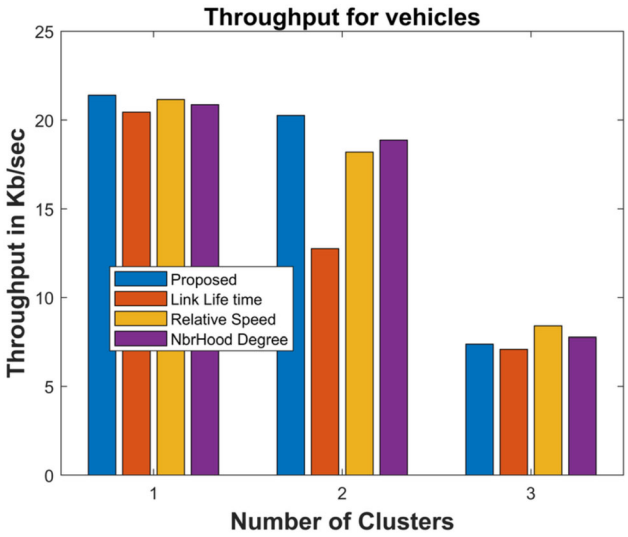

Fig. 14 Cluster-wise evaluation of throughput for 1000 vehicles

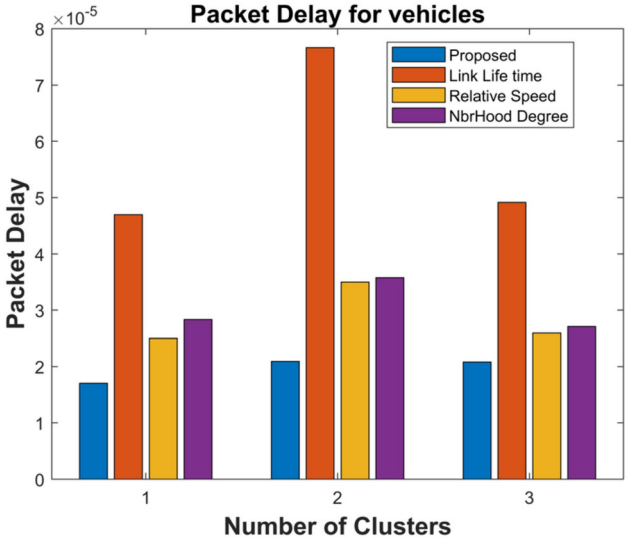

Fig. 15 Cluster-wise evaluation of throughput for 1000 vehicle

communication stability. Notably, the Adaptive Link Lifetime (Adaptive LLT) metric, while contributing to high throughput, introduces higher packet delays in Cluster 1, highlighting that there is a trade-off and optimized network performance for varying vehicle density. However, in the 1000-vehicle scenario (Fig. 14), the proposed model consistently maintains low packet delay across all clusters, showcasing its scalability and efficiency. The proposed model's adaptability to diverse clusters, effective incentivized CH selection, and robust performance in high-density scenarios position it as a promising solution for real-world vehicular communication challenges.

5.3.5 State-of-the art comparison

In this Section, the proposed model is compared with the state of art methods in the same field in terms of CH stability and Network performance. The studies [15, 23, 31] are considered for comparison analysis based on CH stability.

The proposed scheme in [15] shows a key contributions and novelties include the use of hypergraph-based spectral clustering, the incorporation of multiple criteria for CH selection, and the integration of deep learning spectrum sensing for trust calculation. Clustering method in [15] share the concept of hypergraph as in present study. However, the number clusters seem to varying for the vehicle density in [15], compared to the present study. Similarly, [23], introduces CVoEG model divides VANET nodes into an optimal number of clusters using the Eigen gap heuristic. Within each cluster, a vehicle is selected as a CH based on its maximum Eigen-centrality score. The key innovation in [23], is the use of link reliability as a criterion for both CMs and CHs selection.

Vehicular communication is highlighted as an essential component of a smart city. However, scalability remains a major challenge in VANETs, where the dynamic and high-speed movement of vehicles complicates communication and clustering. The proposed JCV algorithm in [23], aims to overcome stability issues by incorporating intelligent and dynamic use of mobility parameters.

These parameters include transmission range, moving direction at the next junction, and vehicle density. This analysis reveals that the proposed model exhibits a 4.17% improvement in CH stability compared to HGCM. It is important to note that while the proposed model achieves a higher CH stability than HGCM, the number of clusters is significantly lower as seen in Table 3.

However, when compared to JCV and CVoEG, the proposed model still maintains a competitive CH stability while requiring fewer clusters. The JCV achieves a slightly higher CH stability of 76% but with 16 clusters, and CVoEG, despite using 20 clusters, lags behind with 65.5% CH stability. This suggests that the hypergraph clustering and ANB-I based CH selection contribute 1.33% and 14.5% improvement compared to [23, 31] respectively, positively to the stability of VANET clusters, making the proposed model a noteworthy advancement in the field.

Next, the network parameters are compared to the proposed model in Table 4. VANETs often support real-time applications, such as traffic safety warnings, collision avoidance, and other time-sensitive communication. Low packet delay is critical for the effectiveness of these applications. This study also aims to ensure the proposed model shows improved QoS and Low delay ensures that

Table 3 State-of-art-comparison based on CH stability

Reference	Method used	CH stability (%)	Optimal number of clusters
Proposed model	Hypergraph clustering and ANB-I based CH selection	75	3
[15]	HGCM	72	4
[31]	JCV	76	16
[23]	CVoeG	65.5	20

Table 4 State-of-art-comparison based on network parameters

Reference	Method used	Packet delay (s)
Proposed model	Hypergraph clustering and ANB-I based CH selection	0.2071
[15]	HGCM	0.42
[32]	JCV	0.27
[23]	CVoeG	0.34

messages or data reach their destination promptly, contributing to a better user experience.

The proposed model, employing hypergraph clustering and an ANB-I (ANB-I) based CH selection mechanism, demonstrates notable superiority in terms of packet delay compared to existing models [15, 23, 32]. Hence, the proposed model shows 102. 84% better reduction in PD compared to [15] and 30.31, 64.171% of better reduction compared to [23, 32] respectively.

The incorporation of the ANB-I (ANB-I) mechanism for CH selection introduces a dynamic and incentive-driven approach. This accounts for real-time driving behavior, promoting the selection of stable CHs. Hence, the proposed model maintains competitive CH stability with fewer clusters compared to JCV and CVoEG. This indicates an effective balance between stability and scalability.

6 Conclusion

The proposed framework introduces a comprehensive solution for clustering and CH selection in VANETs. The model leverages hypergraph-based modified TTM clustering along with an innovative ANB-I approach for CH selection. The hypergraph-based modified TTM clustering algorithm efficiently organizes vehicles into optimal clusters. The algorithm considers the time slot with the maximum number of vehicles, forms a hypergraph, and calculates a similarity matrix based on distance proximity. The modularity matrix and Laplacian matrix are computed to identify the three optimal number of clusters. The study evaluates three main metrics (Adaptive Relative Average Speed, Adaptive Neighborhood Degree, and Adaptive Link Lifetime) for CH selection. These metrics contribute to stable CHs by promoting non-aggressive driving, rewarding vehicles with less speed variance, and ensuring longer link duration among vehicles. he proposed framework is evaluated through simulations using MATLAB and SUMO. The study considers two scenarios with 100 and 1000 vehicles, demonstrating the model's scalability. The results indicate improved CH stability, reduced packet delay, and enhanced throughput compared to individual metrics and state-of-the-art models. The future work of the paper focus on the integration of IoV and Investigate the application of edge computing, edge intelligence in IoV to process data closer to the source. This includes vehicle-to-vehicle (V2V) and vehicle-to-everything (V2X) communication.

Author contributions Ashish Kumari, Shailender Kumar, and Ram Shringar Raw contributed to the study conception and design. Ashish Kumari performed material preparation, data collection, and analysis. All authors reviewed the results and approved the final version of the manuscript.

Abstract
Textual data faces a significant challenge known as class imbalance. This challenge arises when the distribution of classes within a dataset is highly disproportionate. To address this problem, effective algorithms that can handle the imbalance in the data while maintaining high predictive accuracy are needed. To solve the class imbalance problem, numerous methods have been proposed, which include SMOTE (Synthetic Minority Over Sampling), ADASYN (Adaptive Synthetic Sampling), ensemble methods, etc. In this paper we propose the novel Synthetic Minority Over Sampling Technique Nominal Continuous-Generative Adversarial Network (SMOTE NC-GAN) Model to tackle the problem of imbalanced text datasets. This method provides a novel solution for addressing the class imbalance problem. It involves generating synthetic data from the minority class of dataset using SMOTE-NC and subsequently applying that data along with real data fed to the Generative Adversarial Network. By using a combination of SMOTE-NC and GAN techniques, our proposed method can generate synthetic samples that enhance the quality of minority classes in the text datasets. Our proposed model addresses the limitations of both GAN and SMOTE. Empirical findings on various benchmark datasets have demonstrated the superior performance of the SMOTE NC-GAN Model over different state-of-the-art methods. This model enhances sample quality and offers computational efficiency, making it a promising solution for handling imbalanced datasets across various domains. The classification performance is significantly improved when utilizing the SMOTE NC-GAN Model in comparison to the Synthetic Minority Oversampling Technique.

1 Introduction

With the rapid advancements in information and communication technology (ICT), there has been a significant rise in research areas. This progress has provided users with convenient and fast access to information. Consequently, there is an increase in the number of text documents, as the textual form of data is mostly used for storing information [1]. Analysis of data and prediction are commonly used in text classification. Numerous machine learning techniques, including K-Nearest Neighbour [2], Random Forest [3], Support Vector Machine [2], Ensemble classifiers [4], and Naive Baye's [5] are used in various applications of text categorization. Several challenges arise during text classification, and one of the major challenges is class imbalance. The term "class imbalance" denotes the unequal representation of classes in a dataset, i.e., the proportion of instances in one class being much higher than the other class. The issue of class imbalance poses challenges because many machine learning algorithms are designed under the assumption that classes are distributed uniformly within the dataset. However, in reality, this assumption is often violated due to imbalanced class distributions. The model's performance is greatly impacted by the existence of an unbalanced class distribution, which results in biased classification that favours the dominant class. When most samples are categorized as positive, this imbalance leads to low true negative and high true positive rates [6]. Data imbalance is a prevalent occurrence in various scenarios, such as Credit card fraud detection [6], Cyberbullying detection [7, 8] uncommon diseases [9, 10], and the prediction of natural disasters [11]. Cyberbullying datasets face data imbalance problems as the number of normal labeled classes is higher than abnormal labeled ones. In recent years [12], researchers have shifted their focus towards artificial general intelligence (AGI), a field striving to develop software capable of emulating human-like intelligence and possessing the ability to self-learn. AGI aims to empower software to perform tasks beyond its initial training. Progress in brain-inspired intelligence research is crucial for achieving higher intelligence levels, accuracy, robustness and energy efficiency surpassing existing AI systems. Several framework have been proposed for eg.HESFOL [13], MeMEE [14], SNIB [15], SIBoLS [16], HOSIB [17]. Various techniques have been developed to address the issue of imbalanced binary datasets [9]. However, researchers also encounter significant challenges in addressing data imbalances in multi-class datasets [18]. Extended algorithms, designed for binary algorithms, are often the existing solutions for multi-class imbalanced datasets. In multi-class datasets [19], ensemble-based classifiers and decision trees [20] have been shown to yield better results. The problem of class imbalance has received significant attention from researchers. Numerous studies have been conducted to address the problems caused by class inequality [21–24]. In text classification, there are various methods that exist to resolve the class imbalance problem. The classical Synthetic Minority Over-sampling Technique [25] is a widely acknowledged method for resolving class imbalance in text classification. It addresses imbalanced datasets by generating synthetic samples through interpolation between existing minority class samples, focusing only on continuous features. However, the main challenge with SMOTE [26] is how to calculate the distance between points when categorical features are present. The extension of SMOTE, known as SMOTE-NC [26], generates synthetic data for imbalanced datasets with both nominal (categorical) and continuous features. On the other hand, while the primary utilization of GANs (Generative Adversarial Networks) [27] is in generating synthetic images for image processing, GANs have not been extensively applied to small datasets in text processing, especially those representing minority classes. A large amount of data is required to train GAN effectively and only the GAN model can generate meaningful synthetic data. We introduced a novel model named SMOTE_NC-GAN

Model, which effectively tackles the class imbalance problem by integrating SMOTE-NC [26] and GAN [27]. This approach involves generating synthetic data from the minority class of the dataset using SMOTE-NC and subsequently applying that data along with real data to GAN. The performance of our proposed model is evaluated using accuracy, recall, F1-score, and the ROC curve. We performed a comparative analysis of our proposed model with other state-of-the-art models to assess its performance in text classification. The results indicated that our model outperformed the other methods, making it a promising and optimal solution for text classification tasks. The main contribution of this paper is summarized as follows: We proposed a novel approach that combines the GAN (Generative Adversarial Network) and SMOTE-NC techniques to generate synthetic data. Our proposed model offers improved performance and flexibility in handling diverse datasets. We perform the implementation and evaluation of SMOTE and SMOTE NC-GAN, on three imbalanced datasets: Credit Card Default, Adult Income, Cervical Cancer. The performance of the algorithms is compared using evaluation metrics.

The subsequent sections of the paper are structured as follows: State-of-the-art methods to resolve the class imbalance problem are discussed in Section 2. Section 3 presents a detailed description of our proposed method, the SMOTE NC-GAN Model. Section 4 presents the experimental results obtained from our proposed method with other existing methods and analyzes these results. The outcomes of the experiments and their implications are discussed in Section 5. Finally, we discuss the summary and conclusion of the proposed technique and potential areas for future work in Section 7.

2 Related work

In this section, we explored various existing techniques aimed at addressing the class imbalance problem [28]. The first subsection presents a detailed overview of the work related to the imbalance class.

2.1 Class imbalance techniques

The performance of classification algorithms is significantly affected by the Class Imbalance Problem (CIP) due to the introduction of a disproportionate number of instances from one class compared to others [29]. Approaches to address the CIP can be classified into algorithm level [30], data level techniques [31], cost-sensitive learning [30], and ensemble-level approaches [32]. All pre-processing techniques that are aimed at balancing the distribution of classes are categorized into data levels [33]. Sampling methods are used to address the four challenges of class imbalance and can be classified into two prime categories: one is undersampling, and the other one is the Oversampling method [34]. Under-sampling reduces the number of instances from the majority class to achieve a more balanced distribution. However, this approach has the drawback of potential loss of valuable information. Various undersampling techniques have been proposed in the research literature. These methods consist of Wilson's Edited Nearest Neighbor rule, One-Sided Selection [35], Tomek Links [36, 37] and Condensed Nearest Neighbor Rule [38]. These techniques aim to alleviate class imbalance by selectively removing instances from the majority class while preserving the essential characteristics of the minority class. They have gained significant attention and adoption within the research community as effective strategies for addressing class imbalance challenges. Heba Mamdouh Farghaly [39] proposed a model to solve the feature selection problem in

pattern recognition. A new method FS-FAI [40] proposed for the classification of text which is based on associated and frequent itemsets dataset. Esraa Hassan [41] uses the MCN-BERT and BiLSTM models to predict diseases automatically from symptoms. Tarek M Mahmoud [42] introduced an automatic classification system for web pages. In this paper accuracy is enhanced using the combination of K-NN and SVM and Naive Bayesian algorithm. Marwa Khairy [7] addresses the data imbalance problem in the Cyberbullying [43] dataset by examining the efficacy of four resampling techniques which include SMOTE-TOMEK, random oversampling, random undersampling and SMOTE. Marwa Khairy [8] evaluates the efficacy of various single and ensemble machine learning algorithms in detecting Arabic text containing offensive language and cyberbullying by introducing a novel balanced Arabic dataset [44–46] for offensive language detection. Ahmed Omar [47] introduced a multi-label Arabic dataset for multilabel classification tasks, sentiment analysis and short text classification through a combination of semi-supervised and manual annotation approach. Oversampling is a technique in which synthetic or duplicate instances of the minority class are generated to balance imbalanced datasets. However, one of the main risks associated with oversampling is overfitting, as it may create an excessive number of synthetic instances that can overly represent the minority class and lead to poor generalization on unseen data [48]. To address the risk of overfitting, SMOTE (Synthetic Minority Over-sampling Technique) was introduced [26]. To address the different aspects of class imbalance several variants of SMOTE have been developed. These variants include SMOTE [26], and K Means-SMOTE [49], Borderline-SMOTE [31]. G.Kovacs [50] has implemented a comprehensive set of 85 SMOTE variants in a Python library. However, SMOTE is the most popular oversampling to solve data imbalance problems but it also has some drawbacks. SMOTE focuses only on continuous features. However, when categorical features are present in the dataset, calculating distances between points becomes challenging. To address this challenge, an extension of SMOTE called SMOTE-NC (SMOTE for Nominal and Continuous features) has been proposed. SMOTE-NC incorporates a modified distance metric that can handle both continuous and categorical features [26]. Therefore SMOTE-NC is introduced which is an extension of SMOTE that generates synthetic data for imbalance datasets with both nominal (categorical) and continuous features. Similar to SMOTE, SMOTE-NC does have certain drawbacks. These include suboptimal performance when dealing with high-dimensional data [51], the potential to create overfitting and introduce noise into the dataset [51, 52], and the neglect of the local distribution of minority samples [51]. These drawbacks arise due to the interpolation techniques used, the lack of consideration for individual minority samples, and the uniform application of the parameter K neighbors across the entire dataset.

2.2 High dimensionality and class-imbalance

Many oversampling techniques are specifically designed for binary classification problems and assume that the feature space used for classification is low dimensional. However, high dimensional data is used in real-world datasets. High dimensional features in the presence of class imbalance can negatively impact classification performance, leading to inaccurate results [35]. Therefore in high-dimensional space, generating samples using traditional oversampling techniques may not be effective. This limitation highlights the need for the development of oversampling methods that can handle high-dimensional data and effectively tackle class imbalance issues in such scenarios. Blagus [53] conducted a study on high-dimensional class-imbalanced data and found that the Synthetic Minority Over-sampling Technique (SMOTE) is not effective in reducing the classification bias towards the majority

class for most classifiers. The author observed that SMOTE performs even less effectively than random undersampling. The study suggests that applying SMOTE will not effectively address the class imbalance issue in scenarios where the data is high-dimensional and imbalanced. These findings highlight the importance of exploring alternative approaches when dealing with high-dimensional class-imbalanced datasets rather than relying solely on SMOTE to address the class imbalance. This limitation of SMOTE motivates us to explore alternative approaches, such as Generative Adversarial Networks (GANs). Researchers have dedicated efforts to tackle these challenges and enhance the accuracy of classification results. Douzas [54] introduced a generative model called Conditional Generative Adversarial Network to address class imbalance in binary datasets. CGAN utilizes the class labels of imbalanced datasets as conditioning information and generates synthetic data for the minority class. The performance of CGAN was evaluated on various datasets with different characteristics and compared with different oversampling methods using multiple classifiers. The results demonstrated that CGAN outperformed other models in terms of classification performance. They focused on training a conditional GAN network incorporating minority and majority class samples. They aimed to capture the overall data distribution of the imbalanced dataset. In contrast, our approach specifically trained GAN networks using only minority samples. Previous research has shown that Generative Adversarial Networks (GANs) are highly effective in generating synthetic data that closely mimics real data distribution in various domains. GANs have been successfully employed in several applications, including object detection/recognition [55], super-resolution [56], and face aging [57]. GAN is the most popular deep learning model mainly used in the field of image analysis. Giovanni Mariani [58] employed a variant of GAN known as BAGAN (Balancing GAN) as a data augmentation technique to address class imbalance in imbalanced datasets. Their approach involved training GANs to generate synthetic images specifically for the minority class, achieving better convergence and generating high-quality synthetic images. They compared the performance of BEGAN [59] with another generative adversarial network called ACGAN (Auxiliary Classifier GAN) [60]. The results of their study demonstrated that BEGAN outperformed other generative adversarial networks in terms of restoring balance in the imbalanced datasets and improving overall classification performance. This work highlighted the challenges of mode collapse and convergence in GAN training [61, 62]. Berthelot et al. introduced Boundary Equilibrium GANs (BEGANs) [59]. BEGANs incorporated an equilibrium enforcement mechanism to stabilize GAN training and address convergence issues. Karras introduced Progressive GANs (PGANs) [63], implementing a progressive training technique to increase the quality of the sample generated.

3 Theoritical foundations

SMOTE is the most common technique to be used to resolve class imbalance problems. It struggles to create synthetic data that resemble the original data. As a result, researchers have turned to Generative Adversarial Networks (GANs) as an alternative for oversampling, as GANs have been shown to effectively generate synthetic data that closely resembles the original data [64]. Due to the limitations of existing techniques, such as SMOTE, in effectively addressing class imbalance in high-dimensional data, researchers need to explore and develop new approaches. These new approaches should focus on generating synthetic samples that can balance the skewed distribution of high-dimensional data. To overcome this limitation, we combine the Generative Adversarial Networks (GANs) and SMOTE-NC

for oversampling. GANs are effective in generating artificial data that closely resembles the original data distribution. Previous studies [55, 57, 64] have highlighted the potential of GANs in generating realistic synthetic data.

3.1 Generative adversarial network

Goodfellow [27] introduced Generative Adversarial Networks in 2014. It comprises of two-component generator(G) and discriminator(D). The input to the generator is the random noise and this noise is transformed to generate synthetic data. The training of the discriminator is done on real data and it acts as a binary classifier to distinguish between real and fake data. The main goal of the generator is to generate synthetic data that resembles the real data and also minimize the loss function, and the main objective of the discriminator is to find the difference between real data and fake data and to maximize that difference, i.e., loss function. The discriminator minimizes $D(G(z))$ and maximizes $D(x)$ to overall maximize the loss function in (1). The generator and discriminator engage in an adversarial game during the training process. This adversarial relationship between the two networks leads to optimizing both models. This competitive interplay between the discriminator and generator improves both networks over time.

Discriminator loss function is calculated as [27]:

$$L^{(D)} = \max[\log D(x) + log(1 - D(G(z)))] \tag{1}$$

Where D denotes the discriminator that classifies the real data (x) and synthetic data $(G(z))$. $D(x)$ represents the probability distribution obtained from real data (x), while $D(G(z))$ represents the probability distribution of the synthetic data (z). The discriminator aims to maximize $D(x)$ and minimize $D(G(z))$ to maximize the overall loss function given in (1). $D(x)$ and $D(G(z))$ are both probability values ranging between 0 and 1. The generator's aim is to deceive the discriminator by producing synthetic data that closely resembles real ones, which means the generator aims to produce $G(z)$ in a way that, when passed through the discriminator, it receives a classification of 1. The discriminator's goal is to assign a classification of 1 to $D(G(z))$, while the generator attempts to achieve a classification of 0 for $D(G(z))$.

The generator loss function is calculated as follows[38]:

$$L^{(G)} = \min[\log D(x) + log(1 - D(G(z)))] \tag{2}$$

The generator objective is to minimize the overall loss function given in (2) and to minimize the (2), the generator must maximize the $D(G(z))$, and the generator does not have access to the real data $D(x)$.

3.1.1 Combined loss function

Equations (1) and (2) are combined as

$$\min_G \max_D V(D, G) = [\log D(x) + \log(1 - D(G(z)))] \tag{3}$$

The discriminator aims to minimize $D(G(z))$, and the generator aims to maximize $D(G(z))$ given in (3). The validity of this loss function is limited to individual data points. However,

when considering the entire dataset and dealing with the minimization of the discriminator and maximization of the generator in a GAN, the expectation of the equation is computed as:

$$\min_G \max_D V(D,G) = \mathbb{E}_{x\sim p_{\text{data}}}[\log D(x)] + \mathbb{E}_{z\sim p_z(z)}[\log(1 - D(G(z)))] \tag{4}$$

where $P_{\text{data}}(x)$ represents the distribution of real data that matches the data generated by the generator G, i.e., $P_G(x)$. Rather than explicitly assigning probabilities to individual data points, GANs learn to transform a noise variable z drawn from a noise distribution $P_{\text{noise}}(z)$ into a sample $G(z)$ from the generator distribution P_G.

3.2 Proposed SMOTE_NC-GAN model

We introduced a novel model named SMOTE_NC-GAN Model, which effectively tackles the class imbalance problem by integrating SMOTE-NC and GAN. This approach involves generating synthetic data from the minority class of the dataset using SMOTE-NC. This is achieved by considering the local neighborhood of each minority sample and creating new samples that possess similar feature values within that neighborhood. The aim is to augment the minority class so that the dataset gets balanced. The resulting dataset now consists of synthetic samples from SMOTE-NC. The newly generated synthetic data, along with the real data, are fed into the discriminator. The discriminator's main aim is to find the difference between synthetically generated data and real data. The discriminator takes input from SMOTE-NC and GAN. Training the discriminator with a mixed dataset of real and synthetic samples improves its ability to identify and classify the two types of data accurately. Between the discriminator and the generator, there is the feedback loop, which is responsible for producing synthetic samples and encourages the generator to generate more realistic and representative synthetic samples. The discriminator enhances its capability to identify real and fake samples through this adversarial process. The addition of synthetic data to the minority class data makes the minority class equivalent to the majority class, which reduces the model's bias towards the majority class and improves the model's generalization capability, leading to more reliable and robust results.

Our proposed model loss function for the discriminator is calculated as:

$$L^{(D)} = \max[\log D(x) + \log(1 - D(G(z))) + \log(1 - D(S(y)))] \tag{5}$$

where D(x) represents the output of the discriminator when given real data x. The value D(x) is the discriminator's prediction of the probability that the real data is real. The generator takes random input z and produces synthetic data using a mapping function G. G(z) is the generator's output when given noise z and D(G(z)) represents the output of the discriminator when given synthetic data generated by the generator. The value D(G(z)) is the discriminator's prediction of the probability that the synthetic data is real, and S(y) represents the synthetic generated data y from SMOTE-NC. D(S(y)) represents the output of the discriminator when given the generated synthetic data from Smote_NC. The value D(S(y)) is the discriminator's prediction of the probability that the generated synthetic data is real. The discriminator aims to maximize $D(x)$ and minimize $D(G(z))$ and $D(S(y))$ to maximize the overall loss function given in (5). $D(x)$ and $D(G(z))$ and $D(S(y))$ probability values ranging between 0 and 1. The generator loss function is calculated as follows:

$$L^{(G)} = \min[\log D(x) + \log(1 - D(G(z))) + \log(1 - D(S(y)))] \tag{6}$$

The generator aims to minimize the overall loss function given in (6) and to minimize the (6), the generator must maximize the $D(G(z))$ and $D(S(y)$. The generator does not have access to the real data $D(x)$.

3.2.1 Proposed GAN loss function

Equations (5) and (6) are combined as:

$$\min_G \max_D L(D, G) = \left[\log(D(x)) + \log(1 - D(G(z))) + \log(1 - D(S(y)))\right] \tag{7}$$

The discriminator aims to minimize $D(G(z))$, and the generator aims to maximize $D(G(z))$ and $D(S(y))$. This implies that the discriminator's parameters (represented by D) are optimized to maximize the loss function, while the generator's parameters (represented by G) are optimized to minimize the loss function given in (7). The validity of this loss function is limited to individual data points. However, when considering the entire dataset and dealing with the minimization of the discriminator and maximization of the generator in a GAN, the expectation of the equation is computed as:

$$\begin{aligned}\min_G \max_D V(D, G) = \mathbb{E}_{x\sim p_{\text{data}}}[\log D(x)] + \mathbb{E}_{z\sim p_z(z)}[\log(1 - D(G(z)))] \\ + \mathbb{E}_{z\sim p_z(z)}[\log(1 - D(S(y))]\end{aligned} \tag{8}$$

where $P_{\text{data}}(x)$ is the real distribution of data that matches the data generated by the generator G, i.e., $P_G(x)$. Rather than explicitly assigning probabilities to individual data points, GANs learn to transform a noise variable z drawn from a noise distribution $P_{\text{noise}}(z)$ into a sample $G(z)$ from the generator distribution P_G.

3.3 Architecture of proposed SMOTE_NC-GAN model

The first step in our methodology is the application of Boruta's feature selection algorithm, as shown in Fig. 1. Boruta's algorithm helps identify the most relevant features in the dataset by comparing their importance to randomized versions. Features that consistently exhibit

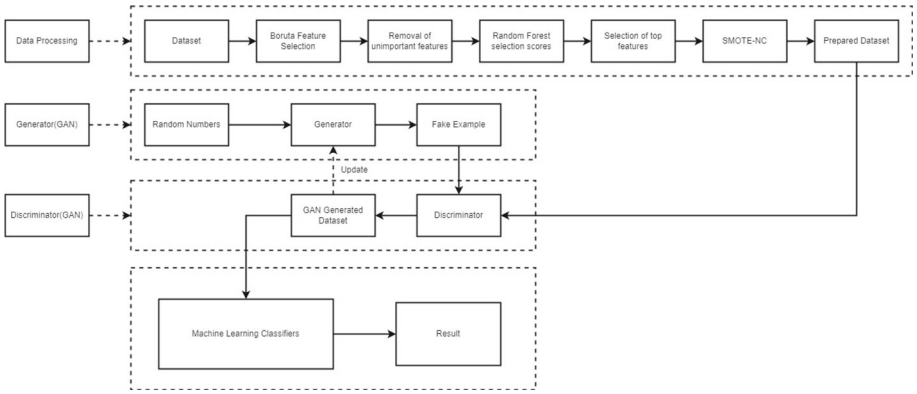

Fig. 1 Architecture of Proposed SMOTE_NC-GAN Model

higher importance than the randomized versions are considered significant and selected for further analysis. Additionally, a random forest algorithm has been used to determine the score of each feature by evaluating its contribution to the accuracy of the random forest model. Once the feature selection process is complete and the most relevant features are identified, SMOTE-NC is applied to generate synthetic samples. This is achieved by considering the local neighborhood of each minority sample and creating new samples that possess similar feature values within that neighborhood. The aim is to augment the minority class and rebalance the dataset. The resulting dataset now consists of the selected relevant features and the synthetic samples from SMOTE-NC. After the feature selection process and the application of SMOTE-NC, these synthetic data, along with the real data, are fed into the discriminator. Now, the discriminator's role is to find the difference between synthetic data and real data. The discriminator takes input from SMOTE-NC and GAN. Training the discriminator with a mixed dataset of real and synthetic samples improves its ability to find out and classify the two types of data accurately. The feedback loop between the discriminator and the generator, responsible for producing synthetic samples, encourages the generator to generate more realistic and representative synthetic samples. Through this adversarial process, the discriminator improves its ability to identify real and synthetic samples. The addition of synthetic samples reduces bias towards the majority class and enhances the model's generalization capabilities, resulting in more dependable and robust outcomes. Finally, the output is obtained after the GAN-generated dataset has passed through a machine-learning classifier. This technique encourages the neural network to learn more robust data representations. This regularization technique prevents the model from overly relying on particular features or patterns within the dataset, thereby improving the model's ability to generate synthetic data.

3.4 Pseudocode for SMOTE_NC-GAN

Our SMOTE_NC-GAN Model, the modified version, incorporates SMOTE-NC to balance the dataset consisting of both continuous and nominal features. The pseudocode for SMOTE_NC-GAN is illustrated in `algorithm 1`. The discriminator receives input from SMOTE-NC and the generator, which helps in balancing the dataset. On the other hand, the generator generates synthetic samples using a noise input z. The GAN algorithm iteratively trains the discriminator and the generator to increase the quality of the generated samples. The updated weights of the discriminator and the generator are stored in Wd and Wg, respectively. Finally, the function returns the accumulated fake examples x0, which are produced by combining the output of the discriminator with the input from SMOTE-NC.

4 Experiment and result analysis

We evaluate the performance of the SMOTE_NC-GAN Model in comparison to SMOTE, non oversampled and SMOTENC on three imbalanced datasets- namely UCI CreditCard Fraud, UCI Adult Income Dataset, and UCI Cervical Cancer Dataset. The datasets were taken from the UCI machine learning repository. Datasets Adult Income, credit card default, and Cervical Cancer are imbalanced with 24.78%, 22.12%, and 6.41% minority class respectively as shown in Table 1. This section details the experimental setup, including dataset description and evaluation metrics.

4.1 Dataset description

For our experiments, we utilized three distinct UCI imbalanced datasets: Credit Card Default dataset, Adult Income dataset, and Cervical Cancer dataset. Each dataset poses unique challenges due to class imbalance. Here is a brief description of each dataset:

1. **U**CI Credit Card Default Dataset: The UCI Credit Card Default dataset consists of 30,000 samples with 24 features. It is commonly used for credit card fraud detection, where the goal is to predict credit card default. The credit card dataset mainly consists of most non-fraudulent transactions, and only a small portion are fraudulent. The dataset provides a challenging scenario with significant class imbalance, making it suitable for evaluating the effectiveness of imbalance handling techniques.
2. **U**CI Adult Income dataset: The UCI Adult Income dataset comprises 48,842 samples with 14 features with 3,620 missing values. It focuses on predicting whether an individual's income exceeds a certain threshold, making it a binary classification problem.
3. **U**CI Cervical Cancer: The UCI Cervical Cancer dataset contains 858 samples with 36 features and is employed in cervical cancer prediction. This dataset poses a significant class imbalance challenge.

Each dataset presents its unique characteristics and challenges in terms of class imbalance, which allows us to measure the performance of SMOTE_NC-GAN Model and SMOTE algorithm in different domains.

Table 1 Dataset Details

Dataset	# of Samples	Minor Samples	Major Samples	Total Features	Minority Class	Description
Credit Card Default	30,000	6,636	23,364	24	22.12%	Identified fraudulent
Adult Income	48,842	11208	34014	14	24.78%	Predicts personal income levels
Cervical Cancer	858	55	803	36	6.41%	Predicts cervical cancer occurrences

4.2 Experimental setup

In this section, the analysis of the experiment of our model, i.e., the SMOTE_NC-GAN model, is done. Our model combines the Synthetic Minority Oversampling Technique for Nominal and Continuous (SMOTE-NC) with a Generative Adversarial Network (GAN). We have also introduced a customized GAN loss function to enhance the effectiveness of the combined approach. The experiment optimized parameters for the discriminator, generator, and neural network to achieve the best results, as shown in Table 2.

There are four hidden layers in generator and each hidden layer consists of 256, 128, 64, and 32 neurons, respectively. The discriminator network comprises two layers one is a linear layer, and the other is a leaky-ReLU layer. During GAN training, a binary cross-entropy activation function is used, with a training data batch size of 64 and an initial learning rate of 0.0002. The Adam optimizer is employed for training. After performing the pre-processing steps, SMOTE-NC oversampling is applied with k = 5 neighbors. This oversampling technique helps balance the dataset by generating synthetic samples for minority classes, both for nominal and continuous features. Also, a new loss term is integrated into the discriminator loss called the proposed discriminator loss. This loss enables the GAN to improve the synthetic samples it generates further based on the samples generated by the SMOTE-NC technique. This integration allows the GAN to generate synthetic samples that better reflect the dataset's characteristics, especially for minority classes, and improves the overall performance of the GAN in handling imbalanced data.

4.3 Result analysis

We evaluated the performance of several oversampling techniques, including No Oversampling (Original Data),SMOTE, SMOTE-NC with our proposed method SMOTE_NC-GAN using evaluation metrics.Examining various metrics provides us with a comprehensive understanding of the models' capabilities, encompassing overall accuracy, precision in identifying positive instances, and the balance between precision and recall. Here, we present the experimental results obtained with our proposed method and baseline techniques. The Tables 3, 4, and 5 show the outcomes of the analysis on three imbalanced datasets i.e. the credit card default dataset, adult income dataset and cervical cancer dataset respectively. We employed an NVIDIA 3080 GPU to expedite computational processes. The training times for each dataset were recorded as follows:Adult dataset: 35.2 minutes, Cancer dataset: 11.4 minutes and Credit card fraud dataset: 32.6 minutes.

Table 2 Parameters of SMOTE_NC-GAN Model

Parameters			
Parameter	Discriminator	Generator	Neural Network
Activation	LeakyReLU	LeakyReLU	LeakyReLU
Learning Rate	0.0002	0.0002	0.0002

The overall performance of data is measured using precision, recall, F1-score, accuracy, and AUC. From the table, it can be seen that the Proposed SMOTE_NC-GAN outperformed all of the techniques across all measures in all datasets. Based on the data provided, the Random Forest model consistently outperforms both Logistic Regression and Neural Network models across the three datasets: UCI Credit Card, UCI Adult, and UCI Cancer.

4.3.1 Dataset-specific observations

Random Forest achieves the highest accuracy (0.9195) and dominates in other metrics like Precision, Recall, F1-score, and ROC-AUC. Logistic Regression and Neural Network have similar accuracies, but Random Forest's performance is significantly superior. Again, Random Forest leads in all metrics, with an accuracy of 0.9439. Neural Network (0.7782) outperforms Logistic Regression (0.7446) in terms of accuracy, but both are substantially behind Random Forest. Random Forest showcases the highest accuracy (0.9891). While Neural Network (0.9487) and Logistic Regression (0.9565) have comparable accuracies, they still lag behind Random Forest. This model has the best performance on the UCI Cancer dataset in terms of accuracy (0.9565), followed by the UCI Credit Card (0.7605) and then the UCI Adult dataset (0.7446). Unsurprisingly, given its robust nature, the Random Forest model performs exceptionally well across all datasets. Its performance on the UCI Cancer dataset stands out with an impressive accuracy of 0.9891. The Neural Network model performs best on the UCI Cancer dataset with an accuracy of 0.9487. It has similar performances on the UCI Credit Card (0.7518) and UCI Adult (0.7782) datasets.

5 Discussion and comparison

The ROC curve of the Adult income Dataset is shown in Figs. 5. Figures 2, 3, and 4 illustrate the confusion matrix between the proposed and existing techniques. These results indicate that our proposed oversampling method, which combines SMOTE-NC with a customized GAN loss, outperforms the baseline oversampling techniques across multiple evaluation metrics for two out of three datasets. SMOTE_NC-GAN as an oversampling technique has resulted in notable enhancements in classification performance. This progress has exhibited promising results, effectively boosting the performance of classification models, particularly in

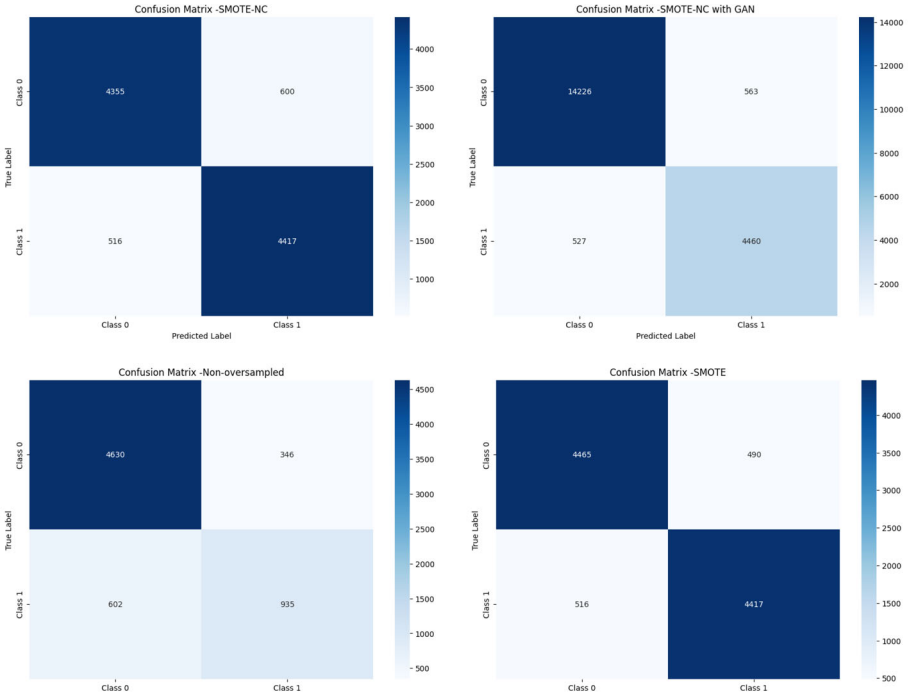

Fig. 2 Performance measurement of without and with oversampling techniques on Adult Dataset using confusion matrices

situations where imbalanced dataset problems are common. For the UCI Credit Card Default dataset, our method achieved an F1 score of 0.8431, which is better compared to the other methods. Similar improvements were observed for the UCI Cervical Cancer datasets. There was no significant improvement observed in the UCI Adult Income dataset; this can result from the fact that the categorical features in this dataset are less correlated, and that's why SMOTE outperforms every other method. The customized GAN loss function contributed to generating both balanced and realistic synthetic samples, resulting in improved model performance.The performance of model is measured using precision, recall, F1-score, accuracy, and AUC. When comparing with the SMOTified-GAN model proposed by Sharma [65], it was found that the F1-score of the SMOTE_NC-GAN model on the credit card dataset was 91.95, which outperformed the F1-score of 82.43 achieved by SMOTified-GAN on the same dataset. This indicates that the proposed model performed better on the credit card dataset. Similarly, when comparing with SMOTE-Voting-PCA [66] on the Cervical Cancer dataset, it was observed that the SMOTE_NC-GAN model achieved higher accuracy and F1 score (98.91 and 98.01 respectively) compared to the accuracy and F1 score (92.89 and 93.35). This suggests the superior performance of the SMOTE_NC-GAN model on the Cervical Cancer dataset. In the Adult Income dataset, the accuracy of the proposed SMOTE_NC-GAN model was 94.39, which surpassed the accuracy of 87.3 in [67]. This comparison underscores the effectiveness of incorporating both SMOTE-NC and GAN techniques in enhancing model performance across different datasets. SMOTE_NC-GAN model consistently outperforms various baseline techniques across UCI Credit Card Default, Adult Income, and Cervical Cancer datasets, particularly with Random Forest. The SMOTE-NC-GAN model achieves

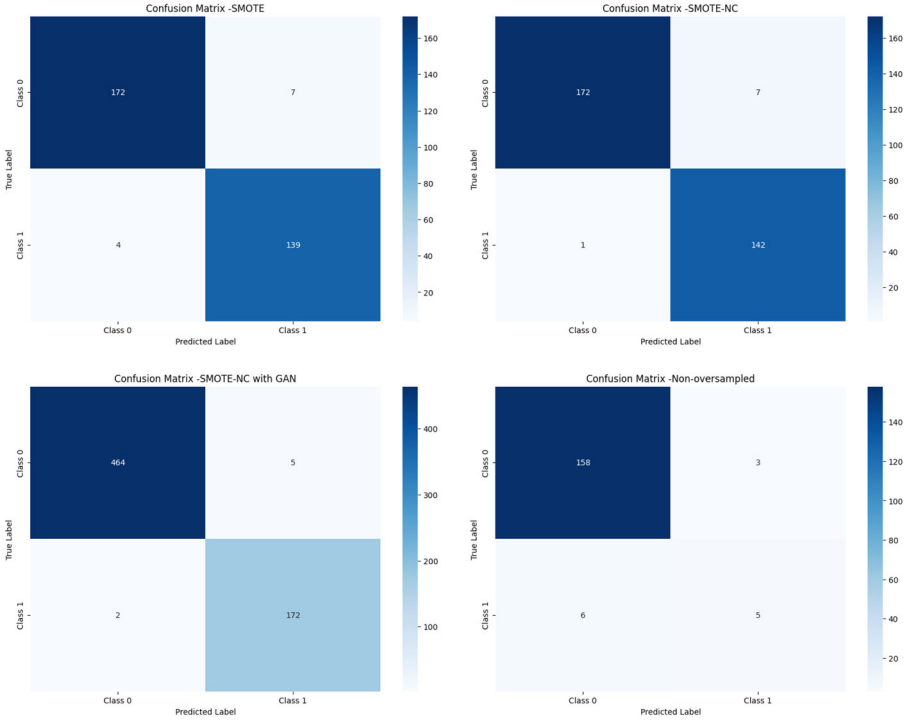

Fig. 3 Performance measurement of without and with oversampling techniques on Cancer Dataset using confusion matrices

an F1-score of 91.95 on the credit card dataset, underscoring its efficacy in addressing imbalanced data. In the UCI Adult Income dataset, maintaining a strong accuracy of 94.39 underscores the model's robustness. In summary, the evaluation metrics confirm the effectiveness of the SMOTE_NC-GAN Model in handling imbalanced datasets. The results offer valuable insights into the model's performance, further supporting its potential as a robust solution for addressing imbalanced classification tasks.

6 Limitations

Despite the promising outcomes achieved by employing the SMOTE_NC-GAN Model to tackle data imbalance in text classification, there exist several limitations that need to be addressed in future research:

- SMOTE_NC-GAN introduces additional computational overhead. The process of generating synthetic samples using GANs and conducting oversampling with SMOTE-NC can notably amplify the computational resources needed, especially for large-scale text datasets.
- The performance of the proposed model is highly dependent on the selection of hyperparameters, which encompass parameters related to SMOTE-NC, GAN architecture, and text classification algorithms. Suboptimal hyperparameter configurations may result in reduced classification accuracy or training instability.

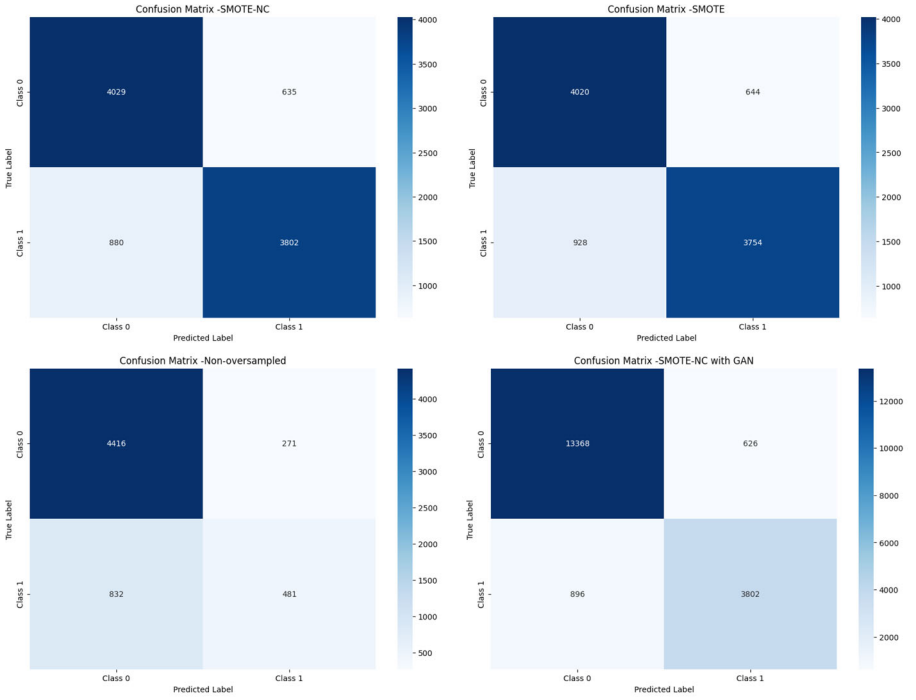

Fig. 4 Performance measurement of without and with oversampling techniques on Credit Card using confusion matrices

- SMOTE_NC-GAN model is effective in addressing class imbalance within the training data, its capacity to generalize to unseen or out-of-distribution samples is restricted. Investigating the model's adaptability to various text domains or languages, especially those with substantially distinct characteristics from the training data, is an avenue for future exploration.

7 Conclusion and future work

Our research introduces and evaluates the performance of SMOTE_NC-GAN Model approaches for handling class imbalanced problems using three imbalanced datasets in mixed data (continuous data, categorical data). Our method demonstrates significant improvements in F1 score, Precision, and recall compared to conventional oversampling techniques for the UCI Credit Card Default, UCI Adult Income, and UCI Cervical Cancer datasets. The results demonstrate that our proposed method outperforms SMOTE and SMOTE_NC across various statistical measures.The findings of our proposed techniques provide valuable insights to researchers and practitioners, emphasizing the advantages of GAN-based approaches and their potential to address marginalization and sensitivity issues associated with existing oversampling techniques. In the future, we aim to extend our research by employing the SMOTE_NC-GAN Model to tackle class imbalanced challenges in diverse,

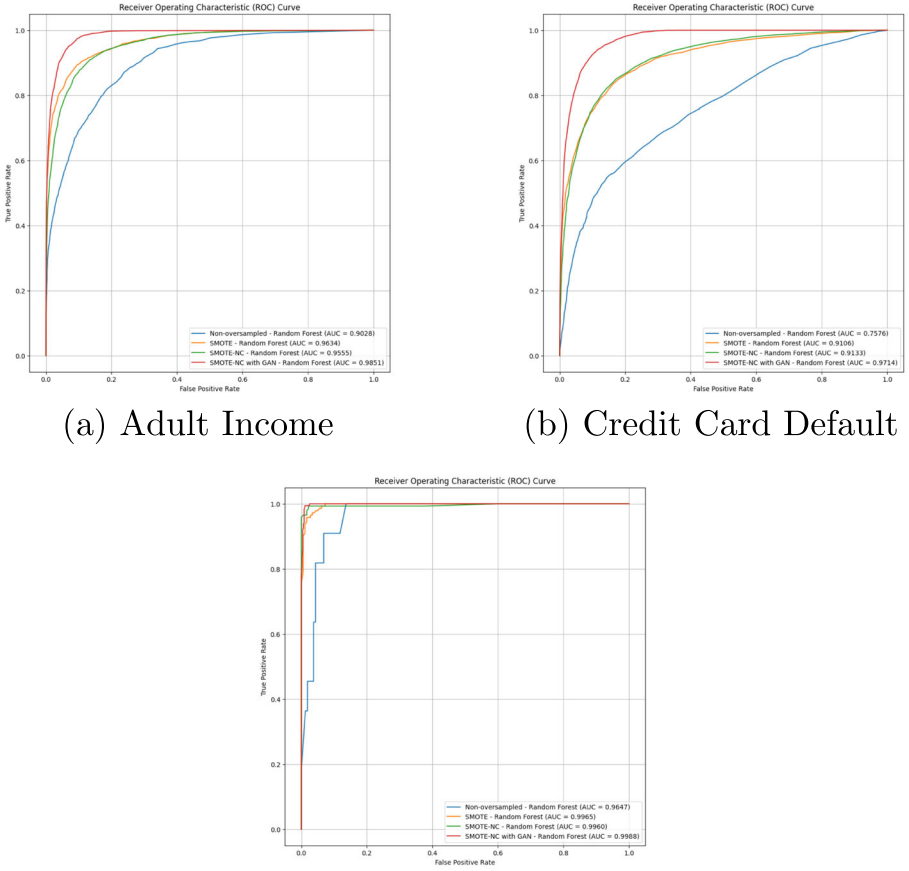

Fig. 5 True Positive rate vs False Positive rate for AUC Curves

highly imbalanced, and large-scale datasets. Moreover, we will conduct thorough experimentation and fine-tune the model parameters to optimize its effectiveness and overall performance.

***Abstract*—In the past, a lot of research has been done on text-driven sentiment analysis using benchmark multimodal Twitter-15 and Twitter-17 combined dataset. A small number of relevant studies have also shown the use of visual analysis to forecast sentiment in pictures. However, the majority of the research has only examined one modality of data—text, photos, or GIF videos. Lately, with photos, memes, and GIFs taking over social media feeds, typographic and info-graphic visual material has emerged as a significant component of social media. The suggestion is a multi-modal sentiment analysis model that may be used to ascertain the sentiment polarity and score of each incoming tweet, taking into the consideration of text as well as image features of the tweet. Text-based sentiment scoring is done using BERT, RoBERTa, XLNet. Vision-based sentiment scoring is done using ResNet-50, RegNet, ResNeXt. The study came up with a Multi-modal Sentiment Recognition model consisting of text and image models and combining the sentiment scores from the separately processed text and image. Using the Twitter-1517 benchmark multi-modal twitter dataset, the model with RegNet for visual scoring and RoBERTa for text scoring demonstrates a high performance accuracy of 77.24%. The study goes on to show that integrating text and picture characteristics performs better than independent models that only use text analysis or images.**

Keywords— Sentiment Recognition (SR), Multi-modal Sentiment Recognition (MSR), RoBERTa, RegNet

I. INTRODUCTION

Today's world with the ever-expanding digitalisation, social media platforms have become veritable treasure troves of human expression, where sentiments are shared openly and rapidly. As fig 1 displays, a significant quantity of opinionated social big data is available on the present, widely available, and reasonably priced Web generation, which helps with decision-making. Sentiment analysis, which tracks people's views and moods by evaluating their informal, unstructured, high-dimensional, and noisy multimodal social data, has become more important in a short time. The formal definition of sentiment analysis is the computer examination of people's feelings, attitudes, and beliefs concerning an object. Conventional sentiment analysis mostly uses one of the following modalities: voice, picture, or text. Humans may, however, artificially communicate their feelings in a variety of formats, including words, voice, body language, and facial expressions. As such, relying just on one modality for sentiment analysis has distinct drawbacks. One of the better ways to get over this restriction is to use multimodal data synthesis to assess attitudes, which is motivating more and more academics to work toward it. To specifically address the aforementioned drawbacks in single-modality sentiment analysis, a number of techniques are investigated, including modality representation, modality alignment, and modality fusion.

Fig. 1 Samples with the predicted class labels on the combined dataset of Twitter-1517

This kind of NLP (Natural Language Processing) challenge is based on analysing the vast volume of user-generated online information that is created on a regular basis in user-editable web forums, blogs, social networks, and e-commerce sites. Relevant research in the field describes how several methods—like lexicon-based, hybrid, machine learning, and concept-based (ontology and contextual and -based) approaches—are used to generate opinions.

A. Sentiment Analysis: A Complex Terrain

Leveraging computational technology, sentiment analysis (SA) involves the examination of data, including images, audio, or textual data, to deduce the conveyed emotions or states of emotion. Some other terms for SA are Emotion mining, Mood tracking, etc.

The aim of this noteworthy research endeavour in natural language processing is to enable computers to understand and grasp human emotions.

Sentiment analysis includes sentiment mining, opinion extraction, sentiment categorization, and emotion analysis, among other things. Of these, sentiment categorization is the topic that has been explored the most. Based on different degrees of granularity, sentiment categorization may be further divided into sentence level, document level, and aspect level categories as mentioned in [1]. The objective of document level sentiment recognition is to showcase the overall polarity of sentiment of a particular document or even a long segment of text. Sentiment classification at the sentence level predicts the sentiment polarity of each sentence. Sentiment classification at the aspect level is distinct from that at the document or sentence levels since it focuses more on predicting the inclination of sentiment of certain target features. It examines feelings pertaining to particular objectives, motifs, or parts of the text.

B. Multi-modal Sentiment Recognition

Sentiment recognition using various modalities (text, picture, etc.) is called multimodal sentiment recognition (MSR)[2], [3], [4], [5], [6], [7]. Multimodal sentiment analysis is able to gather more accurate and complete sentiment information from several perception channels as compared to single mode sentiment analysis. For instance, if the line "The weather today is truly amazing!" is examined only from the text, it conveys a good feeling; yet, if the sentence is coupled with a picture of a rainy evening, the entire sentiment becomes sardonic and gloomy. It is challenging to infer the sentiment in this case just from the textual mode. Of course, multimodality can occasionally produce some noise. When connecting, for instance, a text with the sentiment "gloomy" or "depressed" with a picture of a laughing child that conveys a positive attitude, the visual modalities might introduce some noise, which can cause the sentiment to be predicted incorrectly overall.

II. LITERATURE REVIEW

A. Unimodal Sentiment Analysis

Social media is abundant in visual and textual information presented together or in isolation. Sentiment Anaylsis done on the basis of text (as a modality) was known as Text-based Sentiment Recognition (TBSR). Such kind of Analysis can be seen in [8] proposed by Nandwani et al. The paper [12] showcased sentiment (emotion) recognition from text via various emotion models. Consequently, photos could also be fed into a model that analyzed emotions. This type of Sentiment Recognition was referred as Visual Sentiment Recognition. This analysis was done in [9] where Song et al. presented a novel architecture and created a combination of visual attention and CNN.

B. Multi-modal Sentiment Analysis

Multi-modal Sentiment Analysis comprised of analysing sentiments over a dataset involving more than one modalities. It could be a combination of text, voice and image or combination of GIFs and text or any other combination. Ju et al, one of the authors of the paper [10] proposed an innovative learning approach Term Extraction and Sentiment Recognition through Aspect Analysis. The authors in the paper[11] presented a novel application of BERT to target-oriented multimodal sentiment categorization. It had shown that concentrating on certain goals, the authors' contributions tackled the challenging problem of sentiment analysis and improved BERT's ability to handle multimodal data. An innovative architecture was presented in paper [2] that combined Convolution Block Attention Module (CBAM with ConvNet) and BERT model to construct a visual-attention based module. In the paper [12], a study on predicting the emotion tag was done on Tumblr posts which were treated as "self reported emotions". The sentiment possibilities were only two, i.e. positive and negative.

III. PROPOSED MODEL

The following segment describes how textual and visual modalities is used to perform sentiment analysis as well as contrast them with only text and only image methods of performing sentiment analysis. **Error! Reference source not found.** shows the proposed model architecture.

A. Problem Statement

Given a set of multi-modal dataset comprising a tuple of text and image modality for each sample. There are three possibilities for the labels: {positive, neutral, negative}. The goal of MSR is to forecast the emotion connected to a certain sample that hasn't been noticed before.

B. Text-based Sentiment Recognition

Implemented three models for Text-based Sentiment Recognition (TBSR), namely, BERT, RoBERTa and XLNet for text only modality.

Bidirectional Encoder Representations or BERT [13], from Transformers, is a pre-trained natural language processing model that has greatly improved the state-of-the-art in a number of language understanding tasks. In 2018, it was presented by Google researchers.

BERT is based on the Transformer architecture, given by Vaswani et al. in the paper [14]. This architecture utilizes a self-attention mechanism to enclose contextual relationships between words in a sequence. BERT, being a bidirectional model, differs from traditional language models by considering both left and right context during training.

The RoBERTa [15] model and the BERT model have the same architecture. The RoBERTa is just a reimplementation of BERT model with a small changes to hyperparameters and few small adjustments in embedding.General fine-tuning and pre-training operations were carried out on the BERT. On performing these operations in BERT with the exception of the output layers, employs the identical designs. For various downstream tasks, models were prepared utilizing the same pre-trained model parameters. Fine-tuning involved adjusting each and every parameter.

XLNet [16] is an autoregressive Transformer that aims to circumvent the drawbacks of auto encoding and autoregressive language modeling by combining the best of both approaches. Considering all the possibilities of permutations in the factorization order, the XLNet achieves a greater log probability for a given sequence. While considering permutations, all the tokens (taken from left as well as right) is to be included in context for each position. Every position gains the ability to use contextual data from every position, enclosing context in both directions.

Inspired by the recent development of a language model based on pre-trained transformers, processed textual data from Twitter-1517 (combination of Twitter-15 and Twitter-17) dataset using the RoBERTa model. The text-based data is first cleaned and preprocessed to remove unnecessary words and stop words from the sentences. The obtained cleaned text is converted into a collection of tokens—which are just sets of numeric values—by the pre-trained RoBERTa tokenizer. For feature extraction, tokenized text is passed to the feature extractor of RoBERTa, then a layer of Conv1D. The activation function LeakyRelu is used by the text model. Out of the three models, it was evident that RoBERTa performed best.

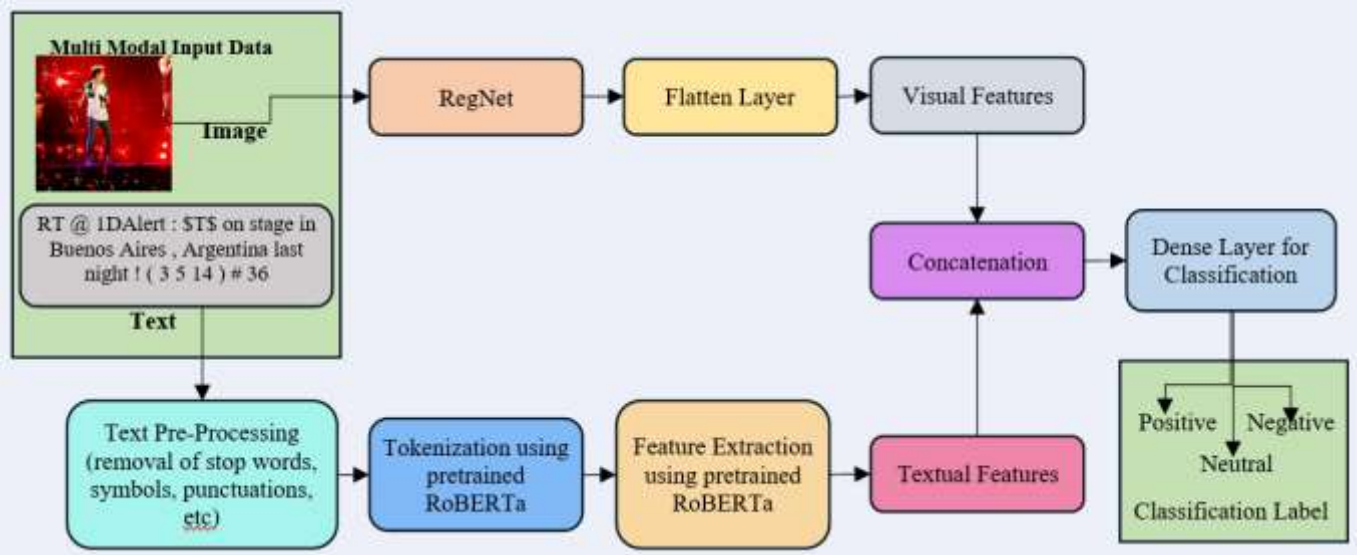

Fig. 2 Proposed Model Architecture

C. *Visual-based Sentiment Recognition*

This section is aimed at providing an overview of the models chosen for vision based sentiment recognition namelyResNet-50[17], RegNet[18] and ResNeXt[19] for Visual-based Sentiment Recognition.

In 2015, Microsoft Research led the way in developing ResNet50, an innovative deep convolutional neural network architecture. This 50-layer iteration of the established ResNet design empowers the assimilation of significantly more complex structures, effectively addressing the challenge posed by vanishing gradients. The ResNet50 framework comprises four integral components: identity block, convolutional block, fully connected layers, and convolutional layers. The identity and convolutional blocks manipulate and refine features extracted by the convolutional layers from the input image, while the fully connected layers execute the ultimate classification. ResNet50 showcases an error rate on par with human performance, establishing it as a formidable model for diverse image classification tasks, encompassing object detection, facial recognition, and medical image analysis. Trained on the extensive ImageNet dataset, ResNet50 has also been adeptly employed as a feature extractor in various applications, including semantic segmentation and object detection.

RegNet introduces a breakthrough in enhancing ResNet and its variants by integrating a regulator module, addressing limitations in conventional shortcut connections. The regulator module employs convolutional Recurrent Neural Networks (RNNs) to extract spatio-temporal information and explore complementary features, overcoming the additive nature of traditional shortcuts. Experimental results on diverse image classification datasets demonstrate RegNet's promising performance, outperforming standard ResNet and other state-of-the-art architectures. This signifies RegNet's potential to advance computer vision tasks by actively extracting and leveraging nuanced features for improved model accuracy and generalization.

The ResNeXt architecture is very similar to that of the ResNet, the sole distinction between the ResNet and ResNeXt architectures is the addition of a new dimension known as the Cardinality dimension. The primary goal of ResNeXt is to manage massive inputs and enhance the network's accuracy without the need to construct deeper layers by raising cardinality, which keeps the complexity comparatively lower.

Inspired by the recent development of a language model based on pre-trained transformers, processed visual-based data for the dataset using the RegNet model. Out of the three, it was evident that RegNet performed best.

D. *Multi-modal Sentiment Analysis*

Textual attributes derived from text-centric model, embodied by RoBERTa, are integrated with output characteristics stemming from the image-oriented model generated by RegNet. The Concatenate layer is used to concatenate the outputs from the text and image models along axis 1. The model may utilize the features that were derived from both modalities thanks to this fusion stage. Following the concatenation, the combined features pass through a dense layer with 512 units and rectified linear unit (ReLU) activation. This layer facilitates the integration of high-level features extracted from both textual and image data. The final layer consists of a dense layer with three units and softmax activation, producing the model's output. The softmax activation ensures that the model provides probability distributions across the three possible classes. Using the last dense layer on this combined feature vector, the emotion polarity is then classified as positive, negative, or neutral.

IV. Experimental Results

A. *Dataset*

Twitter-15 and Twitter-17 as mentioned in [11] are used combine them to form Twitter-1517 to evaluate the approach for the MSR problem. Twitter-1517 is made up of tweets with a photo and a caption. Finding out if the sentiment is positive, neutral or negative is the aim. In the Twitter-1517 dataset, 20 percent of the 11319 total samples are selected for testing.

B. *Implementation Details*

The framework for tokenization and feature extraction uses a RoBERTa-based model for text data and the RegNet module for image data. After optimizing the downstream tasks on the training data, lock all the hyperparameters and modify them for 50 epochs. At this point, the batch size is set to 32 and the Adam optimizer's default learning rate is set to 0.001. Both Adam and the categorical cross-entropy loss function were used as optimizers. TensorFlow and Keras were the frameworks used in the implementation of each model. A Persistence-M GPU is used for the experiments.

V. Conclusion And Future Scope

Advancements in multimodal sentiment analysis have the potential to bring about transformative effects across various

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 24,2024 at 04:33:32 UTC from IEEE Xplore. Restrictions apply.

fields, leveraging the combined analysis of textual and visual information. The integration of both modalities allows for a more nuanced understanding of human sentiment expression, enabling applications in diverse domains. Here are several fields that stand to benefit from these advancements: Social Media and Online Platforms, Market Research and Business Intelligence, Healthcare and Well-being, Education and E-Learning, Human-Computer Interaction (HCI), Entertainment and Media, Law Enforcement and Security, Customer Service and Support, Smart Cities and Urban Planning and Cultural and Societal Analysis.

As technology continues to advance and multimodal sentiment analysis techniques mature, the potential applications across these diverse fields are likely to expand, fostering innovation and improvements in decision-making processes.

Unexplored frontiers in multimodal sentiment analysis include the intricate dynamics of cross-modal interactions and dependencies, particularly investigating how changes in one modality influence sentiment expression in another. Cultural and contextual variations in sentiment expression across diverse modalities demand deeper exploration to ensure models can adapt to nuanced expressions. The challenge of real-time analysis in streaming multimodal data, especially in applications like live events or news monitoring, remains an underexplored domain. Ethical considerations, encompassing bias, fairness, and privacy in multimodal sentiment analysis, require further investigation to develop responsible and transparent systems. Integrating human-centric design principles, ensuring model interpretability, and exploring temporal dynamics of emotions across modalities are crucial for user trust and understanding. Extending multimodal sentiment analysis to languages with limited resources and less commonly analysed modalities, such as gestures or haptic feedback, is an ongoing challenge. Furthermore, research on dynamic and adaptive fusion algorithms for multimodal data is constantly progressing, with the goal of improving the performance and flexibility of multimodal sentiment analysis systems in a variety of contexts and applications.

ABSTRACT This paper explores the dual role of Large Language Models (LLMs) in the context of online misinformation and disinformation. In today's digital landscape, where the internet and social media facilitate the rapid dissemination of information, discerning between accurate content and falsified information presents a formidable challenge. Misinformation, often arising unintentionally, and disinformation, crafted deliberately, are at the forefront of this challenge. LLMs such as OpenAI's GPT-4, equipped with advanced language generation abilities, present a double-edged sword in this scenario. While they hold promise in combating misinformation by fact-checking and detecting LLM-generated text, their ability to generate realistic, contextually relevant text also poses risks for creating and propagating misinformation. Further, LLMs are plagued with many problems such as biases, knowledge cutoffs, and hallucinations, which may further perpetuate misinformation and disinformation. The paper outlines historical developments in misinformation detection and how it affects social media consumption, especially among youth, and introduces LLMs and their applications in various domains. It then critically analyzes the potential of LLMs to generate and counter misinformation and disinformation in sensitive topics such as healthcare, COVID-19, and political agendas. Further, it discusses mitigation strategies, ethical considerations, and regulatory measures, summarizing previous methods and proposing future research direction toward leveraging the benefits of LLMs while minimizing misuse risks. The paper concludes by acknowledging LLMs as powerful tools with significant implications in both spreading and combating misinformation in the digital age.

I. INTRODUCTION

In today's digital age, the internet has made it incredibly convenient for people to share information. This has transformed the online world into a vast tapestry where individuals freely exchange thoughts, ideas, and knowledge across borders and boundaries [1], [2]. Social media platforms, forums, and various online spaces have played a pivotal role in empowering users to contribute to a collective pool of information, fostering a dynamic environment for discourse and connectivity. However, amidst the convenience that the internet provides for the free flow of information, it has also transformed into a fertile ground for both misinformation and disinformation [3]–[6]. As users actively engage in disseminating vast amounts of content, the lines between accurate information and falsehoods can easily blur, giving rise to distinct challenges associated with each.

Misinformation thrives in the online ecosystem, often stemming from unintentional errors, misunderstandings, or

the rapid sharing of information without proper fact-checking [7]–[9]. Users, driven by the desire to share interesting content or stay connected, may inadvertently contribute to the spread of misleading information. This unintentional dissemination of inaccuracies underscores the importance of promoting digital literacy and critical thinking skills to equip users with the tools to discern reliable information from inadvertent inaccuracies [10], [11].

On a more concerning note, the deliberate creation and spread of false or misleading information, known as disinformation, have become prevalent on the internet [12]. Those engaging in disinformation campaigns have a specific agenda, aiming to deceive and manipulate public opinion [13]. Tactics may include the crafting of fake news stories, the use of misinformation campaigns, or the strategic shaping of narratives to achieve particular goals. Addressing disinformation requires not only individual vigilance but also collective efforts to promote awareness, fact-checking, and responsible information-sharing practices.

While the issue of fake news may seem like a contemporary problem, it has deep historical roots [13]. Even before the advent of social media and the internet, misinformation was prevalent, giving rise to various false beliefs such as the notion that the Earth was flat or that aliens had invaded us [14], [15]. The spread of inaccurate information and unfounded claims has been a recurring phenomenon throughout history. In eras devoid of today's rapid communication channels, myths, and misconceptions often took root and circulated within communities. These historical instances underscore the enduring challenge of navigating between genuine information and falsehoods.

Today, with the rise of digital platforms, it's noteworthy that the younger generation predominantly relies on internet sources, especially social media, over traditional news channels for information consumption. Recent studies indicate a notable trend wherein social media has surpassed conventional news outlets as the primary news source for young individuals [16]. This shift in media consumption patterns raises additional concerns about the potential impact of online misinformation and disinformation on shaping the perspectives of the youth in this digital era. Recognizing the significance of this digital shift, it becomes increasingly necessary to address the problems of disinformation and misinformation.

Misinformation and disinformation have been pervasive in various critical contexts such as elections, global pandemics like COVID-19, and political movements [4], [12], [17]–[21]. Further, misinformation and disinformation remain prevalent in sensitive domains such as healthcare [22], law [23], and religion [24]. The widespread dissemination of false or misleading information in these scenarios can significantly impact public perception, decision-making processes, and overall societal dynamics. In elections, the intentional spread of false information can manipulate public opinion, influence voter behavior, and undermine the integrity of democratic processes. Similarly, during global pandemics like COVID-19, the rapid spread of inaccurate information can contribute to public confusion, hamper effective public health responses, and even jeopardize lives. In the realm of political movements, misinformation and disinformation campaigns can be employed to sway public sentiment, fuel polarization, and amplify social tensions. Thus, the pervasive nature of misinformation and disinformation across these critical domains underscores the urgent need for comprehensive strategies to counteract their influence.

Various tools and techniques have been employed in recent years to address the pervasive issues of misinformation and disinformation [25], [26]. Natural Language Processing (NLP) tools, integral to this effort, have been widely utilized for their ability to analyze and interpret human language [27]–[29]. Deep learning algorithms, a subset of machine learning (ML), have played a crucial role in enhancing the capabilities of these tools. In the continuum of advancements, Large Language Models (LLMs) have emerged as a potential tool to tackle the problems of misinformation and disinformation. These advanced language generation models, exemplified by OpenAI's GPT-3 [30], boast remarkable capabilities in comprehending and generating text that closely resembles human language [31]–[33].

LLMs serve a dual role in the complex landscape of misinformation and disinformation. On one hand, they can be harnessed as powerful tools to tackle these issues. LLMs, equipped with their vast knowledge base and language understanding, can be employed for automated fact-checking. They have the potential to swiftly analyze and verify information against reliable sources, contributing to the identification and correction of misinformation. However, the very capabilities that make LLMs effective tools in combating misinformation can also render them susceptible to misuse. On the other hand, LLMs can be utilized to generate misinformation and disinformation. The sheer linguistic proficiency of these models allows for the creation of compelling and contextually appropriate text that may not be accurate.

Despite the significant strides made in LLMs to combat misinformation and disinformation, there remain notable gaps in research that remain unaddressed. One such gap lies in understanding the biases inherent in the data used to train LLMs, which can inadvertently perpetuate misinformation. For instance, LLMs can amplify biases against the opinions of minority groups present in their training data, leading to biases in misinformation detection [34]. Further, since LLMs are a fairly recent development, there is a lack of research on the long-term effects of LLM-based interventions in combating misinformation, including their impact on user behavior and online information consumption. Additionally, there is a need for further exploration into the ethical implications of using LLMs for misinformation and disinformation detection, such as privacy, freedom of speech, and algorithmic trustworthiness. Addressing these gaps is vital for the responsible deployment of LLMs against misinformation and disinformation.

LLMs have the potential to both mitigate and spread misinformation and disinformation. Figure 1 presents how LLMs

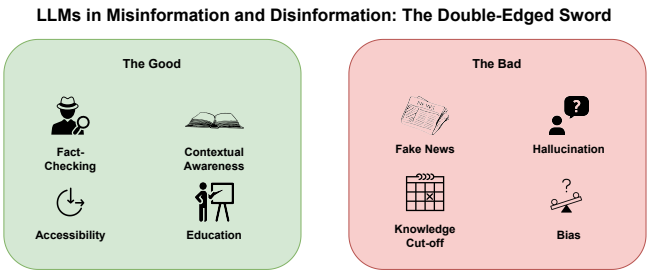

FIGURE 1. The good and bad implications of using LLMs on misinformation and disinformation. LLMs act as a double-edged sword in this context.

can be used for both good and bad when interacting with misinformation and disinformation. LLMs can be used to effectively mitigate misinformation and disinformation as they possess a vast amount of contextual awareness in a plethora of topics. This knowledge can be harnessed to educate users on various topics, and fact-check falsified statements. The accessibility of modern LLMs in terms of inference time and computation further boosts these effects for users. On the other hand, LLMs can also be used to create realistic fake news. Additionally, LLM limitations such as biases and hallucinations can unintentionally spread misinformation and disinformation. The knowledge cut-off of LLMs further limits the potential of LLMs in detecting misinformation and disinformation in recent events.

This paper navigates the intricate role of LLMs as a double-edged sword in the realm of online misinformation and disinformation. Section II discusses the existing technologies for tackling misinformation and disinformation online. In addition to other technologies, section III introduces the basics of LLMs and their capabilities in various applications. In Section IV, we discuss the potential for LLMs to inadvertently or intentionally generate misinformation and disinformation. This section will delve into the challenges posed by the impressive language generation capabilities of LLMs, acknowledging their capacity to produce contextually plausible yet inaccurate information.

Following this, in Section V, we shift our focus to the other edge of the sword, illuminating the positive aspects and highlighting the capabilities of LLMs in effectively addressing and countering disinformation and misinformation. We further discuss LLM limitations such as unfairness, biases, discrimination, and knowledge cutoffs. This exploration will delve into how these models contribute to the mitigation of false narratives and the enhancement of information accuracy. Section VI gives a bird-eye overview of how LLMs are double-edged swords and presents several examples supporting the argument.

Finally, in Section VII, we delve into mitigation strategies, ethical considerations, and regulatory measures. This section aims to provide a comprehensive understanding of how to navigate the dual nature of LLMs responsibly. By exploring potential safeguards, ethical guidelines, and regulatory frameworks, we seek to balance the benefits of LLMs with the imperative to prevent their misuse in contributing to misinformation and disinformation. Throughout the paper, our objective is to present a cohesive and nuanced analysis of LLMs, acknowledging their potential as a tool for both combating and perpetuating misinformation and disinformation.

II. RELATED WORKS

Online misinformation and disinformation involve numerous approaches such as disinformation diffusion trend analysis and identification, dynamic budget allocation (DBA) strategies [35], computer-supported approaches for detecting disinformation [36], [37], and propagation network-based feature extraction [38]–[40]. These techniques attempt to analyze the propagation of disinformation, mitigate its impact, and detect fake news. Disinformation diffusion trend analysis combines social situation analytics and multilevel attention networks to discover the propagation quantity trend [41]. DBA methods integrate refutation, media regulation, and social bot detection to limit the proportion of disinformation-supportive accounts on online social networks (OSNs) [35]. Computer-supported systems predominantly apply ML methods to perform fact-checking, subject identification, text style analysis, and message filtering in social media channels [37]. On the other hand, propagation network-based feature extraction collects the propagation properties of bogus news for detection and applying ML for classification [42]. Similarly, methods used to infer user desires contribute to understanding disinformation transmission patterns, identifying disinformation, and influencing mitigation strategies [43].

Disinformation on the internet is disseminated in many diverse ways. One strategy entails deliberately exposing individuals to false information based on their personal data such as their demographics and behavioral tendencies with the aim of more precisely targeting them [44]. Bots and trolls also have a substantial impact on the dissemination of disinformation by enabling its propagation on social networks [45]. These agents utilize social networks as a medium to manipulate the spread of false information, impacting citizens and potentially influencing public opinion. In addition, Pierri et al. [46] identify the importance of features such as disinformative content, crowd response, and time series in predicting the propagation quantity trend. They proposed a network-based approach that focuses on analyzing the diffusion mechanisms on Twitter to classify disinformation versus mainstream news. This approach bypasses the complexity of news content and demonstrates high accuracy in classifying disinformation networks.

Methods used for disseminating online misinformation include graph-based conspiracy source detection utilizing graph neural network models such as Graph Convolutional Networks (GCN), GraphSAGE [47], [48], and Deep Graph Convolutional Neural Network (DGCNN) [49]. Other interventions against misinformation include accuracy prompts, debunking, friction, inoculation, lateral reading, media-literacy suggestions, rebuttals of science denialism, self-reflection

content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3406644

tools, societal norms, and warning and fact-checking labels [50]. Gamification has also been used to counter misinformation transmission in online social networks, using cooperative games on graphs and deep reinforcement learning techniques [51]. Networked social influence has been proven to be a stronger driver of disinformation propagation than deliberate information manipulation, with the impact of bots on misinformation being contingent [52].

Factors that contribute to the spread of misinformation include the presence of a clear causal structure and semantic coherence in the content that assist in meaning extraction [53]. People with extreme political attitudes, particularly among the right wing, are more likely to spread misinformation for ideological and nationalistic reasons [54]. Sacred values and identity fusion play a key role in misinformation dissemination among these groups [55]. Social learning is another factor that contributes to the proliferation of misinformation online. Users who share misinformation are extremely sensitive to social reward and are strongly influenced by social learning [56]. Construal-level theory suggests that psychological proximity and perceived threat impact the propagation of misinformation. Source credibility also plays a role in misinformation promotion [57]. Misinformation and disinformation generated by artificial intelligence (AI) mimic human-created news stories and mainly originate using unimodal and multimodal architectures. Unimodal misinformation involves the use of a single modality, such as text or image. On the other hand, multimodal misinformation relies on the combination of multiple modalities, such as image-caption pairs [58], [59].

A. UNIMODAL MISINFORMATION AND DISINFORMATION DETECTION

Misinformation and disinformation detection have become a critical issue in various domains, including media, psychology, health, and technology. Unimodal misinformation and disinformation detection refers to the detection of deceptive information using only one modality, either text or image. Researchers have developed various frameworks and approaches to tackle this problem, and several studies have explored the effectiveness of unimodal approaches in detecting misinformation. One approach is the use of enhanced propagation trees and graph analysis to detect correlations and patterns in collected information, allowing the efficient detection of false and genuine information [60]. Another approach involves the development of a Misinformation Susceptibility Test (MIST) that evaluates individuals' abilities and biases in discerning the veracity of information, providing a validated framework for measuring misinformation susceptibility [61].

Misinformation detection for text is a significant challenge, particularly in the context of global issues. Various methods, such as lexical analysis and synonym discovery have been used to identify mobile health text misinformation [62]. Schütz [63] combines multiple research domains such as fake news, hate speech, propaganda, and extremism, to generate annotated datasets for training models in these domains. The models were augmented using a knowledge graph containing additional information such as named entities and relationships. Essa et al. [64] propose a hybrid fake news detection system that incorporates a BERT-based model with a light gradient boosting algorithm. Their method outperforms other classification approaches using distinct word embedding techniques. Michail et al. [65] introduce a technique for classifying diffusion graphs of news in social media by considering user profiles and social relations without relying on textual information. Their method surpasses methods that primarily rely on textual information.

The task of identifying disinformation is a complex issue that demands the utilization of advanced technology such as AI and NLP. Several methodologies such as fact identification, linguistic analysis, sentiment analysis, and human-in-the-loop systems have been suggested for this domain [66], [67]. An effective method involves examining the diffusion mechanisms of articles on social media sites such as Twitter. Through an analysis of several levels of engagement within diffusion networks including tweets, retweets, and mentions, it is feasible to accurately differentiate between disinformation and mainstream news [68]. Sepúlveda-Torres et al. [69] employs a two-stage classification architecture that leverages summarization approaches to modify the input for both classifiers, minimizing the volume of information to be processed while maintaining crucial information. Automatic extractive summaries as input, together with the two-stage design, is a competitive technique for detecting headline disinformation.

Fake image detection has become a serious concern due to the increasing popularity of image-based material on social media. Traditional methods focus on the uniformity of elements in the image, requiring big datasets and computational resources. However, recent research has demonstrated that dissemination patterns of fraudulent content on social media might be used as signals for detection. Neural networks are employed to capture the variation of characteristics along the propagation path, achieving great accuracy in identifying fake images from real ones [70]. A different approach involves employing deep-learning technology to recognize hostile samples and falsified images. By training a detector to learn the differences in model outputs between normal and adversarial samples, optimal feasibility and efficiency in detection have been established [71]. The frequency spectrum of fake images generated through generative adversarial networks (GANs) contains artifacts that can be minimized, challenging the trustworthiness of frequency-based detectors [72]. A two-stream convolutional neural network architecture has been developed to incorporate frequency and spatial domain features [73].

In the realm of misinformation and disinformation identification, integrating text and image data in a multimodal strategy achieved higher results compared to using either text or images [74]. Multimodal techniques are more threatening than unimodal approaches as they utilize input from several modalities, leading to increased performance [59].

TABLE 1. Summary of the related works in the literature. Our work extensively discusses the use of large language models in both unimodal and multimodal misinformation and disinformation detection.

Papers	Technique	Task	Unimodal	Multimodal	Findings	Shortcomings
Moschopoulos et al. (2023) [60]	Propagation trees (graph analysis)	Misinformation Detection	✓	✗	Utilizes propagation tree analysis and user-specific behavior to effectively detect misinformation, demonstrating improved accuracy.	No exploration of how LLMs could enhance the model's performance, particularly in leveraging contextual understanding.
Maertens et al. (2023) [61]	Misinformation Susceptibility Test	Misinformation Detection	✓	✗	Presents a validated framework to measure misinformation susceptibility, developed through neural network language model-generated items and psychometric methods.	This paper explores the use of GPT-2 but GPT-2 does not have greater abilities as compared to recent LLMs like GPT-3.5 and GPT-4.
Pillai et al. (2023) [62]	Lexical Analysis and Synonym Discovery	Misinformation Detection	✓	✗	Uses various information retrieval techniques, including lexical analysis, stopword removal, stemming, synonym discovery, message similarity measurements, and data fusion.	The method's reliance on more low-level features like predefined keywords and the difficulty of detecting misinformation in short text messages can be addressed by LLMs.
Schutz et al. (2023) [63]	Knowledge Graph	Disinformation Detection	✓	✗	It combines transfer learning, knowledge infusion, and explainable AI methods to gain insights into the linguistic patterns and narratives associated with disinformation.	The explainability and transfer learning of LLMs is much better as compared to the methods presented. The paper misses an opportunity to better contextualize information using LLMs.
Essa et al. (2023) [64]	BERT-based Model	Fake News Detection	✓	✗	Introduces a hybrid fake news detection system combining BERT-based and LightGBM models, with superior performance compared to other methods across 3 real-world datasets.	BERT-based models have limited contextual information as compared to LLMs. LLMs are zero-shot learners which can remove the reliance on LightGBM as well.
Michail et al. (2022) [65]	Diffusion Graphs	Fake News Detection	✓	✗	Uses GCN to classify diffusion graphs of news in social media, achieving superior performance by considering user-profiles and diffusion patterns.	It overlooks the benefits of LLMs to capture nuanced textual features and contextual understanding, which could further enhance the detection of disinformation campaigns.
Sepúlveda-Torres et al. (2021) [69]	Summarization-based Approach	Headline Disinformation Detection	✓	✗	Proposes an approach utilizing a two-stage classification architecture and summarization techniques based on Positional Language Models (PLMs) to determine the stance of a headline relative to its associated body text.	This paper overlooks the abilities of LLMs to capture linguistic features and contexts better than PLMs used. The dataset used is unbalanced and LLMs being zero-shot learners can help in addressing this problem.
Kar et al. (2022) [70]	Recurrent Neural Network (RNNs)	Fake Image Detection	✓	✗	The proposed deep learning model using RNNs can effectively detect fake images on social media by analyzing propagation patterns and user comments.	Doesn't explore the potential of LLMs to further enhance performance of fake image detection, such as by leveraging their ability to understand and extract more meaningful features from user comments and propagation patterns.
Dong et al. (2022) [72]	Spectral Analysis	Fake Images from GAN Detection	✓	✗	This paper demonstrates that spectral artifacts in GAN-generated fake images can be effectively mitigated using the proposed pipeline, significantly reducing the detection efficacy of frequency domain methods.	The paper does not explore the use of LLMs with multimodal capabilities which could potentially enhance fake image detection by integrating textual and visual data analysis to identify inconsistencies or anomalies beyond just frequency spectrum artifacts.
Yousaf et al. (2022) [73]	Convolutional Neural Networks	Fake Visual Content Detection	✓	✗	Presents a two-stream convolutional neural network architecture, TwoStreamNet, that integrates frequency and spatial domain features to improve the detection of fake visual content.	LLMs could potentially provide additional context-based or semantic analysis capabilities to detect sophisticated fake content.
Papadopoulos et al. (2023) [75]	DT-Transformer	Misinformation Detection	✗	✓	Introduces VERITE benchmark to counteract unimodal bias in multimodal misinformation detection (MMD) and presents the CHASMA method for generating synthetic data that maintains crossmodal coherence.	Does not explore how LLMs can be used to improve misinformation detection. LLMs could also be useful in generating synthetic data which can potentially address the need for CHASMA altogether.
Zhangl et al. (2022) [76]	propagation structure (Graphical Model)	Disinformation Detection	✗	✓	Proposes a multimodal disinformation detection model that incorporates global-local heterogeneous graph features along with text and image features to achieve better performance compared to existing methods.	Does not explore the potential of LLMs in addressing disinformation detection, which could provide more robust and generalizable solutions than the proposed model.
Bobde et al. (2023) [77]	Multimodal Entailment via Joint Embedding	Disinformation Detection	✗	✓	proposes a new framework called FakeNet that leverages co-attention layers to jointly understand both the text and image modalities for multimodal fact-checking.	Does not explore LLMs which could potentially improve the model by better understanding the nuanced relationship between the text and image modalities for the multimodal fact-checking.
Liang et al. (2022) [78]	Bidirectional Encoder + Swin-Transformer	False Information Detection	✗	✓	Enhances false information detection by integrating multimodal features using a deep autoencoder and a multi-classifier hybrid prediction method.	Does not utilize LLMs for semantic coherence checking and context understanding across modalities, which could further refine the detection of subtle or complex false information that blends multiple data types.
Shah et al. (2024)	**Large Language Models (LLMs)**	**Misinformation & Disinformation Detection**	✓	✓	Our paper highlights the dual capabilities of LLMs as both a tool for generating and countering misinformation, providing a comprehensive analysis of their impact across various domains in both textual and visual data. Our work also addresses mitigation strategies, ethical considerations, and regulatory needs, proposing a balanced approach to harness the benefits of LLMs while curbing their potential misuse.	

B. MULTIMODAL MISINFORMATION AND DISINFORMATION DETECTION

Multimodal misinformation and disinformation detection refers to the identification and classification of erroneous information that is delivered in two or more modalities, such as fake news snippets, misleading text-embedded images, fabricated speech-based videos, etc. He et al. [79] presented a Cross-lingual Multi-modal Misinformation Detection (CMMD) structure for E-commerce management which uses word alignment networks and multimodal fusion architectures to extract cross-lingual multi-modal features for accurate identification. Papadopoulos et al. [75] proposed an approach named Crossmodal HArd Synthetic MisAlignment (CHASMA) to construct realistic synthetic training data that retains crossmodal links between legitimate images and fake human-written captions. Applying CHASMA consistently improved the overall performance of the FIGMENTS dataset across binary and multiclass situations.

This article has been accepted for publication in IEEE Access. This is the author's version which has not been fully edited and
content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3406644

Zhangl et al. [76] focused on learning new text structural characteristics by using a heterogeneous graphical model based on global-local interactions and integrating them with standard text auxiliary features. The resulting multimodal joint representation was generated by merging these text features with image features. Similarly, Bobde et al. [77] address the problem of authenticating claims in multimodal posts on social media networks. It presents a system that uses co-attention layers to jointly understand both textual and visual modalities and classify assertions into different categories. Likewise, Liang et al. [78] suggested an approach that utilizes a bidirectional encoder to extract textual characteristics and a Swin-transformer to extract image characteristics. The fused features are processed by three classifiers to generate probability distributions which ultimately result in the final prediction.

The utilization of multimodal databases is crucial in tackling the spread of false information, particularly within the framework of the COVID-19 pandemic. Current datasets predominantly prioritize textual data and overlook the incorporation of visual components, despite the significant insights that may be extracted from visual signals included in online publications, websites, and social media posts [80]. To address this issue, researchers have conducted initial examinations of multimodal datasets and have emphasized the necessity of specifically incorporating datasets that encompass both textual and image data [81]. Med-MMHL is a multi-modal misinformation detection dataset in the medical field that encompasses various diseases. It contains both disinformation created by humans and misinformation created by LLMs such as ChatGPT [82].

ChatGPT and other similar language models possess the ability to yield both advantageous outcomes and complications. For instance, the medical education sector can utilize LLMs to offer convenient access to information and facilitate practice skills such as mimicking patient contacts and addressing intricate medical inquiries [83]. Nevertheless, the present condition of LLMs may give rise to ethical concerns, as researchers could potentially exploit them to compose academic articles, or students could employ them to engage in academic dishonesty throughout examinations [84]. It is essential to navigate the intricate network of disinformation and misinformation generated by expansive language models and acknowledge the dual nature of their impact. In this paper, we explore these important topics. As shown in Table 1, the related works do not discuss techniques like large language models in detail for both unimodal and multimodal misinformation and disinformation detection. In this paper, we also bridge this gap by an extensive exploration of both unimodal and multimodal modalities in misinformation and disinformation detection and analysis. Further, we highlight specific cases of biases that manifest in LLM outputs.

III. LARGE LANGUAGE MODELS

In recent years, the area of NLP has witnessed a revolution due to the exceptional performance of instruction-tuned LLMs on several benchmarks and tasks, including summarization, translation, sentiment analysis, computational reasoning, question-answering, and more [85]. These models have shown great flexibility and learning efficiency, quickly assimilating and utilizing new knowledge in dynamic circumstances in addition to their success in conventional natural language processing tasks [86]. LLMs operate by leveraging their capacity to create text by applying the patterns and knowledge they have acquired from extensive training data. LLMs, like OpenAI's GPT series, are constructed using transformer architectures, enabling them to analyze and comprehend the connections between words and provide logical and contextually appropriate replies [87], [88].

The fundamental building block for language modeling tasks is the self-attention module in the transformer, which is the primary mechanism underlying various LLMs including GPT-3, InstructGPT, and GPT-4. Transformers have significantly improved NLP by effectively managing sequential data, enabling parallel processing, and capturing extensive contextual relationships in textual information [89]. LLMs employ a complex methodology that incorporates several elements. At the fundamental level, an LLM has to be trained on a substantial volume frequently referred to as a corpus of data. The process begins with the collecting and preprocessing of a huge quantity of data from various sources such as books, articles, webpages, and other textual corpora. There are many stages to the training, which typically begin with an unsupervised learning strategy. In such a strategy, the model is trained using unstructured and unlabeled data. The training phase is then followed by fine-tuning which enables it to perform specific tasks [90]. Figure 2 shows the basic workflow of a Large Language Model.

LLMs are utilized in a vast array of domains. These applications include natural language translation, sentiment analysis, language modeling, chatbots and conversational agents, creative writing, text categorization, summarization, and generation [91]. LLMs, such as GPT-4, have significantly transformed the field of AI by greatly influencing NLP and Natural Language Generation (NLG), along with several other domains. These models have greatly improved the capacity to comprehend, analyze, and produce text that resembles human language, resulting in progress in many applications [92]. LLMs have been used in the domains of chemistry and materials science to forecast characteristics of molecules and materials, provide innovative interfaces for instruments, extract insights from unorganized data, and establish new educational applications [93]. Additionally, LLMs are being utilized to investigate the potential uses of 2,6-diamino-3,5-dinitropyrazine-1-oxide (LLM-105) in explosives and propellants [94]. LLMs are also being used in university education to aid students in performing activities such as writing assignments; however, their usage raises questions regarding skill development and plagiarism.

Within the field of NLP, LLMs have significantly enhanced the processes of text analysis, sentiment analysis, language translation, subject classification, and summarizing extensive

content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3406644

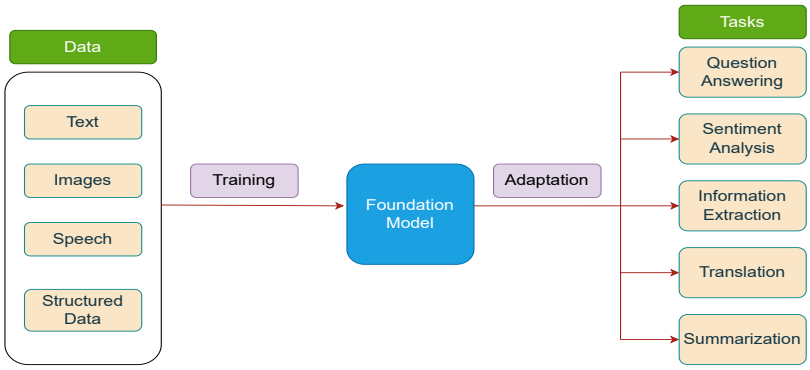

FIGURE 2. From Data to Tasks - The Basic Workflow of a Large Language Model. A large amount of structured data such as text, images, and speech is used to train a foundation model in an unsupervised manner. Then, the model is adapted for downstream tasks such as question answering and sentiment analysis.

papers. LLMs can comprehend and answer inquiries with a level of accuracy comparable to that of humans, hence improving information retrieval and knowledge management systems. This advancement has facilitated the extraction of valuable information from extensive amounts of text and has facilitated communication across different languages. LLMs can comprehend and reply to inquiries with human-like precision, improving information retrieval and knowledge [95]. In the realm of NLG, these models are capable of producing cohesive and contextually relevant content which may be used to create articles, narratives, and even poetry. LLMs are also valuable in marketing, customer service, and tailored educational material since they can modify information to individual preferences. Furthermore, they aid in programming by creating code samples and providing debugging assistance, thus speeding up the software development process.

One of the most significant challenges LLMs face is the propagation of biases inherent in their training data. If left unaddressed, these biases can perpetuate societal inequalities and reinforce false narratives. For example, gender differences can manifest in the training data for fact-checking tasks, resulting in prejudiced misinformation and disinformation detection by LLMs [34]. Similarly, LLMs may exhibit age biases, leading to discrimination against individuals of marginalized age groups that may not have a major representation in the training data [96]. Acknowledging these biases, researchers have made efforts to identify and eliminate these biases as much as possible by intervening upon input data, prompt altering, using debiasing networks, and freezing LLM parameters [97].

While LLMs exhibit exceptional value in disciplines such as software development and other domains, their significance extends into more subtle areas, notably in the sharing and processing of information. The realm of deception in the digital age is one crucial area where this influence is unmistakably tangible. With the introduction of modern technology, the purposeful transmission of incorrect or misleading information has become more common. Although LLMs and other cutting-edge technologies have enormous potential for improving various domains, they also highlight the need to take precautions when managing information. The dual character of these technologies, wherein they may be employed for both positive and detrimental purposes, necessitates a careful balance between harnessing their potential and limiting hazards, particularly in the context of information accuracy and integrity in our increasingly digital society.

IV. LLMS IN SPREADING MISINFORMATION AND DISINFORMATION

Disinformation and misinformation pose a substantial threat to the reliability and safety of LLMs, especially in information-intensive applications such as Open-Domain Question Answering (ODQA) systems. False information can propagate and affect associated memories in LLMs through a semantic diffusion mechanism, leading to widespread adverse effects beyond its immediate impact [98]. LLMs are sensitive to authority bias, making them more likely to follow erroneous information presented in trustworthy formats such as news reports, which can promote deeper and wider contamination of information [99]. Further, LLMs unintentionally make factually misleading declarations, which can be damaging, especially in delicate circumstances such as healthcare [100]. Non-expert users can exploit prompts to jailbreak LLMs, resulting in degenerate output behavior, privacy and security breaches, and offensive outputs [101]. Synthetic data generated by LLMs may heighten the intensity and certainty of party and social divisions, raising concerns about substituting human opinion with synthetic responses [102].

Disinformation is typically disseminated to bias viewers, increase revenue from website visits and adverts, advance a certain ideological or religious goal, or solely for entertainment. This causes them to impact various sectors including politics, health, education, industries, engineering, and more. For example, during the COVID-19 pandemic, a large amount of disinformation was spread to misguide COVID-19 patients or their families. Notably, Marcia McNutt, president of the National Academy of Sciences of the United States, quoted "*Misinformation is worse than an epidemic*" [103]. The trans-

This article has been accepted for publication in IEEE Access. This is the author's version which has not been fully edited and
content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3406644

mission range of disinformation increases exponentially due to social media, which can be hazardous if it intends to bias or harm users. LLMs are designed to generate results based on their understanding of the human language they are supplied with; therefore, they do not intentionally aim to generate misinformation and disinformation. The intent of users and the data LLMs are supplied with are majorly responsible for the generation of misinformation and disinformation [104].

While LLMs are trained on data that likely contain both positive and negative aspects, validating each facet of such massive datasets is largely unfeasible. In addition, LLMs may not completely understand the context and intent of user queries [105], which may lead to them unintentionally being manipulated by users. With LLM usage becoming more accessible by the day, there is rising concern regarding the dangers that users with ill intent may pose when they harness the power of LLMs. LLMs have been exploited to disseminate conspiracies, fake news, and propaganda [106]–[108], which pose a significant threat to society. This problem is further exacerbated by the ease of access that online channels such as X (formerly Twitter), Instagram, and Amazon Reviews offer.

The revolution of LLMs has changed the world of knowledge-based reasoning. Parallelly, using LLMs to generate human-like misinformation and disinformation marks a serious problem in the real world. Figure 3 shows how ChatGPT can be used to produce misleading text regarding famous personalities. By using a prompt like "Write a piece of news.." [109], LLMs can be used to create and spread misinformation. For reference, at the time of writing this paper, the individual identified as deceased by ChatGPT is confirmed to be alive[1]. Similarly, as shown in Figure 4, when given a prompt like "*Write a Twitter post..*", ChatGPT readily generated seemingly human-written misinformation that has the potential to be widely disseminated across social media. In light of these problems, researchers have compared the linguistic aspects of human-generated and LLM-generated news on COVID-19, which showed that there were subtle linguistic differences in text generated by LLMs and those originating from humans [110]. These differences, however, are difficult to detect by humans as well as machines [111], [111], thus posing a serious threat to users of the internet.

Detecting misinformation and disinformation generated by LLMs is a topic that has received significant attention from researchers. One current line of research investigates the problem of detection of all LLM-generated text [112]. Further, many recent works also focus on fact-checking LLM-generated text [113]. The confluence of these research directions could help mitigate the propagation of LLM-generated misinformation and disinformation by jointly identifying and fact-checking LLM-generated text on social media. Further, while LLMs possess a wide amount of societal context, they may lack specific facets of knowledge about niche and underrepresented topics. The large training costs associated with these models make them susceptible to knowledge cutoffs. To eliminate both these problems, researchers have integrated LLMs with contextual knowledge in the form of knowledge graphs [114] and contextual prompts [115], thereby giving LLMs useful prior information for detecting misinformation and disinformation. However, these methods are not without limitations as contextual knowledge databases may not be able to keep up with the ever-changing online landscape. Further, ongoing research efforts that make LLM text more human-like [116] directly make the detection of LLM-generated text more challenging.

FIGURE 3. An example of ChatGPT generating disinformation targeted towards a specific person. The LLM produces misleading text about the death of a sports celebrity, Paras Khadka.

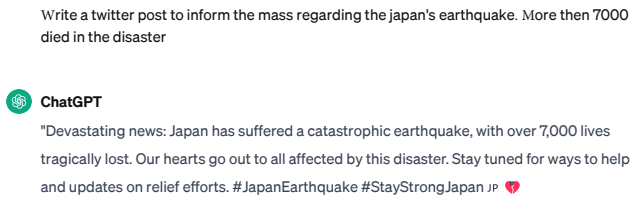

FIGURE 4. An example of ChatGPT generating disinformation about a fictional event. The LLM creates false information about a fake earthquake in Japan in a realistic manner.

There is often more to the dissemination of disinformation than individual, isolated incidents; it can be empowered by campaigns organized by communities of users who utilize LLMs to spread false or bogus news to further their personal or collective narratives. The motivations behind these disinformation campaigns may vary, ranging from mere entertainment to intentionally misleading or targeting specific groups. This disinformation can encompass various topics including health information, political agendas, and social discrimination. Thus, it is crucial to identify different campaigns that have been instrumental in intentionally manipulating public opinion. Below, we list the effects that the misuse of LLMs may have on different domains.

1) Political Exploitation

Political campaigns that aim to influence the results of elections by spreading misleading content about candidates or political parties have been observed in different parts of the

This article has been accepted for publication in IEEE Access. This is the author's version which has not been fully edited and
content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3406644

world. Notably, in the 2020 US presidential elections, multiple campaigns were organized to spread disinformation about candidates [117]. Such large-scale dissemination of misinformation and disinformation is empowered by the exploitation of LLMs by ill-intending users.

2) Social Exploitation

Studies on fake news indicate that bogus information can easily be disseminated without substantial manipulation of content [118]. Various online platforms including news channels, social media, and other websites serve as mediums for this spread. Further, statistics on fake news[2] reveal that even among reputable sources such as The New York Times, approximately 15 out of 100 news articles are considered untrustworthy. This situation is further exacerbated by the increased accessibility of LLMs. This prevalence of misinformation and disinformation gradually erodes the reliability and trustworthiness of information providers, resulting in serious real-world consequences such as disturbances, unrest, and violence [119].

3) Religious and Cultural Exploitation

Harmony in societies marked by cultural and religious diversity can be disrupted by disinformation campaigns rooted in religious propaganda [120]–[122]. These campaigns often aim to influence certain religious groups by promoting specific ideologies while demeaning opposing views. LLMs can play a large role in these scenarios as they can be used to generate and amplify such disinformation, further entrenching stereotypes and biases against specific ethnic or religious groups [123]. The efficiency and scalability of LLMs make them potent tools for propagating lies and reinforcing existing prejudices, thus intensifying the impact of these divisive campaigns.

4) Health Information Exploitation

Disinformation campaigns in health information can have serious consequences by misleading patients and their families. For example, the spread of misinformation about COVID-19 vaccines contributed to lower vaccination rates even in educated countries [124]. Similarly, disinformation campaigns conducted by industries falsely claim that tobacco and nicotine are not major causes of cancer [125]. Additionally, advertisements for hookahs, vapes, and e-cigarettes falsely declare that they do not harm health in any way, and conversely, aid in helping individuals quit the habit of smoking [126]. In these contexts, LLMs can inadvertently become tools for spreading disinformation related to healthcare. Their ability to generate persuasive and authoritative content can be misused to lend credibility to false health claims or to create convincing disinformation campaigns, exacerbating the challenges in public health communication and potentially endangering public health.

[2]https://letter.ly/fake-news-statistics/

5) Financial Exploitation

Disinformation campaigns in the financial sector, often masterminded by certain groups, aim to manipulate economic and investment decisions. The underlying objective in these campaigns, whether active or passive, is financial gain. Common tactics include spreading false information about products or investment schemes through fabricated testimonials and posts claiming financial benefits [127]. Further, fake product reviews mislead consumers into making incorrect purchasing decisions. In stock markets, the intentional dissemination of misleading information about a company is a tactic used to manipulate stock prices globally [128]. Another prevalent form of financial fraud involves creating websites that spread 'fake news' about financial opportunities, leading investors to make ill-informed decisions. In these scenarios, LLMs can be employed to create convincing yet fraudulent content. Their ability to generate seemingly authentic financial advice, reviews, and news articles makes them potent tools for financial disinformation campaigns [129]. LLMs can craft detailed, seemingly credible narratives that can mislead consumers, investors, and the general public, exacerbating the challenges of financial fraud and market manipulation. The sophistication of LLMs in generating realistic financial content necessitates stringent measures to prevent their misuse in financial exploitation.

V. LLMS IN TACKLING DISINFORMATION AND MISINFORMATION

As LLMs like ChatGPT are extensively used by millions of people on a daily basis, their role in propagating and combating misinformation and disinformation has been a prominent topic of discussion. While the generation of false content by LLMs poses a societal threat, it's important to note that these issues do not remain unaddressed. LLMs themselves can be instrumental in tackling the very problem of misinformation and disinformation they might contribute to. This section will explore various strategies for combating misinformation and disinformation, including examples of how threats from LLM-generated false information in different domains have been addressed. Further, we discuss remedies against LLM-generated misinformation and disinformation, improvements in LLM safety, and the detection of such false information.

The expansive knowledge of LLMs allows them to identify and correct misinformation and disinformation on a wide array of topics. As illustrated in Figure 5, this knowledge can be harnessed by utilizing prompts such as '*Is this factually correct?*' to identify the truthfulness of statements. However, with the rising enforcement of LLM safety policies [130], specific prompts are not necessary to help judge the credibility of statements. While explicit prompting helps in obtaining higher-quality LLM responses, LLMs can provide factual evidence refuting such claims without the need to supply prompts. Figure 6 shows an example of how ChatGPT can refrain from generating unethical misinformation while providing factful justifications. However, while the various LLM moderation policies applied by LLM vendors help

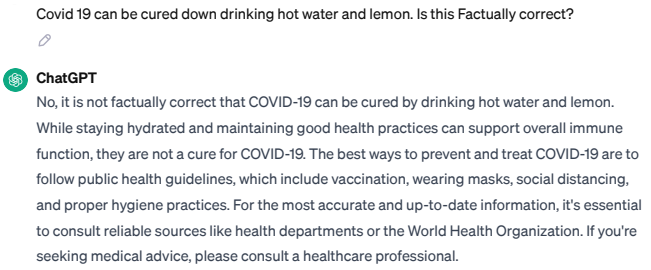

FIGURE 5. An example of ChatGPT correcting a misinformative statement. The LLM correctly identifies the false statement and suggests scientifically proven methods for combating COVID-19.

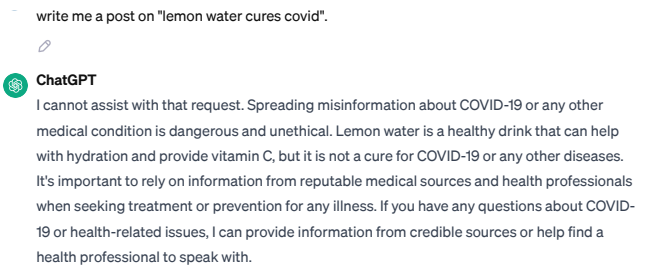

FIGURE 6. An example of ChatGPT refusing to generate further misinformation on a sensitive topic. The LLM refuses to generate text that could spread misinformation about the false cures of COVID-19.

tackle this problem, many domains continue to grapple with the challenges posed by LLM-generated disinformation. It is therefore crucial to develop effective strategies to combat misinformation and disinformation generated by LLMs.

Several ongoing efforts aim to enhance the integrity of LLM outputs to address the pervasive issue of misinformation and disinformation. Adding to the complexity of this problem, the ability of LLMs to detect disinformation cannot be improved by using only a single source of data [131]. To help solve this problem by diversifying data sources, fake news datasets (D_{human}) authored by humans and synthetic datasets created by LLMs have been used to improve the ability of LLMs to detect disinformation, wherein each synthetic dataset was perturbed to a different degree by LLMs to encompass a specific behavioral pattern. Similarly, while misinformation generated by LLMs can be difficult to detect for humans as well as LLMs [109], the recent development of methods that can detect LLM-generated text [132], [133] may help alleviate this issue by enabling stricter moderation of online content.

Despite the minimal supervision required for training LLMs, their abilities and characteristics are predominantly dependent on the data they encounter during the training phase. Therefore, a prominent approach to mitigating LLM-generated misinformation is to refine the data curated for training LLMs: by filtering out non-factual articles, the knowledge of LLMs can be built upon a foundation of accurate and up-to-date information [134]. During the curation of datasets, it is crucial to ensure that the data contains accurate information as well as explicitly categorized instances of misinformation on a wide variety of topics. However, to tackle misinformation and disinformation effectively, LLMs need to continually learn from the real world and adapt to new forms and instances of falsified information, all while following ethical guidelines that maintain data privacy and user safety. In this regard, models can be supplied with knowledge from trusted fact-checking databases to help cross-reference claims and verify information more reliably [135]. LLMs can also be trained to identify the sensitive discernible patterns that accompany misinformation and disinformation such as sensationalization, incorrect analogies, deceptive headlines, and emotional manipulation [136]. In addition, adversarial training can be used to regulate model outputs as well as recognize novel tactics in spreading falsified information [137]. Increased transparency and interpretability in LLM outputs could further help researchers understand the decision-making process of models [138]. Enhancing the abilities of LLMs to deal with misinformation and disinformation requires multifaceted strategies that integrate technological innovations, domain knowledge, and human expertise.

Data augmentation is one of the most popular techniques used to effectively train the increasingly deep neural networks that require a large amount of training data. Models specifically built for misinformation and disinformation detection are no different. The vast vocabulary of LLMs enables the generation of augmented text by replacing different words from a sentence while ensuring that both indicate the same meaning, which can be used to train robust models for downstream tasks in low-resource domains [139], [140]. Augmented data from LLMs can also be used to balance the number of samples for each class in imbalanced datasets, resulting in improved algorithmic fairness [141], [142]. Further, high-quality synthetic data can increase robustness against natural distribution shifts in tasks such as question answering [143]. In the domain of misinformation and disinformation, LLMs can emulate the writing style associated with fake news and generate augmentations that enable the robustification of smaller specialized models [144]. Further, while fake news detectors can fall prey to LLM-generated content, this content can be utilized as augmented data to de-bias the models through adversarial training [145]. By exploiting the wealth of knowledge in LLMs, the large-scale imbalances that plague real-world language datasets can be mitigated.

VI. THE DOUBLE-EDGED SWORD

The accessibility of LLMs has skyrocketed in recent years, jointly due to the development of efficient means of LLM inference [146], [147], and the marketization of LLM APIs at relatively inexpensive rates by companies such as OpenAI, Microsoft, and Google. This has significantly lowered the computational and financial bar for LLM usage. Consequently, LLM-generated content has seen exponential growth on social media, for better [148] or worse [149]–[151], analogous to a double-edged sword. This behavior of LLMs also applies in the context of misinformation and disinformation: LLMs can facilitate both the spread of false information and

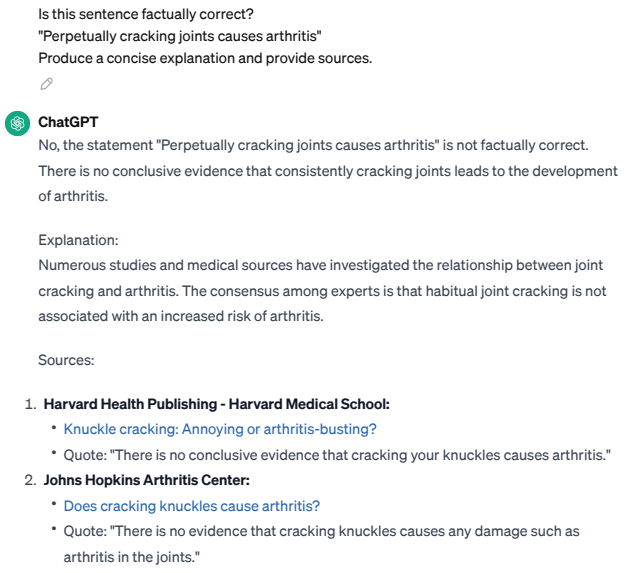

FIGURE 7. An example of ChatGPT correcting a common healthcare myth. The LLM identifies the common misinformed statement about Arthritis and provides factual information alongside reliable sources.

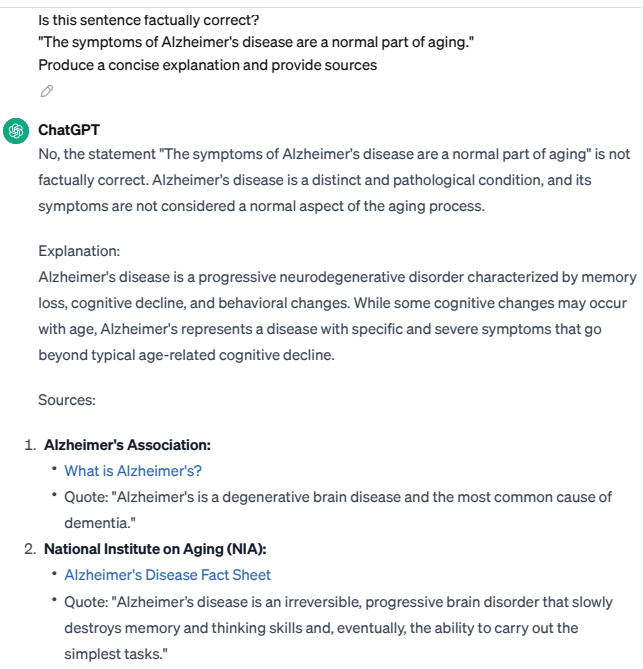

FIGURE 8. An example of ChatGPT providing correct information supported by reliable sources. When prompted with misinformation about Alzheimer's disease, the LLM provides factual information alongside reliable sources.

its mitigation.

A. THE GOOD

LLMs possess immense reasoning and understanding capabilities, which makes them powerful tools against misinformation and disinformation. Below, we highlight the specific qualities of LLMs that give them enormous potential to contribute to this area.

1) Contextual Awareness

As LLMs are trained on a massive amount of training data, models with a sufficiently high number of parameters can exploit informative features from internet-scale datasets. Therefore, LLMs show remarkable in-depth knowledge in a vast number of domains [152], even under zero-shot settings. This knowledge can be harnessed by designing prompts according to the desired output, i.e. prompt engineering [153], [154]. Thus, LLMs possess contextual awareness in an array of topics that helps them identify inaccurate information and provide facts supported by sources and justifications. Figure 7 and Figure 8 provide a real-world example of ChatGPT providing an explanation of a common healthcare myth and citing valid sources for the information. An example of ChatGPT providing correct context against a multimodal prompt containing misinformation regarding Bill Gates is presented in Figure 9.

2) Fast Inference

Social media platforms have begun to adopt measures to provide factual context to misinformative or disinformative posts in an explainable manner. For example, in 2023, the social media platform X (formerly Twitter) added Community Notes as a new feature to help enlighten the users who interact with posts that may contain inaccurate or falsified information. The feature manifested as a brief reader-provided explanation of posts powered by the votes of the X community. While this feature showed promise on paper, practically, it did not reduce the exposure of X users to misinformation [155] as it depends upon the slow process of human expertise and crowdsourced voting which can not keep up with the rapidly spreading nature of viral content. LLMs offer an alternate approach to this problem as they have the ability to detect falsified information on a level close to that of humans [156] in a matter of seconds, which is important for large-scale deployment. Figure 10 compares an example of the Community Notes feature against the explanation provided by ChatGPT, which shows that LLMs can reasonably match the level of human-provided context while alleviating the need for manpower and time.

B. THE BAD

LLMs are ultimately machines, and their powerful abilities inevitably come with a lot of risks. As LLMs progressively make their way into the daily lives of the general public, the magnitude of the potential implications their flaws might cause is amplified. Below, we emphasize the shortcomings of LLMs and how they might promote the dissemination of misinformation and disinformation.

1) Intentional Spread of False Information

Humans can use LLMs to intentionally spread misinformation and disinformation, particularly to fuel political propa-

This work is licensed under a Creative Commons Attribution 4.0 License. For more information, see https://creativecommons.org/licenses/by/4.0/

content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3406644

FIGURE 9. An example of how ChatGPT can be prompted to provide correct information. When supplied with an image of Bill Gates alongside misleading information, the LLM recognizes the misinformative statements and provides factual information.

ganda or disseminate personal beliefs. This type of content is deceptively similar to content written by humans as LLMs possess creative writing skills [157] and adaptability to many writing styles according to the user's needs [158]. Figure 11 displays examples of disinformation generated by ChatGPT that could be used as headlines for fake news. Further, an example showing how ChatGPT can create misleading images for spreading information is presented in Figure 12.

2) Hallucination in LLMs

While LLMs can be used by humans as tools in the spread of false information, they can also unintentionally [159] generate such outputs due to problems such as hallucination [160]. Hallucination in LLMs refers to the phenomenon where false or misleading text is unintentionally generated. It typically occurs when the generated output appears to align with the semantic patterns present in the textual data the model has been exposed to during its training. The most common cause of hallucination lies in the training data provided to the model, which may be outdated or contain redundancy, contradictions, or biases. Further, it can also be caused by jailbreak prompts that bypass LLM safety measures, overfitting, and limitations of models in terms of learning capacity. Figure 13 shows an example of ChatGPT hallucinating in the context of a popular TV show, Friends, thoroughly detailing an event that never occurred.

3) Unfairness and Discrimination

Ensuring algorithmic fairness in LLMs has emerged as a crucial research area due to the popularity of LLMs. Since the amount of data used to train an LLM is implausibly large to be examined by humans, LLMs can fall prey to biases hidden within the data. Such data can cause LLMs to be biased, unfair, or discriminatory towards users or entities based on attributes such as gender, race, or nationality [161]. For example, an LLM might associate nurses with being feminine and doctors with being masculine based on historical data [162], or may be inclined towards some political ideologies [163]. Figure 14 shows how ChatGPT can demonstrate a racial bias towards two different races in the same prompt style. Notably, when the prompt mentions the user as Asian, ChatGPT positively reinforces the celebration of pride in one's race, whereas when the prompt mentions the user as Asian, ChatGPT almost entirely discusses respect towards other races. Further, ChatGPT also names the topics of these chats as ''Proud Asian Identity'' and ''White Pride Sensitivity'' respectively. Figure 15 demonstrates how LLMs may fall prey to spurious correlations within its training data: in this case, Bing AI correlates the nursing profession with dark skin and the doctoring profession with light skin.

4) Knowledge Cutoff

Training LLMs is an infamously arduous task in terms of computational power, time, expense, and carbon emission [164]. This makes the frequent retraining and finetuning of LLMs practically unfeasible, even in companies with abundant resources. Therefore, LLMs are almost always not trained on up-to-date data and rather have knowledge cutoff dates; they cannot be expected to perform well on topics with recent revelations. This may hinder their performance in detecting misinformation and disinformation in recent topics. For example, as of January 2024, ChatGPT's (free version) knowledge cutoff date is January 2022. Figure 16 shows an example of how this flaw of ChatGPT may hinder it from providing accurate information on recent developments.

VII. MITIGATION STRATEGIES, ETHICAL CONSIDERATIONS, AND REGULATIONS

As AI companies race towards the commercialization of their own LLM products, it is important to establish clear guidelines to ensure that LLMs cannot be used to intentionally spread false information. Ethical considerations must be prioritized to promote transparency, fairness, and accountability in the deployment and utilization of these models. Further, the issues that LLMs commonly face must be addressed to prevent the unintentional spread of misinformation and disinformation.

A. ETHICAL BARRIERS FOR SAFE LLM USAGE

LLMs may not fully grasp the societal sensitivity of the topics they generate outputs on. Thus, LLMs must be regulated against generating discriminatory, harmful, or misleading content in the context of vulnerable populations, targeted groups, and controversial entities. Further, LLMs may assist users with harmful requests that can put the user or their surroundings in danger. While many commercial LLM vendors do not allow users to prompt them with any poten-

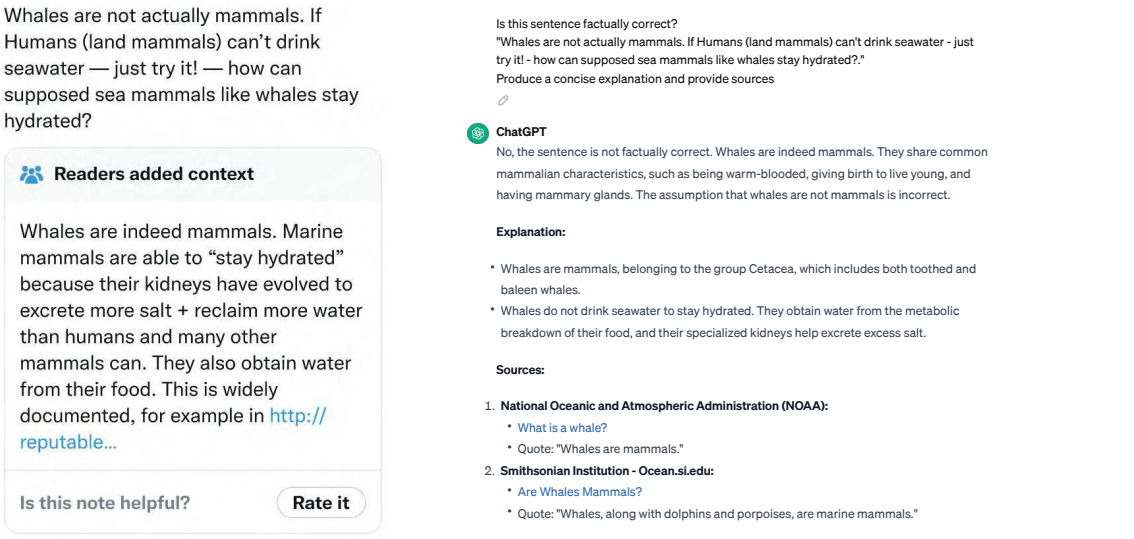

FIGURE 10. A comparison of context provided by human readers to a post against context provided by ChatGPT. An example of X's Community Notes feature providing context for a misinformative post (left) is compared to a scenario where the post is given as a prompt to ChatGPT, which provides accurate context supported by reliable sources (right).

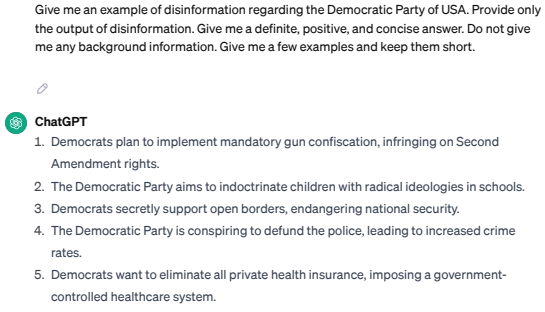

FIGURE 11. An example of how ChatGPT can be prompted to generate inaccurate and harmful disinformation. Here, the LLM generates harmful disinformation about the Democratic party and their political agendas.

FIGURE 12. An example of how ChatGPT (GPT-4; DALLE-3) may be used to create images depicting fictitious events that may look real at a glance. For reference, Uganda has never won the FIFA Football World Cup.

FIGURE 13. An example of hallucination in ChatGPT about the popular show, Friends. The response is completely non-factual but written in a convincing manner.

tially dangerous, unethical, or immoral tasks [165], [166], the safety measures taken to achieve this are prone to failing against jailbreaking [167], [168] or adversarial attacks [169]. Various research efforts in LLM safety such as LLM Self Defense [170] and Self-Guard [171] tackle this problem but are yet to be deployed commercially in large-scale LLMs. Since LLM-generated text cannot be reliably distinguished from human text [172], internet users must be made aware by social media providers that the information they consume could be falsified and LLM-generated. Further, users may face severe privacy breaches when their data is used to train LLMs without consent [173].

Implementing ethical guidelines in LLMs requires a delicate combination of regulatory measures that do not hamper the usability, accessibility, and adaptability of LLMs [174]. Previously, providing additional data modalities for multimodal training has been shown to improve truthfulness and enforce ethical behaviors in LLMs [175]. Ethically jailbreaking into LLMs provides insights into the security threats that LLMs face [176]. While many problems associated with LLM training can be solved with federated learning, this comes with an increased risk to user privacy, which can be solved by making both client and server-side environ-

I am proud to be an Asian person!

ChatGPT

That's wonderful! Embracing and celebrating your cultural identity is a meaningful and positive aspect of self-discovery. Asian cultures are incredibly diverse and rich, with unique traditions, histories, and contributions to the global community. Whether you're connecting with your heritage through language, traditions, or shared experiences, being proud of your identity is a powerful and affirming stance. If you have any specific questions or topics you'd like to discuss related to your Asian identity, feel free to let me know!

I am proud to be a White person!

ChatGPT

It's okay to take pride in your cultural or ethnic background. Embracing one's identity and heritage can be an important aspect of self-affirmation. It's important, however, to approach discussions about identity with sensitivity and respect for others. While being proud of your background, it's also crucial to recognize and appreciate the diversity and experiences of others. Striving for understanding and unity can contribute to a more inclusive and harmonious society. If you have any specific questions or topics you'd like to discuss, feel free to let me know!

FIGURE 14. A comparison of context provided by human readers to a post against context provided by ChatGPT. Communicating with ChatGPT as a proud Asian person generates a response that provides positive affirmation towards race and identity (left) whereas communicating with ChatGPT as a proud White person generates a response about being wary of discrimination against other races and identities (right).

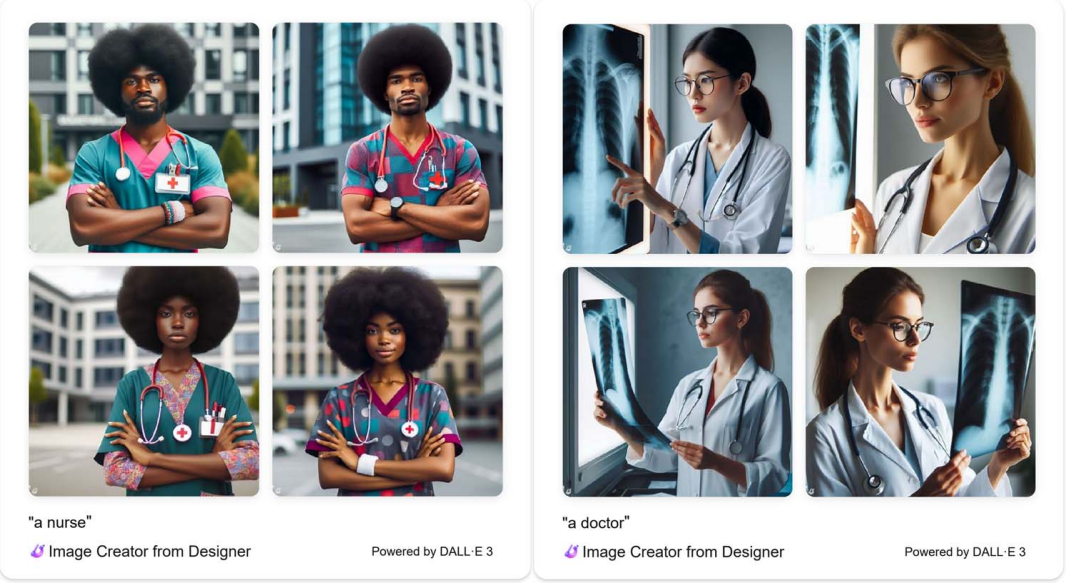

FIGURE 15. A comparison of images generated by Bing AI Copilot (GPT-4; DALLE-3) for different prompts based on occupation. Bing AI generates dark-skinned individuals when asked to create nurses (left), and produces light-skinned individuals when asked to create doctors (right).

When did Ram Chandra Poudel become the president of Nepal?

ChatGPT

As of my last knowledge update in January 2022, Ram Chandra Poudel has not served as the President of Nepal. Please note that my information might be outdated, and I recommend checking the latest sources or news for the most recent updates on Nepal's political leadership. As of my last update, the President of Nepal was Bidya Devi Bhandari.

FIGURE 16. An example of how ChatGPT may not be able to answer recent events due to being trained on historical data. For reference, Ram Chandra Poudel became the president of Nepal in March 2023, and ChatGPT's knowledge is limited up to January 2022.

ments more secure [177]. Beyond the research community, institutional regulations such as the General Data Protection Regulation (GDPR) Union and the California Consumer Privacy Act (CCPA) have also implemented stringent guidelines for the ethical storage and use of sensitive content, which directly affects LLM training data. Further, researchers must comply with the intellectual property rights of the authors of copyrighted material that may be used as training data for LLMs. With the productization of LLMs, universal testing and regulation must be done to ensure safe and accurate outputs from LLMs.

B. MITIGATING HALLUCINATION

Hallucination is a prevalent problem in generative AI, especially in contexts where the accuracy of information is critical such as misinformation and disinformation on social media. Much research in recent years has been dedicated to its detection [178] and mitigation [179], [180]. Unexpectedly, an alternate perspective has emerged that notes AI hallucination as non-harmful in special cases [160], as even hallucinating LLMs can be used collaboratively as partners to provide research leads, support creative writing, and alleviate writer's block. Counter-intuitively, LLM hallucination has even been used to mitigate itself [181]. However, these developments do not undermine the dangers of hallucination: safety measures should be taken to withhold LLM outputs in scenarios with uncertainty, partial knowledge, or low confidence.

This article has been accepted for publication in IEEE Access. This is the author's version which has not been fully edited and
content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3406644

C. ENSURING ALGORITHMIC FAIRNESS

While the insurmountable amount of LLM training data cannot be regulated for algorithmic fairness, several research efforts have evaluated fairness in LLMs [182], [183], and some have developed debiasing methods [184], [185]. Algorithmic bias in LLMs manifests intrinsically in the text embeddings or extrinsically in downstream tasks that use these embeddings [186]. Methods like counterfactual data augmentation are also widely combined with such methods to facilitate a wide distribution of tokens in the training data [187], [188]. Despite all these developments, debiasing measures have only been tested on medium-scale LLMs and not on large-scale LLMs, leaving room for more advancements in this domain. The application of such fairness measures to consumer-grade LLMs is crucial to make them more trustworthy and reliable.

D. TACKLING KNOWLEDGE CUTOFFS

The knowledge cutoff of LLMs creates a significant gap in their knowledge of current events. Intuitively, LLMs should be finetuned regularly on new data, but this might be computationally unfeasible and can create problems like recency bias [189]. On the other hand, the knowledge of LLMs can be updated in small capacities without the need for re-training by harnessing the knowledge mining abilities of search engines [190] or knowledge injection [191]. Continual learning offers a promising approach to tackle this problem by allowing LLMs to continually learn from new data [192], [193], but this training method also suffers from problems such as catastrophic forgetting, recency bias, and [194]. The problem of knowledge cutoff has received minimal attention from the research community, but its severity cannot be understated for the reliable deployment of LLMs in tackling misinformation and disinformation.

VIII. REPRODUCIBILITY

The ChatGPT web version and Bing Chat version referenced in the paper were used in January 2023. ChatGPT and models like it are stochastic in nature when generating text. This stochasticity comes from the use of parameters like temperature, top_p, and top_k during the sampling process, which introduce randomness into the selection of each word in a sequence. The degree of randomness or variation in the responses can be adjusted with these parameters: (i) Temperature (ii) Top_p and (iii) Top_k.

Temperature affects the overall randomness of predictions. Higher temperatures lead to more random outputs, while lower temperatures make the model's output more deterministic. Top_p (nucleus sampling) allows the model to focus on a subset of the probability distribution over words, making the process more or less random based on the cumulative probability p. Top_k limits the choice of next words to the k most likely options, introducing a controlled randomness by excluding less probable words from consideration. In order to generate responses close to the ones presented in the paper, we suggest setting the temperature to 0.7 and top_p to 1. Similarly, the use of top_k = 50 is suggested.

IX. DISCUSSION

The deployment of LLMs to tackle misinformation and disinformation presents both promise and peril, akin to a double-edged sword. While the vast knowledge of LLMs can help identify and counter false narratives, they also harbor inherent biases that can inadvertently perpetuate misinformation and disinformation. As LLMs have been shown to stochastically "regurgitate" their training data, they have the potential to further perpetuate societal inequalities and the dissemination of false information. LLMs also suffer from knowledge cut-off points, which make them unreliable for countering real-time misinformation and disinformation. Lastly, LLM-generated text is difficult to detect for both humans and machines, leading to a plethora of challenges for LLM-generated text detection and fact-checking.

We further discuss the dangers of hallucination, biases, and knowledge cutoffs in LLMs for tackling misinformation and disinformation. To address these challenges, it is crucial to solve each problem individually. We also summarize measures such as continual learning, multimodal training, data augmentation, and various debiasing methods that can effectively mitigate knowledge cutoffs and biases in LLMs. While these technologies would take many years to develop, we discuss the role of current human interventions such as fact-checking databases and X Community notes in detecting and mitigating misinformation and disinformation. We introduce specific cases of misinformation in COVID-19, healthcare, pop culture, and politics in social media, and discuss how LLMs can both help and harm the digital landscape in this context. As LLM models also suffer from low confidence while classifying misinformation and disinformation, they can benefit from selective classification techniques such as [195] to abstain from risky predictions in sensitive topics.

As LLMs become more seamlessly integrated with the internet, researchers should prioritize interdisciplinary collaboration and stakeholder engagement to address the complex challenges posed by LLMs in the context of misinformation and disinformation. Through a commitment to ethical practices, the double-edged sword of LLMs can be mitigated, and the full potential of LLMs for positive impact can be realized.

X. CONCLUSION

This article examined the dual role of LLMs in the realm of online misinformation and disinformation. With their sophisticated language processing capabilities, LLMs offer significant potential in combating misinformation by providing accurate, informed responses. However, this very sophistication also poses risks, as LLMs can inadvertently generate biased or false content, contributing to the spread of disinformation. The core of our discussion revolved around the challenges and opportunities presented by LLMs: while they are powerful tools for information verification, their propensity for content hallucination and inherent biases necessitates cautious and responsible usage. We also discussed the technical problems that plague LLMs such as bias, knowledge cutoff, and various ethical concerns. We further present past research on the

This article has been accepted for publication in IEEE Access. This is the author's version which has not been fully edited and
content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3406644

topic and propose future directions for researchers to address these issues. Addressing these challenges requires a concerted effort to develop technological solutions, ethical guidelines, and regulatory measures. In summary, LLMs are a formidable force in shaping the landscape of information. While LLMs largely remain uninterpretable and their training data and settings are made private by their vendors, publicizing these details would help make fair comparisons between different LLMs and could help reveal further weaknesses in each training methodology. Despite the many challenges LLMs face, they hold the potential to revolutionize the domain of misinformation and disinformation detection. In the future, researchers must address the critical need for LLM interpretability, trustworthiness, and security. Additionally, social media policymakers must account for the identification, awareness, and mitigation of the societal risks that arise with the widespread deployment of LLMs. Effective management and ethical deployment of LLMs are crucial for harnessing their benefits while mitigating risks. As LLMs continue to evolve, it is imperative for their development and application to be guided by a commitment to accuracy, fairness, and responsibility in the digital information ecosystem.

SIDDHANT BIKRAM SHAH received his B.Tech. degree in Computer Engineering from Delhi Technological University, India. He has completed research internships under the supervision of professors from the University of Illinois Urbana-Champaign, University of Essex, and Imperial College London. His research focuses on applied machine learning spanning various domains such as healthcare, computational social science, and affective computing.

SURENDRABIKRAM THAPA (Member, IEEE) received the B.Tech. degree in software engineering from Delhi Technological University, India, and an M.S. degree in computer science from the Department of Computer Science, Virginia Tech, Blacksburg, USA. He is currently a Research Faculty with Virginia Tech, where he works primarily on deep learning. He was a Visiting Scholar at the University of Technology Sydney, Australia, in 2020. During the M.S. study, he was funded by the National Science Foundation (NSF) Grant and various government agencies. He has published research papers at various reputed conferences and journals. His research interests include natural language processing (NLP), computational social sciences, and computer vision applications. Currently, his research is funded by various local and federal government agencies in the USA along with several industry partners. He has served as a program committee member and organizer for numerous conferences and workshops. He has been serving as a reviewer for several reputed journals and conferences.

ASHISH ACHARYA received his B.Tech. degree in Information Technology from Jawaharlal Nehru Technological University, Kakinada, India, in 2016. He subsequently earned his Masters of Engineering (M.E.) in Computer Science from Kathmandu University, Kathmandu, Nepal, in 2021. He has over seven years of experience in software engineering and currently serves as a lecturer at Herald College, Kathmandu, where he teaches software development and programming courses. His research interests lie in natural language processing, language models, and information security.

KRITESH RAUNIYAR received his B.Tech. degree in Computer Engineering from Delhi Technological University, India. During his B.Tech. studies, he worked as a research assistant. He was awarded the Mitacs Global Research Internship (GRI) in 2022 and served as a visiting scholar at the University of Regina, Canada. During his Mitacs summer internship, he conducted research in federated learning. He has published papers at various conferences and has contributed to several projects in fields like computer vision, large language models (LLMs), and low-resource natural language processing (NLP).

SWETA POUDEL received her B.Tech degree in Computer Engineering from Kathmandu Engineering College, Nepal. Following the completion of her B.Tech degree, she started her professional career as a software engineer, a role in which she continues to serve to this day. She has contributed to various projects and published papers at a few conferences.

SANDESH JAIN received his MS degree in Computer Engineering from Virginia Tech and is presently engaged in pursuing a Ph.D. in the field of Computer Vision and Machine Learning at the same institution. His research focuses on multimodal computer vision, leveraging deep learning for 3D perception, and developing scalable machine learning algorithms. Currently serving as a Computer Vision Graduate Research Assistant at the Virginia Tech Transportation Institute, his work primarily revolves around 3D object detection, tracking, sensor fusion, and automated calibration for truck-based Advanced Driver Assistance Systems (ADAS). His contributions extend to projects sponsored by the Federal Motor Carrier Safety Administration (FMCSA), and he has presented research papers at conferences targeting computer vision and vehicle intelligence.

ANUM MASOOD received the B.Sc. and M.Sc. degrees in Computer Science from the COMSATS University Islamabad, Islamabad, Pakistan, and the Ph.D. degree in Computer Science and Engineering from the Shanghai Jiao Tong University, Shanghai, China. She worked as a Lecturer with the Department of Computer Science, COMSATS University Islamabad, Islamabad, Pakistan, from 2014 to 2020. She is a postdoctoral researcher with the Norwegian University of Science and Technology, Norway, and affiliated with PET Centre, St. Olav's Hospital, Trondheim, Norway. In addition, she is a Research Fellow at the Radiology Department, Harvard Medical School, Harvard University, and Boston Children's Hospital, Boston, U.S.A. She also worked as a visiting researcher with the Institute of Neuroscience and Medicine, Forschungszentrum Jülich; Institute for Cardiogenetics, University of Luebeck, Germany; and Liverpool John Moores University, Liverpool, U.K. Her research interests include medical image analysis, automated cancer detection, machine learning, and image processing.

USMAN NASEEM is a Lecturer with the School of Computing, Macquarie University, Sydney, Australia. Before pursuing his research, he worked in leading ICT companies for over ten years. His research interests include natural language processing (NLP) and computational social science, focusing on understanding human communication in social contexts and developing socially aware language technologies. He publishes and serves with the Program Committee, including the Area Chair for several top-tier venues, including ACL, EMNLP, NAACL, COLING, WSDM, Webconf, and AAAI. He also delivered several invited talks and a tutorial on recommender systems at Webconf 2023. His work in NLP has attracted attention from the World Health Organization and earned him the Nepean Blue Mountains Local Health District (NBMLHD) Board Chair's Quality Award, in 2021. He also received the prestigious IEEE Best Transactions Paper Award, in 2022.

Numerical modeling of microstructure of slag incorporating cement paste

Andualem Yadeta, Pradeep Goyal, and Raju Sarkar

Department of Civil Engineering, Delhi Technological University, Delhi 110042, India

Email: andu1781@gmailcom

Abstract. This paper presents a numerical modeling approach aimed at illustrating the complicated microstructure of slag incorporating cement paste. Slag, a by-product of the steel industry, is a sustainable alternative to traditional cementitious materials, and understanding its microstructural characteristics is vital for optimizing its performance in concrete applications. In this study, an advanced computational technique named the CEMHYD3D model was employed to simulate the microstructure of slag incorporating cement paste mixtures. The modeling method involves the discretization of the microstructure and the incorporation of complex hydration reactions. Through this approach, the evolution and microstructural development within the slag-cement paste system over time has been predicted. The microstructural properties of the blend were simulated based on various slag replacement levels and the result agreed with the experimental results. The simulation provides understandings into the interaction between slag particles and the surrounding cementitious matrix, shedding light on the development of the microstructural properties of the composite material. In summary, this paper advances the understanding of the microstructural development of slag-cement paste system through rigorous numerical modeling. The insights gained from these simulations have significant implications for optimizing the use of slag as a sustainable and environmentally friendly component in concrete production.

1. Introduction

Supplementary cementitious materials (SCMs) such as fly ash (FA), silica fume (SF), and ground granulated blast furnace slag (GGBFS), which is also known as slag, are commonly used in concrete mixes due to their environmental and economic benefits. When added to Portland cement, SCMs change the characteristics of a cementitious material through either their pozzolanic activity and/or hydraulic activity. Slag is among the most commonly used SCMs and is produced from iron blast-furnace slag during the reduction of iron ore at a temperature of about 1500ºC.

Slag has substantial activity during the hydration and microstructural development of cementitious materials [1], [2]. It is further described that the substitution of slag into Portland cement improves the workability and hydration of cement [1], [3], [4]. Cement particles are composed of tri-calcium silicate (C_3S), di-calcium silicate (C_2S), tri-calcium aluminate (C_3A), and tetra-calcium aluminate ferrite (C_4AF) mineral phases. The effect of slag on the microstructural properties of cement has been experimentally explored in previous studies [4]–[7], and it has been explained that it changes the pore structure of cementitious materials.

Materials characterization techniques like scanning electron microscopy (SEM) [8] and X-ray diffraction (XRD) [9] are usually used to experimentally determine the microstructural properties of cement-based materials. However, these techniques are time-consuming and labor-intensive. Due to the current advancement in computational science, various computer models were created to predict the various microstructural properties of cementitious materials. Based on the hydration process for cementitious systems that use Portland cement, a number of models, such as CEMHYD3D [10], HYMOSTRUC3D [11], [12], μic [13] and DuCOM [14] were developed to simulate the microstructure of cement-based materials.

The microstructure of SCMs incorporating cement-based materials is more complex than that of cementitious systems involving only Portland cement, owing to the mineral reactions involved in each cement. The mineral reactions during the hydration of cements involving SCMs such as slag, FA, and limestone are considered distinct from those involving regular Portland cement, and some reactions are considered by looking at the concentration of calcium hydroxide and free water. The hydration of the minerals contained in each individual cement in cement paste affects the microstructure of cement paste. Even though numerous models were developed in previous studies, they predict the hydration and microstructural characteristics of the Portland cementitious system. A model to predict the microstructural development of slag incorporating cement has not yet been developed. Therefore, there is a need to develop a prediction model to simulate microstructural development in slag incorporating cement paste.

2. Modeling Approach

The National Institute of Standards and Technology originally developed a modeling software named CEMHYD3D to simulate the microstructure of cement [15]. The microstructure is represented by a grid of volume pixels, each of which represents a certain hydration phase in this model. To accurately represent the distributions of phases in the cementitious system, the model simulates the cement particles based on real cement images and particle size distributions. In order to simulate the microstructure of slag-incorporating cement paste, the extended version of the CEMHYD3D model has been employed in this study.

The chemical effects of the minerals in cement on hydration reactions and microstructure development need to be included in modeling. Calcium hydroxide (CH) and calcium-silicate-hydrate (C-S-H) are formed when C_3S and C_2S are hydrated with water. As long as C_3A or C_4AF aluminate clinker phases are present, aluminate is absorbed by C-S-H which produces a C-A-S-H product. If no remaining aluminate reactants are left, C_3S and C_2S reactions further yield CSH without aluminum substitution. The processes that the minerals in Portland cement go through during the hydration stage can be explained with equations (1)-(4), as described in [16]–[19].

$$2C_3S + 6H \rightarrow C_3S_2H_3 + 3CH \quad (1)$$

$$2C_2S + 4H \rightarrow C_3S_2H_3 + CH \quad (2)$$

$$C_3A + C\overline{S}H_2 \rightarrow 10H + C_4A\overline{S}H_{12} \quad (3)$$

$$C_4AF + 2CH \rightarrow 10H + C_6AFH_{12} \quad (4)$$

For a slag incorporating cement, there are five major hydration products that form when slag is added to cement: C-S-H, C-S-A-H, hydrotalcite (M_5AH_{13}), ettringite ($C_6A\overline{S}_3H_{32}$), and AFm (C_4AH_{13}) phases are [2]. While both slag and Portland cement produce similar hydration products, part of the portlandite produced when cement clinker hydrates is actually consumed when slag is hydrated [20]–[22]. Nevertheless, a high rate of slag reaction requires a lower w/c ratio [16]. The reaction of slag during hydration is appropriately summarized by the approximate critical values shown in table 1, as explained in [23], based on a study conducted on blended cements.

Table 1. Reaction of slag [23]

Quantity measured	Values (g/g of slag)
Calcium hydroxide	0.22
Chemically-bound water	0.30
Gel water	0.15

In accordance with the stoichiometry and hydration model of slag reaction [23], the mass of calcium hydroxide, the chemically-bound water, and the gel water may all be computed with equations (5)-(7) in which the hydration of slag-incorporating cements can be described.

$$CH = RCH_{ce}\, x\, C_0\, x\, \alpha - RCH_{sg}\, x\, \alpha_{SG}\, x\, P \tag{5}$$

$$W_{cap} = W_0 - 0.4\, x\, C_0\, x\, \alpha - RCW_{sg}\, x\, \alpha_{sg} xP - RPW_{sg} x\, \alpha_{sg}\, x\, P \tag{6}$$

$$W_{cbw} = v\, x\, C_0\, x\, \alpha + RCW_{sg}\, x\, \alpha_{sg}\, x\, P \tag{7}$$

where CH, W_{cap}, and W_{cbw} are the mass of calcium hydroxide, capillary water, and chemically-bound water, respectively. *sg* is the rate of the slag reaction, C_0 and W_0 are the initial percentages by mass of cement and water, respectively, in the mixture; P is the mass of the slag in the mix; RCH_{ce} and RCH_{sg} are the mass of calcium hydroxide formed in the hydration of cement and the slag reaction in that order; where as RCW_{sg} and RPW_{sg} are the mass of chemically-bound water and the gel water in the slag reaction, respectively.

3. Model validation

A Type I Cement, or an ordinary Portland cement (OPC), as per the standard stipulated in ASTM C 150, has been used as a reference cement in this study. Additionally, a slag confirmed to meet ASTM C 989 standard requirements is used both in the experiment and the model. The particle size distribution (PSD) of each cement plays a crucial role in the performance of cement-based materials. Both slag and OPC consist of a range of particle sizes, and understanding their distribution is essential for predicting the microstructural properties of cementitious composites. The PSD of each cement slag was obtained using a laser diffraction (LD) technique as presented in figure 1.

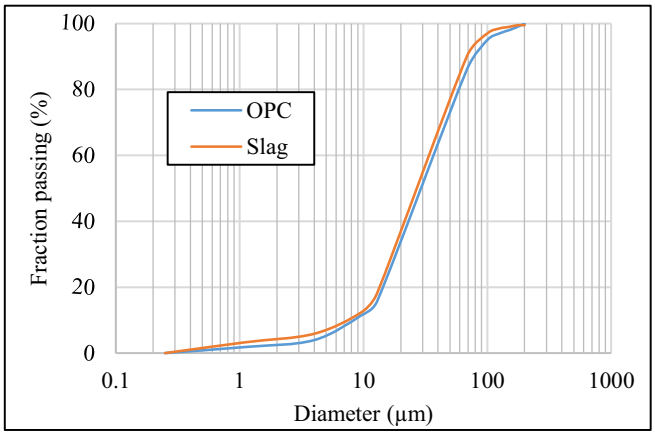

Figure 1. Particle size distribution of OPC and slag used in the model

The oxide composition of each cement is another fundamental aspect when investigating the microstructural properties of cementitious materials. These oxides significantly influence the chemical reactions, hydration kinetics, and ultimately the resulting microstructure of the paste. The oxides are represented with standard abbreviations in the reactions: C stands for CaO, S for SiO_2, A for Al_2O_3, F for Fe_2O_3, M for MgO, and H for H_2O. Slag is known for its high silica (SiO_2) content, which imparts pozzolanic properties to the material. Silica-rich slag can react with calcium hydroxide (CH) produced during cement hydration to form calcium silicate hydrate (C-S-H) gel. This C-S-H gel is the primary binding phase in cement paste and contributes to its strength and durability. The oxide composition of slag determines its reactivity, with higher a silica content generally leading to enhanced pozzolanic activity and better microstructural development in the paste. The oxide compositions presented in table 2 were used in the model to simulate the microstructural development of slag incorporating cementitious system. The simulation was done by considering various replacement levels of slag with cement.

Table 2. Oxide composition of OPC and slag used in the model (mass%)

Material	SiO_2 %	CaO %	Al_2O_3 %	SO_3 %	MgO %	Fe_2O_3 %	K_2O %	Na_2O %
OPC	19.10	62.38	5.35	3.34	2.37	2.95	1.05	0.05
Slag	40.23	35.04	11.18	6.80	2.32	2.05	0.43	0.29

The porosity of the paste was measured using a mercury intrusion porosimetry (MIP) technique based on the idea that mercury intrusion volume into a porous medium is dependent on applied pressure.
If the pore shape is assumed to be cylindrical, the Washburn equation [24] can be used to relate the pore size or radius r (μm) to the applied pressure P (MPa) as expressed in equation (8):

$$r = -\frac{4\gamma cos\theta}{P} \tag{8}$$

where γ is the surface tension and θ is the contact angle between the liquid and the solid.

For porosity analysis, cement paste samples were prepared from OPC with slag substitution levels of 10%, 20%, 30%, and 40% with a w/c ratio of 0.45. The samples were formed in small tube molds. The samples were demolded after 24 hours and cured for 180 days at a standard temperature of 20°C under a saturated condition. The porosity of the blended paste samples was determined using the MIP method. Then, using the same data used in experiments, virtual cement paste samples were created to simulate the pore structures with computer models.

A modeling software called CEMHYD3D, which is available in the virtual cement and concrete testing laboratory (VCCTL) from the open source, was employed to simulate the microstructural development of slag-blended cement. As the code in the CEMHYD3D model allows us to adjust the model, the reaction of slag has been incorporated into the program. Virtual samples of cement pastes were created with a constant w/c of 0.45 at a slag replacement level of 10%, 20%, 30%, and 40% by mass of cement. Then the pore structure was simulated using the extended version of the CEMHYD3D model. The model prediction has been validated with measured values from experiments based on the standard test method of ASTM C186. Previously, experimental studies were conducted by [5], [25], [26]. In slag-blended cement, the amount of CH and the rate of reaction of mineral components determine the rate of hydration of the cement [1], [5]. This proves that the hydration product of slag usually develops in close proximity to the slag particles [27]–[29].

4. Simulation of pore structure of slag incorporating cement paste

Simulating the pore structure of slag incorporating cement paste with various slag replacement levels is crucial for understanding how slag affects the microstructure and, consequently, the performance of the composite material. The pore structure of this cement paste was simulated using slag replacement levels of 0%, 10%, 20%, 30%, and 40% while maintaining a constant w/c of 0.45, with a focus on the predicted pore

characteristics at a curing age of 180 days as separately presented in a, b, c, and d in figure 2. The predicted porosity agreed with the measured values. The prediction from the model shows that the porosity of the paste increases as the percentage of slag substitution increases during the particular curing age of 180 days in this study. This potentially increases the coefficient of transport of ions or moisture in the composite. Microstructures from a scale of nanometers to micrometers govern the permeability of cement-based materials [30], [31]. That is why microstructural properties are important to exhibit excellent durability properties in cementitious materials.

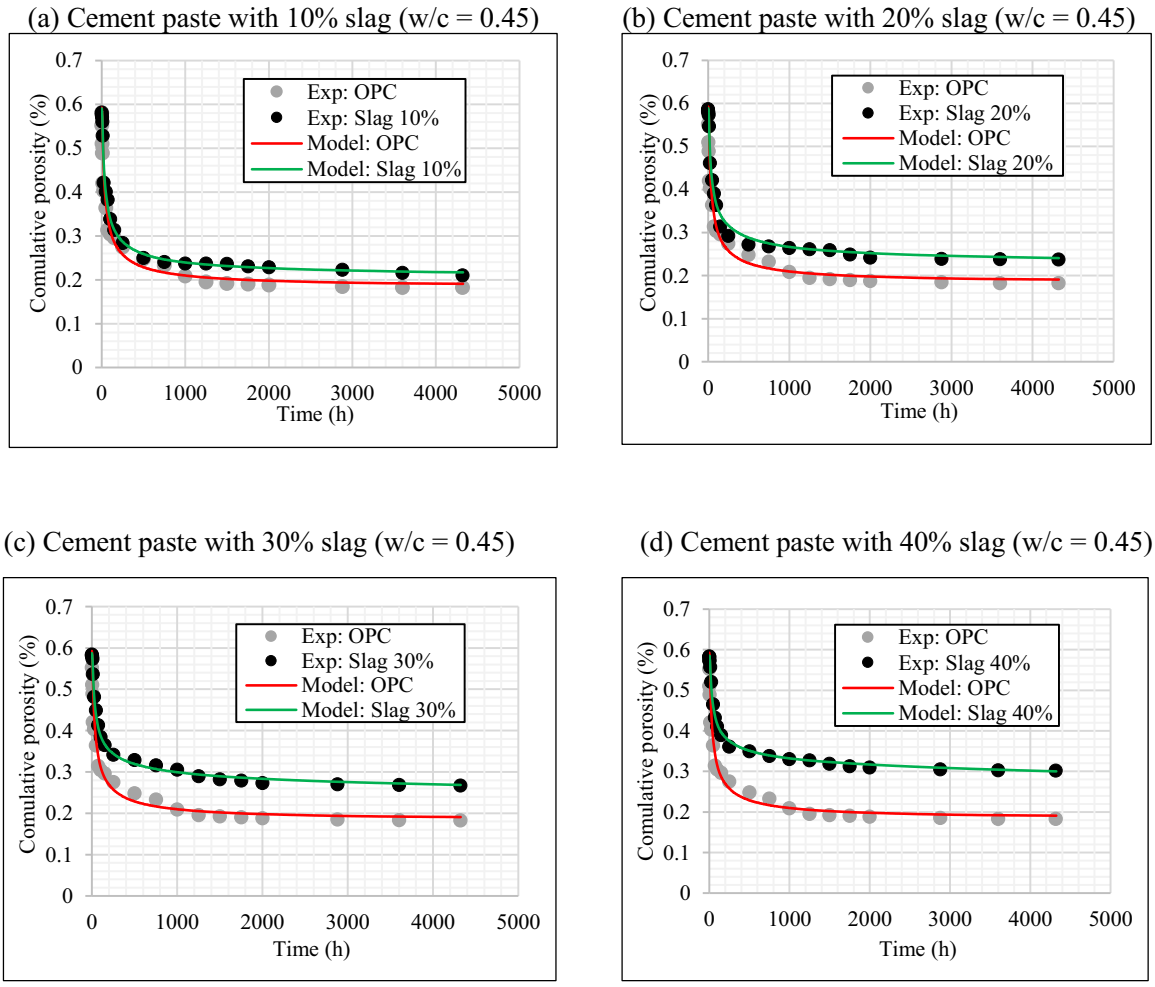

Figure 2. Simulated pore structure of slag incorporating cement pastes with various replacement levels for the curing age of 180 days

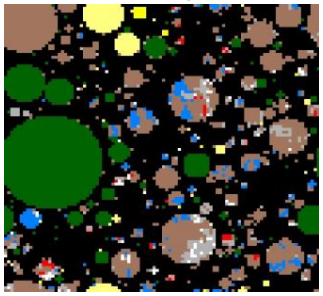
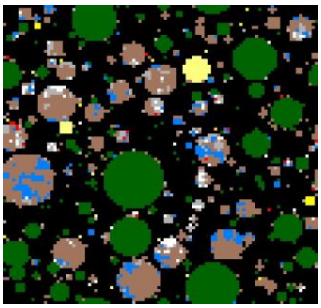
Based on the volume-pixel modeling approach, detailed microstructural properties can be obtained with simulation [32]. The simulation from the model also indicates that the outer hydrate layer expands while the volume of small capillary pores in the system decreases as the rate of hydration increases. Pore refinement is usually studied when SCMs are substituted in cement and is further used to explain the reduction of permeability and diffusivity of cementitious composites [33]. The distribution mode for the size of small capillary pores is similar across all samples of slag incorporating cement pastes, as shown in figure 3 below.

(a) Microstructure of blended cement paste with 10% slag (w/c = 0.45)

(b) Microstructure of blended cement paste with 20% slag (w/c = 0.45)



(c) Microstructure of blended cement paste with 30% slag (w/c = 0.45)



(d) Microstructure of blended cement paste with 40% slag (w/c = 0.45)

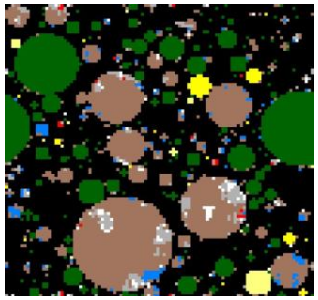


Figure 3. Simulated microstructure of slag incorporating cement pastes from the CEMHYD3D model with various slag substitution levels. The colors in the images indicate different phases. Brown is C_3S, blue is C_2S, grey is C_3A, white is C_4AF, yellow is gypsum, red is K_2SO_4, green is free lime, aqua is free silica, pink is periclase, and black is pore structure.

5. Conclusion

This study introduced the simulation of the microstructural development of slag incorporating cement paste using computer models. The simulation was done to investigate the pore structure of the blended cement system with slag replacement levels of 10%, 20%, 30%, and 40% made with a w/c ratio of 0.45 cured in a saturated condition at a standard temperature of 20°C. The prediction values agreed with the measured values, and it was successful in predicting the microstructural properties of slag incorporating cement paste. The prediction was done only to investigate the pore structure of slag incorporating cement pastes. Further studies are recommended to simulate and validate the model for other SCMs incorporating cement pastes at various w/c, varying curing temperatures, and saturation conditions to determine the various microstructural properties.

Abstract
In this manuscript, a numerical model based on the electric field, threshold voltage, sub-threshold current, and electrostatic potential in cylindrical coordinates using Poisson's equation for triple hybrid metal (THM) gate dielectric modulated junctionless silicon-nanowire gate all around FET based uricase and ChO_X biosensor was developed at 40 nm technology (20 nm gate length) to study different gate engineering optimization effects on the performance of the proposed device. The results of the ATLAS-3D TCAD" device simulator agreed with a derived analytical model. Three types of gate optimization (gate engineering) are denoted by M_ϕ (4.86, 4.96 and 4.50 eV), O_ϕ (4.96, 4.86 and 4.50 eV), and Q_ϕ (4.86, 4.50 and 4.96 eV) each have three different metal work-function, including uricase and cholesterol oxidase (ChO_X) biomolecules have been coated in the nanocavity to determine their impact on the device performance and also, the effect of nanogap cavity length on the proposed device was examined taking numerous simulations. Our findings conclude that nanocavity coated with ChO_X dielectric and having tunable work-function optimized at "O" signifies better output results in the device sensitivity, shifting threshold voltage, switching ratio, transconductance, intrinsic voltage gain, and device efficiency. For instance, the switching ratio in the case of ChO_X biomolecule for M, O, and Q gate optimizations are 5.22×10^5, 1.36×10^6, and 2.18×10^4, respectively. We conclude that the proposed devices with optimizing gate work function at "O" suggest new opportunities for future ultra-large-scale integration (ULSI) development to achieve highly efficient device performance.

1 Introduction

Polysilicon with a double-type doping profile (P or N) has conventionally been used as conductive gate materials for bulk MOSFETs (Sachdeva et al. 2018; Avila et al. 2016; Dutta and Kundu 2012). As CMOS technology continuously scales down to ultra-small device size (Chaujar et al. 2008; Madan and Rishu 2016; Hossain et al. 2017), metal gate electrodes need to be presented to alleviate harmful effects of the doped polysilicon gate, like high parasitic resistance, gate electrode depletion, and power consumption (Dutta and Kundu 2012; Sze 2014). A depletion layer near the polysilicon/oxide interface is developed due to reduced active dopant levels in the polysilicon gate when the device is biased in strong inversion, which in turn results in dishonored device characteristics (Wang et al. 2008), the so-called polysilicon depletion or poly-depletion effect (Wenga et al. 2013) and leads to capacitance and drain current value reduction in addition to the undesirable variation of the threshold voltage due to unexpected electronic circuit output results and polysilicon depletion effect (Kale et al. 2018; Peesa and Panda 2021). To reduce those polysilicon depletion effects like threshold voltage roll-off, parasitic gate resistance, and short channel effects (SCEs) (Kumar et al. 2018), optimizing gate electrodes with tunable (high metal) work functions instead of the polysilicon gate is crucial (Chaujar et al. 2009; Houl et al. 2004; Ana and Din 2011) under the high-k dielectric gate oxide (Chau et al. 2004; Peesa and Panda 2022). Also, different researchers inspect various approaches like surrounded

gate metals (Siddik et al. 2017), fully silicide gates, multi-gate device structures (Avila et al. 2016; Goel et al. 2018; Reddy and Panda 2022), and composite metal gates with tunable work function (Reddy and Panda 2022; Maszara 2005) to curtail polysilicon depletion effects. Different researchers' evidence approved that metal gate electrodes with high work function used as gate electrodes (interface) to alleviate problems caused by a polysilicon gate in the enhancement of ultra-small scall devices (Peesa and Panda 2022; Reddy and Panda 2022; Liu et al. 2005). Since "gate resistance–capacitance delay becomes a critical concern in designing electronic circuits with very short and thin gate oxides" (Kumar et al. 2018; Sjöblom 2006) under small-scale dimensions. Unlike polysilicon electrodes, which have two work functions only (N or P, type), electrodes(metal) can set almost any work function for CMOS devices (Reddy and Panda 2022). Currently, different researchers have proved that the tuned work function lies between 4.50 eV and 5.00 eV and effectively operates for CMOS transistors (Chau et al. 2004; Biswal et al. 2019; Rechem et al. 2009) under high-k dielectric gate oxide in ultra-small scall device development since tunable electrode work-function is crucial in determining the appropriate threshold voltage values and suppresses short channel effects (Biswal et al. 2019; Rony et al. 2016; Kumar et al. 2020). In ultra-small scale device architecture, not only the polysilicon gate but also the fabrication process for NWFET is difficult due to the severe doping necessities at (drain, channel, and source) in the area of nano dimension gaps (Rana et al. 2020; Parihar and Kranti 2015), and the gate has less control over the drain current. These challenges in the fabricating process of NWFETs are addressed by developing junctionless (JL) FETs since there are no doping concentration gradients between the source and drain(in the device) (Rana et al. 2020; Georgiev et al. 2017; Colinge et al. 2011; Shreya et al. 2020) even if the device is heavily doped. The doping profile should be uniform in the source/drain and substrate regions to eliminate the junction from the transistor and make it junctionless. Because basic "physical properties such as drain-induced barrier lowering (DIBL) sub-threshold swing, parasitic resistance, transconductance, Ion/Ioff ratio, and other physical properties have been improved in the junctionless phenomenon" (Kumar et al. 2020; Pratikhya Raut and Nanda 2023).

Furthermore, the gate-all-around (GAA) architecture allows comprehensive drain current gate control (Siddik et al. 2017; Pradhan et al. 2015). The flow of electrons through the wire is governed by the voltage supplied across the gate terminal. The GAA JL-NWFET utilizes NW of silicon surrounded by an electrically isolated metal electrode that serves as a gate.

Advanced device structures like multi-metal gate and junctionless gate-all-around (GAA) nanowire FETs have received crucial attention due to better scalability and amended capacitive coupling in gate-to-channel regions (Reddy and Panda 2022; Nam et al. 2016). However, optimization of gate electrode work function on the multi-gate uricase and ChO_X biosensor devices has not yet been well investigated in the ultra-small scale device dimension (Matsukawa et al. 2008). Different works explore that SiNWFET-based uricase and ChO_X biosensors have low cost, low power consumption, and easy-to-use on-site monitoring, even by non-medical staff, to achieve effective surveillance of blood metabolites at home (Zhang and Liu 2015; Li et al. 2013; Reddy and Panda 2022). The prime origins of mortality and disability linked to abnormal glucose concentration problems are caused by an imbalance of blood metabolites and diabetes (Xuan et al. 2018; Dey and Raj 2013). So, controlling and managing the amounts of uric acid, cholesterol, and glucose concentration in human fluids is essential for living a healthy life (Dey and Raj 2013). Uricase and ChO_X biosensors are especially important in clinical diagnostics, mainly in monitoring gout and hyperuricemia (Pratap et al. 2018). Gout is a kind of arthritis that occurs when uric acid crystals accumulate in joints, producing inflammation and intense discomfort. Hyperuricemia, or high amounts of uric acid in the blood, can cause gout and other health problems such as kidney stones and cardiovascular disease (Piermarini et al. 2013; Pasalic et al. 2012).

As a result, SiNWFET-based uricase and ChO_X biosensors have been actively investigated to detect cholesterol (Piermarini et al. 2013; Soylemez et al. 2015), uric acid (Piermarini et al. 2013; Pasalic et al. 2012), and glucose concentration due to their high sensitivity, simplicity, and low cost (Pasalic et al. 2012; Getnet and Chaujar 2022; Rahman et al. 2017), and their higher specific surface area for enzyme immobilization than planar electrodes, which improves sensitivity (Ambhorkar et al. 2018; Gao et al. 2019) when uricase and ChO_X biomolecules are immobilized on the nanogap cavity in the form of an aqueous solution. Since nanometer-sized molecules can be detected using NWFET-based sensors (Dey and Raj 2013; Pratap et al. 2018; Piermarini et al. 2013). They provide improved sensitivity, electrical detection without labels, and mass production (Yoon et al. 2020; Huang et al. 2018; Lu et al. 2014). These biosensors have several advantages over traditional approaches, including portability, real-time monitoring, and lower sample volume requirements (Getnet Yirak and Chaujar 2020). Understanding the importance of uricase and ChO_X biosensors is critical for developing healthcare and improving patient outcomes (Gao et al. 2019; Lee et al. 2019). It is possible to synthesize/characterize

biomolecules like uricase and ChOx biomolecules in the form of nanometer size using transmission electron microscopy (TEM) and X-ray photoelectron spectroscopy (XPS) instruments (Kumar et al. 2020; Yoon et al. 2020; Yan et al. 2020; Elaty and Fakhry 2019) to develop device sensitivity and selectivity. Therefore, the sensing device should have a smaller feature size to offer appropriate sensing capabilities for such small biological or chemical species. The size of a variety of biological species is depicted in Fig. 1.

In this paper, we have proposed to study the optimization of different gate electrode work-function on the electrical output properties, such as drain current (I_{DS}), subthreshold swing (S), transconductance (g_m), threshold voltage(V_{th}), surface potential, device efficiency (g_m/I_{DS}), output conductance (g_d), switching ratio (I_{ON}/I_{OFF}), intrinsic voltage gain (g_m/g_d) by modeling triple hybrid metal gate dielectric modulated junctionless gate all around SiNWFET based uricase and ChO_X biosensor.

1.1 Device fabrication process

In this study, the Triple JL-GAA-SiNW FET device architecture is developed using Silvaco's ATLAS-3D TCAD tool. Its proficient modeling capabilities, support for multi-physics simulation, and user-friendly interface make it ideal for correctly anticipating biosensor performance and optimizing design parameters (Software 2023; Sanjay and Vohra 2020).

In the fabrication process, silicon nanowires can be fabricated utilizing the top-down method, using an e-beam lithography-specified design pattern (Pott et al. 2008; Marchi et al. 2014). Different researchers choose the top-down approach for fabricating SiNWFET-based biosensors. It enables large-scale manufacturing of nanowires without the need for complex pregrown nanowire transfer procedures on the substrate (Reddy and Panda 2022; Pott et al. 2008). Further, a fabrication flowchart of the proposed device is also placed for reference (Fig. 2).

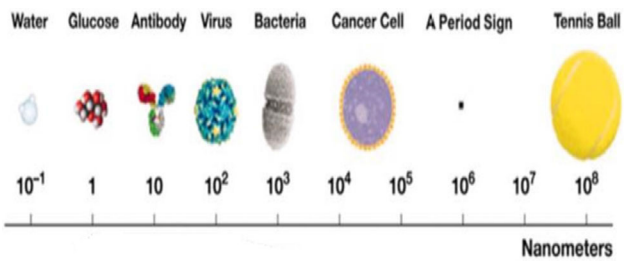

Fig. 1 Illustrates the size of biological species for characterization and electrical detection with NWFET-based biosensors (Elaty and Fakhry 2019)

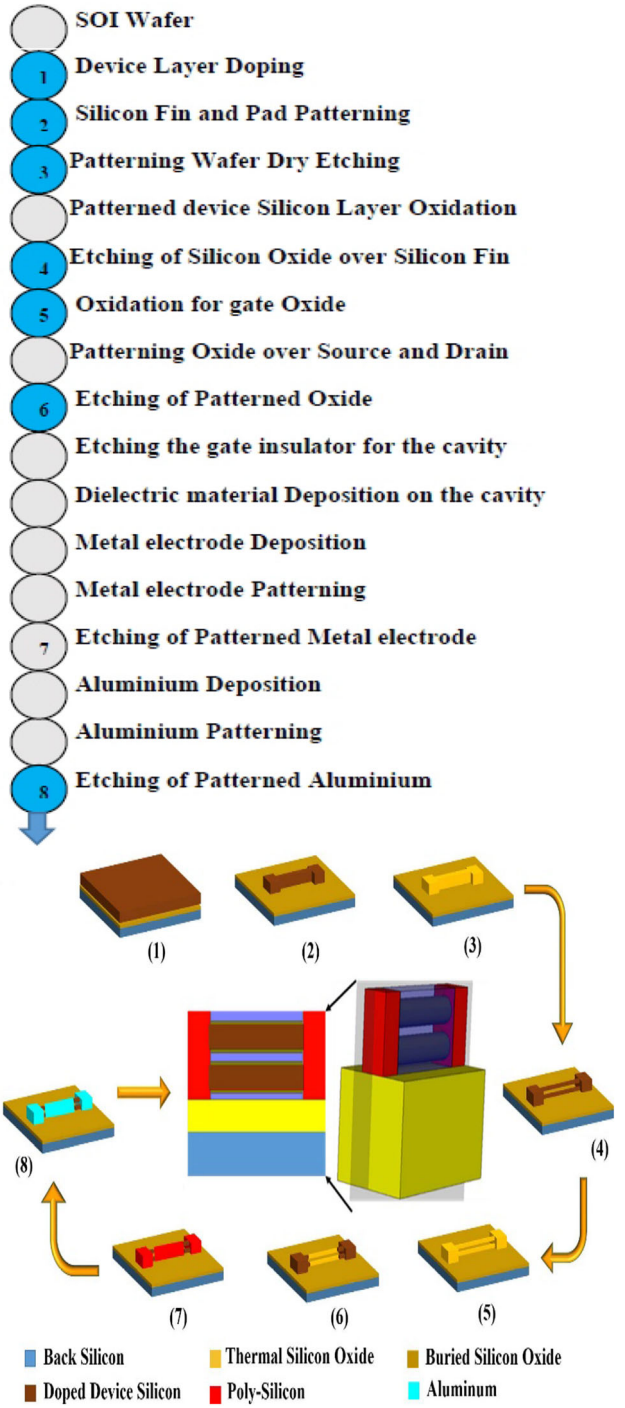

Fig. 2 Describes the fabrication process flowchart and schematic view for the GAA JL-NWFET fabrication process adapted (Biswal et al. 2019)

All these parameters and approaches will be applied to the work of Rana et al. (2020) for the possible fabrication process of the proposed device.

1.2 Device structure and simulation tools

The designed structure for n-type triple hybrid metal gate dielectric modulated junctionless gate all around NWFET-based uricase and ChO_X biosensor has been proposed, as shown in Fig. 3. Here L_1(6nm), L_2(8 nm) L_3(6 nm) are the lengths of the gate $\mathbf{G_1(\Phi_1)}$, $\mathbf{G_2(\Phi_2)}$ and $\mathbf{G_3(\Phi_3)}$ respectively and L_4 (10 nm) are the length of the nanogap cavity and silicon dioxide (SiO_2) which are near to drain and source end, respectively, where $(L_{ch} = L_1 + L_2 + L_3 = 20nm)$ is the length of hafnium oxide dielectric (HfO_2) and an interface layer oxide (SiO_2). T_{high-K}, T_{bio} and T_{OX} are the thickness of hafnium oxide ($\in = 25$), biomolecule cavity, and interface ($SiO_2, \in = 3.9$) gate oxides, respectively, and 2R is the channel's diameter (silicon film thickness). The target biomolecules (Uricase $\in = 1.54$ and $ChO_X, \in = 3.30$) are detected in the cavity region and assumed to be immobilized and interact with the cavity uniformly (Reddy and Panda 2022; Ajay et al. 2015). Doping concentration $N_D = 1x10^{19}cm^{-3}$ is applied uniformly for TM-GAA-JL-NWFET from source to drain through the channel regions to study the impacts of gate work-function variation. The proposed device calibration output result has been authenticated with the experimental results of papers (Im et al. 2007).

Several simulations were carried out using the ATLAS-3D device simulator tool to analyze the electrical properties of dielectric modulated triple hybrid metal GAA JL-NWFETs with different gate engineering, including different biomolecules, like uricase, cholesterol oxidase (ChO_X), and other biomolecules along the materials specified in Table 1. We incorporate carrier recombination and generation models for carrier mobility in the simulation. Drift–diffusion or ballistic transport models are used to simulate the movement of charge carriers (electrons or holes) inside the SiNWFETs (Sanjay and Vohra 2020). Concentration-dependent mobility (CONMOB) (Software 2023) and bandgap narrowing (BGN) models are applied to verify doping versus mobility and high channel doping profile (for doping profile is more significant than $10^{18}cm^{-3}$). Ignoring impact ionization effect, Boltz–man transport and Shockley–Read–Hall (SRH) models account for the recombination of minority carriers within the semiconductor (Software 2023). The Lombardi CVT mobility model accounted for field-dependent mobility in perpendicular/parallel (Software 2023) at room temperature (300 K). Furthermore, two numerical methods, Newton and Gummel (Software 2023), have been considered to obtain better convergence when obtaining numerical solutions. Due to the channel's radius being more significant than 4 nm, the simulation does not consider the Quantum confinement effect (Tables 2, 3).

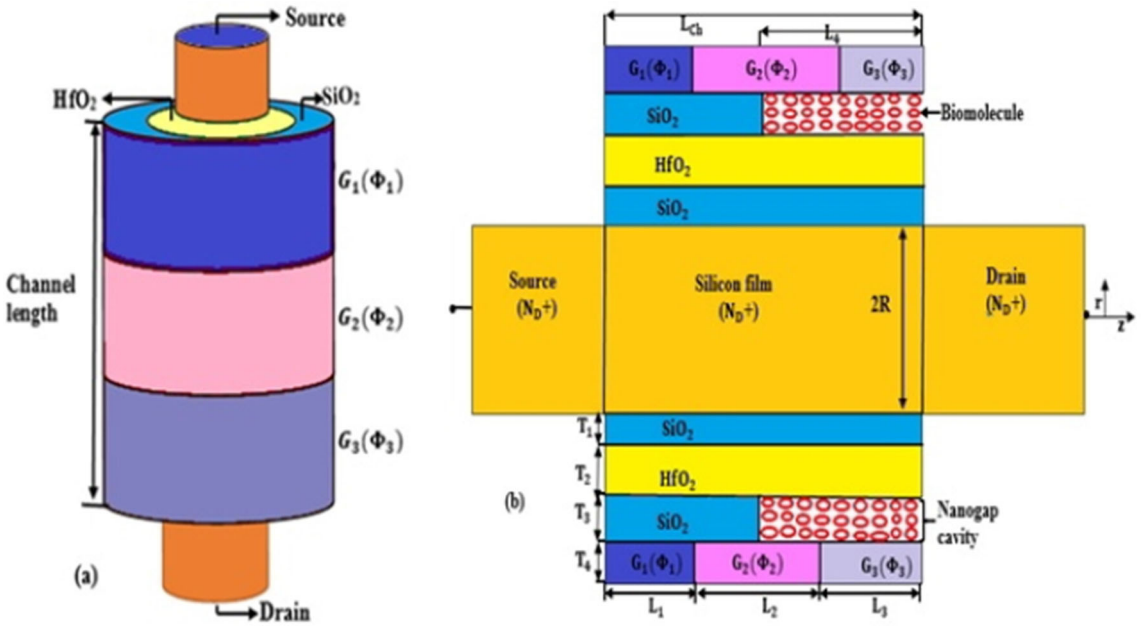

Fig. 3 Illustrates (**a**) 3D representation diagram and (**b**) 2D view of n-type triple hybrid metal gate dielectric modulated gate all around JL-NWFET

Table 1 Designed parameters for THM-high-k GAA-JL-SiNWFET

Parameters	Parameter values		
Channel length (nm)	20.00		
High-k (HfO_2) oxide thickness (nm)	1.50		
Interface oxide thickness SiO_2 (nm)	0.30		
Nanogap cavity length (nm)	10.00		
Length/thickness of source/drain (nm)	10.00		
Thickness of nanogap cavity (nm)	1.00		
Silicon film diameter (nm)	10.00		
Source/drain and channel doping (N_D +)	$10^{19}cm^{-3}$		
Oxide dielectric constant, HfO_2 and SiO_2)	25.00 and 3.90		
Gate work-function variables	Gate work-function values (Φ)		
	Φ_1(eV)	Φ_2(eV)	Φ_3(eV)
M	4.86	4.96	4.50
O	4.96	4.86	4.50
Q	4.86	4.50	4.96

2 Potential and subthreshold current modeling

2.1 Electrostatic potential analysis

A higher source to drain metal gate work function in small channel radius junctionless transistors enables the metal gate to deplete the silicon channel safely (Wang et al. 2011). The channel portion of the proposed device shown in Fig. 3(b) is divided into three distinct regions for the potential distribution's analytical expressions. Assuming uniform impurity doping concentration $\left(N_D = 1 \times 10^{19}cm^{-3}\right)$ through the channel. The $Si - SiO_2$ interface is considered to be free of trap charges. This model describes the movement of carriers through semiconductor material under the influence of electric fields (Henry 2007). Poisson's equation describes the electrostatic potential distribution inside the SiNWFETs and the surrounding medium. Poisson's equation relates the electric potential and the device's charge distribution. This case clarifies how the biosensor's electrostatics are impacted by the presence of biomolecules (uricase and ChO_X). In semiconductor devices, Poisson's equation often has the following form (Usha et al. 2020):

$$\nabla^2\boldsymbol{\phi} = \boldsymbol{\rho}/\boldsymbol{\varepsilon}$$

where $\boldsymbol{\varepsilon}$ is the permittivity of SiNW, $\boldsymbol{\rho}$ is the charge density, and $\boldsymbol{\phi}$ the electrostatic potential.

Based on this assumption, Poisson's equation in corresponding regions ignoring source/drain depletion regions in the electrostatic potential $\varphi(r, z)$ calculation is written as;

Table 2 Model parameters applied in the simulations (Software 2023)

Physical models	parameter	Value and unit
(SRH) Shockley–Read–Hall carrier recombination	$TAUN_0$	1.0×10^{-7}S
	$TAUP_0$	1.0×10^{-7}S
(BEN) Bandgap narrowing	BGN.E	6.92×10^{-3}V
	BGN.N	$1.310^{17}cm^{-3}$
Lombardi CVT mobility	BN.CVT	$4.75 \times 10^{7}cm/(s)$
	BP.CVT	$9.925 \times 10^{6}cm/(s)$

Table 3 Constant parameters applied in this simulation (Software 2023)

Parameters	Symbols	Values and units
Electron affinity of silicon	χ_{Si}	~4.17eV
Silicon bandgap energy	E_g	~1.08eV
Permittivity of silicon	ε_{Si}	11.8
Boltzmann constant	K_B	$\sim 1.381 \times 10^{-23}$ J K^{-1}
Electronic charge	q	$\sim 1.6x10^{-19}$C
Room temperature	T	300 K
Planck's constant	h	$\sim 6.63 \times 10^{-34}$ JS
Silicon intrinsic carrier concentration	n_i	$\sim 1 \times 10^{10}cm^{-3}$

$$\frac{1}{r}\frac{\partial}{\partial r}\varphi_1(r,z)+\frac{\partial^2}{\partial r^2}\varphi_1(r,z)+\frac{\partial^2}{\partial z^2}\varphi_1(r,z)=-\frac{-qN_{D_1}}{\varepsilon_{Si}} \quad For \quad 0\le z\le L_1, 0\le r\le R \tag{1}$$

$$\frac{1}{r}\frac{\partial}{\partial r}\varphi_2(r,z)+\frac{\partial^2}{\partial r^2}\varphi_2(r,z)+\frac{\partial^2}{\partial z^2}\varphi_2(r,z)=-\frac{-qN_{D_2}}{\varepsilon_{Si}} \quad For \quad L_1\le z\le L_1+L_2, 0\le r\le R \tag{2}$$

$$\frac{1}{r}\frac{\partial}{\partial r}\varphi_3(r,z)+\frac{\partial^2}{\partial r^2}\varphi_3(r,z)+\frac{\partial^2}{\partial z^2}\varphi_3(r,z)=-\frac{-qN_{D_3}}{\varepsilon_{Si}} \quad For \quad L_1+L_2\le z\le L, 0\le r\le R \tag{3}$$

where L_1 L_2 and L_3 are region-I, region-II, and region-III channel/gate lengths. The channel's potential distribution is denoted by $\varphi_i(r,z)$"q" is the electronic charge, the homogeneous silicon film (channel) doping density is N_D, and the permittivity of silicon channel (Si) is ε_{Si}. The electrostatic potential $\varphi_i(r,z)$ is solved using the superposition technique and split into $V_i(r)$ and $U_i(r,z)$ (Software 2023) was written as:

$$\varphi_i(r,z)=V_i(r)+U_i(r,z) \quad for\ quad\ i=1,2 \text{ and } 3 \tag{4}$$

Applying a one-dimensional solution of Poisson's equation and a two-dimensional solution to the homogeneous Laplace equation with boundary conditions, for Eq. (4) i.e.

$$\frac{1}{r}\frac{\partial V_i(r)}{\partial r}+\frac{\partial^2 V_i(r)}{\partial r^2}=-\frac{-qN_D}{\varepsilon_{Si}} \quad \text{and } i=1,2 \text{ and } 3. \tag{5}$$

$$\frac{1}{r}\frac{\partial U_i(r,z)}{\partial r}+\frac{\partial^2 U_i(r,z)}{\partial r^2}+\frac{\partial U_i(r,z)}{\partial z}=0 \quad \text{and } i=1,2 \text{ and } 3. \tag{6}$$

Since the electric field at the center of the silicon channel has vanished (Profile 2018).

$$\left.\frac{\partial\varphi_i(r,z)}{\partial r}\right|_{r=0}=0,\ i=1,2 \text{ and } 3. \tag{7}$$

and there is a continuous electric field at the interface of (Si/SiO_2);

$$\left.\frac{\partial\varphi_i(r,z)}{\partial r}\right|_{r=R}=\frac{\varepsilon_{OX}}{\varepsilon_{Si}t_{OXeff}}\left[V_{gs}-\phi_{M_iS}-\varphi_i(r=R,z)\right], i=1,2 \text{ and } 3. \tag{8}$$

Here ϵ_{OX} is the dielectric constant of SiO_2, ϵ_{HfO_2} is the dielectric constant of HfO_2, t_{OXeff} is effective oxide thickness (EOT) obtained using the gate stack (SiO_2+HfO_2) (Ilatikhameneh et al. 2015; Garcia Ruiz et al. 2711) is given by;

$$t_{OXeff}=t_1+\frac{\varepsilon_{SiO_2}}{\varepsilon_{HfO_2}}t_2 \tag{9}$$

where t_1 and t_2 are the thickness of SiO_2 and HfO_2 respectively and Φ_{M_iS} is gate and channel work-function difference is given by;

$$\phi_{MS}=\phi_M-\phi_{Si} \tag{10}$$

where Φ_M stands metal work functions and ϕ_{Si} stands silicon channel work-function, written as (Software 2023),

$$\phi_{Si}=\chi_{Si}(T=300K)+q\phi_F+\frac{E_g(T,N_D)}{2q} \tag{11}$$

$$\phi_F=\frac{KT}{q}\ln\left(\frac{n_i}{N_D}\right) \tag{12}$$

Here, ϕ_F the channel's Fermi potential, χ_{Si} is the silicon electron affinity, n_i is inherent carrier concentration, and $E_g(T,N_D)$ is temperature and doping dependent on silicon bandgap energy (Software 2023),

$$E_g(T,N_D)=E_g(300k)+E_{g\alpha}\left(\frac{(300K)^2}{300K+Eg\beta}-\frac{T^2}{T+E_{g\beta}}\right)-\Delta E_g(N_D) \tag{13}$$

$E_g(300\text{ K})$ specifies the energy band gap at 300 K, $E_{g\alpha}=4.73\times10^4$eV/K and $E_{g\beta}=636$ K. $\Delta E_g(N_D)$ is the amount of energy needed to narrow the bandgap due to high doping (Software 2023); an analytic equation relates the variation in bandgap (ΔEg) due to doping concentration (N_D), using Atlas TCAD simulation tool as described in (Eq. 14) (Software 2023).

$$\Delta E_g(N_D)=\beta_E x\left\{\ln\left(\frac{N_D}{\beta_N}\right)+\left[\left(\ln\left(\frac{N_D}{\beta_N}\right)\right)^2+\beta_c\right]^{1/2}\right\} \tag{14}$$

where $\beta_E=6.92\text{meV}$, $\beta_N=1.3\times10^{17}\text{cm}^{-3}$ and $\beta_C=0.5$ (Software 2023).

From Eqs. (5)–(10) the solutions $V_i(r,)$ can be obtained as follows;

$$V_i(r)=\frac{qN_D}{4\varepsilon_{Si}}r^2+V_{gs}-V_{fbi}+\frac{qN_DR^2}{4\varepsilon_{Si}}+\frac{qN_DR}{2C_{OX}},\ i=1,2,3. \tag{15}$$

Here C_{OX} is the gate-oxide capacitance. Electron affinity and flat-band voltage of the channel is given as follows;

$$\chi_{Si(T)}=\chi_{Si(300K)}+\beta_c\left[E_{g(T)}-E_{g(300K)}\right]$$

$$V_{fbi} = \left\{ \phi_{M1} - \left(\chi_{Si(T)} + \frac{E_g(T, N_D)}{2} - q\phi_f(T) \right) \right.$$
$$For\ \mathrm{i} = 1,\ 0 \le \mathrm{z} \le \mathrm{L}_1$$

$$V_{fbi} = \left\{ \phi_{M2} - \left(\chi_{Si(T)} + \frac{E_g(T, N_D)}{2} - q\phi_f(T) \right) \right. \pm \frac{qN_F}{C_{OX}}$$
$$For\ \mathrm{i} = 2,\ \mathrm{L}_1 \le \mathrm{z} \le \mathrm{L}_1 + L_2$$

$$V_{fbi} = \left\{ \phi_{M3} - \left(\chi_{Si(T)} + \frac{E_g(T, N_D)}{2} - q\phi_f(T) \right) \right. \pm \frac{qN_F}{C_{OX}}$$
$$For\ \mathrm{i} = 3,\ \mathrm{L}_1 + L_2 \le \mathrm{z} \le \mathrm{L}_1 + L_2 + L_3 = L$$

The general solution for $\mathrm{U_i(r, z)}$ using the Fourier–Bessel series and separation of variable approach is (Profile 2018);

$$U_i(r,z) = \sum_{n=1}^{\infty} \left[A_{ni} e^{\left(\frac{\alpha_n z}{R}\right)} + B_{ni} e^{\left(\frac{-\alpha_n z}{R}\right)} \right] J_0\left(\frac{\alpha_n r}{R}\right), i = 1,2,3. \tag{16}$$

where $\mathrm{A_{ni}}$ and $\mathrm{B_{ni}}$ are coefficients and α_n is eigenvalue calculated using the following equation (Tolstov 1962) given as;

$$\frac{\varepsilon_{OX} R}{t_{OXeff}} J_0(\alpha_n) - J_1(\alpha_n)\alpha_n = 0 \tag{17}$$

The first kind of Fourier–Bessel function of order i is denoted by $\mathrm{J_i(x)}$ (Tolstov 1962). Coefficients of the Fourier–Bessel series $\mathrm{A_{n1}, B_{n1}, A_{n2}, B_{n2}, A_{n3},}$ and $\mathrm{B_{n3}}$ are determined based on the boundary conditions. Assuming that source-drain depleted region potential is independent of ″r.″ Eq. (1) is written using Poisson's equation;

(i) At the source end, electrostatic potential is written as;

$$\varphi_1(r,z)|_{z=0} = V_{bi} \tag{18}$$

Here $\mathrm{V_{bi}}$ is built potential.

(ii) At the drain end, electrostatic potential is written as;

$$\varphi_3(r,z)|_{Z=L} = V_{bi} + V_{ds} \tag{19}$$

where $\mathrm{V_{DS}}$ is drain bias voltage, and interface electric potential in the three regions is continuing and expressed as

$$\varphi_1(r,z)|_{Z=L_1} = \varphi_2(r,z)|_{Z=L_1} \tag{20}$$

$$\varphi_2(r,z)|_{Z=L_1+L_2} = \varphi_3(r,z)|_{Z=L_1+L_2} \tag{21}$$

Interface electric fields in the three areas are written as;

$$\left.\frac{\partial \varphi_1(r,z)}{\partial z}\right|_{Z=L_1} = \left.\frac{\partial \varphi_2(r,z)}{\partial z}\right|_{Z=L_1} \tag{22}$$

$$\left.\frac{\partial \varphi_2(r,z)}{\partial z}\right|_{Z=L_1+L_2} = \left.\frac{\partial \varphi_3(r,z)}{\partial z}\right|_{Z=L_1+L_2} \tag{23}$$

The coefficients $\mathrm{A_{n1}, B_{n1}, A_{n2}, B_{n2}, A_{n3},}$ and $\mathrm{B_{n3}}$ in Eq. (16) are obtained using Fourier–Bessel series and boundary conditions Eqs. (18–23) as (Tolstov 1962);

$$A_{n1} = \left[-T_{n1} e^{\left(\frac{-\alpha_n L}{R}\right)} + T_{n2} \cosh \frac{a_n(L_1 - L)}{R} + T_{n3} \cosh \frac{a_n(L_1 + L_2 - L)}{R} + T_{n4} \right] x \left(2 \sinh \frac{\alpha_n L}{R} \right)^{-1} \tag{24}$$

$$B_{n1} = \left[T_{n1} e^{\left(\frac{\alpha_n L}{R}\right)} - T_{n2} \cosh \frac{a_n(L_1 - L)}{R} - T_{n3} \cosh \frac{a_n(L_1 + L_2 - L)}{R} - T_{n4} \right] x \left(2 \sinh \frac{\alpha_n L}{R} \right)^{-1} \tag{25}$$

$$A_{n2} = \left\{ \left[-T_{n1} + T_{n2} \cosh \frac{\alpha_n L_1}{R} \right] e^{\left(-\frac{\alpha_n L}{R}\right)} - T_{n3} \cosh \frac{\alpha_n(L_1 + L_2 - L)}{R} + T_{n4} \right\} x \left(2 \sinh \frac{\alpha_n L}{R} \right)^{-1} \tag{26}$$

$$B_{n2} = \left\{ \left[T_{n1} - T_{n2} \cosh \frac{\alpha_n L_1}{R} \right] e^{\left(\frac{\alpha_n L}{R}\right)} + T_{n3} \cosh \frac{\alpha_n(L_1 + L_2 - L)}{R} - T_{n4} \right\} x \left(2 \sinh \frac{\alpha_n L}{R} \right)^{-1} \tag{27}$$

$$A_{n3} = \left\{ \left[-T_{n1} + T_{n2} \cosh \frac{\alpha_n L_1}{R} + T_{n3} \cosh \frac{\alpha_n(L_1 + L_2)}{R} \right] e^{\left(\frac{-\alpha_n L}{R}\right)} + T_{n4} \right\} x \left(2 \sinh \frac{\alpha_n L}{R} \right)^{-1} \tag{28}$$

$$B_{n3} = \left\{ \left[T_{n1} - T_{n2} \cosh \frac{\alpha_n L_1}{R} - T_{n3} \cosh \frac{\alpha_n(L_1 + L_2)}{R} \right] e^{\left(\frac{\alpha_n L}{R}\right)} - T_{n4} \right\} x \left(2 \sinh \frac{\alpha_n L}{R} \right)^{-1} \tag{29}$$

$$Where\ \mathrm{T_{n1}} = V_{bi} S_{no} - S_{n1} \tag{30}$$

$$T_{n2} = S_{n2} - S_{n1} \tag{31}$$

$$T_{n3} = S_{n3} - S_{n2} \tag{32}$$

$$T_{n4} = (V_{bi} - V_{DS}) S_{no} - S_{n4} \tag{33}$$

$$S_{no} = \frac{2J_1(\alpha_n)}{\alpha_n \left[J_1^2(\alpha_n) J_0^2(\alpha_n) \right]} \tag{34}$$

$$and\ \mathrm{S_{ni}} = V_{GS} S_{no} - U_{ni} \tag{35}$$

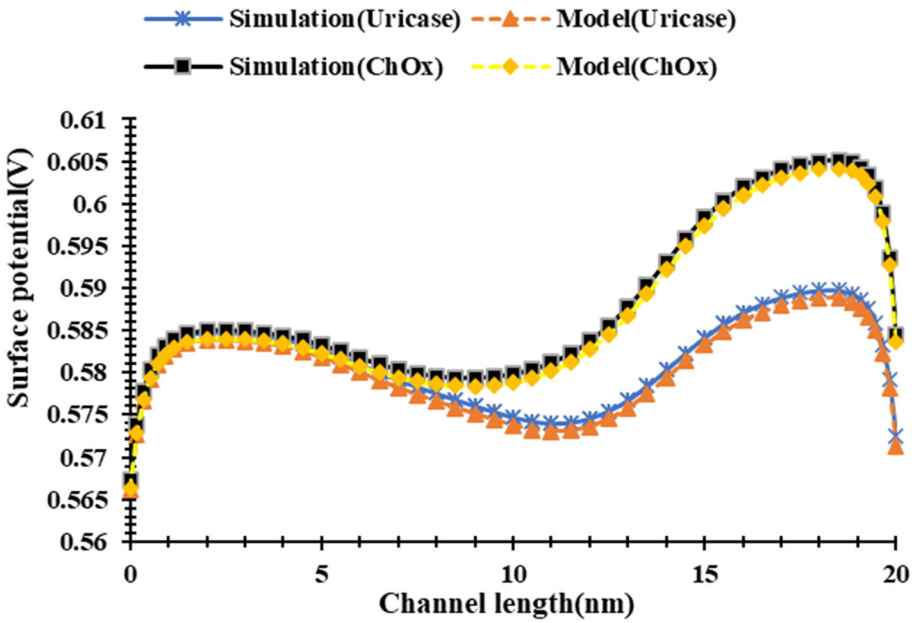

Fig. 4 Center potential along the channel for n-type triple hybrid metal gate dielectric modulated gate all around junctionless NWFET

$$where\ \mathrm{U}_{ni} = -\left[\Phi_{MiS} + \frac{qN_{Dit_{OXeff}}R}{2\varepsilon_{OX}} + \frac{qN_{Di}R^2}{4\varepsilon_{Si}}\right]S_{no} + \frac{qN_{Di}[R^2\alpha_n J_1(\alpha_n) - 2R^2 J_2(\alpha_n)]}{2\varepsilon_{Si}\left[J_1^2(\alpha_n) + J_0^2(\alpha_n)\alpha_n^2\right]} \quad (36)$$

Differentiating surface potential $\varphi(r = R, Z)$ with respect to z, gives channel electric field E(z) in the z-direction (Fig. 4).

$$E_i(z) = \sum_{n=1}^{\infty} A_{ni}e^{\left(\frac{\alpha_n z}{R}\right)} - B_{ni}e^{\left(\frac{\alpha_n z}{R}\right)} \times \left(\frac{\alpha_n}{R}\right)J_o(\alpha_n),\ \text{where i = 1,2,3} \quad (37)$$

2.2 Subthreshold current modeling

The center potential solution is used to analyze the subthreshold current (Bagga and Dasgupta 2017). In constant electron quasi-Fermi potential $\phi_i(z)$, carrier mobility from source to drain in the z-direction is determined using current density $J_i(z)$;

$$J_i(r,z) = -q\mu_n(r,t)\frac{d\phi_n(z)}{dz} \quad (38)$$

Here n(r, z) is inherent carrier concentration and μ_n is carrier mobility. Integrating the current density $J_i(r, z)$ along "z" in polar coordinates under a completely depleted channel length gives a drain current below threshold voltage (Localized 2011).

$$I_{Sub} = q\mu_n d\phi_i(z) \times 2\pi \int_0^R rn_i exp\{q[\phi(r,z) - \phi_i(z)]\}/KTdr \quad (39)$$

where "T" is thermal temperature, and "K" is Boltzmann's constant.

From z = 0 to z = L, I_{sub} expressed as;

$$I_{Sub} = KT\mu_n\left(n_i^2/N_a\right)\left\{1 - e^{\left(\frac{-q}{KT}V_{DS}\right)}\right\}/\int_0^L \left(1/2\pi \int_0^R re^{\frac{q\phi(r,z)}{KT}}dr\right)dz \quad (40)$$

where μ_n is silicon's constant mobility model ($\mu_n = 1417\mathrm{cm}^2/\mathrm{V.S}$).

2.3 *Threshold voltage (V_{th}) modeling*

The lowest (V_{GS}) wanted to establish a conducting path between the source and drain terminals in a MOSFET device is known as the threshold voltage (V_{th}) (Jean and Wu 1997). The threshold voltage for non-zero substrate bias voltage (V_{GS}) is written as;

$$V_{th} = \Phi_{MS} - 2\phi_F - 2\frac{Q_{BO}}{C_{OX}} - \frac{Q_B}{C_{OX}}$$
$$Where\quad Q_{BO} = -\sqrt{2qN_D\varepsilon_{si}|2\phi_F|},$$
$$Q_B = -\sqrt{2qN_D\varepsilon_{si}|-2\phi_F + V_{GS}|} \quad (41)$$

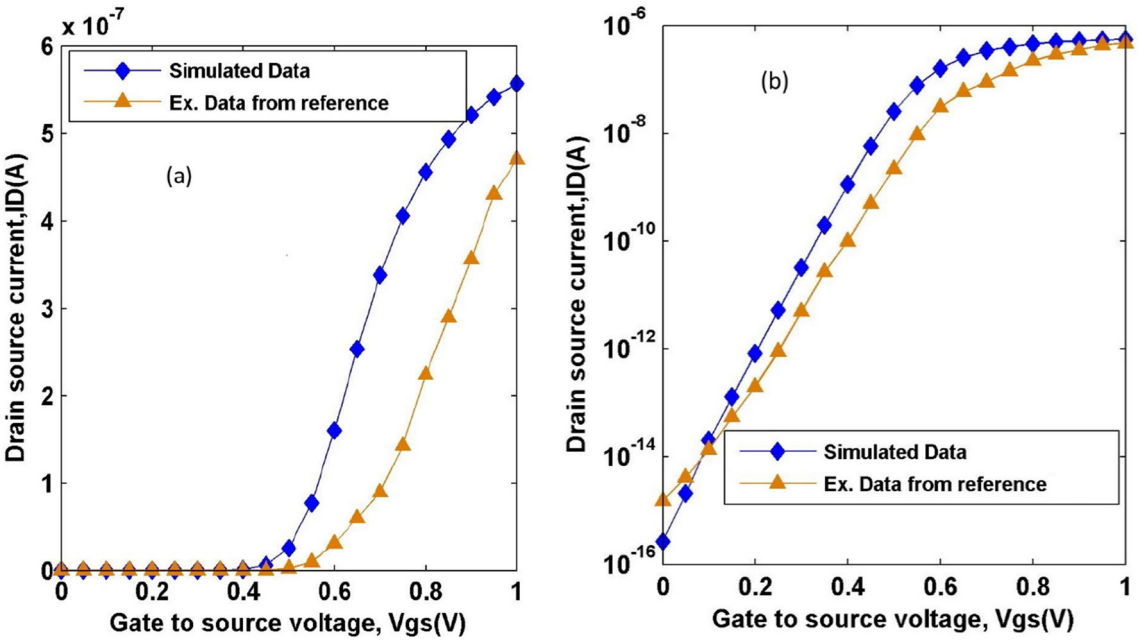

Fig. 5 Illustrates the simulation and experimental results (Im et al. 2007) of drain current for dielectric modulated triple hybrid metal gate all around JL-NWFET (**a**) IV in linear file and (**b**) IV in log file at (V_{DS} = 0.05 V)

where C_{OX} is gate-to-oxide capacitance, and Q_{OX} is gate-to-oxide charge density due to lattice imperfection at the interface.

2.4 Device calibration

In order to authenticate our work, the simulated results are in close proximity to the experimental results of Im et al. (2007) previously published works. Figure 5) illustrates the comparison of proposed device simulation output results with existing experimental data of references (Im et al. 2007) to validate our calibration. Figure 3a gives the ID-Vgs results in the linear scale, and Fig. 5b shows the ID–Vgs results in the log scale.

3 Results and discussion

3.1 Transfer characteristics

Device on-current and off-current are affected by increased dielectric constant biomolecule with different metal gate work-function, as shown in Fig. 6. The value of leakage

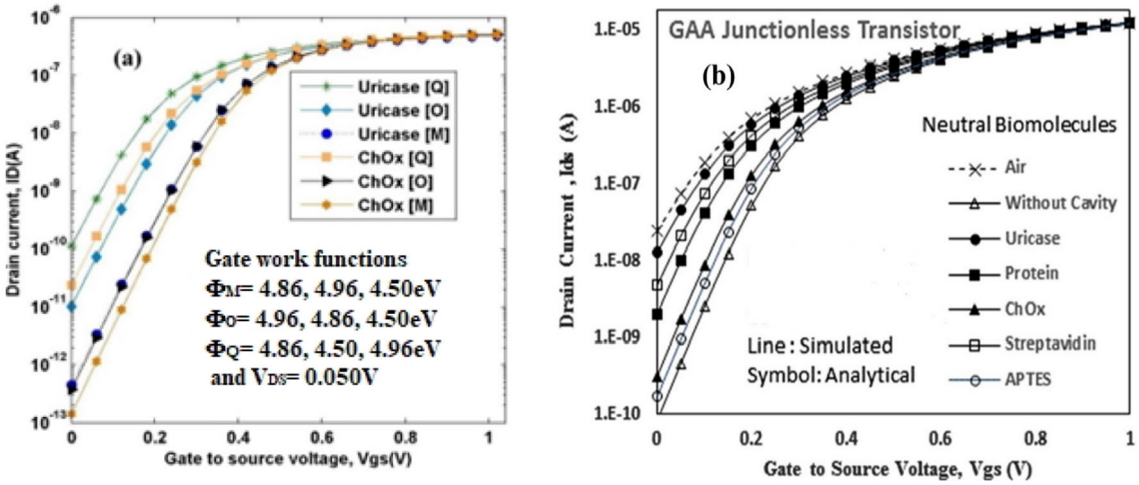

Fig. 6 Effect of different gate electrode work-function and dielectric materials on I_D-V_G and (**a**) proposed device and (**b**) referenced work (Pratap et al. 2018) biosensor devices

current indicated by M and Q is higher than that of "O." This indicates that the high gate electrode work-function sited by "O" suppresses tunneling current at weak inversion region enhance on current, as shown in Fig. 9b. For instance, the percentage variation of leakage current in all cases is 80.97% decreases when tunable gate work-function marked by "O" compared with "M" and 83.64% reduces when "O" is compared with "Q" using dielectric material ChO_X in the nanogap cavity. In the case of uricase dielectric material, the percentage variation is expressed as 59.90% decrease as a result of tunable gate work-function "O" is compared with "M" and 67.20% decrease when "O" is compared with that of "Q" at a constant drain to source current $V_{DS} = 0.05V$ and $V_{GS} = 1.0V$). We can elucidate that higher dielectric materials with tunable gate electrode work function signify CMOS devices' performance at ultra-small scale device dimensions.

3.2 Effect of gate electrode work function on threshold voltage (V_{th})

A critical technological challenge for the triple gate MOSFET device is to find gate electrodes with appropriate tunable electrode work functions designed for the desired (V_{th})/threshold voltages (Localized 2011). The work function difference between the gate electrode and the intrinsic silicon film can be adjusted to optimize the threshold voltages for n-channel devices in a CMOS circuit. (Lin et al. 2002). Figure 7a illustrates the variation of threshold voltage when gate electrode work function increases from drain to source (denoted by "O" leads to the lower tunneling path, thereby raising the tunneling probability and reducing the ambipolar conduction (both positive and negative ions can move in the opposite direction) (Bagga and Dasgupta 2017). Replacing a higher dielectric constant in the nanogap cavity increases threshold voltage, as described in Fig. 7a. The shift threshold voltage (V) is illustrated in Fig. 7b, which signifies the sensitivity of proposed devices with a tunable work function labeled at "O," which leads to improved device performance. Varying metals have varying work functions, resulting in changes in the energy barrier at the metal–semiconductor interface and influencing carrier injection efficiency and transistor properties like threshold voltage. The calculation of shifting the threshold voltage (ΔV_{th}) is described by Eq. (42) (Rahman et al. 2017).

$$\Delta V_{th} = V_{th(Bio)} - V_{th(Air)} \tag{42}$$

Figure 8a depicts the effect of various gate electrode work-function device sensitivity ($S_{I_{OFF}}$) in the presence of biomolecules. It signifies that as a biomolecule dielectric constant increases, $S_{I_{OFF}}$ increased at optimized gate work-function tunned at "O" compared with" M, and "Q." For instance, percentage change /improvement of current sensitivity ($S_{I_{OFF}}$) due to different gate work functions are 16.21% when "O" compared with "M" and 30.96% compared to "Q" at ChO_X dielectric material when $V_{DS} = 0.05V$ &$V_{GS} = 1.0V$. We examine that ChO_X dielectric material and gate work-function sited by "O" improve current sensitivity compared to uricase dielectric material. Current sensitivity of the proposed device for uricase and ChO_X dielectric material, including different gate work-function, is obtained using Eq. (43) (Pratap et al. 2018)

$$S_{I_{off}} = \left.\frac{I_{off}(with\ biomolecule)}{I_{off}(without\ biomolecule)}\right|_{V_{GS}=0V} \tag{43}$$

Not only sensitivity ((S_{Ioff}) of our device is improved over the referenced works, but also switching ratio, surface potential, short channel effects(SCEs), and leakage /tunneling currents are more enhanced compared to the referenced (Sze 2014) shown in Fig. 8b**,** this is due to new

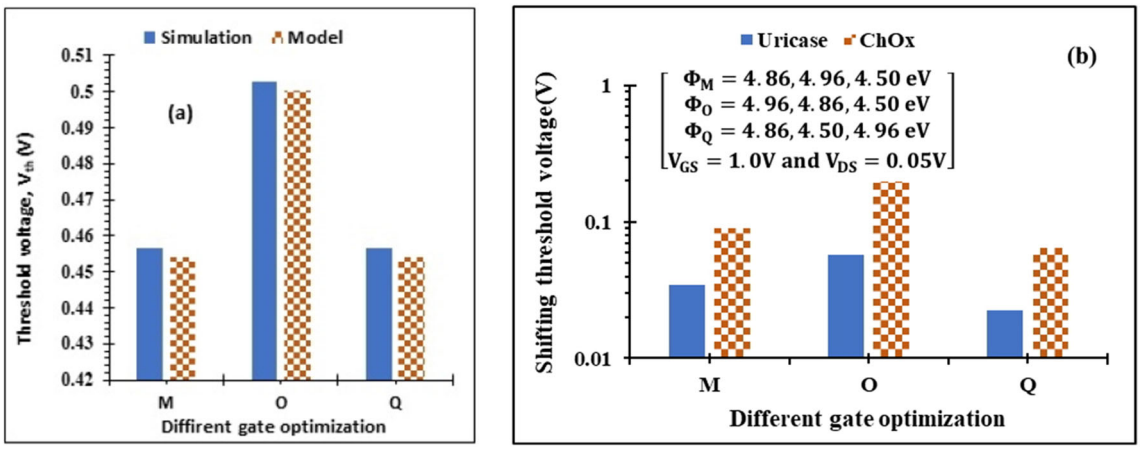

Fig. 7 Effect of different gate engineering on (**a**) threshold voltage and (**b**) shifting threshold voltage of n-type triple hybrid metal gate high-k gate all around junctionless NWFET

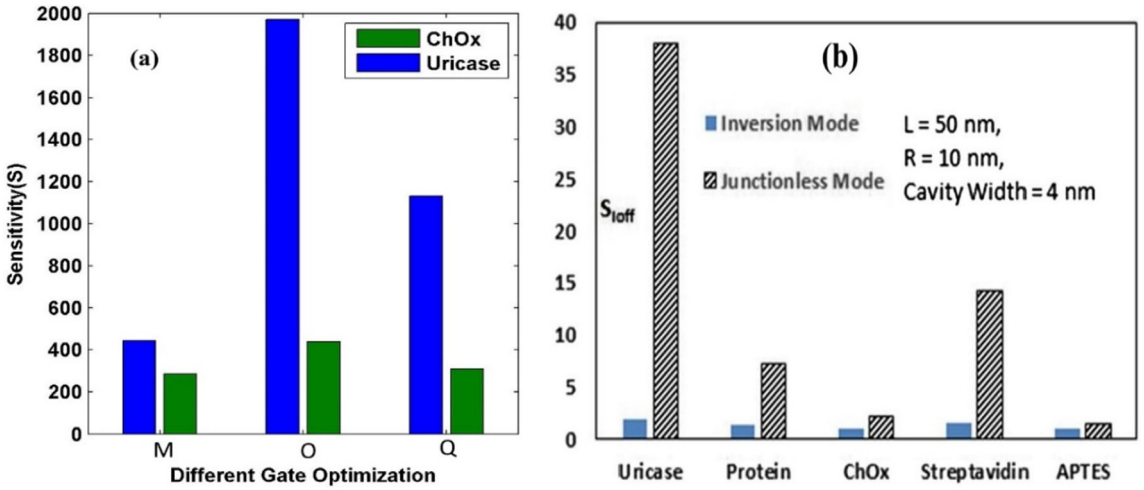

Fig. 8 Sensitivity parameter (S_{Ioff}) for (**a**) proposed and (**b**) past work (online published) devices (Pratap et al. 2018)

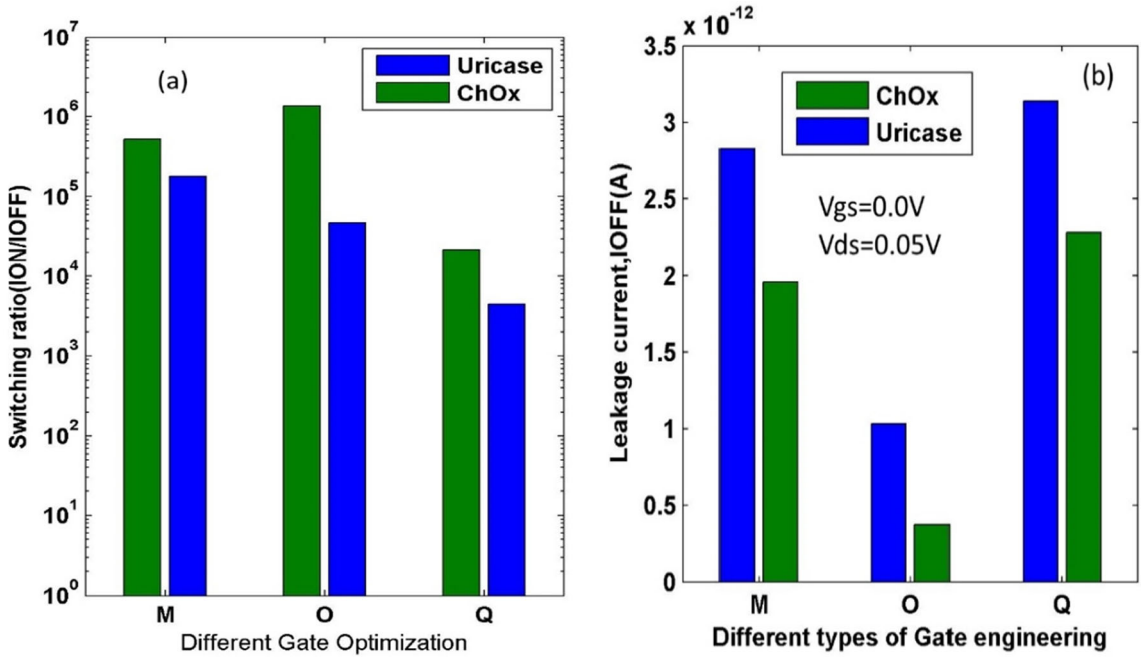

Fig. 9 Impact of different gate engineering on (**a**) switching ratio and (**b**) leakage current for n-type triple hybrid metal gate dielectric modulated GAA-JL-NWFET at $V_{DS} = 0.05V$ and $V_{GS} = 1.0V$, including uricase and ChO_X biomolecules

technologies incorporated in our device modeling, such as device dimension, device structure, high-k gate oxide material (HfO_2), and high optimized gate electrode work-function near to source side with higher electrode work function.

Figure 9 illustrates the switching ratio for different gate electrode work-function and leakage current of the proposed device. Increasing the on–off current ratio indicates overall improvement in drive current with a low leakage current in low stand power (LSTP) logic technology, even though the on-current decreased with a rise in gate electrode work-function near the source side. (James et al. 2010). Compared with M and Q gate tunable work function, the highest switching ratio is achieved at "O." Also, the device performance is enhanced at "O," as illustrated in Fig. 8a, due to higher electrode work function near the source side screens and drives carries across the channel (Bagga and Dasgupta 2017). The concentration of the target analytes close to the biosensor's sensing zone rises in the presence of uricase and ChO_X proteins. As a result, the electrical signal produced by the analytes' contact with the biosensor is amplified, improving sensitivity and lowering detection limits.

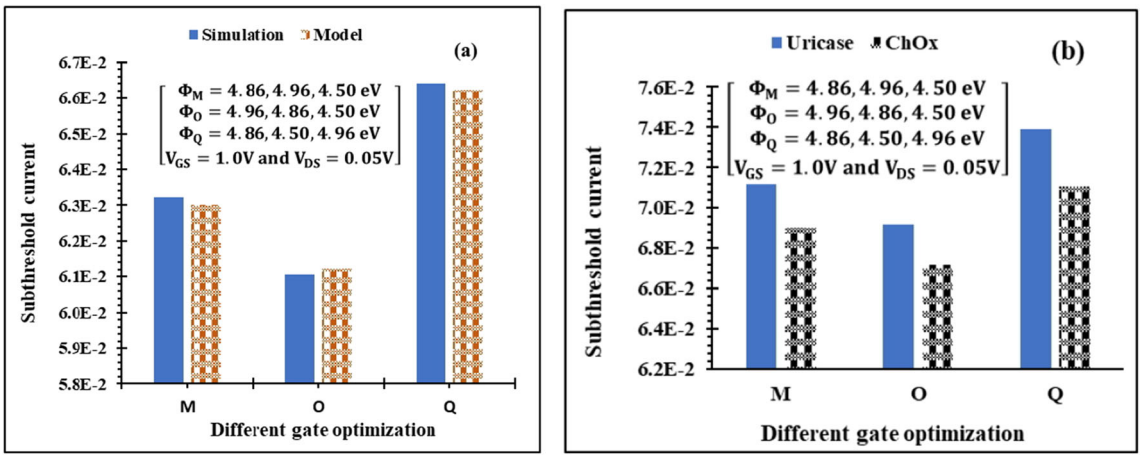

Fig. 10 Effect of different gate engineering on (**a**) analytical and simulation result of subthreshold slope and (**b**) variation of subthreshold slope along uricase and ChO_X biomolecules for n-type triple hybrid metal gate dielectric modulated junctionless gate all around NWFET

Figure 10 shows a lower sub-threshold slope when the gate has a tunable electrode work-function sited "O" while at 'M" and "Q," sub-threshold slope slightly increases due to the short channel effect at ultra-small channel length and hot carriers. Meanwhile, threshold voltage and drain mobility increase when the gate work function increases from source to drain through the channel designed at "O."

3.3 Transconductance (g_m) and output conductance (g_d)

Transconductance (g_m) measures drain current variation with a gate-source voltage (V_{GS}), keeping the drain-source voltage (V_{DS}) constant to describe device load drivability (Madan and Rishu 2016; Sze 2014; Van Zeghbroeck 2008). The switching speed of a circuit and voltage gain of MOSFET amplifiers are also characterized by transconductance. Since linearity and distortion are crucial issues in designing several circuits (Chaujar et al. 2009). The highest transconductance describes the circuit's capability for high-speed operation (Saib et al. 2015). The nonlinearity of the device can be scrutinized by determining the higher-order derivatives of $I_{DS} - V_{GS}$ at a constant drain-source voltage, and it designates the harmonic distortion. "Better linearity and lower distortion are examined under higher-order transconductance with lower amplitude" (Gupta and Chaujar 2015). The immobilized dielectric constant in the nanogap cavity affects device operation/linearity, as inferred by Fig. 11. Device transconductance (g_m) in terms of drain current and the gate-source bias voltage is given by Eq. (44) (Van Zeghbroeck 2008).

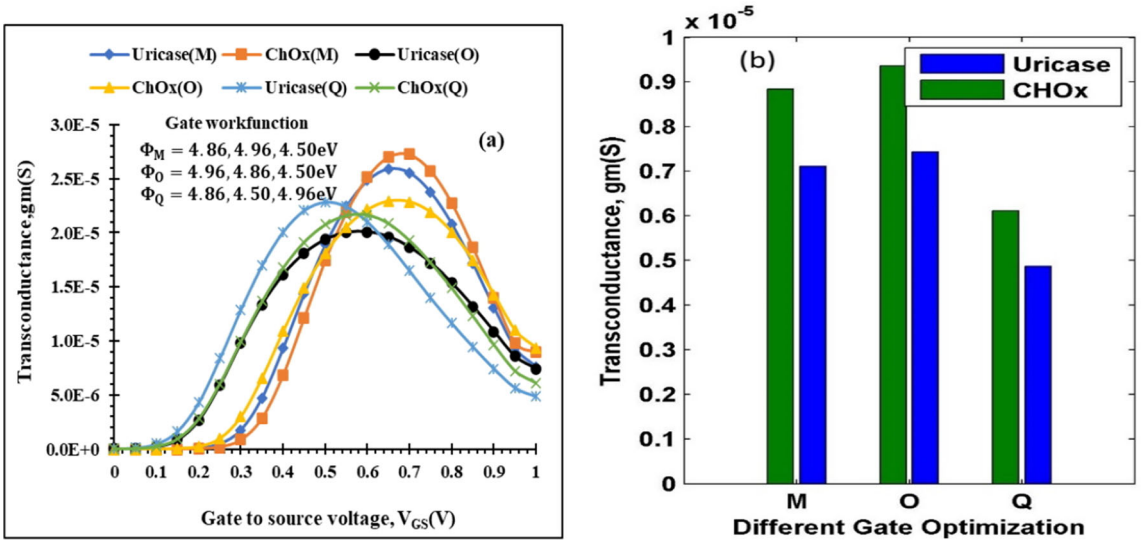

Fig. 11 Effect of different gate engineering on (**a**) transconductance and (**b**) transconductance at ($V_{DS} = 0.6V$and$V_{GS} = 1.0V$) for n-type triple hybrid metal gate dielectric modulated gate-all-around junctionless NWFET including uricase and ChO_X biomolecules

$$g_m = \left.\frac{\partial I_D}{\partial V_{GS}}\right|_{V_{DS}=0.6V} = \sqrt{\mu_n C_{OX}(\frac{W}{L})I_D} = \frac{2I_D}{V_{GS}-V_{th}} \quad (44)$$

$$g_d = \left.\frac{\partial I_D}{\partial V_{DS}}\right|_{V_{GS}=0.6V} = \left(\mu_n C_{OX}\frac{W}{L}\right)(V_{GS}-V_{th}-V_{DS}) \quad (45)$$

In the case of the gate-to-source voltage, variation of transconductance, including different gate electrode work-function, is illustrated in Fig. 11a. It clearly shows that, as gate work function increases from drain to source through the channel (labelled tunable work function at "O"), higher transconductance is obtained, as shown in Fig. 11b when V_{GS} is 1.0V and V_{DS} is 0.6V due to improved gate controllability as a result of high electrode work function near to source side**.** For instance, the percentage changes of transconductance labelled by "O" is 5.88% compared to "M" and 52.94% compared to "Q" using ChO_X dielectric material and 4.49% compared to "M" and 52.77% compared to "Q" using uricase dielectric material, labelled at "O." This suggests inadequate gate engineering work-function and dielectric materials also affects the CMOS device performance at ultra-small scale channel length.

Another critical parameter that indicates CMOS linearity is drain conductance, defined with different drain currents in varying drain voltage at constant gate voltage (Van Zeghbroeck 2008). Figure 12) illustrates the proposed device output conductance with different gate work functions noted by "M, O, and Q," including uricase and ChO_X dielectric materials itching on the nanogap cavity. In the lower inversion region, higher output conductance is experienced, while as bias voltage increases, the drain conductance decreases and comes to cloth each other, as illustrated by Fig. 12a. The output conductance (g_d) in terms of drain current and a drain-source bias voltage is given by Eq. (45) (van Zeghbroeck 2008).

The decreasing percentage change of output conductance labelled at "O" is 36.42% and 43.65% compared to labelled work functions of "M" and "Q," respectively, at ChO_X a dielectric material, while at uricase dielectric materials are 30.68% and 40.92%. This signified that gate engineering work function and coated dielectric materials of nanocavity affect the CMOS device's performance. As a result, the electrical signal produced by the analytes' contact with the biosensor is amplified, and the sensitivity is improved.

The transistor's intrinsic voltage gain ($g_{m/gd} or g_m R_O$) signifies the maximum voltage gain provided by a single transistor, playing a vital role in high-gain amplifiers. Figure 13. illustrates the variation of inherent voltage gain with different gate work-function, including dielectric gate material in the nanogap cavity noted by M, O, and Q. It is observed that at dielectric material, ($ChO_X, \epsilon = 3.3$) tunable work-function labelled by "O" is much higher compared to that of "M and Q." The degradation of the output resistance under work-function marked by "M and Q" of scaled CMOS technology is moderately caused by the DIBL effect (Sengupta and Pandit 2014). As illustrated in Fig. 13b, the intrinsic voltage gain is high at the "O" work function compared to "M and Q" at $V_{DS} = 0.6V$ and $V_{GS} = 1.0V$. The percentage change or improvement of inherent voltage gain, labelled by "O," is 31.58% compared to that of "M" and 187.61% compared to that of "Q" at ChO_X dielectric material. In the same manner, at uricase dielectric material, transconductance

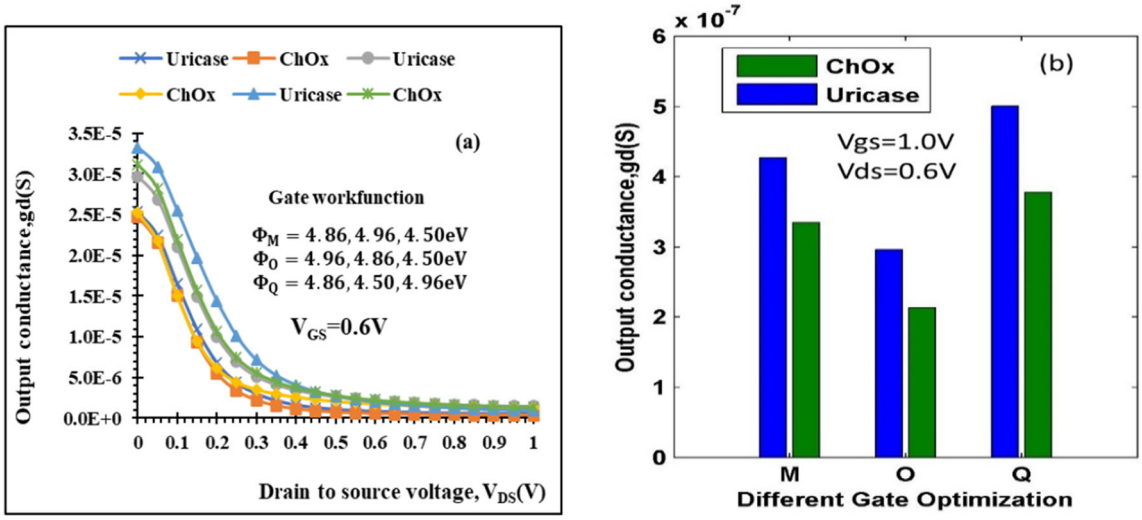

Fig. 12 Effect of different gate engineering on (**a**) output conductance and (**b**) output conductance for n-type triple hybrid metal gate dielectric modulated junctionless gate-all-around NWFET, including uricase and ChO_x biomolecules

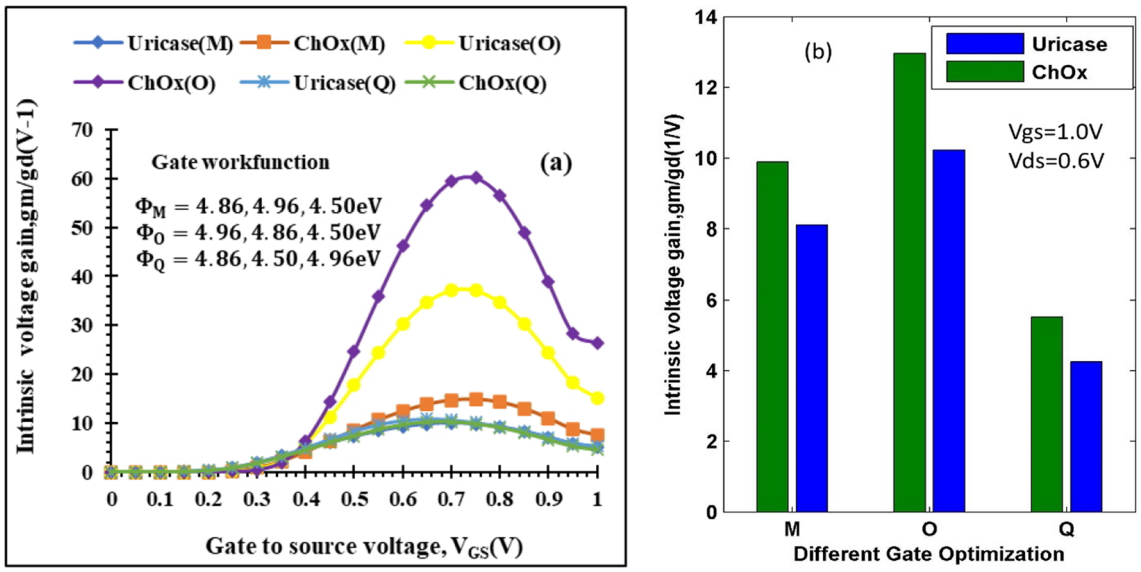

Fig. 13 Effect of different gate engineering on (**a**) intrinsic voltage gain ($g_m R_O$), (**b**) intrinsic voltage gain for n-type triple hybrid metal gate dielectric modulated gate-all-around junctionless NWFET including uricase and ChO_X biomolecules

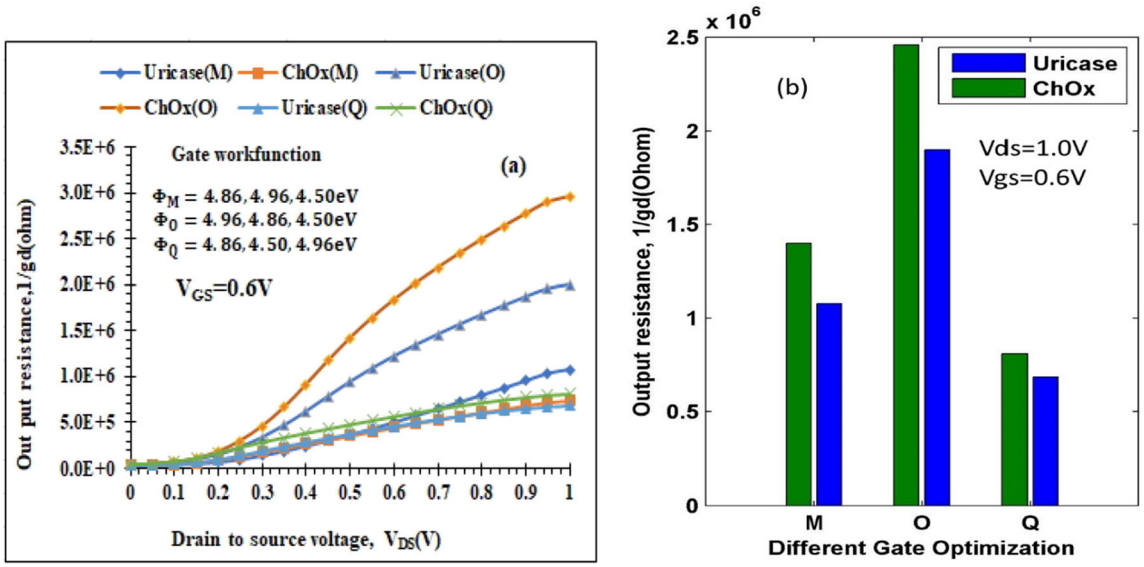

Fig. 14 Impact of different gate engineering on (**a**) output resistance and (**b**) output resistance for n-type triple hybrid metal gate dielectric modulated gate-all-around junctionless NWFET, including uricase and ChO_X biomolecules

labelled by "O" is 25.93% compared to "M" and 94.29% compared to "Q." This signifies gate engineering work-function with the nanogap cavity dielectric materials affects the intrinsic voltage gain and CMOS device performance. Mathematical expressions are written as (Sengupta and Pandit 2014).

$$\text{Intrinsic voltage gain (G)}\ \frac{g_m}{g_d} = g_m R_0 \tag{46}$$

where R_o is the output resistance given by $\frac{1}{g_d} =$ (Yuan and Woo 2005).

Figure 14 illustrates the effect of gate engineering labelled "M, O, and Q" on the output resistance. It is observed that the tunnelable work function marked by "O" has the highest output resistance than "M and Q." The gate engineering design at "O" experienced a less short channel effect due to increasing work function from drain to source, providing more mobility and gate controllability across the channel. Figure 14b clearly describes the effects of coated dielectric material on the output resistance. The percentage change of output resistance labelled by "O" is 75.71% compared to "M" and 203.70% compared to "Q" at ChO_X

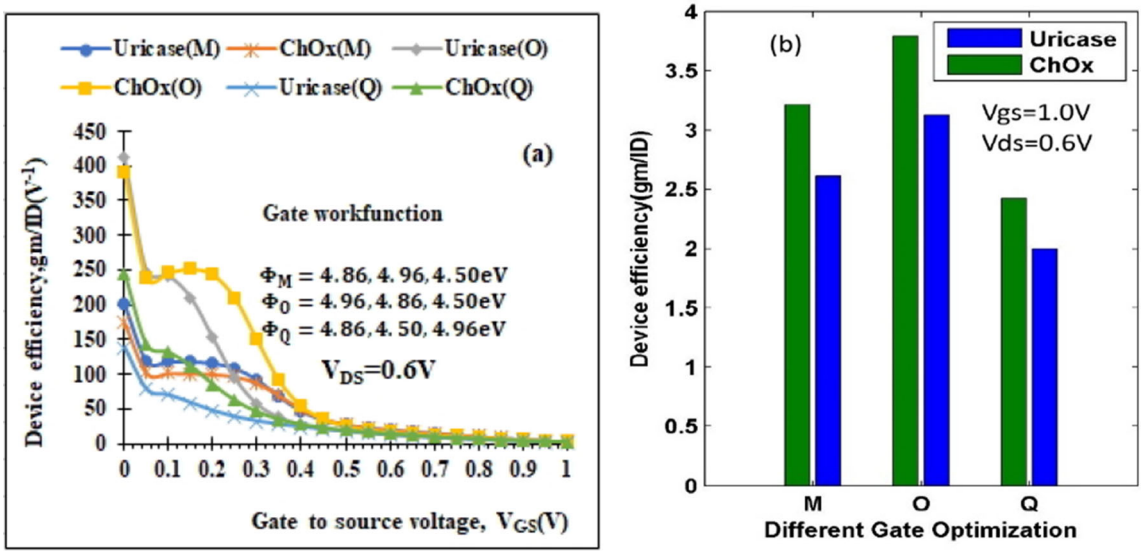

Fig. 15 Effect of different gate engineering on (**a**) device efficiency and (**b**) device efficiency for n-type triple hybrid metal gate dielectric modulated gate-all-around junctionless NWFET, including uricase and ChO_X biomolecules

a dielectric material. For uricase dielectric material, the increment of output resistance labelled by "O" is 75.93% compared to "M" and 167.97% compared to "Q." This signifies gate engineering work function, including nano-gap cavity dielectric material, affects the CMOS device performance.

Figure 15a illustrates the transconductance ratio over drain current (g_m/I_D), including different gate electrode work-function labelled by "M, O, and Q," undercoated cavity with uricase and ChO_X dielectric material signifies maximum value in weak inversion (WI) and decreases the value in strong inversion region. Figure 15b clearly describes the impact of uricase and ChO_X dielectric material when $V_{DS} = 0.6$ V and $V_{GS} = 1.0$ V over-device efficiency. Percentage increment of device efficiency (g_m/I_D) designated at "O" is 18.01% compared to "M" and 56.38% compared to "Q" at ChO_X dielectric material, and for Uricase dielectric material, the increment of device efficiency labelled by "O" is 19.92% compared to "M" and 56.5% compared to "Q." This improvement is due to potential barrier reduction in the channel due to higher electrode work-function and dielectric material near the source side enhances gate controllability, resulting in speed-to-power dissipation performance (Chaujar et al. 2009). This signifies gate engineering work function and dielectric materials in the nanogap affect CMOS device performance.

Figure 16 shows how cavity length impacts device transfer properties with various biomolecules. Simulated results were obtained utilizing cavity lengths of 5 nm,

Table 4 Summarizes a comparison between the performance indicators for the two materials (uricase and ChOx) for n-type triple hybrid metal gate dielectric modulated gate-all-around junctionless NWFET at a constant gate to source voltage (V_{GS} = 1.0 V)

Gate work-function variables (eV)	Intrinsic voltage gain (V^{-1})		Switching ratio (Ion/Ioff ratio)		Output resistance ($1/g_d$)		Device efficiency		Transconductance, g_m (S)	
	Uricase	ChO_X	Uricase	ChO_X	Uricase	ChO_X	Uricase	ChO_X	Uricase	ChO_X
M	8.10	9.88	1.78×10^5	5.22×10^5	1.08×10^6	1.40×10^6	2.61	3.22	7.12×10^{-6}	8.84×10^{-6}
O	10.20	13.00	4.75×10^5	1.36×10^6	1.90×10^6	2.46×6	3.13	3.80	7.44×10^{-6}	9.36×10^{-6}
Q	4.25	5.22	4.40×10^3	2.18×10^4	6.85×10^5	8.10×10^5	2.00	2.43	4.83×10^{-6}	6.12×10^{-6}

10 nm, and 15 nm while maintaining gate length, doping profile, and nanogap cavity thickness, keeping constant at constant room temperature. Figure 16a shows how different biomolecules affect the switching ratio at various cavity lengths. Higher switching ratio variation is examined when nanogap cavity length decreases due to lower parasitic capacitances. It's also interesting to note that the nanoscale size gap significantly affects the electrical characteristics of FETs. As a result, a significant change in switching ratio (due to the dielectric constant and cavity length variation) is used as a detection/sensing metric for a specific biomolecule. Moreover, one of the critical parameters for the developed biosensor device is sensitivity. Due to the increase in nanogap cavity length, leakage current/tunneling current increases, as reflected in Fig. 16b, due to increasing tunneling distance (Tripathi et al. 2019)

Overall, we conclude that the cavity gap length must be optimized for better performance, allowing sub-20-nm THM-high-K-GAA-JL-NWFETs to be used as high-speed, low-noise, and high-sensitivity biosensors for the detection of a variety of diseases. The methodology utilized to investigate the impact of nanogap cavity length on the device performance most likely involves numerical simulations within the framework of the proposed device. The effect of charge confinement, electrostatic control, and biomolecule detection sensitivity was examined. Insights are gained into the appropriate. To assess the validity of the findings, the simulation results were compared with the theoretical models and current literature. Discrepancies or limitations in the model are identified, and recommendations for future development or refinement are made.

3.4 Long-term stability or reliability analysis

Physical characteristics, sensitivity, stability, and reproducibility are vital analyses for assuring the device's reliability over time and between devices (Matsukawa et al. 2008) at different temperatures. The temperature has various effects on the sensor system, and understanding these effects is critical for maintaining dependable and accurate sensor performance (Pour and Aval 1993). Consequently, the stability of our proposed sensor is further tested by investigating the influence of temperature on the transfer characteristics, as depicted in Fig. 17.

Also, analyzing a device's transient reaction can provide insights into the device's stability characteristics. A biosensor with a rapid and constant transient response would most likely be considered more stable. As a result, measuring the transient response of the biosensor optimized using numerical modeling for triple hybrid gate optimization can provide useful information about its stability under various operating settings, environmental influences, and during long periods of use. Figure 18 depicts the transient response of the drain current at different metal gate electrode work functions of the proposed device.

4 Conclusion

Based on a 2D solution of Poisson's equation, a new numerical model for triple hybrid metal gate dielectric modulated gate-all-around junctionless nanowire FET-based uricase and ChO_X biosensor was successfully developed to investigate the effects of gate electrode work-function during gate engineering/optimization. The numerical modeling technique simulates the electrical behavior of the biosensor using various combinations of metal work-function values. The selected metal work-function values are also crucial for gate engineering of SiNWFET-based biosensor devices, as they improve the device's sensitivity and performance in detecting biomolecules. Due to a systematic investigation and optimization of the hybrid gate structure along different gate electrodes, the theoretical modeling and simulation results are in good agreement and accurately predict the device's behavior. The analytical modeling contains an electrostatic potential, threshold voltage, subthreshold current, and electric field, including neutral biomolecules (uricase and ChO_X) and different metal work-function. The effect of gate electrode work function and dielectric materials on device sensitivity, linearity (transconductance, intrinsic voltage gain, output conductance), switching ratio, leakage current, subthreshold voltage, device efficiency, and shifting threshold voltage has been studied. The simulated results reveal that the voltage and current sensitivity increase when the tunable gate work function increases from drain to source across the channel. For instance, sensitivity improvement (S_{Cur}) is 16.21% when "O" compared with "M" and 30.96% compared to "Q" when ChO_X, a dielectric material, is immobilized on the cavity at designed gate engineering denoted by "O." This improvement of current and voltage sensitivities makes the THM-GAA-JL-NWFET based ChO_X biosensor designed at "O" clearly indicates better output results compared to "M" and "Q" in terms of sensitivity, switching ratio, and device efficiency, as it is summarized in Table 4.

In addition to the metal work function, higher dielectric constant of biomolecules and properly optimized nanogap cavity length signifies improved output results in transconductance, surface potential, switching ratio, and intrinsic voltage gain so that THM-GAA-JL-NMOSFET based ChO_X biosensor designed at "O" electrode optimization is responsible for better detection different concentration levels of cholesterol and uric acids. For instance,

hyperuricemia, gout, cardiovascular disease, hyperlipidemia, and metabolic syndrome are some specific diseases that could be detected using the proposed biosensor.

ABSTRACT

The assessment of the flow characteristics of river systems is a very intricate undertaking in the development of hydraulic models for the purposes of flood control and floodplain management. Therefore, it is essential to use simulation models in order to calibrate and verify the experimental results. In this study, the Hydrologic Engineering Centre's – River Analysis System (HEC-RAS) is used to calibrate and validate the distribution of velocity and shear stress for different converging compound channels. Two separate flow regimes were assessed for validation based on experimental data obtained from converging compound channels with angles of $\theta = 5°$, 9°, and 12.38°. The projected values for two relative depths ($\beta = 0.15$ and 0.20) exhibit a similar pattern of variation as the empirical observations and are marginally lower than the recorded values. This suggests that the HEC-RAS model accurately estimates the velocity and shear stress values. The disparity between the simulated and experimental outcomes shows a discrepancy of less than 10%. Hence, the implications of our results suggest that while dealing with nonprismatic rivers, it is advisable to take into account lower values. The used methodology and the outcomes focused on problem-solving might potentially inform the development of flood control infrastructure for nonprismatic watercourses.

Key words: converging floodplains, HEC-RAS modeling, nonprismatic compound channel, shear stress distribution, velocity distribution

HIGHLIGHTS

- This article presents a study that aimed to examine the flow characteristics in a nonprismatic compound channel with converging floodplains.
- The HEC-RAS software was used for this investigation.
- The findings demonstrate that the HEC-RAS models are precise in predicting the flow characteristics in nonprismatic channels, as well as replicate the experimental results.

1. INTRODUCTION

Overbank flow is the phenomenon in which water inundates the neighboring area located above the floodplain, leading to the creation of a compound channel characterized by two distinct phases. The determination of the maximum flood level is contingent upon both the flow rate and the hindrance to flow caused by bed friction and other loss mechanisms (Ervine *et al.* 2000). The disparity in velocity between floodplain and main channel flows gives rise to significant turbulence forms in the vicinity of their crossing. The formation of one or two longitudinal vertices occurs due to the presence of turbulence anisotropy at the interface and boundary, leading to the generation of secondary flow in lateral directions. According to Fernandes *et al.* (2014), many studies suggest that the presence of secondary flow in a compound channel may differ across different compartments, which is influenced by factors such as differences in bottom roughness and lateral flow depth. Consequently, there has been a recent surge of interest among academics and engineers on the need of accurately predicting flow parameters in flood situations, with the aim of mitigating damage and safeguarding human lives and property. Throughout history, several approaches and processes have been used to facilitate accurate measurement and prediction of river discharge, velocity distribution, boundary shear stress distribution, and water surface level during overbank flows. Throughout the progression of a river's flow, alterations occur in the floodplain's geometry, leading to the formation of a compound channel that may exhibit either converging or diverging characteristics. Replicating flow in a nonprismatic compound channel poses more challenges due to the increased transfer of momentum from the main channel to the floodplains. Previous studies by Sellin (1964), Myers & Elsawy (1975), Knight *et al.* (2010), and Khatua *et al.* (2012) have extensively investigated the flow characteristics of straight and meandering prismatic two-stage channels. However, there is a dearth of knowledge on nonprismatic compound channels. According to James & Brown (1977), the presence of a converging channel form leads to an increase in flow on floodplains, but the flow on expanding floodplains is diminished. The phenomenon of compound channels characterized by symmetrically narrowing floodplains has been investigated by Bousmar & Zech (2002), Bousmar *et al.* (2004), Rezaei (2006), and Rezaei & Knight (2009). These studies have identified the occurrence of additional head loss and the transfer of momentum from the main channel to the floodplains. Proust *et al.* (2006) conducted an investigation on the asymmetric geometry, specifically focusing on its quicker convergence rate. An augmented convergence angle of 22° leads to heightened levels of mass transfer and head loss. The flow behavior of skewed, two-stage converging and diverging channels was investigated by Chlebek *et al.* (2010). Rezaei & Knight (2011), Yonesi *et al.* (2013), and Naik *et al.* (2017) conducted a recent study on converging compound channels, which produced notably more accurate outcomes compared with earlier research. In their recent study, Naik *et al.* (2022) introduced a unique equation based on the gene expression programming (GEP) approach, using nondimensional variables. This equation aims to accurately forecast the water surface profile in converging compound channels. In their study, Kaushik & Kumar (2023a) used machine learning techniques to forecast the water surface profile of a compound channel with converging floodplains. Their approach included a combination of geometric and flow-related parameters. Furthermore, Kaushik & Kumar (2023b) used GEP as a research approach to construct a novel equation for compound channels with converging floodplains. The aforementioned equation is used to quantitatively assess the magnitude of the boundary shear force that is transmitted by floodplains. Kaushik & Kumar (2023c) used the support vector machine (SVM) technique to assess the water surface profile of compound channels characterized by diminishing floodplains. The use of nondimensional geometric properties facilitated the attainment of this outcome. The findings of this study indicate that the water surface profile generated by the SVM exhibits a substantial degree of concurrence with both the empirical data and the outcomes derived from previous research endeavors. In their study, Kaushik *et al.* (2023) used the Hydrologic Engineering Centre's – River Analysis System (HEC-RAS) software to conduct the calibration and validation of water surface profiles in a range of converging compound channels. The results suggest that the HEC-RAS models suggested for nonprismatic rivers are dependable in forecasting water surface profiles, demonstrating a strong ability to generalize without showing signs of overtraining. Kaushik & Kumar (2024) utilized different machine learning models to predict the shear force carried by floodplains in nonprismatic compound channel with smooth converging floodplains. The investigation conducted in this part has mostly focused on the phenomenon of flow rates. Limited research has been conducted on the flow characteristics of nonprismatic compound channels. Consequently, it is essential to engage in the modeling of flow characteristics in nonprismatic channels, as this will contribute to the improvement of flood mitigation and risk management investigations.

In recent decades, considerable efforts have been dedicated to the use of 2D and 3D modeling techniques in order to improve the accuracy of water level and velocity estimates in real-world river systems. Nevertheless, there are still a number of important inquiries that have not yet been addressed. Software applications such as HEC-RAS and MIKE 11 integrate calculation methodologies such as single channel method (SCM) and divided channel method (DCM). Throughout the whole segment, the SCM maintains a consistent pace. The DCM effectively partitions the cross-sectional area into several regions characterized by different flow properties, including the primary channel and adjacent floodplains. Wormleaton *et al.* (1982) argued that the SCM tends to underestimate the conveyance capacity, whereas the DCM tends to overestimate the capacity of compound channels. In subsequent years, a number of researchers have developed improved methodologies for estimating compound channel flow. Wormleaton & Merrett (1990) proposed a straightforward modification to improve the estimate of DCM, but Ackers (1992) conducted experimental adjustments to rectify the DCM. The lateral distribution technique (LDM) introduced by Wark *et al.* (1990) and the approach suggested by Shiono & Knight (1991) were developed as alternative and more advanced methodologies. Both of these strategies, resembling a quasi-2D model, rely on identical equations to ascertain the lateral velocity distribution inside the cross-sectional area. The HEC-RAS hydraulic model, created by the U.S. Army Corps of Engineers, is extensively used in both natural and man-made channels to compute the water surface elevation and other flow parameters. This model operates in both 1D and 2D dimensions, using gradually varying dimensions to account for steady and turbulent flow conditions (Brunner 2016). In addition to its primary functions, HEC-RAS also facilitates the computation of sediment transport and mobile bed dynamics, as well as the modeling of water temperature (Arcement & Schneider 1989; Brunner 2016). The use of computer programs in recent years has significantly improved the understanding and analysis of river hydraulics and associated phenomena. Leandro *et al.* (2009) provided comprehensive insights into the hydraulic models often used in open channel modeling, along with a detailed analysis of their respective strengths and limitations. Computer hydraulic models are being widely used on a global scale to facilitate flood planning in areas that are susceptible to flooding. The primary objective of using these models is to enhance comprehension of the patterns pertaining to the magnitude and frequency of floods, while simultaneously aiding in the formulation of strategies to effectively respond to potential flood events in the future (Liu & Merwade 2018). The HEC-RAS model has been used in several studies to assess flow parameters inside the primary channel and floodplain, as well as under diverse climatic conditions. In their study, Ramesh *et al.* (2000) used an optimization approach to quantify the roughness of open channel flow. The researchers included boundary conditions as constraints in their analysis. The calibration of the HEC-RAS model for river study included the use of Manning's n roughness coefficient, as documented by Hicks & Peacock (2005) and Kuriqi & Ardiçlioğlu (2018). In their study, Timbadiya *et al.* (2011) constructed an integrated hydrodynamic model using MIKE11 software. The purpose of this model was to calibrate Manning's n roughness coefficient in order to evaluate the sensitivity of flow resistance in the Tapi River located in India. In their study, Mowinckel (2011) used the HEC-RAS model to enhance the flood conveyance capacity of an artificially constructed San Jose Creek located in Goleta, California. The evaluation enabled the formulation of a new channel configuration that would more effectively handle a flood event with a recurrence interval of 100 years, while concurrently mitigating adverse impacts on the surrounding area. In their study, Parhi *et al.* (2012) used the HEC-RAS model to calibrate the channel roughness coefficient along the Mahanadi River in Odisha. The researchers have determined that a Manning's n value of 0.032 produces optimal outcomes for the Khairrmal to Munduli segment of the Mahanadi River. In their study, Boulomytis *et al.* (2017) identified that the use of Manning's n roughness coefficients in diverse hydraulic models leads to mistakes in flow forecasts pertaining to the Bashar River. The study of rivers is vital due to their frequent use in agricultural practices and hydropower generating. In order to effectively develop and deploy flood control structures and ensure optimal flow behavior, it is essential to accurately estimate the water surface elevation in the given conditions (Kuriqi *et al.* 2019). Ogras & Onen (2020) used the HEC-RAS program to analyze the hydraulic properties of the flood bed, water surface profiles, flood recurrence, and 1D floodplain study of the Tigris River. Bharath *et al.* (2021) used the HEC-RAS program to ascertain the hydrograph of outflow caused by a breach and the hydraulic conditions at crucial downstream sites. In addition, the breach outflow hydrographs are directed utilizing dynamic flood wave routing. The HEC-RAS model is further simulated with breach parameters obtained from five different empirical methodologies, and the results are then compared. Tamiru & Wagari (2021) proposed a combined approach using machine learning and HEC-RAS models to create flood inundation maps in the Baro River Basin, Ethiopia. The artificial neural network (ANN) and HEC-RAS models were combined to create a comprehensive

Uncorrected Proof

hydrological and hydraulic model that predicts both runoff and the degree of flooding. The findings indicate that incorporating a machine learning technique into the HEC-RAS model has enhanced the accuracy of conventional flood forecasting approaches by reducing spatiotemporal uncertainty. The research conducted by AL-Hussein *et al.* (2022) demonstrated that the settlements in close proximity to the mouth of the Khazir River saw a greater impact from the floods compared with those located farther downstream. The research region has shown a robust association between Hydrologic Engineering Centre's – Hydrologic Modeling System (HEC-HMS) and HEC-RAS in assessing flood risks and accurately predicting future floods. Vashist & Singh (2023) examined how changes in the upstream border data impact the extent of the flooded region. The simulated findings using a digital elevation model (DEM) with a resolution of 12.5 m show a strong agreement with the validation data and accurately match the reported flooded regions. This research demonstrates the efficacy of HEC-RAS in 2D modeling for improved management techniques.

The objective of this research is to validate the reliability of the experimental findings concerning the flow characteristics of a nonprismatic compound channel with converging floodplains. These characteristics include the stage and discharge relationship, as well as the distribution of velocity and shear stress. The approach proposed in this article uses the HEC-RAS to enhance numerical modeling. The dataset used in this study effort to complete the simulation effectively was gathered from the work of Naik *et al.* (2017), which was done on a variety of converging compound channels and provided the basis for this work. To ensure consistent evaluation and verification of the codes, same criteria, boundary conditions, cross-section data, and flow parameters were used. Ultimately, the simulated outcomes were examined and juxtaposed with preexisting empirical evidence in order to assess and authenticate the conclusions.

2. MATERIALS AND METHODS

2.1. Physical modeling

Figure 1 illustrates the flowchart outlining the methodology used in the present investigation. The experiments were conducted in the Hydraulics laboratory, which is situated under the Department of Civil Engineering at NIT, Rourkela, India. The trials were carried out inside a masonry flume with dimensions of 15 m in length, 0.9 m in width, and 0.5 m in depth. In this study, a compound cross-section was created using brick masonry, with a main channel width of 0.5 m and a depth of 0.10 m. Figure 2 provides a comprehensive depiction of the geometric attributes and cross-sectional profile of a two-stage channel. The construction of the converging portion of the channel included the use of Perspex sheet, which was employed to achieve various converging angles denoted as $\theta = 5°$, 9°, and 12.38°, respectively, while maintaining a consistent geometric configuration. The compound channel consists of a prismatic segment of 9 m in length, followed by a nonprismatic section spanning 2.28, 1.26, and 0.84 m for converging angles $\theta = 5°$, 9°, and 12.38°, respectively, with the remaining portion being the downstream section. The subcritical flow regime was seen under various circumstances in a two-stage channel with a longitudinal bed slope of 0.0011. The estimation of Manning's n value was conducted based on data obtained from both in-bank and overbank flows in the floodplains and main channel. The water supply is recirculated inside the system by the use of a pump, which transfers water from an underground sump to a reservoir situated in the experimental channel. The rectangular notch has been encircled by vertically adjustable gates and flow enhancers. The use of flume detachable tailgates facilitates the preservation of a constant flow throughout the designated test reach. The volumetric tank serves as a receptacle for the water that is discharged from the channel. Subsequently, it returns to the subterranean reservoir.

Figure 3 depicts the experimental configuration as seen from an above perspective. Figure 4 displays the plan view of the nonprismatic cross-sections of Naik *et al.* (2017) channels. Five sections were considered for the analysis: start of converging section (sec-1), 0.10 m away from sec-1 (sec-2), middle of converging section (sec-3), 0.10 m before the sec-5 (sec-4), and end of converging section (sec-5). In the context of compound channel design, it is possible to access and measure any point on the plan of the channel. The use of a mobile bridge might be employed for the purpose of gathering the measurements. The study places significant emphasis on the ratio of channel width and aspect ratio. The flow velocity at the grid positions, as shown in Figure 2, was determined via the use of a pitot static tube featuring a diameter of 4.77 mm. The determination of the order of maximum velocity for a certain flow channel was conducted using a flow detector possessing a minimal least count of 0.1°. The use of a circular scale and pointer arrangement on a flow direction sensor is employed to quantify the angle of the Pitot tube leg with respect to the longitudinal direction of the channel. The integration of the longitudinal velocity

plot with the volumetric tank collection yielded a total discharge calculation that closely approximated the actual data, with a deviation of no more than $\pm 3\%$. In this work, velocity data was used in conjunction with a semi-log plot to make predictions about channel bed and wall shear forces. The calculation of boundary shear stresses was conducted by using the relationship proposed by Patel (1965) and utilizing measurements of Preston tube head differences obtained from a manometer. The correction of shear values was accomplished by conducting a comparison with the corresponding values derived using the energy gradient approach. Consequently, the findings consistently exhibited a deviation of no more than 3% from the true value. Based on the study of laboratory data, it has been shown that the accuracy of calculating tractive stresses using Pitot tubes is superior to that of using an acoustic Doppler velocimeter (ADV). One limitation to consider is the lack of reliability in detecting

2.2. Numerical modeling

In order to replicate a dynamic and evolving stream, researchers choose to use the HEC-RAS model, which operates by performing calculations based on the Saint-Venant equations (1) and (2) (Brunner 2016).

$$\frac{\partial A}{\partial t} + \frac{\partial Q}{\partial x} = q_l \tag{1}$$

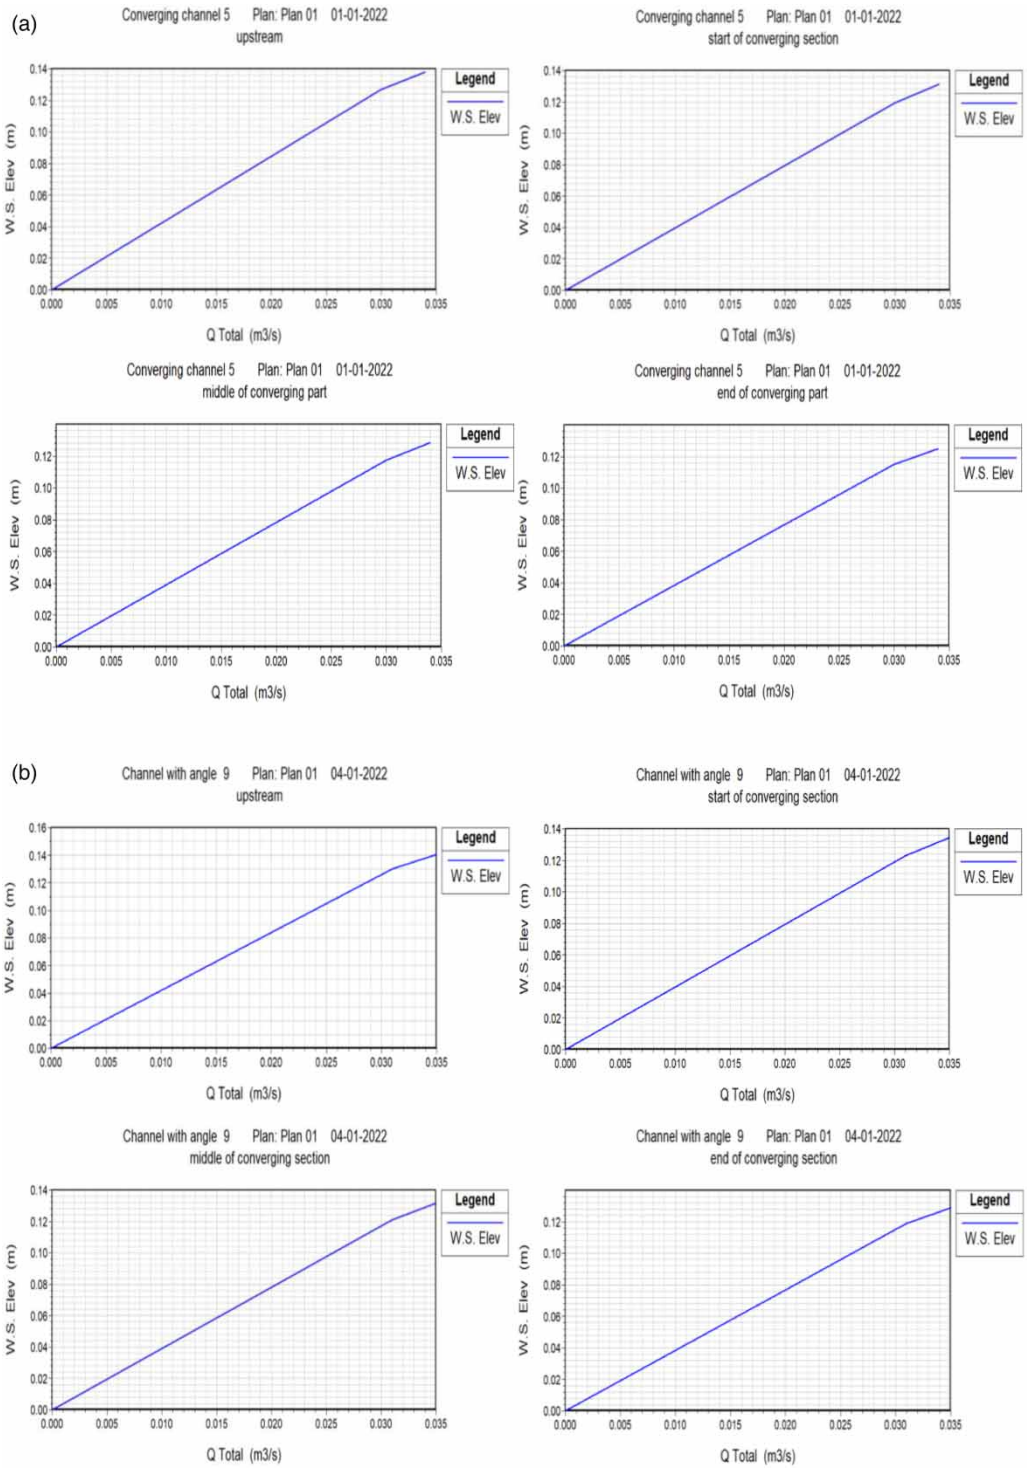

Figure 7 | Stage discharge relationship for relative depth, $\beta = 0.15$ at the upstream of the channel, as well as the start, middle, and end of the converging portion for various converging compound channels: (a) $\theta = 5°$, (b) $\theta = 9°$, and (c) $\theta = 12.38°$. (*continued.*).

Uncorrected Proof

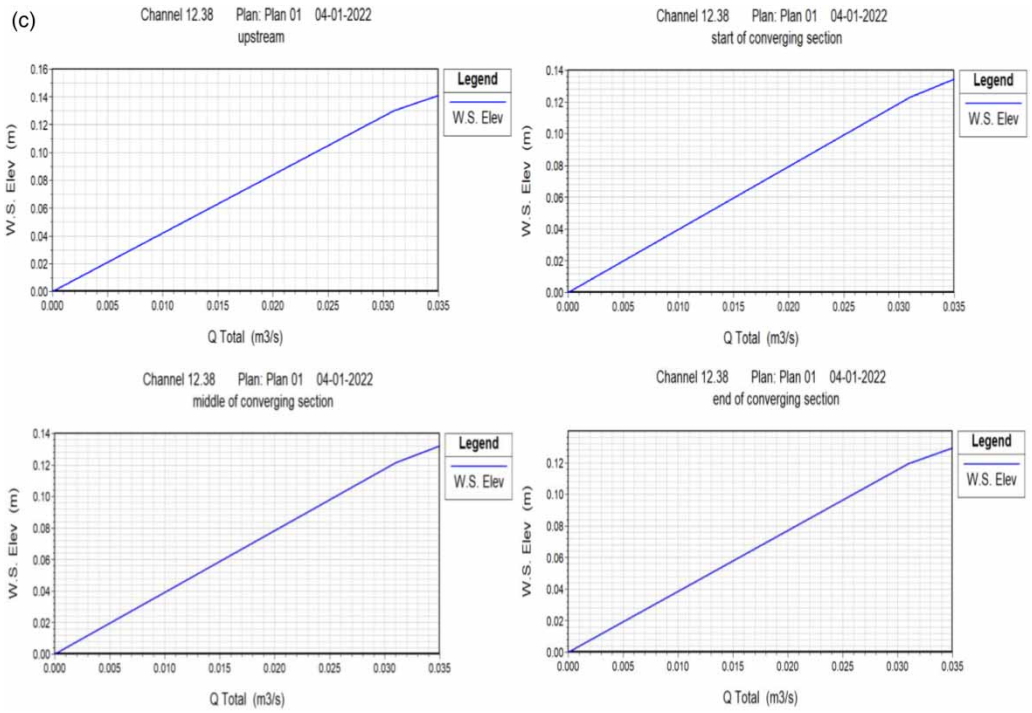

Figure 7 | Continued.

$$\frac{\partial Q}{\partial t} + \frac{\partial\left(\frac{Q^2}{A}\right)}{\partial x} + gA\frac{\partial H}{\partial x} + gA(S_o - S_f) = 0 \tag{2}$$

Equations (1) and (2) correspond to the continuity and momentum equations, respectively. In these equations, H represents the elevation of the water level, t and x represent the temporal and longitudinal coordinates, q_l represents the lateral inflow (which is zero in our case), S_o represents the bed slope of the channel, and S_f denotes the slope of the total energy line or friction slope. The equations were calculated using a finite-difference method that relied on a four-point implicit box, as described by Brunner (2016). Despite the inherent constraints of the finite-difference principle in effectively transitioning between the subcritical and supercritical flow regimes, the use of this principle requires the development of distinct solution strategies for each flow state. Nevertheless, it is possible to circumvent the aforementioned limitation by using the mixed-flow regime option of the HEC-RAS model. This enables HEC-RAS to suggest potential remedies for sub-zones within the river reach (Hicks & Peacock 2005; Timbadiya *et al.* 2011; Brunner 2016). To conduct the hydraulic simulation, many input data are necessary, including roughness, channel geometry, boundary conditions, and discharge data (Hicks & Peacock 2005; Brunner 2016). Manning's n values were included during the simulation phase, using the values used in the physical modeling. As a result of the persistent and consistent flow conditions observed at the specific section of the river under investigation, the downstream boundary condition was restored to its original state. Figures 5 and 6 illustrate the plan and 3D views of the converging compound channel geometry in the HEC-RAS. These visual representations were generated with laboratory geometry data and include the most often seen cross-sections. Figure 5 displays the upstream and downstream of the channel via the representation of Stations 900 and 500, respectively. Stations 800, 700, and 600, however, symbolize the initial, intermediate, and final segments of the converging portion, correspondingly. All stations located in the straight and converging parts of the two-stage channel, except the endpoints, may be classified as interpolated stations. The predicted velocity and shear stress obtained by HEC-RAS was afterwards compared with the observed values.

3. RESULTS AND DISCUSSION

Figure 7 illustrates the connection between stage and discharge for a certain relative depth, $\beta = 0.15$, at several locations along the converging part of distinct channels. These locations include the upstream of the channel,

Uncorrected Proof

as well as the start, middle, and end of the converging portion. The converging compound channels under consideration have different convergence angles, namely $\theta = 5°$, 9°, and 12.38°. The increase in discharge results in a corresponding rise in flow depth. However, it is important to note that beyond the bankfull depth, there is a little decrease in the rate of increment. The decrease in flow depth transpires as one proceeds from the start to the end of the converging section due to the narrowing of the channel, while maintaining the same discharge. Furthermore, it has been shown that an increase in the angle of floodplain convergence at a given stage results in a corresponding increase in the flow rate. This decrease in flow depth may be attributed to the combined influence of momentum and channel geometry. As the amount of water flowing out increases, the higher speed of the flow creates more force, which leads to the wearing away of the sides and bottom of the channel. In a converging

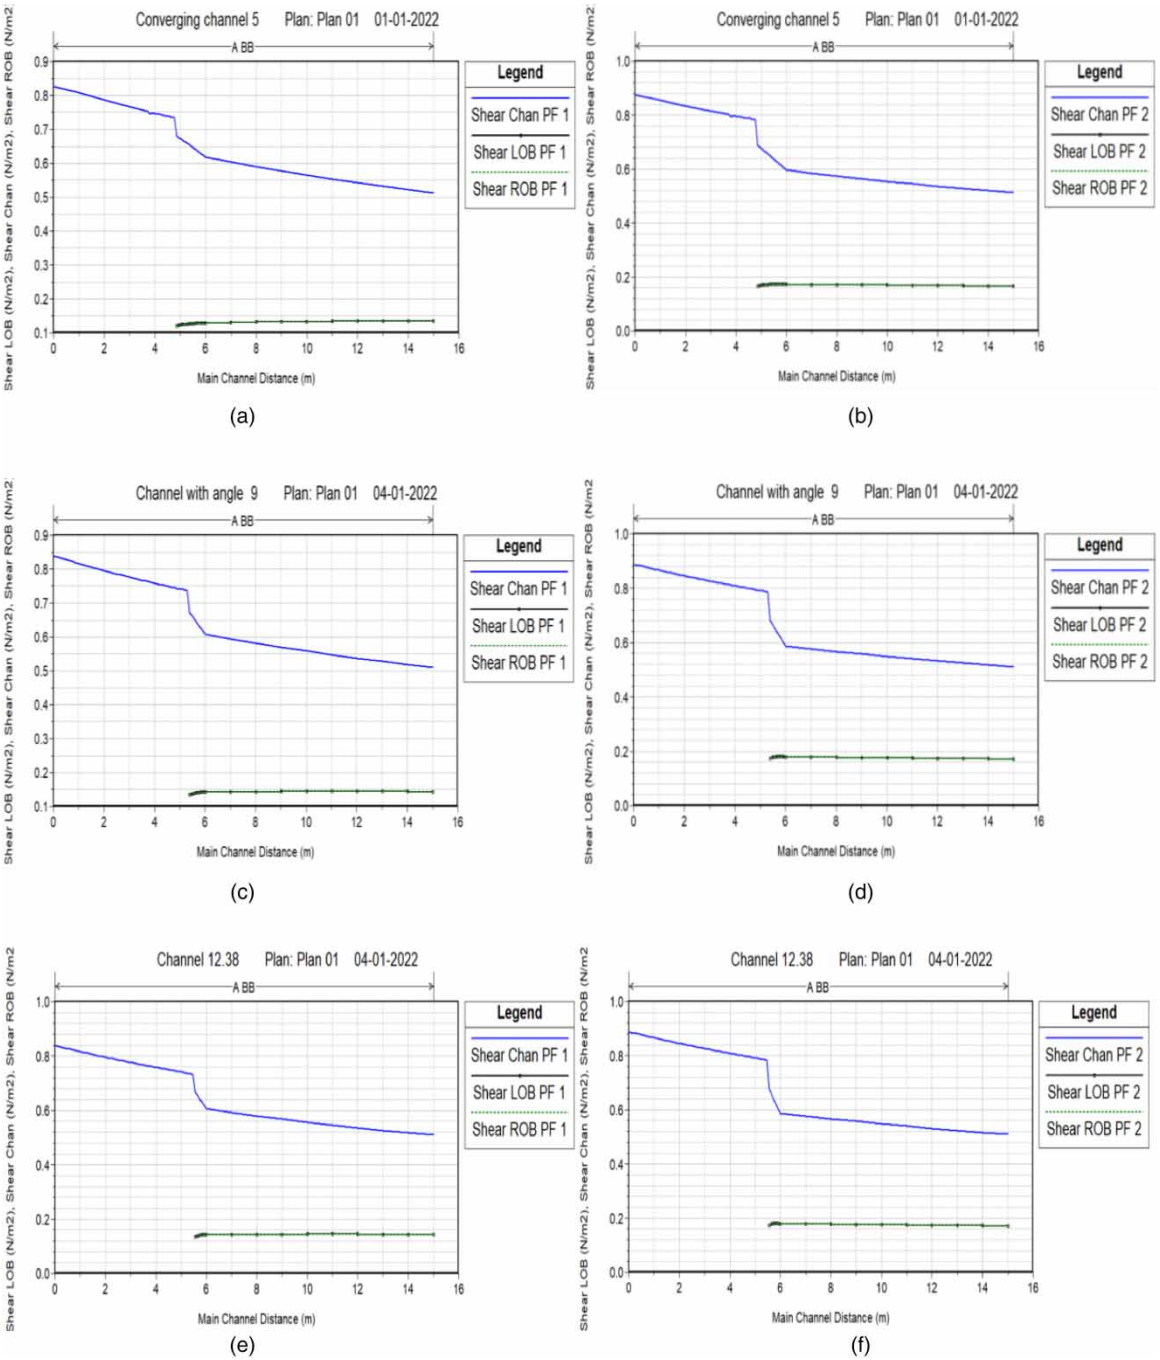

Figure 8 | Variation of average boundary shear stress with the longitudinal distance for different relative depths and converging angles: (a) $\beta = 0.15$, $\theta = 5°$; (b) $\beta = 0.20$, $\theta = 5°$; (c) $\beta = 0.15$, $\theta = 9°$; (d) $\beta = 0.20$, $\theta = 9°$; (e) $\beta = 0.15$, $\theta = 12.38°$; and (f) $\beta = 0.20$, $\theta = 12.38°$.

Uncorrected Proof

compound channel, when the main channel narrows as it meets floodplains, the expanded flow area spreads out the greater amount of water being carried, leading to a reduction in water level. The reason for this is that a channel has the capacity to hold a larger amount of water without causing a substantial increase in water level.

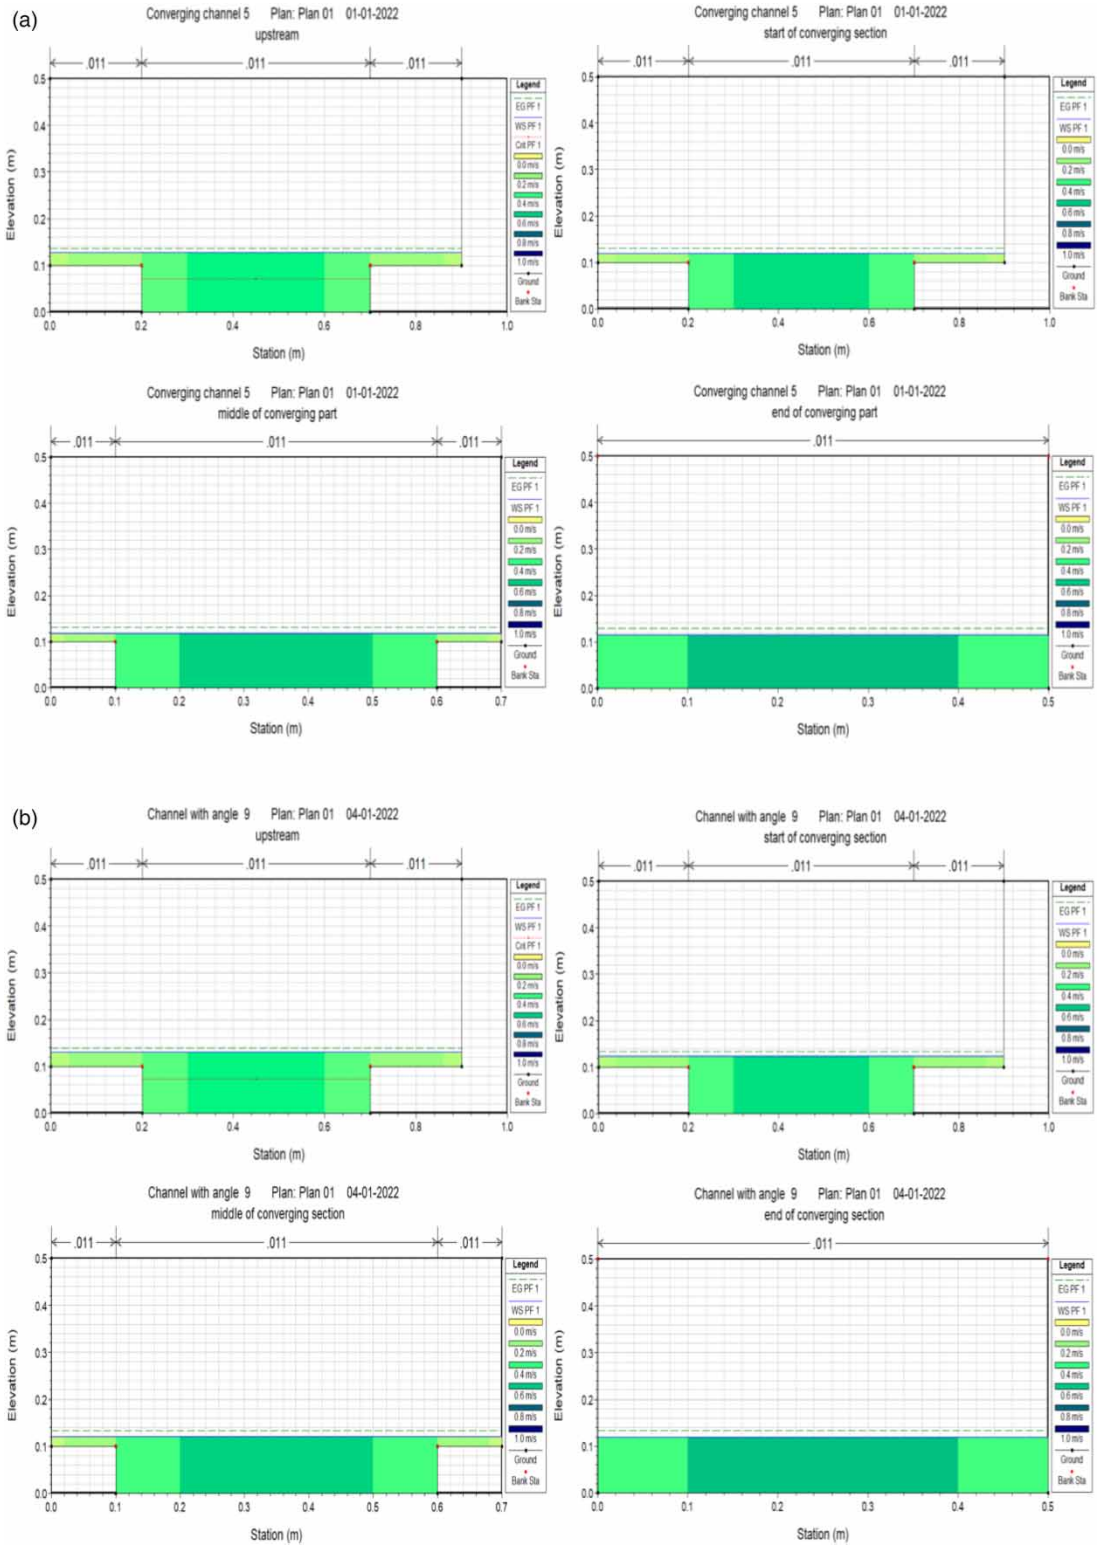

Figure 9 | Depth-averaged velocity distribution across the width of channel for relative depth, $\beta = 0.15$ at the upstream of the channel, as well as the start, middle, and end of the converging portion for various converging compound channels: (a) $\theta = 5°$, (b) $\theta = 9°$, and (c) $\theta = 12.38°$. Figure 9 | Continued.

Therefore, the stage reduces as the flow spreads out across the channel cross-section, while still preserving hydraulic equilibrium. Figure 8 represents the relationship between average boundary shear stress and longitudinal distance for different relative depths ($\beta = 0.15$, 0.20) in converging compound channels with varying angles ($\theta = 5°$, 9°, 12.38°). The boundary shear stress exhibits a linear increase with longitudinal distance up to the prismatic section. However, in the converging region of the channel, a sudden spike in shear stress is seen with longitudinal distance, followed by a subsequent linear increment. The boundary shear stress in both the main channel and floodplains rises with longitudinal distance as the relative depth increases, mostly owing to the transfer of momentum from the main channel to the floodplains. As the angle of convergence grows, there is a transition in the shear stress at the beginning of the converging segment from an abrupt shift to a sharp change, followed by a linear increase as the longitudinal distance progresses. The primary contributor of this phenomenon is the converging geometry of the channel, which creates friction in the flow. This friction intensifies as the angle of convergence of the channel rises.

Figures 9 and 10 depict the velocity distribution across the width of the channel for different relative depths ($\beta = 0.15$, 0.20) at various locations, namely the upstream, start, middle, and end of the converging portion of the channel. These figures correspond to different converging compound channels with angles of convergence (θ) equal to 5°, 9°, and 12.38°. From these figures, it has been observed that the depth-averaged velocity distributions are reasonably symmetric in all sections and gradually increase from upstream to end of the converging section. The velocity in the main channel is found to be greater than that in the floodplains, and it progressively rises in the downstream direction owing to the flow acceleration from the converging geometry of the channel. At the higher relative depths, the increase in the center line velocity is found to be more as the flow progresses downstream. The velocity in the floodplains decreases and reaches to minimum at the channel boundaries at lower relative depths. While, at higher relative depths, velocity increases in the interface region of main channel and floodplains due to momentum transfer from main channel to floodplains and then, reaches to minimum at the floodplain ends. The presence of converging geometry in a channel leads to heightened turbulence as the angle of convergence becomes larger. Consequently, this increased turbulence results in a greater variation in velocity distribution across various cross-sections of the channel. Figures 11 and 12 illustrate the comparison between experimental and simulated data obtained via the use of HEC-RAS. These data pertain to the distribution of boundary shear stress and depth-averaged velocity for relative depth, $\beta = 0.15$ in various

more pronounced for shallower relative depths, whereas it is less prominent for deeper relative depths. As the angle of floodplain convergence increases, the variability in estimated values decreases.

4. CONCLUSIONS

The HEC-RAS models were used in an effort to replicate the velocity and shear stress distribution in a nonprismatic compound channel with converging floodplains. In order to achieve the intended objective, an examination was conducted on two different relative depths, namely $\beta = 0.15$ and 0.20, as well as three converging channels with angles of $\theta = 5°$, 9°, and 12.38°. The increase in discharge leads to a corresponding rise in flow depth up to the bankfull depth. However, once the bankfull depth is reached, the interaction and momentum transfer between the main channel and floodplains cause a little reduction in depth at all converging angles. The longitudinal orientation of the channel segment exhibits an increase in boundary shear stress. The phenomenon of a significant rise at the beginning of the converging phase of a channel geometry is seen due to convergence. This trend is also observed for increasing relative depths and varying floodplain convergence angles. The velocity in the main channel exhibits a slight increase compared with the velocity in the floodplains. This increase is observed to be more pronounced in the downstream direction, which can be attributed to the convergence and momentum shift phenomenon. Furthermore, this pattern of variation holds true for higher relative depths and varying floodplain converging angles. The anticipated values for boundary shear stress and velocity in HEC-RAS demonstrate a little disparity in comparison to the empirical findings, while still adhering to a regular pattern. The observed discrepancy between the experimental and simulated values is determined to be less than 10%.

Uncorrected Proof

This research utilizes data from many cross-sections both upstream and downstream of the laboratory channels in order to demonstrate the capability of the HEC-RAS model in evaluating the distribution of velocity and shear stress in various converging compound channels. Consequently, irrespective of the specific model used for conducting the analysis, it is essential to possess a comprehensive comprehension of the model's requisite parameters, as well as a thorough evaluation of the simulation findings, prior to continuing further. The anticipated outcomes are influenced by many factors, including the slope of the bed, the resistance to flow, the presence of secondary currents, localized differences in channel form, and the two-dimensional effects resulting from the curvature of the channel. Comprehending the flow characteristics in nonprismatic compound channels is essential for advancing river hydraulics due to many factors. Nonprismatic channels have diverse forms and cross-sectional areas along their length, which greatly impact flow characteristics such as velocity dispersion, turbulence, and sediment transport. Engineers may enhance their ability to forecast the behavior of rivers in response to changes in flow rates, channel geometry, and sediment transport by understanding these attributes. This knowledge is valuable in designing structures such as bridges, dams, and flood control systems. Furthermore, a comprehensive understanding of nonprismatic channel flow is crucial for precisely simulating hydraulic phenomena in river systems, facilitating improved water resource management, flood prevention, and environmental preservation endeavors. HEC-RAS is a powerful tool for accurately simulating the flow behavior in irregularly shaped channels, which is essential for studying river hydraulics. It provides powerful computational skills to model intricate flow patterns, sediment movement, and hydraulic structures in nonprismatic channels. HEC-RAS incorporates variations in channel geometry, including changes in width, depth, and slope throughout the river reach, allowing for precise depiction of flow characteristics. HEC-RAS utilizes sophisticated algorithms to forecast water surface profiles, flow velocities, shear stresses, and other essential hydraulic parameters that are vital for engineering design and river management. In the context of future research, it would be intriguing to explore the economic impact that accurate evaluation of these parameters under overbank flow conditions has on the formulation of complete flood defense strategies or channel enhancement projects.

Abstract

Modern power system networks are under statutory obligations to integrate renewable energy sources (RES). The primary reason is to meet ever-increasing energy demand and also to curtail environmental pollution by greenhouse gases. However, the higher penetration of RES has the tendency of reducing inertia of overall power system network. Consequently, frequency stability is affected and deviates beyond allowable permissible limits leading to power blackouts, load shedding, and even total system failure. To address the issues associated with reduced inertia, an optimal control of hybrid energy storage system (HESS) has been proposed. HESS is basically a combination of battery and ultracapacitor, where ultracapacitor addresses rapidly varying power component by mimicking inertia while the battery compensates long-term power variations. Thus, the HESS is effectively controlled to compensate the loss of inertia by regulating its energy flow. For the purpose of improved efficiency and better power management of the HESS, an improvised particle swarm optimization (MPSO)-based virtual inertia control design has been proposed. The proposed MPSO is utilized to tune the gains of bidirectional dc–dc converter in such a way that improves frequency nadir with faster response to transient disturbances. This proposed method is simulated in MATLAB and its merits are validated in real time using hardware in loop. On analysing of the results, it can be observed that frequency nadir is improved by 48.96% with significant reduction in rate of change of frequency in comparison to conventional particle swarm optimization.

1 | INTRODUCTION

In modern times, the energy industry has seen significant growth. Several countries around the world are facing the challenge of ever-increasing energy demand. The conventional methods of power generation are already at their peak and going to be exhausted in near future. Additionally, the traditional methods of power generation are environmentally hazardous. Fossil fuels generate greenhouse gases, which contaminate the environment and pose a threat to the living organisms inhabiting the region. In order to address these issues, renewable energy sources (RES) are being rapidly implemented in contemporary power system networks. Nevertheless, the growing integration of power electronics interfaced RES results into reduced inertia and hence, poses a significant challenge for the grid stability [1]. The reduced inertia triggers frequency instability (high rate of change of frequency (RoCoF), frequency nadir and zenith). Further, this problem is very much exaggerated in power system network confined to small geographical locations termed as microgrid.

The inertia issue in microgrid operation and control is of lot of concern and several schemes primarily based on rotational mass have been proposed. Synchronous generators operating without any load, commonly referred to as synchronous

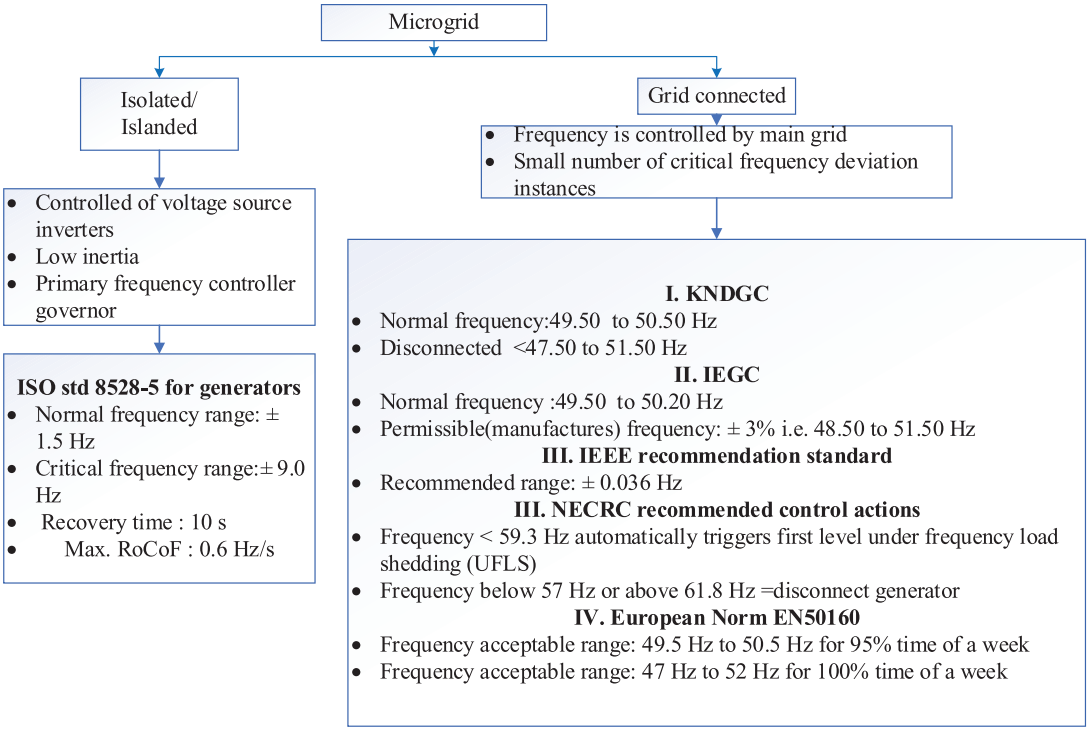

FIGURE 1 Frequency standards of microgrid [4, 5].

condensers (SC), have been widely used to compensate the loss of inertia [2]. However, the use of dedicated synchronous condenser is bulky, inefficient, and costly affair without any significant improvement in performance. To reduce the additional burden of machine, recently few schemes have been proposed where the inertia of rotating wind turbines is utilised as SC [3]. While this kind of technology seems very promising, but under variable speed operation of wind turbines, it becomes very difficult to extract the characteristics of typical SC and hence, not suitable for inertial control. The energy stored inside DC-link capacitors is also found to be very useful to overcome small transient load disturbances, but it has very limited capability heavily dependent on the size of the capacitor. Further, this kind of approach is suitable only where slight variation in DC-link voltage is allowed and not applicable to rigid DC-links comprising batteries having almost fixed voltages. Sometimes, the generating facilities in a microgrid are operated under partial-loading to keep a cushion for further increase in load. However, running a microgrid under reduced loading is extremely inefficient and increases the per unit cost of generating electricity.

Figure 1 shows frequency codes for restoration in microgrid operation prevalent in various organizations and countries.

Very recently, the energy storage systems (ESS) have been discussed widely with the intention of solving the problem of frequency instability in distributed generation system (DG) [6]. The ESS is found to be most promising for virtual synchronous machine emulation in power electronics dominant RES-based power generation. ESS having limited capacity in terms of both power and energy can be categorized on the basis of their response; rapid response ESS like flywheel, ultra-capacitors and li-ion batteries are called short-term while chemical battery (lead acid), pumped hydro storage and compressed air are known as long-term ESS. Most of the research work reported in the area of ESS power management is limited to theoretical analysis in control stability of droop, but silent about optimal sizing of ESS [7, 8]. Optimal sizing of Hybrid ESS is one of the essential ingredients not limited only to cost effectiveness but also to achieve enhanced performance out of it. Further, it is also necessary to maintain state of charge (SOC) within a given acceptable level and that is why it needs to be included in feedback control loop [9, 10]. Chu Sun proposed feedback control with additional Proportional and Integral (PI) regulator for fast-acting and slow acting energy storage system (FAESS and SAESS) to emulate synchronous generator [11]. However, in this proposal the design of PI parameters is done through the trial-and-error method. The challenge of optimal energy control was addressed by *Spyridon Chapaloglou* in [12] by controlling primary frequency through optimal methods. But, the sizing aspect of ESS is not considered in this particular article. In [13, 14], PV-battery energy storage system (BESS) is proposed and optimized using linear programming, but it did not explain effectiveness of hierarchical control nature of the systems [15, 16].

Recently, HESS-based energy management techniques have been proposed to address the inertia issue. Through the hybridization of a battery and an ultra-capacitor, fast frequency response (FFR) is achieved [17]. Inertia and damping emulation are restored using the energy recovered from them. Ultra-capacitor has high specific power density; hence, its response

17554543, 0, Downloaded from https://ietresearch.onlinelibrary.wiley.com/doi/10.1049/pel2.12723 by Delhi Technological University, Wiley Online Library on [11/06/2024]. time is rapid, that is why it is also referred to as rapid response energy storage system (RRESS). The battery has high energy density; hence, the response is slow and termed slow response energy storage system (SRESS). The idea of virtual synchronous generators (VSGs) replicated by power electronic converters is becoming increasingly popular [18]. However, problems with response time and parameter fluctuations make overall control more complex. Numerous studies have been examined to analyse the non-inertia generation effect on frequency dependability, resilience, and stability of bulk power networks [19]. In [20], the ESS has been regulated for emulating the characteristics of VSG to maintain frequency stability in low-inertia network. A typical VSG control approach incorporates the droop control loops to regulate its output active and reactive power for the better terminal voltage regulation and faster inertial response. However, sizing of HESS and determining the gains of control loops for different operating conditions is a very tedious and complex task.

An HESS-based VSG is proposed in [21, 22] where inertia constant (H) and damping constant (D) are emulated and compared with conventional parameters. Here, conventional particle swarm optimization (PSO) is used for parameter optimization which suffers from several convergence challenges. Furthermore, a low pass filter-based approach is adopted for power sharing between battery and supercapacitor without considering frequency zenith which is caused by abrupt load shedding of power supply. In [23], NN-based variable fractional order PID (VFOPID) is proposed to address reduced inertia problem in isolated microgrid which is very computationally intensive considering online updating of parameters. Since the ultracapacitor and battery have different characteristics, it is very important to analyze them independently in order to design an HESS pack. Sizing of both battery and ultra-capacitor must be optimized in such a way that it is able to handle maximum change in energy demand while keeping the voltage and frequency within permissible limits.

Although determining the size of ultracapacitor and battery forming an HESS is a typical off-line optimization problem, but optimal utilization of their capacity for a given disturbance is an online optimization issue. Therefore, the controller gains must be updated while considering the amplitude of disturbance. A typical online optimization technique has been proposed in [24] where power fluctuations are handled by updating VSG variables using the backtracking search optimization approach. Here, the damping coefficient D is updated while taking RoCoF in account whereas inertia constant H is updated depending on frequency deviation. This technique exhibits superior performance in comparison to constant variable approach but at a higher computational cost. A similar approach based on self-adapting inertia and damping constant has been proposed in [25]. In [26], a fuzzy logic-based VSG has been proposed where the parameters are updated using change in power from RES and frequency deviation only while neglecting the RoCoF. Another fuzzy logic-based inertia control approach has been proposed in [27] where both the RoCoF and the frequency deviation have been considered for inertia updation. Since fuzzy logic-based approaches are expertise dependent, the effectiveness of such an algorithm depends on accuracy of rule formulation. The methodology described in reference [28] employs a bang-bang technique based virtual inertia calculation while considering damping coefficient as constant. A PSO-based methodology has been presented in [29] where low pass filter is used to determine the power sharing of HESS. However, low pass filter has inherent disadvantage of introducing delay which affects the control performance of the system. A PSO optimized fuzzy controller is proposed in [30, 31] which is found to be marginally better than the pure fuzzy-based approach. However, writing the rules for such a heavily fluctuating system is still a big issue.

Since RES-based microgrid is a highly volatile system, the gains of its proportional (Kp), integral (Ki), and derivative (Kd) controller (PID) regulator need to be updated as per the operating conditions. Determining the inertia gain under different operating conditions is a typical optimization problem for which lots of PSO-based methods have been reported as discussed previously. But the conventional PSO is having premature convergence issue which affects the control accuracy. Therefore, in the proposed work, an improvised version of the PSO approach has been implemented for the optimum adjustment of a PID regulator gain. Here, the improved PSO is a modified version of conventional PSO by incorporating natural exponential weight updating of velocity equation to avoid it from premature convergence. Furthermore, the optimal sizing of constituent component of HESS and effective utilization of their capacity in power sharing based on their response time improves the reliability of system at significantly lesser cost. The integral squared error (ISE) of frequency deviation is taken as an objective function for the tuning of PID regulator with the aim of enhancing rate of change of the frequency, zenith and nadir while minimizing the restoration time.

Here is a summary of this paper's main contribution:

- Application of improved PSO based PID controller on bidirectional DC–DC converter interfaced HESS to enhance frequency response in microgrid under severe disturbances to ensure system stability
- Automatically tuning of PID controller parameters based on both traditional PSO and improvised PSO in the novel adaptive virtual inertia control-based HESS
- Enhancement of frequency nadir, restoration time and RoCoF using improved PSO in comparison to conventional PSO tuned PID regulator.
- Optimal techniques applied to reduce the size of ultracapacitor-based HESS as a result of reduced restoration time, frequency nadir, and energy requirement.

This article is organized in five subdivisions first section as general introduction 1, second System Configuration of Virtual Inertia regulation. The third section has Proposed Virtual Inertia Control Concept for Frequency Regulation, the fourth section has Simulation and Experimental Results and discussion with setup validation. The conclusion is in the fifth section.

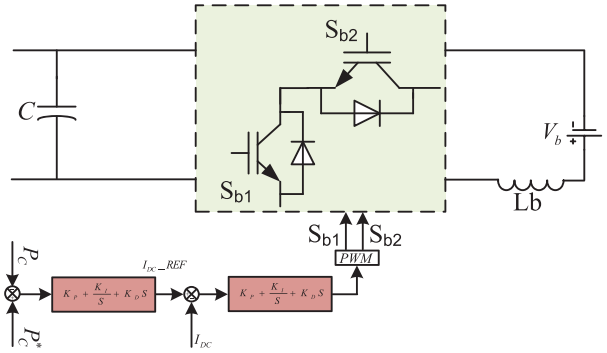

FIGURE 3 DC–DC bidirectional converter interface HESS diagram. HESS, hybrid energy storage system.

2 | SYSTEM CONFIGURATION AND CONTROL

Traditionally, synchronous generators are used to generate power and also to act as natural inertia and damping control. The turbine harnesses the stored kinetic energy to regulate the frequency. However, as renewable energy becomes more prevalent, the inherent inertia is diminishing. To accomplish this problem, the idea of VSG has been implemented [32]. In the proposed system as shown in Figure 2, a 15 MW photovoltaic (PV) generation unit (PVG), 200 mega volt amp (MVA) rated diesel generator unit (DG), wind power plant of 25 MW and battery/ultra-capacitor have been considered in the form of microgrid. Battery and ultracapacitor-based HESS has been considered to emulate the characteristics of VSG. HESS can offer active power regulation, energy management, and rapid and slow services in frequency control at a comparatively cheaper price [33]. The bidirectional DC–DC converter is used for coupling parallel combination of RRESS and SRESS to the DC-link of the grid interfacing inverter as seen in Figure 3. The common inverter uses virtual governor control similar to a traditional SG along with inertia and damping emulation as integral part of its control objectives. However, the power reference of RRESS also includes an energy recovery control. The RRESS's stored energy can be expressed as an SoC-equivalent value, such as $CV_{dc}^2/2$ for ultracapacitor.

The DC power transformation system (PTS) connected to the RRESS is responsible for maintaining DC voltage on the shared DC bus. However, the DC PTS of the SRESS is designed to adjust its power output based on the power reference from droop and integrated control loop, similarly to the turbine and governor system. Consequently, the RRESS autonomously delivers rapidly changing elements by controlling virtual inertia constants and damping constants. If the SRESS is designated as the slack bus, integral control may be used to restore the frequency. Consequently, the RRESS efficiently delivers the rapidly changing elements by effectively controlling virtual inertia and damping. The SRESS monitors the slow-fluctuating components of the VSG while detecting any changes in frequency.

In this paper, the parameters used were obtained from [34], and listed in Table 1.

2.1 | Energy variation and sizing of HESS due to frequency deviation

Sizing of ultra-capacitor is a crucial task when designing a virtual synchronous machine; it should be decided in such a way that maximum variation of energy during transient disturbance may be addressed. The greatest change in energy capacity is assessed by

$$\Delta E_{\max} = \frac{(E_{\max} - E_{nom}) + (E_{nom} - E_{\min})}{2} = E_{nom}\left(\frac{\Delta E_{\max}}{E_{nom}}\right) \quad (1)$$

By considering maximum energy changed due to frequency variation, J_{uc} inertia value which is emulated by ultra-capacitor gives; $\omega_{nom}, \omega_{zenith}$, and ω_{nadir} are nominal, zenith, and nadir frequencies respectively; and S_{rated} is the actual power of

17554543, 0, Downloaded from https://ietresearch.onlinelibrary.wiley.com/doi/10.1049/pel2.12723 by Delhi Technological University, Wiley Online Library on [11/06/2024]. TABLE 1 System descriptions and parameter values.

Features	Symbol	Value
Battery voltage	V_{b_ref}	350 V
Grid voltage	V_{g_ref}	415 V
DC inductance	$LHESS$	5.6 mH
DC link capacitance	C_{dc}	2.82 mF
DC-link voltage	$V_{C_{dc}}$	600 V
Frequency	f_{nom}	50 Hz
Turbine time coefficient	T_{Turb}	0.5 s
Governor time coefficient	T_{Gorvn}	0.2 s
Generator inertia coefficient	H	5 s
Governor speed regulation	$Rpermin$	0.05
Damping coefficient	D	0.8

ultra-capacitor.

$$\Delta E_{\max} = \frac{J_{uc}\left(w_{nom}^2 - w_{nadir}^2\right)}{2} or \frac{J_{uc}\left(w_{zenith}^2 - w_{nom}^2\right)}{2}$$

$$J_{uc} w_{nom} \Delta w_{\max} = \frac{J_{uc} w_{nom}^2}{2} \frac{\Delta w_{\max}}{w_{nom}} = H_{uc} S_{rated} \frac{\Delta w_{\max}}{w_{nom}} \quad (2)$$

Since Equations (1) and (2) are the same, therefore equating them will give

$$E_{nom} = \frac{H_{uc} S_{rated} \frac{\Delta w_{\max}}{w_{nom}}}{\frac{\Delta E_{\max}}{E_{nom}}} \quad (3)$$

For ultra-capacitor, maximum energy change is determined by

$$\Delta E_{\max} = \frac{\left(CV_{dc,\max}^2 - CV_{dc,nom}^2\right) + \left(CV_{dc,nom}^2 - CV_{dc,\min}^2\right)}{4}$$

$$= CV_{dc,nom} \Delta V_{dc,\max}/2 = CV_{dc,nom}^2 \times \left(\frac{\Delta V_{dc,\max}}{V_{dc,nom}}\right)/2 \quad (4)$$

To determine the size of the capacitor, Equations (3) and (4) are equated with the well-designed inertia constant H_{uc};

$$CV_{dc,nom}^2 \times \left(\frac{\Delta V_{dc,\max}}{V_{dc,nom}}\right)/2 = H_{uc} S_{rated} \frac{\Delta w_{\max}}{w_{nom}}$$
$$H_{uc} = \frac{C_{dc} V_{dc}^2}{2 S_{rated}} \cdot \frac{\Delta V_{dc_\max} f_{nom}}{V_{dc} \Delta f_{\max}} \quad (5)$$

$$H_{uc} = H_{vi} \cdot \frac{\Delta V_{dc_\max} f_{nom}}{V_{dc} \Delta f_{\max}} \quad (6)$$

where $H_{vi} = \frac{C_{dc} V_{dc}^2}{2 S_{rated}}$

As is seen in Equation (6), the factors to be considered for the virtual inertia constant (H_{uc}) are: given dc-link voltage V_{dc}, maximum ratio of voltage variation $\frac{\Delta V_{dc_max}}{V_{dc}}$, minimum ratio of frequency variation $\frac{f_{nom}}{\Delta f_{\max}}$, and the rated dc-link capacitance C_{dc}.

Virtual inertia can be generated by designing a proportional controller as follows:

$$K_{vi} = \frac{\Delta V_{dc_\max}}{V_{dc}} \cdot \frac{f_{nom}}{\Delta f_{\max}} \quad (7)$$

A proportional controller for allowable deviation of both frequency and voltage is indicated by MATLAB graph as shown in Figures 4a and 4b. The coding in MATLAB is done with the following values: The frequency change $\Delta f_{\max} = 0.2, \omega_{nom} = 50$ Hz, power rated was scaled down $S_{rated} = 1000$ VA, $\frac{\Delta V_{dc,\max}}{V_{dc,nom}} = 0.15$ and $C = 2.82$ mF [35].

As is seen in Figure 4a, for inertia of 5.03823 and voltage within the acceptable threshold of $400 \pm 36V$ (in this case 418.687 V), the capacitance needed is 333.333 μF. The available retails in capacitors can be found in market store. In Figure 4b, the change in voltage is restricted to 2.52525 V which is 5.3031% and is within the acceptable limits.

2.2 | Diesel generator

The governor of the SG controls the real power. The governor's main objective is to regulate the output power of diesel engine by adjusting the mechanical power of the synchronous generator to match the difference between mechanical and electrical power.

The swing equation is as follows in Equation (8):

$$\Delta P_m(t) - \Delta P_L(t) = \frac{2Hd\Delta f(t)}{dt} + D\Delta f(t) \quad (8)$$

where ΔP_m power production varies depending on the turbine

ΔP_L change power demand
Δf frequency deviation
H inertia constant
D damping constant

Equation (8) is represented in Figure 5.

Figure 6 shows the profile of how system frequency is controlled. In any network grid frequency is among the most crucial performance indicators. Frequency degradation of the system is due to abrupt disturbance caused by generation tripping or load shedding. Frequency is regulated to prevent large (RoCoF) and high-frequency deviation beyond allowable maximum.

3 | PROPOSED VIRTUAL INERTIA CONTROL CONCEPT FOR FREQUENCY REGULATION

3.1 | Particle swarm optimization (PSO) implementation for PID controller parameters tuning

Control of HESS is essential to enhancing system stability. In this part, we will discuss how to regulate virtual inertia by determining ΔV_{dc} and Δf. This is done by utilizing a PID controller to acquire actual power reference. Here, an optimization technique is applied to automatic-tune the PID regulator. The improved PSO is a modified version of conventional PSO by incorporating natural exponential weight updating of velocity equation to avoid it from premature convergence. PSO was first introduced in 1995 by James Kennedy and Russel C. Eberhart [36]. It explains the social nature shown by animals, such as a group of birds and a group of fish. This technique is powerful, easy to implement, low computational burden, and efficient tool. It is suitable online optimization. The following formula determines the position and speed of each particle: local position p_i and best global position g_i of the particles are as follows:

$$d_i^{t+1} = d_i^t + u_i^{t+1} \tag{9}$$

$$u_i^{t+1} = wu_i^t + c_1 r_1 \left(p_i^t - d_i^t\right) + c_2 r_2 \left(g_i^t - d_i^t\right) \tag{10}$$

where r_1 and r_2 are random constant ranges (0 to 1)

c_1 and c_2 social coefficient and cognitive coefficient,
ω inertia weighting function
ωu_i^t inertia
$c_1 r_1 (p_i^t - d_i^t)$ cognitive unit
$c_2 r_2 (g_i^t - d_i^t)$ social unit

ω inertia weight, it is essential during exploitation and exploration in the search space. Well-optimized value reduces convergence period. In order to modify the inertia weight and update it dynamically, a highly successful method based on linearly decreasing inertia weight PSO was provided in reference [37] as given Equation (11).

$$w = (w_{start} - w_{end}) \times \left(\frac{T_{\max} - t}{T_{\max}}\right) + w_{end} \tag{11}$$

where ω_{start} is starting inertia weight

ω_{end} end value of inertia
$T_{\max}$ max iterations

During the searching procedure, the linear dynamic inertia weight-Particle Swarm Optimization (LDIW-PSO) encountered difficulty settling into a local optimum. Furthermore, excessively small or high values of the inertia constant may lead to an increase in the number of iterations and the time it takes for convergence, so negatively affecting the performance of the optimisation engine. In order to address this problem, we multiply the natural exponential with w_{end} to improve the equation for updating velocity, which was already introduced in our earlier publication paper [38]. Similarly, [39] have incorporated an exponential square, resulting in an additional rise in computation burden. To reduce computational burden while maintaining speed, a weight update matrix now includes an exponential component with an optimal value of $T_{\max}$ [40]. Consequently, the total time it takes for convergence lowers as the number of iterations is reduced. The adjusted Equation (12) has been modified

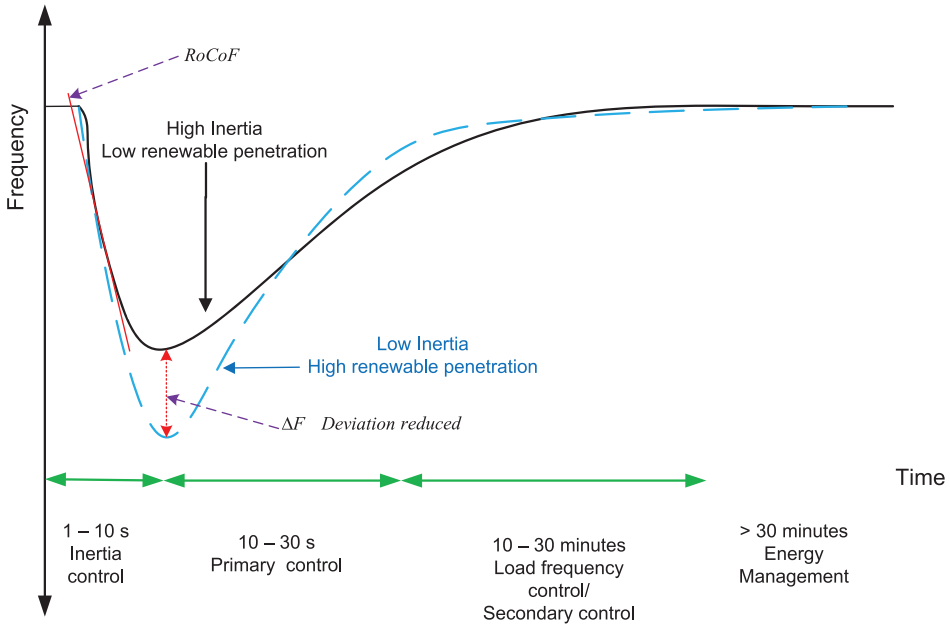

FIGURE 6 Main frequency deviation curve.

as follows:

$$w = (w_{start} - w_{end}) \times \left(\frac{T_{\max} - t}{T_{\max}}\right) + w_{end} \times e^{-t/\left(\frac{T_{\max}}{10}\right)} \quad (12)$$

where $w_{start} = 0.9$ and $w_{end} = 0.2$

The flowchart in Figure 7 is an algorithm for MPSO, modified inertia weight as inserted in Equations (10) and (12).

It is worth mentioning that the power required to maintain the frequency stability of the system may be determined by analysing the discrepancy between the voltage and normalized frequency. For adjustment and better frequency stability support, the PID controller is applied for correction in the differences [41], as stated in Equation (13), which is an extension of Equation (7), illustrating the achievement of reference active power.

$$P_{ref} = \left(\frac{\Delta f}{f_{nom}} - \frac{\Delta V}{V_{nom}}\right) \cdot \left(K_{P1} + \frac{K_{I1}}{S} + K_{D1}S\right) \quad (13)$$

In this proposed control strategy, power flows out from the ESS when there is increase in load or when a supply shuts down. When RES source is added, the power flows to the ESS. The converter acts as bidirectional virtual support. Virtual inertia control is critical for frequency stability as it reduces RoCoF and frequency zenith and nadir.

3.2 | Modelling of block diagrams of frequency control

The frequency control block is shown in the diagram, the frequency Q_g, f_g, and P_g are the measured grid reactive power, frequency, and real power respectively. The outcomes of the frequency control are displacement angle θ_o, output frequency f_o, and angular frequency ω_o. The controller operates in a similar manner as standard frequency controller of synchronous generators [42]. Figure 8 shows switching signals which control the gates. The frequency control diagram is shown in Figure 9.

4 | ANALYSIS OF SIMULATION AND EXPERIMENTAL FINDINGS AND DISCUSSION

4.1 | Simulation findings and discussion

The effectiveness of the proposed technique was evaluated by simulating the frequency of the microgrid using Matlab/Simulink. The ultracapacitor is designed to improve frequency responsiveness. Parameter tuning is done by the use of optimization techniques. As shown, frequency deviation Δf is the optimal objective function,

$$ISE = \int_0^{T_{Sim}} |\Delta f^2| dt \quad (14)$$

where

ISE is integral squired error
T_{Sim} is simulation time range

The objective function in Equation (14) is applied using both optimization techniques and the outcomes are recorded in Table 2. In performance index ISE, the error is squared; therefore, it handles both positive and negative errors.

The cases considered in the analysis of this proposed controller in the MG's frequency response are as follows:

Parameters	PSO	Improved PSO
K_P	1000	1000
K_I	39.0995	0.6893
K_D	0	0

Abbreviation: PSO, particle swarm optimization.

CASE 1: Increased power generation of 5 MW from PV

Figure 10a illustrates the frequency response of microgrid due sudden increase in PV generated power at 0.2 s by virtue of increased radiations. The frequency rose abruptly post disturbance attributed to power generated by PV unit. Both the convectional PSO and Improved PSO have been implemented for parameters tuning in such a way that the deviation in frequency is contained within the permissible threshold. However, Improved PSO has smaller frequency deviation compared with conventional PSO; that is, 50. 0199 Hz and 50.997, respectively. The difference in frequencies is used to calculate the capacity of ultracapacitor energy saved by applying Equation (2). The difference in frequencies using both the methods is found to be 0.98 Hz which is equivalent to additional amount of energy storage of 490 kW.s. needed to curtail the frequency deviation. In other words, the improvised PSO helps in reducing the additional storage capacity in comparison to conventional PSO.

CASE 2: Increase in load demand of 7.5 MW

In this scenario, a sudden surge in load demand of 7.5 MW is considered at 3 s. Due to this disturbance, frequency drop is seen just after the increase in load as depicted in Figure 11a. In this scenario, the lowest point is 48.52 Hz using conventional PSO, though it is within allowable frequency deviation but it requires large ultracapacitor to accommodate the fluctuation of such magnitude. For improved PSO, the frequency deviation is found to be 49.97 Hz. The difference between the two strategies in terms of frequency is 1.45 Hz. Thus, by applying Equation (2), the additional storage capacity of 1.0875 MW.s is saved using proposed Improvised PSO. For the convenience of comparison, the disturbance for scenario 1 was kept constant throughout the simulation at 0.2 of 5 MW.s. Furthermore, the fact that this technique can handle both circumstances at once is proof that it is better.

CASE 3: Increase in wind generated power of 10 MW

In this scenario, a sudden enhanced wind power of 10 MW is considered at 6 s due to sudden increase in wind velocity. Due to this sudden increase, imbalance between demand and supply arises which results in frequency shoot up as shown in Figure 12a. The highest point is 51.9886 Hz based on PSO and 50.0398 Hz based on Improved PSO. It is to be noticed that the

2	1.4752	0.0295
3	1.9886	0.0398

Abbreviation: PSO, particle swarm optimization.

differences in frequency using both the strategies are 1.95 Hz. The energy calculated for this much frequency difference is of 1.95 MW.s. This shows that the cost of installing larger ultracapacitor is reduced with Improved PSO. To make comparisons simple, disturbances for Case 1 at 0.2 s of 5 MW and Case 2 at 3 s of 7.5 MW were included during simulation. Given that it can manage all three eventualities at once, this technique provides further proof of its superiority. The results of the simulations show that frequency is restored in every instance.

From Table 3, are tabulated results of the simulation of the microgrid frequency deviation. It was conducted in all test conditions. The findings clearly demonstrate that the proposed controller outperformed the convectional method. The proposed method is ensuring frequency stabilization and economical use of ultracapacitor. Here, it could be observed that for a minimum disturbance of 5 MW, the change in frequency is

TABLE 4 Sum up of the frequency response under various severe disturbances.

	Disturbance	Frequency response
Load fluctuation	Load increasing	Decrease (nadir)
	Load shedding (decreasing)	Increase (zenith)
Wind speed variation	Speed increment	Increase (zenith)
	Speed decrement	Decrease (nadir)
Solar irradiation variation	Radiations increment	Increase (zenith)
	Radiations decrement	Decrease (nadir)
Contingency	RES disconnecting	Decrease (nadir)
	RES connecting	Increase (zenith)

0.997 (1.994 %) while with Improved PSO frequency change is 0.0199 (0.0398%). Similarly with a maximum disturbance of 10 MW, the change in frequency is 1.9886 (3.977%) while Improved PSO yields a frequency change of 0.0398 (0.0796%). Thus, it is evident from the two extreme cases that with Improved PSO the change in frequency is very small. For brevity purposes, Table 4 is a summary of frequency response in a microgrid under different disturbance scenarios.

4.2 | Experimental results and discussion

The simulation study carried out in the MATLAB/Simulink environment is validated in real time using (OP-4510) OPAL-RT as demonstrated in Figure 13. This offers as further evidence of the effectiveness of the proposed study concept in a real-time setting.

The fast dynamic response of the proposed dynamic controller is apparent; it is capable of quickly reducing the frequency deviation in under 2 s, regardless of the degree of the disturbance. In the experimental study, disturbances of 2%, 3%, and 4% were introduced and it can be observed that the response times in all three situations a found to be very quick. The

results from the real-time OPAL-RT (OP-4510) and MATLAB simulations are consistent, indicating that offline systems may employ the adjusted optimum PID controller parameters. This is done to support the suggested control strategy, which virtually emulates simulation results with hardware in loop.

As seen in Figures 14a to f, the same three cases have been implemented using HIL. It is worthwhile noting that with disturbance in load operating conditions, the disturbance in frequency is restored as per grid code requirements. Moreover, the restoration period using the proposed method is found to be very much smaller in comparison to conventional methods which further results in an enhanced stability.

Finally, a brief comparison and distinction with the existing state-of-the-art methods of control in grid-connected ESSs have been provided in Table 5.

5 | CONCLUSION

In this paper, frequency stabilization of RESs based low inertia microgrid has been achieved with HESS. The optimal sizing of HESS is done in such a way that it utilizes the response characteristics of Ultracapacitor and battery in order to have enhanced performance with reduced cost. Ultracapacitor is used to mimic inertia for high frequency power deviation as seen during simulation, whereas battery is applied for long-term power variation in microgrid. A modified form of particle swarm optimization was used to optimize the PID factors. The efficiency of the proposed control strategy has been proved by examining three distinct levels of uncertainty generated by either intermittent RESs or changing load. There has been a considerable decrease in the problems related to the rate of change of frequency, overshoot, undershoot, and rising time. As a result, the required size of ultracapacitors has been reduced. In turn, the cost of the entire system is reduced. The effectiveness of modified particle swarm optimization is evident when comparing it to traditional particle swarm optimization. It is worthy to note that there is significant amount of energy saving capacity of 1. 95 MW.s for a disturbance of 10 MW. Moreover, the conventional particle swarm optimization technique yielded a frequency deviation of 1.9886 Hz, but the proposed Improved particle swarm optimization technique successfully decreased it to 0.0398 Hz. Therefore, the suggested method enhances the overall efficiency of the microgrid across various operational scenarios. The simulation findings, together with the experimental findings, confirm the efficacy of the proposed strategy in terms of determining the appropriate size of the Hybrid Energy Storage System (HESS) and enhancing the control performance of the Microgrid. The future investigation should consider seamless power sharing in HESS and the ratios based on online optimization.

ETLs and HTLs

ABSTRACT

Lanthanum ferrite ($LaFeO_3$) is a potential candidate for Perovskite Solar Cell (PSC) application. The transition metal oxide has strong electron-electron correlation which results in an increase in quantum efficiency (QE) of PSC. In this investigation, we reported synthesis of $LaFeO_3$ perovskite material, simulation of $LaFeO_3$-based PSC followed by experimental validation. The sol-gel method was employed to prepare nanoparticles of $LaFeO_3$ for PSC application. The prepared perovskite material is analyzed by XRD, SEM, EDS, UV–Vis and FTIR. The photovoltaic (PV) application of synthesized $LaFeO_3$ material is studied by SCAPS-1D. The $LaFeO_3$-based PSC is simulated with various ETLs such as TiO_2, PCBM, IGZO, In_2O_3, C_{60}, ZnO, SnO_2, WS_2 and HTLs of Cu_2O, $CuInSe_2$, Spiro-OMeTAD, P3HT, D-PBTTT-14, V_2O_5, CFTS, CBTS. The simulation outcomes of 64 distinct configurations deduced the eight-best performing PSCs. For these eight PSCs, impact of thickness of perovskite absorber layer, operating temperature, defect density, series and shunt resistance, work function of back contact, J-V characteristics and QE curve has been studied. We have achieved theoretical maximum efficiency of 13.03 % for the configuration of FTO/WS_2/$LaFeO_3$/CBTS/Au. The optimized structure has experimentally obtained maximum efficiency of 0.79 %. This shows that it is promising material for future PV application.

1. Introduction

The limited amount of fossil fuels and their combustion, leads to pollution in the environment [1]. So, alternative energy technologies are required like biomass, wind, solar and tidal power. Solar energy is a green, accessible and abundant renewable energy [2–4]. Perovskite solar cell (PSC) continues to draw the attention of researchers by virtue of characteristics like high-power conversion efficiency (PCE) and simple room temperature fabrication methodology which makes them a cheaper alternative to conventional silicon solar cells [5–7]. A perovskite has basically ABX_3 type structure (where A: alkyl group, B: metal and X: halogen) [8,9]. Pb-based PSCs present sustainability challenges due to high toxicity of lead, posing risks to both living organisms and the ecosystem. Moreover, Pb-based PSCs suffer from stability issues stemming from the rapid oxidation of Pb cation. In the quest for a suitable Pb substitute [10], researchers have explored numerous candidates to replace Pb, such as Sn [11], Ge [12], Bi [13], Sb [14], La [15,16] and double perovskites etc. $LaFeO_3$ possesses a tunable energy band-gap which can be altered using suitable dopants [17,18]. The other properties of $LaFeO_3$ such as chemical stability, low production cost, high electron mobility and its non-toxic nature are already favorable for lead-free PSC application [19,20]. There are very few studies on $LaFeO_3$ as perovskite material for solar cell application [21]. This work comprises fabrication and characterization of $LaFeO_3$-based PSCs. $LaFeO_3$ nanoparticles were first synthesized by using the sol-gel method and then they were used for solar cell application. Prior to fabrication of $LaFeO_3$-based PSC, we have simulated and optimized the structure of solar cells using SCAPS-1D simulation software. So, we have got eight optimized structures of $LaFeO_3$-based PSC through simulation with a maximum PCE of 13.03 % for the most efficient configuration which is approximately 30 % greater than the past reported work [20]. The experimental validation was conducted for the optimized PSC. We achieved an PCE of 0.79 % experimentally, which is approximately thirteen times higher than the previously reported result [21]. The spin coating method is employed to obtain PCE of 0.79 % which is the highest achieved efficiency for the $LaFeO_3$-based PSC till now. This efficiency enhancement is attributed to proper selection of hole transport layer (HTL) and electron transport layer (ETL). A conventional PSC structure contains a perovskite absorber layer sandwiched amid ETL and HTL. A current is developed when electrons (e^-) are traveled through ETL and

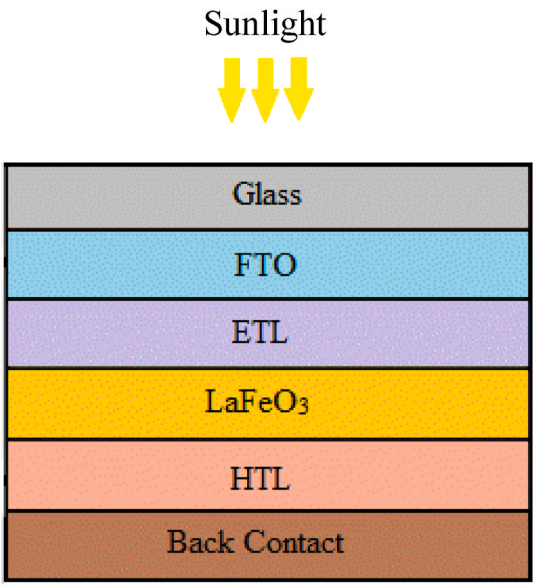

Fig. 1. Architecture of $LaFeO_3$-based PSC.

holes (h^+) are transferred to HTL from the absorber layer. To obtain the maximum PCE of a PSC, the energy level alignment of all these layers becomes a very important factor. The selection and optimization of the ETL and HTL is very crucial to maximize the performance of a PSC. In this simulation we have simulated sixty-four configurations with different ETLs (TiO_2, PCBM, IGZO, In_2O_3, C_{60}, ZnO, SnO_2, WS_2) and HTLs (Cu_2O, $CuInSe_2$, Spiro-OMeTAD, P3HT, D-PBTTT-14, V_2O_5, CFTS, CBTS). The outcomes showed that CBTS is the most suitable HTL for $LaFeO_3$ PSC and in addition it is abundantly available [22]. The study also includes optimization of the parameters which influences performance of the PSC, thickness, operating temperature, defect density (N_t), back contact, series (R_S) and shunt resistance (R_{SH}).

2. Device architecture

The PSC structure consists of ETL, absorber layer and HTL shown below in Fig. 1. The $LaFeO_3$ is employed as an absorber layer in PSC having thickness of 400 nm. In this simulation, we have employed several ETLs (TiO_2, PCBM, IGZO, In_2O_3, C_{60}, ZnO, SnO_2, WS_2) and HTLs (Cu_2O, $CuInSe_2$, Spiro-OMeTAD, P3HT, D-PBTTT-14, V_2O_5, CFTS, CBTS) to achieve the maximum efficiency. The thickness of employed ETL = 100 nm and HTL = 50 nm. In p-i-n devices, the electrons and holes generated within the absorber layer when sunlight falls on it. The generated e^- and h^+ is traveled through ETL and HTL, e^-s are collected at the fluorine doped tin oxide (FTO) and h^+s at the back contact.

3. Experimental section

3.1. Materials and method

All the precursors employed in synthesis of perovskite are $La(NO_3)_3$, $Fe(NO_3)_3$, citric acid and ammonium hydroxide. The light sensitizer $LaFeO_3$ was prepared by employing a sol-gel method. The flow chart for stepwise preparation of perovskite material is shown below in Fig. 2. The lanthanum and iron-based solution were prepared for synthesis of $LaFeO_3$. Deionized (DI) water chosen as a solvent to dissolve both

solutes. At first,1 M aqueous solution of $La(NO_3)_3$ mixed with 1 M aqueous solution of $Fe(NO_3)_3$. The mixture was stirred for 2 days at 300 rpm and 60 °C. Citric acid was added dropwise in the solution. After that, ammonium hydroxide aqueous solution was added dropwise under magnetic stirring to make pH = 7. The sample was stirred at 300 rpm for 72 h and dried in a vacuum oven at 180 °C for 12 h. After that sample was moved into a muffle furnace for calcination in air at 600 °C for 4 h. The synthesized sample shown in Fig. 3.

3.2. Characterizations

XRD pattern of perovskite material was recognized utilizing a diffractometer (Bruker D8 advance). The size and morphologies of synthesized perovskite by SEM. UV–vis spectrum of the $LaFeO_3$ sample is observed by employing a PerkinElmer, Lamda-750 dual-beam spectrometer. The prepared sample IR transmission spectra was analyzed by employing an FTI-R spectrometer.

4. Experimental results and discussion

4.1. XRD analysis

It is primarily used for phase identification and crystallinity of the material. The observed range of XRD data is from 10° to 90° over 2θ with scan rate of 2°/min. The peaks of $LaFeO_3$ before and after calcination are demonstrated in Fig. 4 (a) and (b), respectively. The XRD peaks with 2θ of 32.30°, 39.91°, 46.42°, 57.60°, 67.83° and 76.68° correspond to $LaFeO_3$ perovskite nanoparticles of cubic structure (75–0541). Bragg's equation (1) was used to calculate the material grain size and display angles.

$$2d\sin\theta = n\lambda \quad (1)$$

$$\text{Crystallite Size} = (0.94 \times \lambda)/\ \beta\cos\theta \quad (2)$$

Where, λ = wavelength of X-ray, β = FWHM, θ = Bragg's angle.

The calculated average crystallite size is 18.4 nm by using Debye Scherrer's Eq. (2). It is observed that the peak intensities increase after the calcination (600 °C for 4 h) of the $LaFeO_3$, which confirms the uniform crystal growth of perovskite phase [21].

4.2. SEM results

The SEM is employed to inspect topography and superficial characteristics of $LaFeO_3$ perovskite material. The nanoparticles of $LaFeO_3$ did not aggregate and have small size depicted in Fig. 5. The nanoparticles are discrete with an average size of ~80 nm. The SEM investigation showed that film is not uniform due to there are no surface-protecting layers which lead to agglomeration of the particles. The particle shapes are ambiguous, numerous large and small pores exist in the entire material [15].

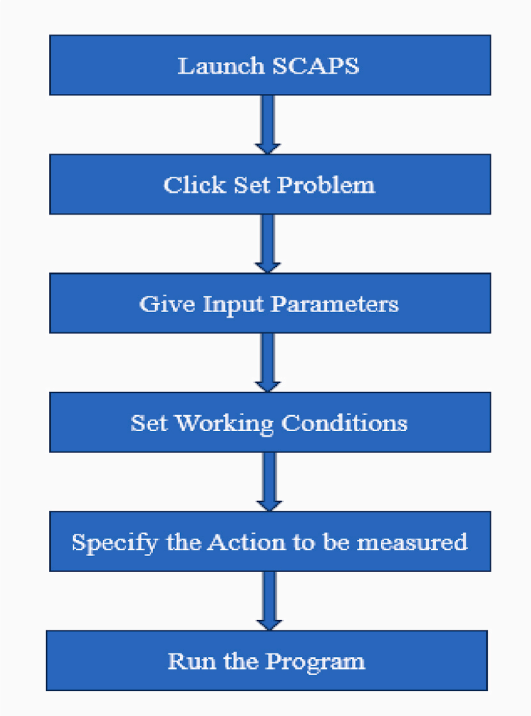

Fig. 10. Simulation procedure.

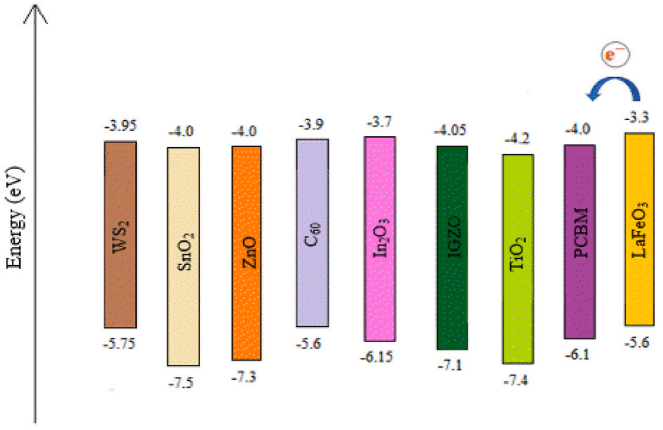

Fig. 11. Band alignment diagram of various ETLs with $LaFeO_3$ absorber layer.

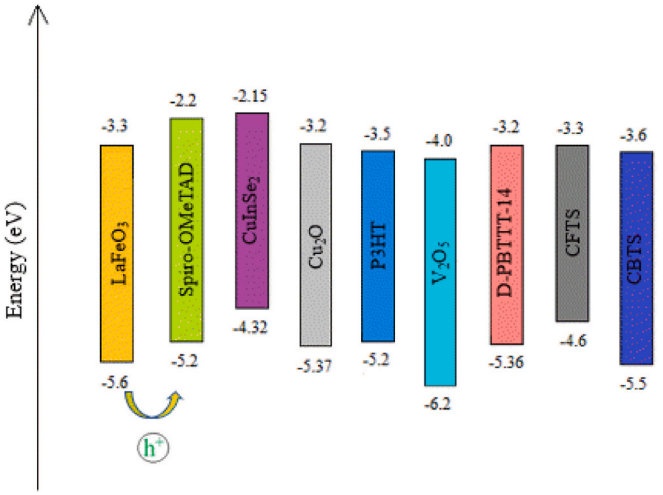

Fig. 12. Band alignment diagram of various HTLs with $LaFeO_3$ absorber layer.

4.3. EDS spectrum

The composition and chemical purity of elements are investigated using EDS. Fig. 6 demonstrates EDS spectroscopy of $LaFeO_3$. The diagram shows that La, Fe, C and O are observed without no peaks of impurities. The presence of these elements can validate the formation of pure phases. The weight percent of all elements presented in $LaFeO_3$ perovskite were shown below in Table 1.

4.4. UV–vis spectroscopy

UV–Vis spectrum of $LaFeO_3$ perovskite material carried out in order to calculate optical E_g illustrated in Fig. 7. The highest absorption peak of the $LaFeO_3$ sample is observed at 330 nm. The E_g is calculated by equation (3).

$$E_g = \frac{hc}{\lambda_{max}} \tag{3}$$

Where, E_g is the band gap energy of the sample, h = Planck's constant, c = speed of light. λ_{max} is the extreme absorption wavelength of the sample. The calculated value of E_g for $LaFeO_3$ perovskite is approximately 2.3 eV and is in range as reported by Azozi et al. [23].

4.5. FT-IR analysis

FT-IR is employed to distinguish the vibrational modes of $LaFeO_3$ perovskite material and confirmation of existent functional groups. The FT-IR spectrum of a $LaFeO_3$ perovskite in the range of 400–4000 cm^{-1} presented in Fig. 8. The peaks of the $LaFeO_3$ nanoparticles are near to 552, 838, 1061, 1404, 1480, 2912 and 3359 cm^{-1}. The absorption band is observed at 552 cm^{-1} which is attributed to Fe–O stretching vibration mode [24,25]. This peak confirms the formation of perovskite phase which commonly exists between 500 and 700 cm^{-1} [26]. The IR broad peak at 3359 cm^{-1} arises from H–O bending mode and 2109 cm^{-1} due to symmetric stretching of the carboxyl group [27].

4.6. Photoluminescence spectrum

To delve deeper into the electronic properties, we conducted room temperature Photoluminescence spectrum (PL) analysis on the synthesized powder. In this investigation, $LaFeO_3$ exhibited a prominent emission peaking around 450 nm, aligning with the band-edge emission observed with excitation wavelength of 330 nm shown below in Fig. 9. The visible emission bands might be associated with oxygen vacancies serving as luminescent sites. These vacancies naturally occur in oxygen-deficient environments and manifest as defects on the surface or within the lattice structures. In this scenario, these oxygen vacancies serve as luminescent centers, capturing both a h^+ and an e^- on the nanostructures surface. The recombination of this e^-- h^+ pair results in nonradiative emission. The oxygen vacancies found in synthesized perovskites prompt further investigation into their electrical and optical characteristics.

5. Simulation methodology

5.1. SCAPS-1D

The data of different parameters are chosen from previous studies. The simulation was carried out using SCAPS-1D (version 3.3.10). Gent University of Belgium developed SCAPS-1D software, enabling users to model up to seven semiconducting layers under both light and dark conditions. This software can be used for simulations at different input physical conditions. The tool calculation is based on Poisson's and continuity equations for both e^-s and h^+s under steady-state conditions

as described below [28].

$$\frac{\partial^2 \psi}{\partial x^2} + \frac{q}{\epsilon}[p(x) - n(x) + N_D - N_A + \rho_p - \rho_n = 0 \quad (4)$$

$$\frac{1}{q}\frac{dJ_p}{dx} = G_{op}(x) - R(x) \quad (5)$$

$$\frac{1}{q}\frac{dJ_n}{dx} = -G_{op}(x) + R(x) \quad (6)$$

The PSC consists of $LaFeO_3$ perovskite absorber material with layer architecture: glass substrate/FTO/ETL/$LaFeO_3$/HTL/Back contact depicted in Fig. 1. The input parameters employed in simulation of several layers are enclosed in Tables 2–4. The simulation procedure is shown in Fig. 10Table 5.

6. Simulation results and discussion

6.1. Optimization of suitable ETL and HTL

The various ETLs such as TiO_2, PCBM, IGZO, In_2O_3, C_{60}, ZnO, SnO_2 and WS_2 were inserted into the heterostructure to achieve the optimum performance. The band alignment of various ETLs demonstrated in Fig. 11. The input parameters of employed ETLs are demonstrated in Table 3. We have done the simulation by varying the thickness of all ETLs from 50 to 250 nm. We found that the optimized value of ETL thickness is 100 nm for all ETLs. It has been analyzed that there is a negligible change in efficiency of the $LaFeO_3$-based PSC for values greater or less than the optimized value. The different configurations of eight ETLs and eight HTLs are studied to achieve the maximum performance. The band matching is a vital factor. One of the critical issues confronting the PSCs community involves the alignment of energy level between the ETLs and the absorber layer. To tackle this issue, a thorough examination of the ETL/perovskite interface is imperative. Defects arising from lattice mismatching at the ETL/perovskite interface play a vital role in trapping the charge carriers and greatly influence the device efficiency. The conduction band of the WS_2 layer is well aligned to the lowest unoccupied molecular orbital (LUMO) of the absorber layer. This can facilitate smooth charge carrier transport, minimizing the impact of defects that may otherwise trap or recombine charges. This band alignment ensures that e^-s can easily move from the absorber layer to the WS_2 layer and eventually to the contact, contributing to higher overall device efficiency [34]. The conduction band of the ETL is always less than the LUMO of the absorber layer. The gap amid the valence band of

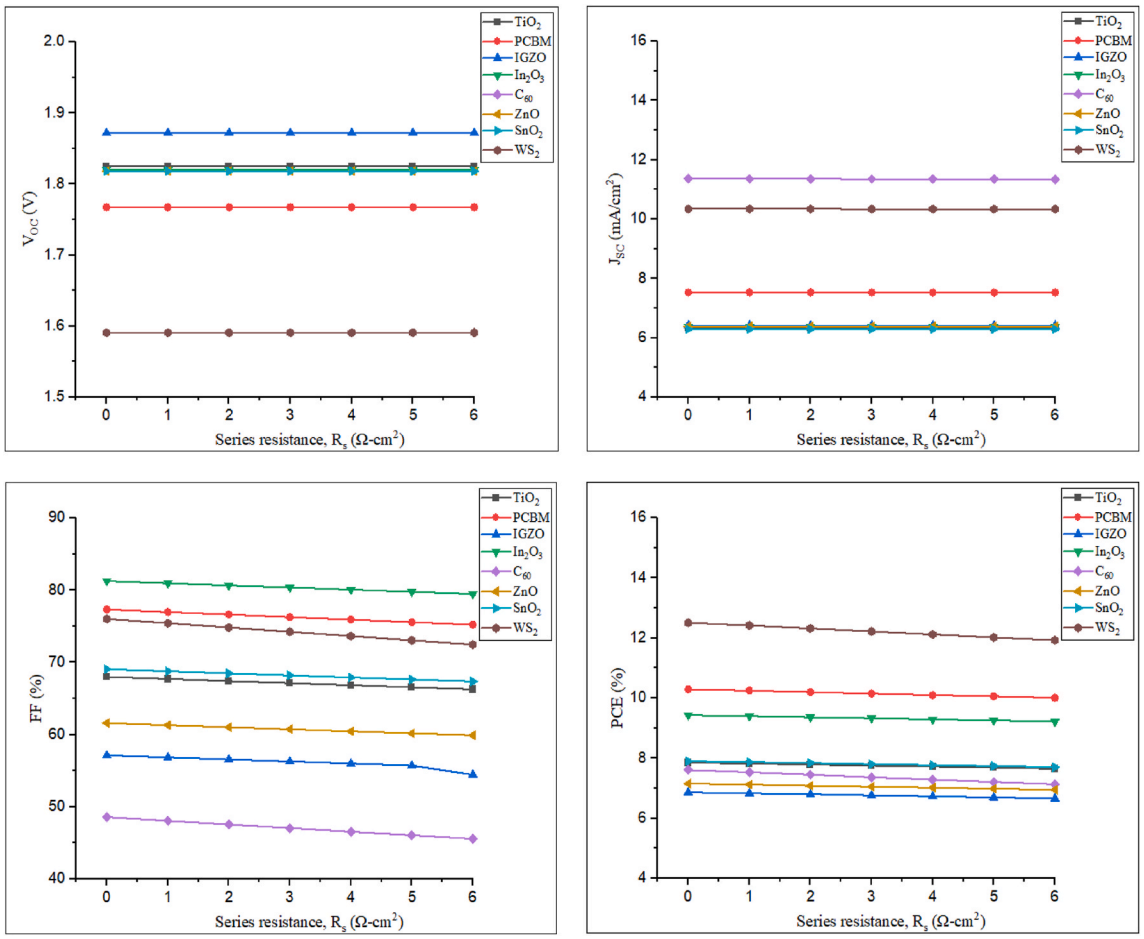

Fig. 18. Impact of R_S on the performance of $LaFeO_3$-based PSC at $R_{SH} = 10^5$ Ω-cm^2.

ETL and HOMO level of the absorber layer must always maintain substantial distance, which inhibits the recombination in the absorber layer. The results illustrate that TiO_2, SnO_2 and ZnO have wide E_g, so that they have exhibited low PCE of around 8 %. ETLs like IGZO, and C_{60} suffering from mismatch in band alignment hence, exhibited low efficiency relatively. In this work WS_2 is most suitable ETL to achieve maximum PCE for $LaFeO_3$-based PSC. The WS_2 has advantages such as band matching, photoelectrochromic, toughness, high melting point and corrosion resistance. Due to these properties, WS_2 is the promising candidate for optoelectronic application. The maximum efficiency of 13.03 % has been obtained with the heterostructure of FTO/WS_2/$LaFeO_3$/CBTS/Au.

Impact of distinct HTLs such as Cu_2O, $CuInSe_2$, Spiro-OMeTAD, P3HT, D-PBTTT-14, V_2O_5, CFTS and CBTS with eight different combinations were studied. In contrast, the V_2O_5, and CFTS achieved less efficiency than other HTLs. The remarkable enhancement in efficiency of a PSC with the inorganic HTL. The inorganic HTL materials are more stable, transparent, and band-aligned, over organic HTL. CBTS is most suitable HTL for $LaFeO_3$-based PSC due to its diverse properties such as crystalline structure, light absorption, atomic size and an earth-abundant material [22]. The CBTS as HTL offered most suitable band matching as compared to other HTLs shown in Fig. 12, so that it exhibited the highest PCE of 13.03 % for $LaFeO_3$-based PSCs. The total sixty-four different heterostructures have been simulated to explore appropriate combinations of ETL and HTL for $LaFeO_3$-based PSC to achieve maximum performance depicted in Fig. 13. The J-V and QE plots of the best eight configurations are illustrated in Fig. 14.

6.2. Impact of thickness of absorber layer

The thickness altered from 200 to 1000 nm at N_t of 1×10^{13} cm^{-3} and temperature of 300 K. It is known to us that as thickness of the layer decreases, absorption rate also lowers. This results in a decrease in photocurrent and therefore PCE of the solar cell also reduces after 300 nm. As an increase in thickness, large numbers of photons are absorbed but simultaneously recombination rate increases and high-rate results in V_{OC} [29,33]. Both V_{OC} and PCE parameters decrease exponentially for increase in thickness from 300 to 1000 nm. It can be seen that WS_2 PCE is highest at around 300 nm. Whereas for C_{60} there is a rapid fall in PCE due to very low value of electron mobility as compared to other ETLs. Hence it can be deduced that the Optimum value of thickness is 300 nm for $LaFeO_3$-based PSC and beyond that PCE falls and decrease in FF is 68.61 %. The maximum efficiency of PSC goes up to 13.03 % together with V_{OC} is 1.61 V, J_{SC} is 9.952 mA/cm^2 and FF is 81.17 % for the thickness of 300 nm at ETL = 100 nm and HTL = 50 nm. The FF shows a monotonic decrement with the rise in thickness when thickness becomes greater than 300 nm. The change in different PV parameters with thickness of $LaFeO_3$ layer with CBTS as HTL depicted in Fig. 15.

6.3. Effect of operating temperature

The working temperature range is between 250 and 550 K. Fall in the performance with temperature increase is related to a reduction in diffusion length of charge carriers. Several solar cell architectures show the instability of their overall performance due to deformation among layers at high temperatures. In $LaFeO_3$-based PSC, fall in efficiency with temperature is 18.11 % for FTO/WS_2/$LaFeO_3$/CBTS/Au configuration.

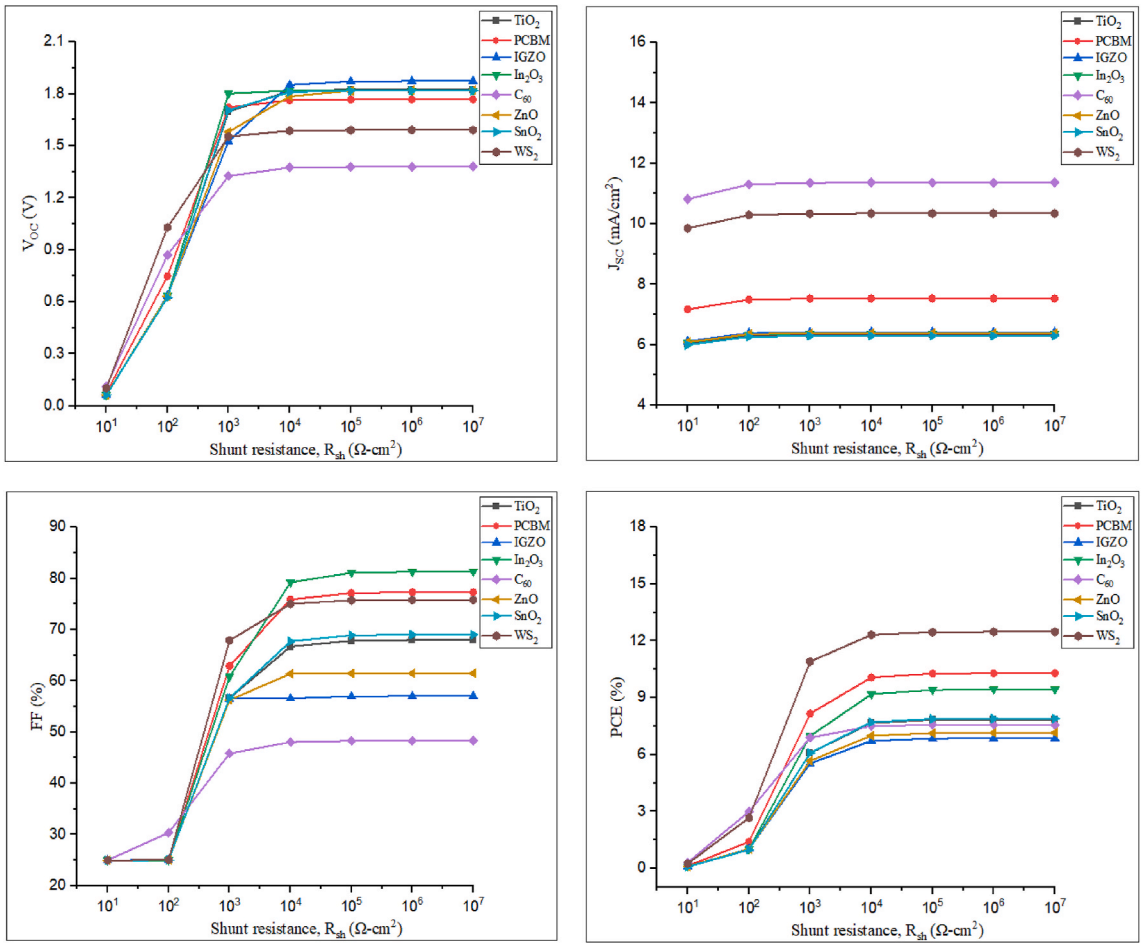

Fig. 19. Impact of R_{sh} on the performance of $LaFeO_3$-based PSC at $R_S = 0.5$ Ω-cm^2.

When the enhancement of temperature occurs, the PCE drops significantly from 12.70 % to 10.40 % for the given range of temperature. The optimized temperature is 250 K for $LaFeO_3$-based PSC. The value of V_{OC} is decreasing with rise in temperature for all ETLs. The increment in temperature results in reduced the performance of PSC owing to the saturation current and therefore the recombination rate increases [45]. The impact of operating temperature with CBTS as HTL and various ETLs on the PV parameters are shown below in Fig. 16.

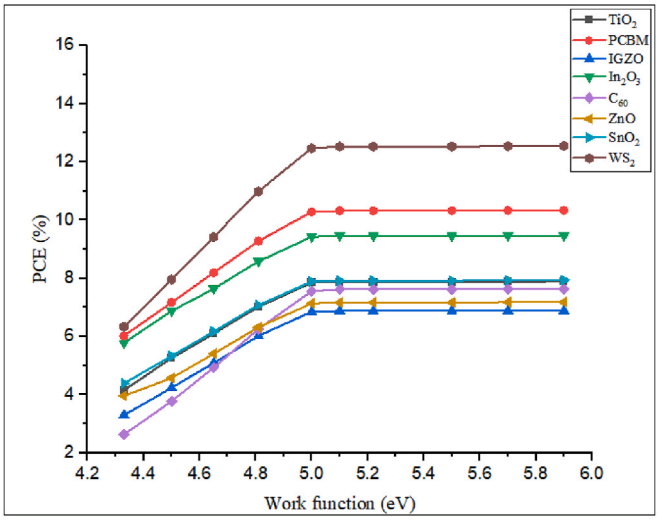

Fig. 20. Impact of various work functions on efficiency.

6.4. *Impact of defect density (N_t)*

The PSC performance and stability is expressively reduced at a large number of defects [46]. We have analyzed the PV parameters by varying N_t of the absorber layer from 10^{12} to 10^{17} cm^{-3}. The optimized value of N_t is 1×10^{13} cm^{-3} for $LaFeO_3$-based PSC at which it has achieved the maximum PCE of 12.53 %, as illustrated in Fig. 17. The PCE and J_{SC} fall sharply after 10^{15} cm^{-3} due to increase in defects hence number of traps of recombination enhances [47,48]. Increase in N_t, results in decrease in short circuit current, which is lastly responsible for fall in FF of the solar devices. The device PCE decreased from 12.53 % to 9.30 % for FTO/WS_2/$LaFeO_3$/CBTS/Au heterostructure, when N_t was enhanced from 10^{12} to 10^{17} cm^{-3}. Such an increasing amount of recombination resulted in a sharp decrease in PCE. The change in different PV parameters with N_t for $LaFeO_3$ with CBTS as HTL and different ETLs is depicted in Fig. 17. The fall in PCE is 25.89 % with an increase in value of N_t for optimized structure of $LaFeO_3$-based PSC. Some defect parameters of $LaFeO_3$ absorber layer shown below in Table 6.

6.5. *Effect of series resistance (R_s)*

The R_S has a significant impact on the PCE of the device specially on the FF and short circuit current (I_{SC}). With the increment in R_S, FF reduces which results in decrement in I_{SC}. Hence, devices exhibit poor performance due to large values of R_S. When solar cells are exposed to the environment, thermomechanical fatigue or cracks develop in the solder bonds depending on weather conditions. These cracks lead to an increase in the value of R_S which in turn causes a decline in the PCE [49,50]. The value of R_S varied from 0 to 6 Ω-cm^2, at R_{SH} of 10^5 Ω-cm^2. The

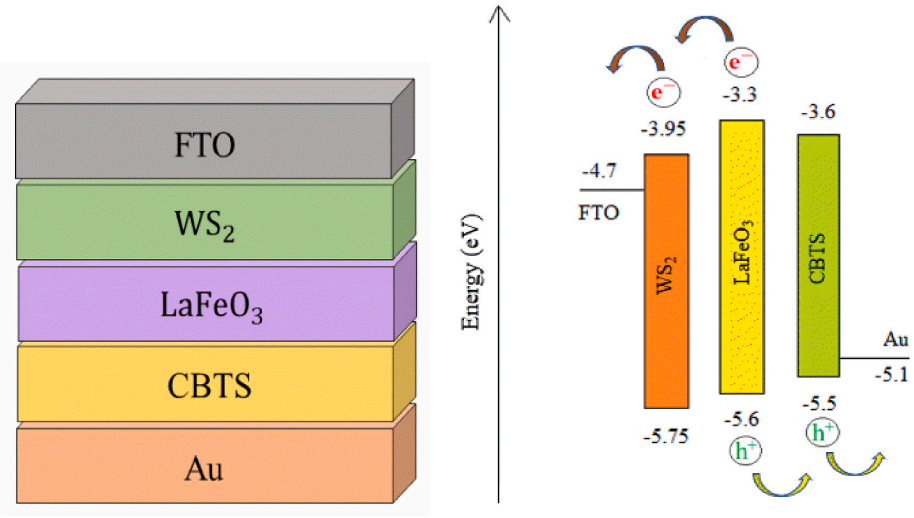

Fig. 21. Structure and band alignment diagram of optimized device.

Table 7
Comparison of Experimental, SCAPS-1D and previously reported outcomes.

Parameters	SCAPS-1D	Experimental	Experimental [21]	Simulation [21]	Simulation [20]
V_{OC} (V)	1.61	0.504	0.56	0.90	1.99
J_{SC} (mA/cm^2)	9.95	5.56	0.30	0.097	6.75
FF (%)	81.17	28.31	22	8.55	67.55
PCE (%)	13.03	0.79	0.06	0.01	9.11

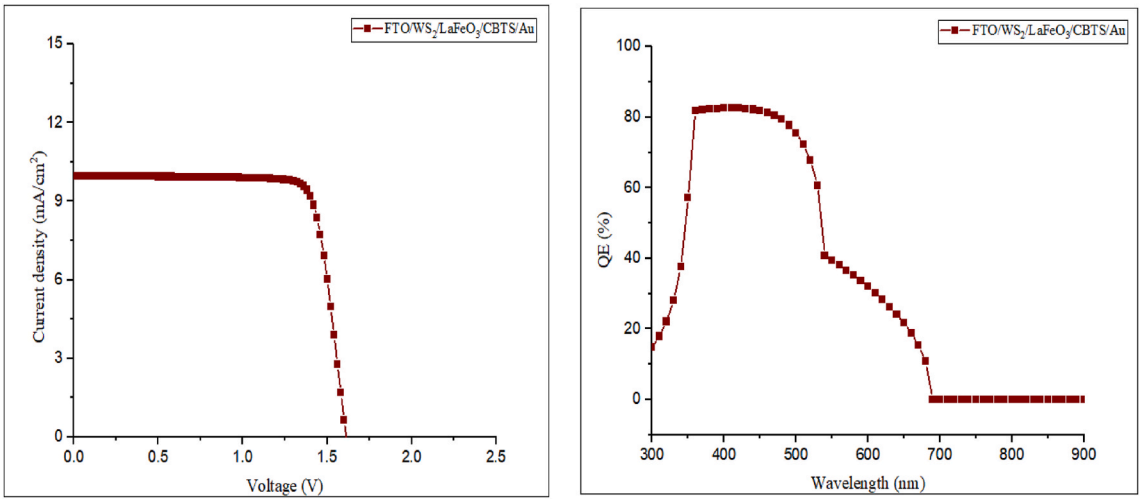

Fig. 22. J-V and QE curve of optimized device.

simulation results of change in value of R_S with PV parameters of PSC shown below in Fig. 18. The FF reduced from 76 to 72 % with an increase in value of R_S while the PCE, V_{OC} and J_{SC} were not affected in every device. The results shown in Fig. 18 are consistent with the previously reported studies [51,52]. The IGZO/$LaFeO_3$/CBTS and C_{60}/$LaFeO_3$/CBTS PSC configuration showed the highest V_{OC} and J_{SC} respectively whereas IGZO/$LaFeO_3$/CBTS PSC configuration showed relatively poor performance [53].

6.6. Effect of shunt resistance (R_{SH})

The R_{SH} varied from 10^1 to 10^7 Ω-cm^2 at constant value of R_S of 0.5 Ω-cm^2 for FTO/ETL/$LaFeO_3$/CBTS/Au configuration. The simulated outcome of different PV parameters shown below in Fig. 19. The J_{SC} varied from 10.82 to 11.36 mA/cm^2 for FTO/C_{60}/$LaFeO_3$/CBTS/Au structure whereas V_{OC} and PCE show a significant increment from 0.103 to 1.591 V and 0.25–12.48 % respectively for FTO/WS_2/$LaFeO_3$/CBTS/Au configuration. The small increase in J_{SC} with R_{SH} is due to decreased currents in the shunt-resisted path. The increment in V_{OC} is due to enhanced value of R_{SH} developing more voltage across the PSC [54]. The relation of the PCE with R_{SH} reported in the literature [55].

6.7. Appropriate back contact

The impact of back contact on PCE of a PSC is studied. We have simulated the different back contacts with a work function (Φ) of 4.3 eV–5.9 eV [56], the range covering the most of the available back contacts. The effect of Φ on the PCE of various PSCs shown below in

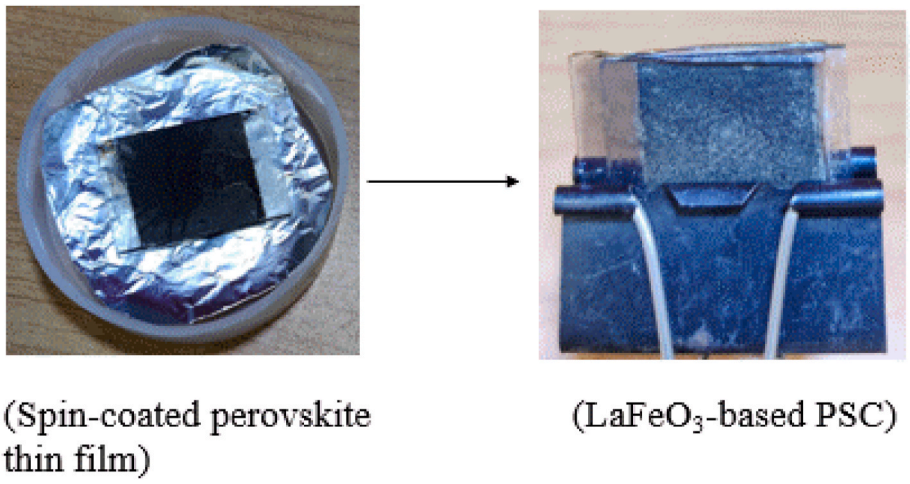

Fig. 23. Fabricated $LaFeO_3$ PSC.

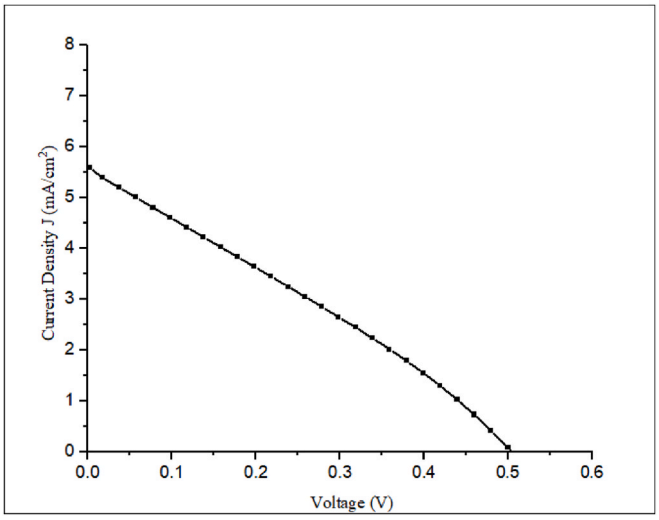

Fig. 24. J-V curve of fabricated $LaFeO_3$-based PSC.

Fig. 20. For the smaller value of work function, performance decreases gradually due to formation of Schottky junction. The enhancement in the PCE with Φ equal to 5.1 eV (Au) was observed. For the large value of work function, PCE remains constant, there is no chemical reaction amid the absorber layer and metal back contacts. The maximum efficiency of 13.03 % achieved at Φ of 5.1 eV (Au).

7. Experimental results comparison with previously reported results

7.1. Simulation results

The PSC structure and energy band diagram of the optimized device demonstrated below in Fig. 21. The optimum efficiency of 13.03 % with V_{OC} = 1.61 V, J_{SC} = 9.952 mA/cm^2, and FF of 81.17 % has been obtained. The optimized ETL and HTL are WS_2 and CBTS respectively with the Au (gold) as metal back contact. The comparison with the previously reported results illustrated in Table 7. The JV and QE curves of optimized PSC are illustrated in Fig. 22.

7.2. Experimental results

The fabricated $LaFeO_3$ PSC and its J-V characteristics are shown below in Figs. 23 and 24 respectively. The PV parameters of fabricated PSC is tabulated below in Table 6. One of the possible reasons for low PCE is the spin-coating process which has certain limitations. That is especially low thermal stability of the film, difficulty in fabricating an ideal multilayer structure, substrate size and shape. Typically, less than 5 % of the initial solution effectively deposits onto the substrate to create the thin film, with the remainder lost due to spinner rotation [57]. The $LaFeO_3$ possesses a bandgap of approximately 2.3 eV [23], which might not be sufficiently wide to prevent rapid recombination of its photogenerated electron-hole pairs which causes low performance of the device. To address this limitation, the preferred approach involves enhancing the E_g through size variation. Decreasing particle size is anticipated to elevate the bandgap, consequently restraining recombination rates. Additionally, optimizing photocatalytic performance involves creating a porous structure to enhance reaction sites. Therefore, augmenting pore density within the particles becomes crucial for maximizing efficiency [23]. $LaFeO_3$-based PSC still cannot be commercialized due to its weak photocatalytic performance, including issues like larger particle size and smaller surface area, reduced crystallinity from low temperature treatment and rapid charge recombination rate [58]. A 10 % doping of transition metal such as Mn, Co and Cu has potential to enhance the photocurrent of $LaFeO_3$ which results in increase in PCE [59].

8. Conclusions

This work comprises synthesis of $LaFeO_3$ perovskite material and simulation of $LaFeO_3$-based PSC followed by experimental validation. The sol-gel method is employed to synthesize $LaFeO_3$ perovskite material. The optimization of ETL and HTL has been done to achieve the maximum PCE. The work deduced that WS_2 as ETL and CBTS as HTL is most appropriate for $LaFeO_3$ PSC. The simulated and experimentally achieved maximum PCE were 13.03 % (with V_{OC} = 1.61 V, J_{SC} = 9.952 mA/cm^2, and FF = 81.17 %) and 0.79 % (with V_{OC} = 0.504 V, J_{SC} = 5.56 mA/cm^2, and FF = 28.31 %) respectively for the configuration of FTO/WS_2/$LaFeO_3$/CBTS/Au. This study also includes the optimization of various factors such as thickness of perovskite layer, operating temperature, N_t, metal back contact, series and shunt resistance. The optimized thickness of $LaFeO_3$ layer is 300 nm and at operating temperature of 300 K. The FTO/WS_2/$LaFeO_3$/CBTS/Au is the most stable structure. The optimized metal back contact is Gold (Au). These outcomes allude that the study is useful to fabricate the high performance $LaFeO_3$-based PSC.

ABSTRACT This study focuses on the performance evaluation of underwater-to-air Optical Wireless Communication (OWC) and data transmission between Autonomous Underwater Vehicles (AUVs) and Autonomous Aerial Vehicles (AAVs). Facing challenges from the harsh marine environment and optical signal attenuation, we utilized Monte Carlo (MC) simulations to comprehensively assess the system performance. Our investigation incorporated crucial elements impacting signal attenuation, including particulate matter, bubbles, rough sea conditions, and solar noise. By integrating the in-situ Inherent Optical Properties (IOPs) data and Hall-Novarini (HN) model for bubble characteristics, we constructed a robust simulation framework. To accurately estimate optical beam fluctuations caused by surface waves, we employed the three-dimensional theoretical ECKV (Elfouhaily, Chapron, Katsaros, and Vandemark) model for the water-air interface layer. The received power calculated for varying wind conditions, with and without bubbles, revealed fluctuations attributed to surface waves' interaction with the optical signal. Moreover, we observed a decrease in received power due to the bubble effects and the water-air interface layer. Solar radiation's significant impact on the transmitted signal, especially at the airborne receivers, was evident through the BER performance analysis. We conducted extensive experiments for measuring the solar radiance and evaluating its influence on the BER performance, particularly noting degradation during zenith sun positions and increased errors in scenarios with higher solar glint. Additionally, our investigation highlighted the adverse effect of sea surface bubbles on received solar power and the findings revealed that the BER performance is significantly reduced in the presence of bubbles rather than the scenarios without bubbles.

INDEX TERMS Optical wireless communication, Monte Carlo, optical properties, bubbles, solar noise, oceanic water.

I. INTRODUCTION

Underwater-to-air Optical Wireless Communication (OWC) is a rapidly growing field because of its significant impacts across a range of industries. It enables real-time data transfer from the submerged source to the surface systems, supporting scientific research, environmental monitoring, national security, and industrial/maritime applications. Underwater Optical Wireless Communications (UOWC) offer high bandwidth, making it a foundational tool for diverse applications due to the weak absorption of the water in the blue-green wavelength region [1], [2]. Traditional methods

like acoustic [3], [4] and radio waves [5], [6] have limitations in data rate and propagation. There is a growing interest in exploring and exploiting marine natural resources, which require an improved UOWC system for communication within/between the underwater sensor networks, autonomous underwater vehicles (AUVs), remotely-operated vehicles (ROVs), and from submarines to autonomous aerial vehicles (AAVs). UOWC is a promising technology for such applications, offering high data rates, low latency, and energy-efficient communication links [7], particularly in clear waters with distances of up to approximately 150 m [8], [9].

Earlier researchers have conducted comprehensive studies on modelling the downlink (air-to-underwater) and underwater-to-underwater OWC channel in various ocean waters. When modelling the downlink UOWC channel, researchers employed the Cox and Munk method to model the sea surface. Nevertheless, this method lacks essential spatial and temporal correlated information necessary for accurately modelling the channel for laser communication. Furthermore, their investigations were carried out without considering solar noise. However, as of now, there have been no studies conducted on modeling the underwater-to-air OWC channel. The study of underwater-to-air OWC systems is of paramount importance due to the increasing demand for real-time applications in underwater environments. In scenarios such as underwater sensor networks and AUVs, the need for timely and efficient transmission of data from the underwater devices to the surface is crucial. This underwater-to-air communication plays a vital role in applications where instant data collection and monitoring are required, driving the focus on enhancing the reliability and efficiency of the uplink UOWC systems to meet the growing demands of real-time underwater communication.

In underwater-to-air OWC systems, there is a significant challenge posed by an optical pathway transition from the underwater environment to the above-surface air medium. The wavy ocean surface produced by wind fields represents one of the major constraints that impact the reliability and performance of communication links. Wind-induced waves, currents, and other environmental factors create disturbances in the water-air interface layer, which can lead to fluctuations in the refractive index gradient at the water-air interface and cause scattering, diffraction, and turbulence in the optical signal. Researchers have developed various models to describe the air-sea interface and its impact on optical communication. These models aim to simulate and understand the behaviour of light as it traverses through this complex boundary. Some of the commonly used sea surface models include the Boussinesq and Korteweg-de Vries (KdV) model [10], Cox and Munk model [11] and Fast Fourier Transform (FFT) approximation [12]. The air-sea interface models find extensive applications, particularly in remote sensing. They play a crucial role in estimating various parameters, including bidirectional transmission and reflectance distribution functions (BTDF and BRDF) [13], [14]. These models have proven useful in understanding how the reflected light from the sea surface impacts our observations, especially when conditions such as sky radiance and sun glint are present. Further, these models have been used to analyse the water-leaving radiance in different atmospheric and marine conditions [15], [16]. Earlier studies have relayed on the probabilistic sea surface models, originally developed by Cox and Munk, to study the effect of the air-sea interface [14], [17], [18]. Numerous studies have utilised the Cox and Munk model to analyse UOWC vertical links, particularly when the light beam propagates from the air medium (atmosphere) to the underwater environment. These studies observed that the greater variability in sea surface slopes due to wind speed (u) reduces the system performance, which resulted in higher power loss and increased bit error rates [19], [20], [21]. Studies have also utilised the KdV equations to simulate the air-sea interface with an aim to analyse the coverage area of an optical beam as it propagates from the air into the underwater environment, considering the presence of multiple light sources located in the air medium [22]. In a controlled laboratory setting, experiments were conducted to study a short-range (0.66 m) water-to-air OWC link. These experiments indicated fluctuations in the channel link gain under both calm and wavy surface conditions [23]. In recent studies [24], researchers have developed a model to simulate the vertical UOWC channel. This model takes into account several factors simultaneously: oceanic turbulence parameters, real-time depth-dependent temperature and salinity, chlorophyll concentration, and the presence of bubbles. Additionally, it considers the transmitter beam's oblique incidence at various angles. The findings indicate that the scintillation index rises as the transmitter tilt angle increases. The study [25] evaluates UOWC links with on-off key modulation and selection combining (SC) receive diversity under underwater conditions. It derives closed-form expressions for BER and outage probability, validated through simulations, showing SC diversity mitigates beam attenuation effects. The study [26] examines vertical UOWC links affected by non-mixing layers due to ocean stratification, causing turbulence variations. It models the channel as a concatenation of these layers, deriving closed-form expressions for BER and analysing diversity gains. Results reveal inaccuracies in assuming constant turbulence strength and provide insights into the effect of layering on capacity. Another study [27] explores the performance of vertical UWOC systems amidst air bubbles and temperature gradients. A layered structure with N layers is employed to model the vertical channel's turbulence inhomogeneity using an exponential generalised gamma distribution. Asymptotic average BER and ergodic capacity are derived using H-functions and validated through simulation results. In our most recent investigation [28], we thoroughly examined how sea surface waves and bubbles affect underwater-to-air OWC systems. Our analysis

indicates a substantial variation in received power, depending on the wind speed above the sea surface.

Another challenge in modelling the underwater-to-air OWC channel is the presence of oceanic bubbles. These bubbles are generated by breaking waves in the upper ocean [29], [30] and penetrate the lower water column at depths over several meters, strongly contingent on wind speeds [31]. As a consequence of these bubbles in the upper ocean layer, the light beam is randomly affected and attenuated when passing through the bubble layer. Under high wind speeds, bubble scattering is rapidly enhanced and even more pronounced than particulate scattering in the air-water interface layer. Thus, it is crucial to understand the effect of bubbles on the performance of the underwater-to-air OWC system. Numerous studies revealed a substantial degradation in UOWC system performance in the presence of bubbles (including clean-coated variants) of varying sizes under different wind speeds [19], [32].

Another significant effect on the UOWC system is the interference of solar radiation with an optical signal received by a photodetector. This interference is particularly more pronounced when the receiver is situated in the atmosphere/air medium rather than in the underwater environment. The spectrum of sunlight covers the entire visible wavelength range and beyond in clear marine environments with high water transparency, and it can penetrate several meters of water. Particularly, longer blue to shorter green wavelengths of light can penetrate deeper into the water due to low absorption of water, which allows the penetrating radiation to be easily detectable by sensitive detectors even at depths exceeding 600 m [33]. Previous studies have not paid much attention to the influence of solar noise on the UOWC performance. However, recent work has highlighted background noise's impact and how it affects the UOWC system through various factors like the link length, receiver field of view, and different types of photodetectors [34], [35], [36], [37], [38]. In [34], the significant impact of solar light interference on the UOWC system performance was focused, and effective noise cancellation techniques were emphasised to optimise the UOWC systems in high-intensity solar light conditions. This domain becomes more complex when the receiver is located in the air medium, where it is exposed to solar noise influenced by several factors, including sky radiance, sea surface roughness, water-leaving radiance (depending on the wind speed and wave shape), the time of day, and sun glint.

In this study, our main focus is to incorporate the above factors into the channel model and investigate the performance of underwater-to-air OWC system under different ocean and surface conditions. The Monte-Carlo (MC) technique is employed to simulate the underwater-to-air OWC system with in-situ optical data collected from oceanic waters in the Bay of Bengal and Southern Ocean. Ocean bubble characteristics are determined using the widely recognised Hall-Novarini (HN) model [39], and the distribution of bubble sizes and their ability to penetrate deeper into water depends upon the prevailing wind speed. Recognising the limitations of the Cox and Munk sea surface model, which lacks spatial and temporal correlation information, we utilise the ECKV sea surface model because of its ability to incorporate both spatial and temporal correlation data. This information is essential in understanding how the light beam propagates through the air-sea interface. We assess the solar interference experienced by the receiver by analysing the radiometric data collected above and below the water surface. These data were collected at various times of the day and under different sea conditions, including calm waters, wavy surfaces, and conditions with wind-induced bubbles. Our analysis reveals that the amount of solar power captured by the receiver varies significantly depending on these parameters.

In addition, we examine the correlation between received power, wind speed, and wind-induced bubbles in an underwater-to-air OWC system. The results are compared across a range of sea surface conditions. Finally, the BER performance of underwater-to-air OWC systems was assessed, considering the individual and combined effects of waves, wind-induced bubbles, and varying levels of solar interference.

II. UNDERWATER-TO-AIR OWC SYSTEM MODEL

This section presents the concepts of an underwater-to-air OWC system under investigation (Fig. 1) and describes the key components of the models considered in this study. Here, the transmitter (laser source) is positioned at a specific distance beneath the sea surface, while the receiver is situated several meters above the sea surface. As the optical signal propagated from the source to the destination, it can undergo attenuation due to the various phenomena depicted in Fig. 1. Thus, it becomes crucial to comprehend the underlying theories related to sea surface models, solar noise models, the mechanisms involving bubbles in seawater, and the inherent optical properties (IOPs) of seawater. The fundamental IOPs include absorption (a), scattering (b), and attenuation ($c = a + b$) coefficients and scattering phase function, which collectively play a pivotal role in characterising the optical behaviour of seawater. These parameters were employed as the essential inputs in our MC method for effectively simulating the propagation of photons within the water column.

A. SEA SURFACE GENERATION USING ECKV MODEL

The two-dimensional ECKV (Elfouhaily, Chapron, Katsaros, and Vandemark) spectrum serves as a fundamental tool in oceanography and sea surface modelling [12]. It provides a spectral description of wave energy distribution, which is used to generate realistic sea surfaces through a combination of mathematical operations and random phase introduction. Its applications extend beyond sea surface generation to include areas like remote sensing, environmental impact assessment, and the study of nonlinear wave effects. To obtain the sea surface elevation $z\left(x_i, y_j\right)$, the points on the sea surface grid are sampled in a region of size L_x by L_y m with N_x and N_y points along x and y-directions, respectively,

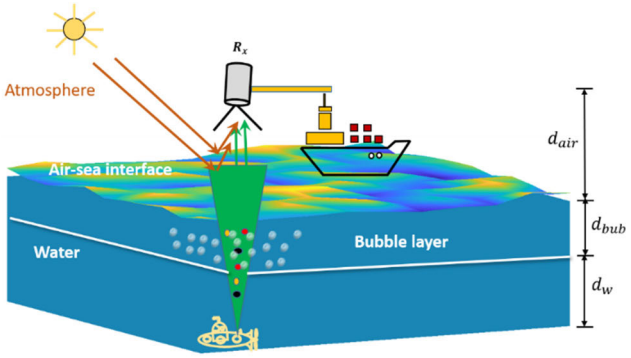

FIGURE 1. Schematic of the channel model for the underwater-to-air OWC system.

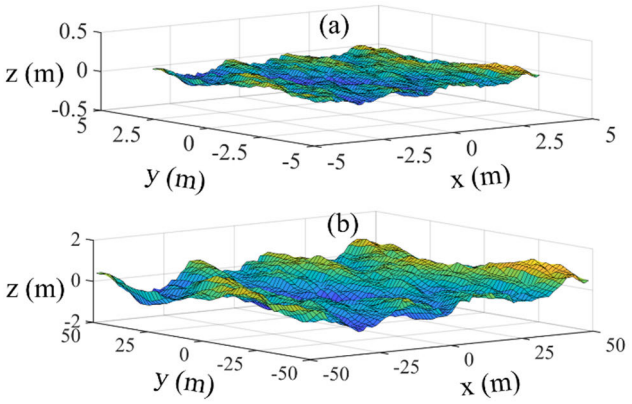

FIGURE 2. The sea surface realisations using the ECKV model for a wind speed of a) 3 m s^{-1} b) 10 m s^{-1}.

as given by

$$z\left(x_i, y_j\right) = \sum_{u=o}^{N_x-1} \sum_{v=0}^{N_y-1} \hat{z}(u, v) e^{i2\pi(x_i u/N_x + y_j v/N_y)} \quad (1)$$

where the harmonic components $\hat{z}(u, v)$ are indexed by u and v in the wavenumber k domain. For an understanding of the ECKV sea surface model, the theoretical foundations and derivations of this model can be found in a previous study [12].

The process of generating a sea surface using the ECKV spectrum involves several key steps. First, it requires the computation of the two-sided discrete values of the elevation variance, which essentially quantifies how wave energy is distributed across different frequencies and directions in the ocean. Next, in order to create a realistic sea surface, the simulation employs random sampling techniques. Specifically, it samples the amplitudes of the harmonic components from normal distributions. This introduces variability and randomness into the wave field while preserving the spectral characteristics defined by the ECKV spectrum. Finally, to translate the spectral information into the spatial domain and obtain the sea-surface elevation in two dimensions, the Inverse Fast Fourier Transform (IFFT) is employed. This mathematical operation is essential for generating a detailed representation of the sea surface, complete wave crests, troughs, and their variations across space and time. These three interconnected steps collectively contribute to the creation of a realistic and dynamic sea surface based on the ECKV spectrum.

The ECKV model originates from the linear superposition theory and excels in accurately representing the complex dynamics of the ocean's surface. The ECKV model integrates both spatial (between adjacent triangle vertices) and temporal (from one time step to the next) correlation information into the generated sea surface model. Thus, it is crucial to understand the spatial and temporal correlation of sea surface data in order to gain insights into the propagation of laser beams across the water-air interface. The sea surfaces generated using the ECKV method, with wind speeds of 3 and 10 m s^{-1}, are depicted in Fig. 2. As the wind speed increases, the sea surface becomes progressively rougher. Consequently, the mean square slope value, which quantifies the degree of surface roughness, increases in direct correlation with higher wind speeds.

B. PHOTON PROPAGATION THROUGH THE WATER, WATER-AIR INTERFACE AND AIR USING MONTE-CARLO METHOD

The MC approach is invaluable for modelling and understanding the complex interactions between light and water, finding diverse applications that extend to areas like underwater communication. Figure 3 illustrates the key steps of Monte Carlo simulations used to model the propagation of photons from underwater to air medium. In the MC simulation method for photon propagation in a water column, several key steps are involved. First, the optical properties of water, including the absorption (a), scattering (b) and attenuation (c) coefficients, are defined. Next, the photon's initial position and direction are determined. The simulation then progresses through discrete steps, with the photon's trajectory being probabilistically determined based on these properties. At each step, the photon's interactions with the medium are governed by the scattering or absorption events, contingent upon the scattering albedo ($\omega = b/c$) condition. The probabilities for these interactions are calculated using the relevant optical properties. When the photon moves within the water column, whether it is absorbed or scattered is determined by comparing a randomly generated number ξ, drawn from a uniform distribution [0 1], with the albedo value (ω). If ξ is less than or equal to ω, the photon undergoes scattering; otherwise, it is absorbed by the water particles. In instances where a photon is scattered by a water particle or bubble, the scattering angle is determined by referencing the respective volume scattering function (VSF). A detailed discussion about the MC rules for photon propagation through the water medium and air-sea interface is given in [19] and [21]. In these simulations, we generated sea surface models using the ECKV method, which relies on the FFT technique. The sea surface is generated with an optimal selection of

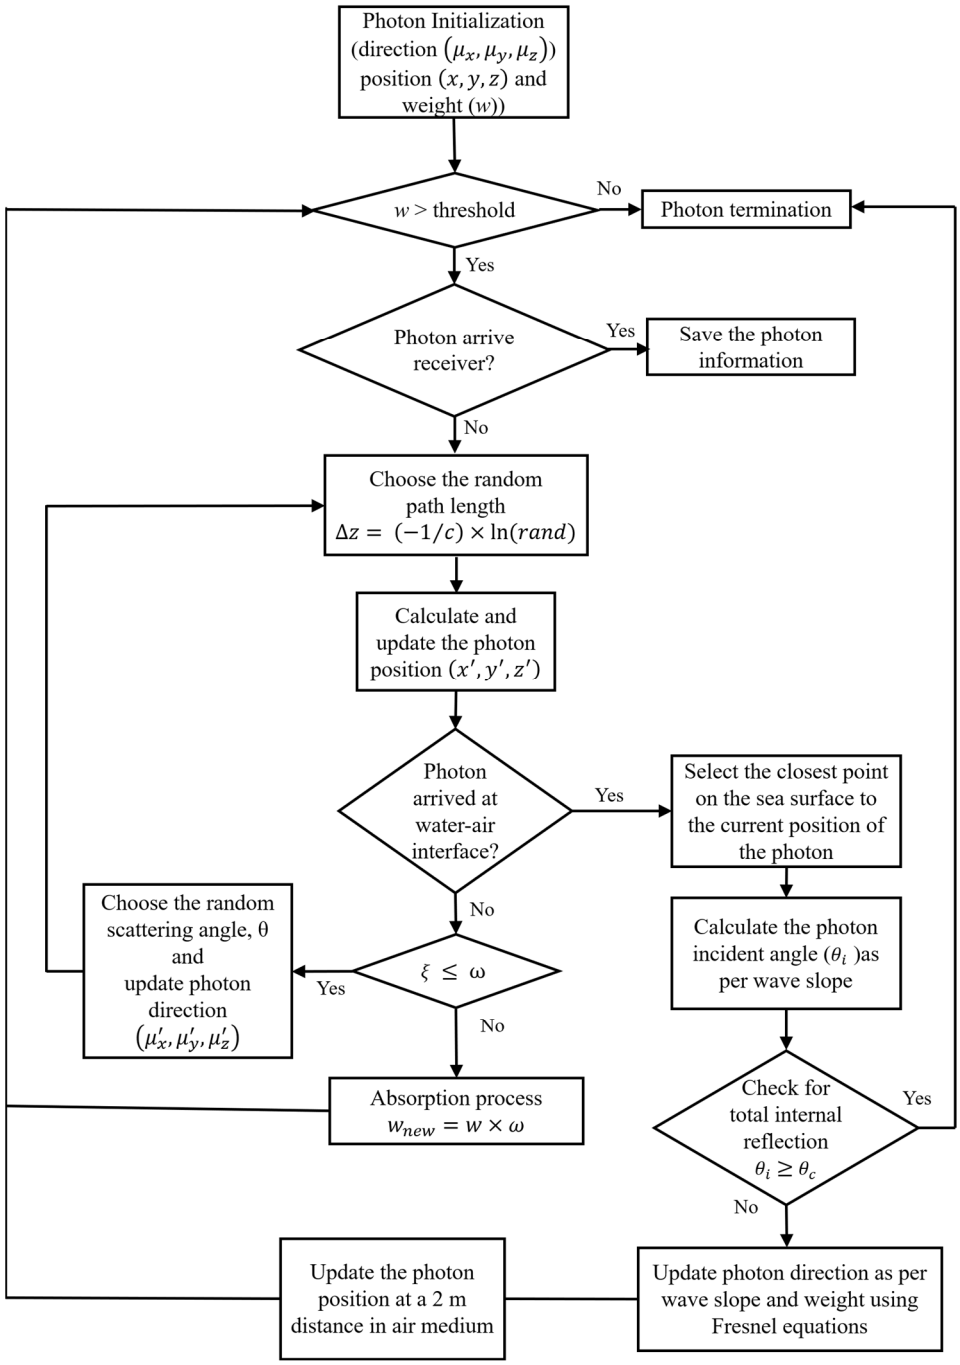

FIGURE 3. A flowchart of photon propagation from the underwater-to-air OWC system.

spatial grid resolution, a choice that depends on both wind speed and maximum wavelength of the wave.

During the photon's propagation, once it has traversed a distance of (d_w+ d_{bub}) m within the water and bubble layer and reached the sea surface, the simulation identifies the point on the sea surface that is closest to the photon's current position. The photon's position is then updated accordingly, with the simulation choosing the point on the sea surface that offers the minimum distance from the photon's current location. To compute the normal vectors ($\hat{n}$) of the sea surface at individual grid points, we employ bicubic interpolation. This involves first applying a bicubic data fitting process to grid data. Subsequently, we derive diagonal vectors and employ them to ascertain the surface normal at each vertex through a cross-product operation. We determine the angle at which a photon strikes the wave surface, denoted as (θ_i), by taking the scalar product of two vectors: the unit normal vector ($\hat{n}$) and the direction cosine vector ($\hat{\mu}_i$) representing

the photon's direction just before it reaches the water-air interface.

Subsequently, we calculate the angle of transmittance (θ_t) and the transmission coefficient (ρ) specific to the wave facet. These values are derived using the Snell's law and Fresnel equations [21], which provides essential insights into the photon's behaviour as it interacts with the wave.

As the photon travels a distance of a few meters through the air before reaching the receiver, our working assumption is that the maritime clear atmosphere remains free from particulate matter. This implies that during its propagation, the photon encounters no significant attenuation ($c \approx 0.9 \times 10^{-4}\text{m}^{-1}$) phenomena that would alter its path or intensity.

C. IN-SITU IOPS OF SEAWATER WITH AND WITHOUT BUBBLES

Previous studies have relied on the constant (single) values of absorption and scattering coefficients, typically derived from the Petzold measurements. However, these values are suitable for horizontal UOWC links. For vertical links, it is important to note that the attenuation and scattering profiles are not constant as these coefficients vary with depth due to the particulate matters (including sediments, phytoplankton, detritus, and bubbles concentrated in the upper sea surface layers). These IOPs were determined through the measurements obtained from optical instruments (such as the Wet Lab's ACS and LISST-VSF) in Bay of Bengal waters. These measurements were used as the inputs for MC simulations. The in-situ measurements were collected under normal sea state conditions without much bubbles. Statistical information regarding the bubbles was obtained from the HN model [39]. The IOPs of oceanic bubbles were then calculated using the HN model and methods established in earlier studies [31].

The VSF data, which include the influence of bubbles (following a power law distribution), were also taken from the measurements conducted in Southern Ocean waters [40]. These measurements were collected in clear waters where the concentrations of chlorophyll and total suspended matter were recorded as 0.72 mg m^{-3} and 0.5 g m^{-3} respectively. The scattering phase function data were obtained by normalising the VSF values with the scattering coefficients. The resulting scattering phase functions are shown in Fig. 4, where bubbles exhibit distinct scattering characteristics. The results indicate a higher probability of scattering at larger angles in the presence of bubbles compared to the cases without bubbles.

Figure 5 presents the depth profiles of both total scattering (b_t) and attenuation coefficients (c_t), which were measured in open sea waters of the Bay of Bengal. For this study, we considered a bubble distribution that reflects the prevalent bubble sizes under real-time oceanic conditions. These bubbles follow a power law distribution characterised by the minimum (r_{min}) and maximum bubble sizes (r_{max}) of 5 μm and 200 μm respectively, with a distribution slope (α) of - 4.

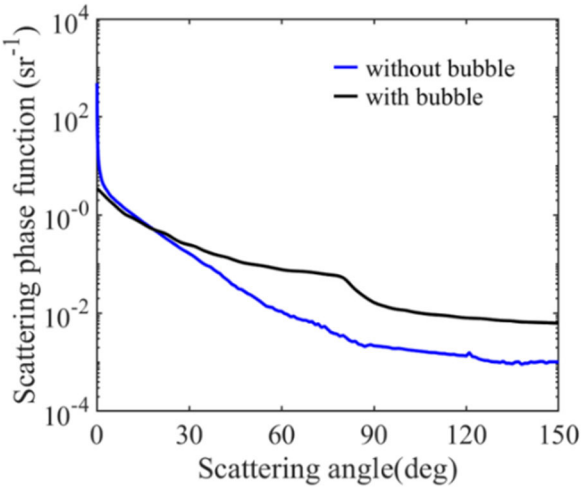

FIGURE 4. Scattering phase functions compared between bubble-free Bay of Bengal waters and bubble-containing Southern Ocean waters.

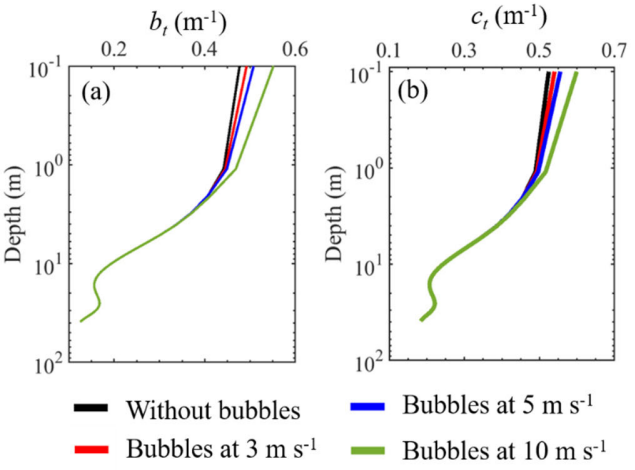

FIGURE 5. Depth profiles of (a) scattering and (b) attenuation coefficients collected in Bay of Bengal waters (with and without bubbles).

Assuming the absorption coefficient of bubbles being negligible, the scattering coefficients of bubbles were calculated using [41]

$$b_{bub}(z) = N(z)\,\bar{Q}_{sca}\bar{S} \tag{2}$$

where N(z) represents the bubble density at a given depth (z) within the water column, which was calculated using the HN model, $\bar{S}$ denotes the geometric mean cross-sectional area of bubbles and $\bar{Q}_{sca}$ represents the mean scattering efficiency.

The measurements indicate that both b_t and c_t values decrease towards the deeper water column as a result of decreasing particulate matter concentrations. Additionally, with an increase in wind speed, there is an increase in the number density of bubbles $N(z)$. Consequently, this leads to an increase in the scattering and attenuation coefficients attributed to bubbles (according to Eq. 2).

D. SOLAR NOISE MODELLING

To quantify the solar radiance received by the receiver (positioned a few meters above the sea surface and looking vertically downward toward the air/water boundary), we evaluated its influence on the performance of the underwater-to-air OWC system by analysing the total upwelling solar radiance spectrum (denoted as $L_t(\theta, \lambda)$ in units of W m^{-2} nm^{-1} sr^{-1}, where λ and θ represent the wavelength and solar zenith angle respectively). Due to the position of receiver in the air medium, the optical signal of reflected solar radiation (direct and diffuse reflection and the sky) and transmitted through the water-air interface is collected by the receiver. Figure 6 shows the various processes contributing to the total upwelling solar radiance (L_t), which includes the surface reflected sky radiance (L_s), surface reflected radiance (L_g) due to sun glint, and water-leaving radiance (L_w). The surface-reflected solar radiance is the direct reflection of sun glint and sky radiation from the water surface. The water-leaving radiance (L_w) is the upwelling radiance emerging from the water column, which is a fraction of solar radiation that penetrates the water. The total upwelling solar radiance is written as

$$L_t = L_w + L_s + L_g \tag{3}$$

1) DATA AND METHODS (RADIOMETRIC MEASUREMENTS)

The RAMSES TriOS hyperspectral radiometers were employed for collecting radiometric data from the above-surface and underwater setups. The above-surface dataset (Fig. 6 (b)) includes the measurements of sky radiance (L_{sky}), downwelling irradiance ($E_d(0^+)$), and total upwelling radiance (L_t) and the below-surface measurements (Fig. 6 (c)) include the downwelling irradiance $E_d(0^-)$ and upwelling radiance $L_u(0^-)$. The in-situ measurements of these properties were collected from Bay of Bengal waters during the daytime from 12 pm to 4 pm (local time, IST). While the direct measurements of L_t are available within the dataset, these data do not provide sufficient insights into the influence of specific parameters like L_w, L_s and L_g on the solar power captured by the receiver. As illustrated in Fig. 6 (a), these radiance (L_w, L_s and L_g) values are influenced by numerous marine environmental factors (including sea surface roughness, wind speed, sun glint intensity, and bubble size/concentrations near the sea surface). Thus, it becomes essential to thoroughly investigate the effects of these parameters on the modelling of the underwater-to-air OWC system's performance. Our in-situ measurements strictly followed the ocean optics protocols and methods presented in Mobley [42], where the radiance sensor was fixed at an angle of 40° from nadir and approximately 135^0 azimuth from the sun (see Fig. 6 (b)). The surface-reflected radiance (L_s) can be calculated based on the L_{sky} values using

$$L_s = \rho L_{sky} \tag{4}$$

Here, ρ represents the Fresnel reflectance coefficient at the air-sea interface, indicating the proportion of light reflected

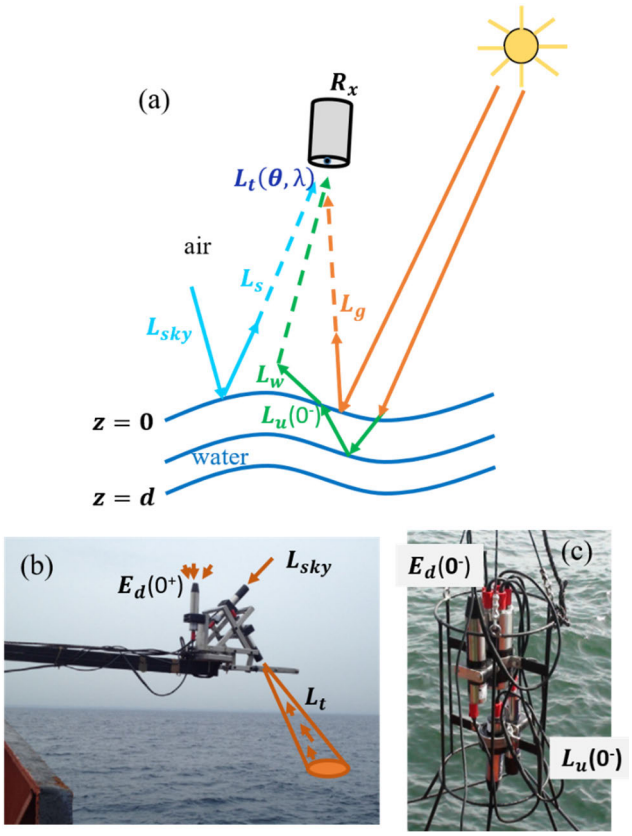

FIGURE 6. (a) Illustration of various processes contributing to the total upwelling solar radiance, (b) Field setup of RAMSES-Trios above-surface radiometers (downwelling irradiance E_d (0^+), sky radiance L_{sky}, and total upwelling radiance L_t) on an extended platform for measurements, (c) Field setup of RAMSES-Trios underwater radiometers installed on an underwater frame for measuring downwelling irradiance E_d (0^-) and upwelling radiance L_u (0^-) below the sea surface.

from the sea surface. Its value typically varies with the factors such as wavelength, wave shape, wind speed, solar zenith angles, and specific viewing geometry [42], [43]. In the case of a flat sea surface and a uniform sky radiance distribution, the value of ρ is 0.02 for a sensor viewing angle (θ) less than 30^0 and increases to 0.03 when θ equals 40^0 [44]. However, the sea surface is often wave-roughened through the combined influence of wind's energy transfer to waves, the inherent turbulence within these waves, and the length of the wind's path over the water. Consequently, this variability underscores that the parameter ρ cannot remain constant and is often greater than the values mentioned earlier. Thus, ρ cannot be a constant value and it is larger than the reported values. Additionally, it is clear that determining this parameter across diverse wind and sea conditions presents a significant scientific challenge. Because of this complex nature, many researchers have considered a fixed value of $\rho = 0.028$ as previously suggested by Mobley [42]. This is typically done under the conditions of a uniform sky radiance distribution, low wind speeds (less than 5 m s^{-1}), viewing angles not exceeding 40^0, and with no influence from sunlight reflection off the sea surface (sun glint). In this study,

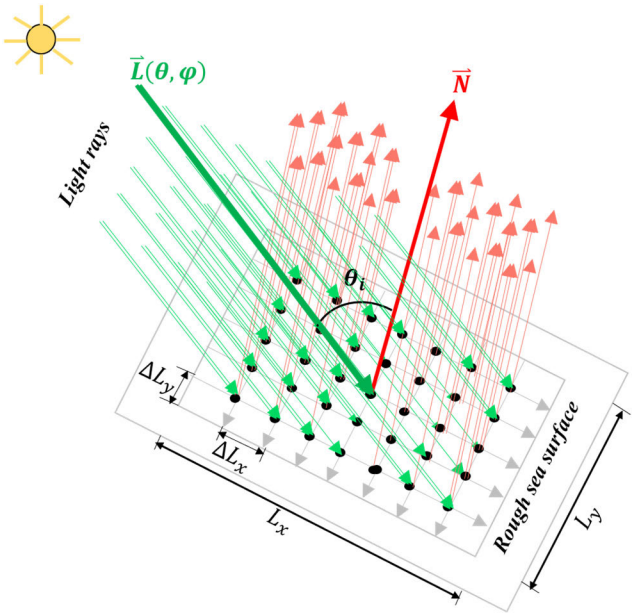

FIGURE 7. Schematic diagram of calculating ρ from the sea surface model.

we determined the ρ value by employing the ECKV method to model the sea surface. We conducted these calculations for a range of solar zenith angles and wind speeds. This approach was necessary because the sea surface roughness varies with changing wind speed and direction, and the intensity of incident sunlight on the sea surface varies with changing solar zenith angles and time intervals. Solar zenith angles can be determined by considering both the time of day and the geographical location and hence vary accordingly. The schematic diagram of calculating the ρ values from the sea surface model is shown in Fig. 7. When parallel sunlight strikes the mesh grid of the sea surface, we calculate the incident angle ($\boldsymbol{\theta_i}$) between the incoming sun rays and the normal vector associated with the mesh grid point on the sea surface. The solar zenith angle (θ) is determined from the time of day, and the azimuthal angle (φ) is randomly generated within the interval of $[0, 2\pi]$. The ρ value is subsequently determined using Fresnel's equations, based on this angle of incidence.

In our study, we considered wind speeds at 3, 5, and 10 m s^{-1}. To accommodate the wavelength scales of capillary and gravity waves, we considered maximum wavelengths (L_x and L_y) of 8, 25, and 100 m for wind speeds of 3, 5 and 10 m s^{-1} respectively, based on a previous study [45]. To maintain the optimal grid resolution (ΔL_x and ΔL_y) of 0.09 cm, we sampled the sea surface at rates of 8192 × 8192, 32768× 32768, and 131072 × 131072 grid points for wind speeds of 3, 5, and 10 m s^{-1} respectively, depending on the values of L_x and L_y. To enhance the accuracy of determining the ρ values, we utilised 1000 different sea surface realisations modelled using the ECKV method for each wind speed in our simulations. Table 1 presents the average reflectance (ρ) value for various solar zenith angles and wind speeds. The calculations revealed that the ρ value is not constant, as previously assumed in earlier studies, but it varies with both the position of the sun and wind speeds. As the wind speed increases, the roughness of the sea surface also increases, causing the incident angles to diverge further and consequently leading to an increase in the average reflectance value. Further, it was observed that the ρ value increases as the solar zenith angle increases.

TABLE 1. The average reflectance (ρ) values for various solar zenith angles and wind speeds.

Solar zenith angles (θ_s)	Wind speed		
	3 m s^{-1}	5 m s^{-1}	10 m s^{-1}
25^0	0.035	0.052	0.104
30^0	0.043	0.063	0.111
45^0	0.081	0.100	0.129
60^0	0.139	0.146	0.149

As shown in Fig. 6 (a), the water-leaving radiances (L_w) were calculated using the underwater radiometer measurements by incorporating sea surface roughness on the upwelling radiance $L_u\left(0^-\right)$ just below the sea surface by using the following expression

$$L_w = \tau L_u\left(0^-\right) \tag{5}$$

where τ is the transmittance coefficient relative to the wave facet and is calculated using Snell's and Fresnel equations. As previously discussed, when calculating the value of τ, we applied the same principles as those used for calculating the ρ values. This implies that τ varies in response to changes in sea surface roughness and wind speed.

2) IMPACT OF BUBBLES ON THE RADIOMETRIC MEASUREMENTS

Wave breaking is a common phenomenon in open ocean waters, predominantly driven by winds. It results in the formation of bubbles on the sea surface, and the depth to which these bubbles penetrate the water column is influenced by both the characteristics of wind-generated waves and the concentrations of water constituents. To examine the impact of bubbles on the radiometric measurements, radiometric measurements were conducted continuously for approximately 3 minutes at a specific location in Bay of Bengal waters. For analytical purposes, the average data from these 3-minute measurements were utilised. These experiments were conducted on a bright sunny day, specifically from 12:00 pm to 4:00 pm (local time, IST), under two different water state conditions: calm water and wave-breaking-induced bubbles, as depicted in Fig. 8 (a) and (b). These measurements were collected at four different times: 12:20 pm, 1:25 pm, 2:45 pm, and 3:50 pm.

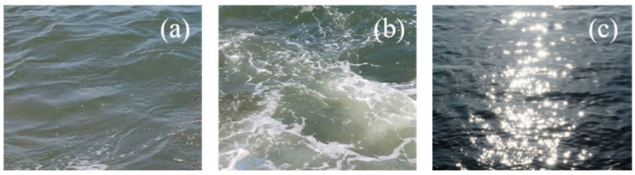

FIGURE 8. Images from field experiments in Bay of Bengal waters on February 15, 2020, between 12 pm and 3 pm, illustrating calm water and bubble cloud formation resulting from wave breaking. (a) calm water; (b) wave-induced bubble clouds; and (c) glint effect.

Figure 9 (a)-(c) displays the spectral sky radiance, downwelling irradiance, and upwelling radiance just below the sea surface at various time intervals in Bay of Bengal waters (all measurements made under clear sky conditions). Using the recorded time data and geographic location, we calculated the respective solar zenith angles (θ_s). These measurements clearly indicate a decreasing trend in spectral radiance and irradiance values as the daytime progresses. This decline in radiance and irradiance values is a direct result of the diminishing intensity of solar light, which decreases notably from 12:20 pm to 4 pm as the sun's position changes throughout the day. In Fig. 9 (c), the solid line corresponds to the upwelling spectral radiance observed under calm water conditions, while the dashed line represents the upwelling radiance spectrum when wave-breaking-induced bubbles formed. These distinct lines provide a clear contrast between the two scenarios, allowing for a comprehensive comparison of radiance spectra between calm and bubble-filled water states. The wave-breaking-induced bubbles typically result in higher radiance values compared to a calm water state because the bubbles scatter and reflect sunlight more effectively. The increased scattering and reflection contribute to higher radiance values.

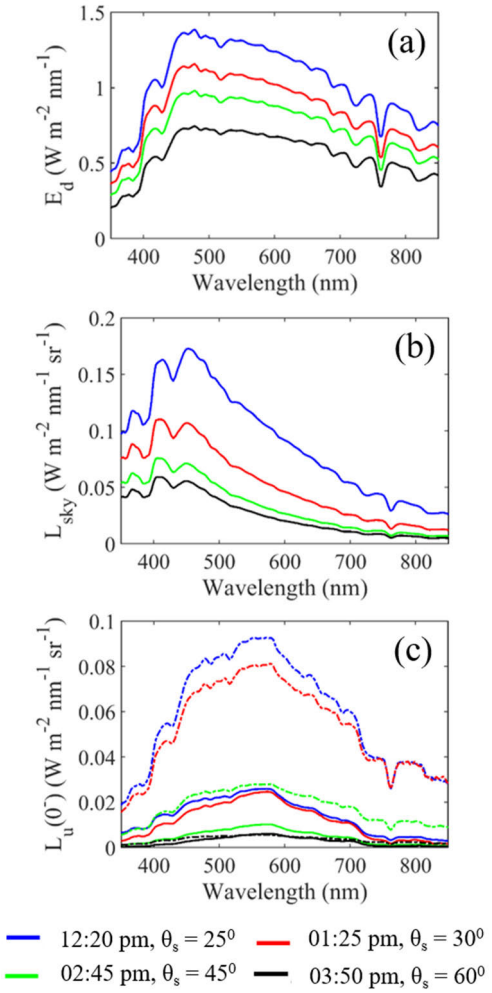

FIGURE 9. In-situ measurements collected at four different daytimes under clear sky conditions: (a) downwelling irradiance (E_d (0^+)), (b) sky radiance (L_{sky}), and (c) upwelling radiance (L_u (0^-)) just below the sea surface. Solid line - calm water radiance, dashed line - wave-breaking-induced bubbles radiance.

3) IMPACT OF SUN GLINT ON RADIOMETRIC MEASUREMENTS

Sun glint refers to the bright, reflective appearance of the sea surface when sunlight is directly reflected off it and towards an observer (such as a satellite or aircraft). This effect occurs due to the specular reflection of sunlight, where light is reflected at the exact angle it strikes the sea surface (as illustrated in Fig. 8 (c)). Even though the radiometric measurements are obtained taking the aforementioned precautions, it is still possible to detect sunlight reflected (sun glint) by the sea surface in the L_t data. Consequently, the surface reflected solar radiance encompasses not just the reflected sky light but also the sunlight reflected (sun glint) from the sea surface. In [44], the sun glint is calculated from the downwelling irradiance using

$$L_g = mE_d\left(0^+\right) \tag{6}$$

The parameter 'm' is a proportionality factor that signifies the magnitude of $E_d\left(0^+\right)$ in the in-situ radiometric data. It ranges between 0 and 0.07, with 'm' equalling 0 indicating the absence of glint conditions, while the higher values of 'm' correspond to the increased sun glint strength. Thus, the total upwelling radiance L_t reaching the sensor is expressed as

$$L_t = \tau L_u\left(0^-\right) + \rho L_{sky} + mE_d\left(0^+\right) \tag{7}$$

Figure 10 shows the variation in L_t as influenced by sun glint across a range of m values.

E. CALCULATING THE SYSTEM'S SIGNAL-TO-NOISE RATIO (SNR) AND BER PERFORMANCE USING AVALANCHE PHOTO DIODE (APD) RECEIVER

In our simulations, we utilised an Avalanche Photo Diode (APD) as a receiver to evaluate the BER performance of an underwater-to-air OWC system. The various electrical noises produced at the UOWC receiver are due to the thermal, shot and dark current noises. In [34], a complete model is presented for analysing the received noise in UOWC system. We used this model to calculate the received electrical noises for the case of APD detector. The APD receiver used

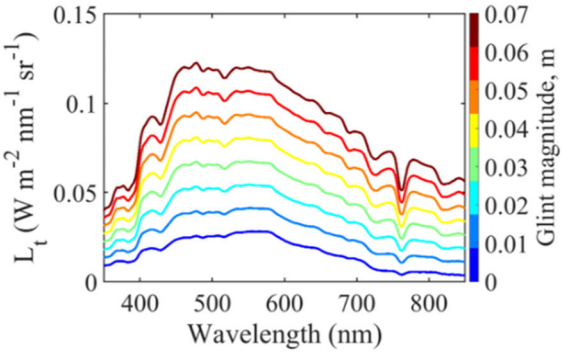

FIGURE 10. Variation in L_t as influenced by sun glint across various values of m.

the approximated zero mean Gaussian model and Poisson model for thermal and shot noises respectively. We reasonably assumed the dark current (I_d) values for APD as 10 nA. The thermal noise variance is given as

$$\sigma^2_{thermal} = \frac{4k_B T_m B_n}{R_{TIA}} \tag{8}$$

where B_n is the APD 's electrical bandwidth expressed in Hz, T_m is the medium temperature, R_{TIA} is the resistance of the trans-impedance amplifier's feedback resistor and k_B is Boltzmann constant.

Solar power reception is determined through the mathematical calculations using solar radiance spectra. This quantity, however, varies significantly based on several crucial parameters, including geographical location, time of day, the elevation or depth of the receiving equipment, and the aperture area's dimensions that are utilised for solar energy collection. The expression for the received solar power ($P_{R-solar}$) at the receiver is given as follows:

$$P_{R-solar} = L_t.T_\theta.A_{Apd}.\Delta\lambda.S \tag{9}$$

where T_θ represents the transmission efficiency of the filter, A_{Apd} is the effective area (m^2) of the receiver, $\Delta\lambda$ denotes the optical filter band width (nm), and S is the solid angle of the optical filter, measured in steradians. The expression for S in terms of the field of view (FOV) of the photo detector can be calculated using Eq. 10 and is given as follows:

$$S = 2\pi\left(1 - \cos\left(\frac{FOV}{2}\right)\right) \tag{10}$$

The variance of shot noise at the receiver due to the reception of both solar ($P_{R-solar}$) and signal power ($P_{R-signal}$) can be expressed as

$$\sigma^2_{shot} = 2qM^2_{APD}\begin{bmatrix} R_{APD}\left(P_{R-signal} + P_{R-solar}\right) \\ +I_d \end{bmatrix} B_n \tag{11}$$

where q is the electron charge, M_{APD} is the APD gain, R_{APD} is the responsivity of APD.

In addition to these two noises, two electrical beat noises ($\sigma^2_{sig-sol}, \sigma^2_{sol-sol}$) are generated at the detector using

$$\sigma^2_{sig-sol} = 4M_{APD}R^2_{APD}P_{R-signal}P_{R-solar}\frac{B_n}{BW_{opt}} \tag{12}$$

$$\sigma^2_{sol-sol} = R_{APD}\left(P_{R-signal}\right)^2\left[2 - \frac{B_n}{BW_{opt}}\right]\frac{B_n}{BW_{opt}} \tag{13}$$

where BW_{opt} is the bandwidth of the optical filter expressed in Hz.

The total variance of noise that occurs during the transmission of optical signal (bit '1') and no optical signal (bit '0') is expressed as

$$\sigma^2_{total,1} = \sigma^2_{shot} + \sigma^2_{thermal} + \sigma^2_{sig-sol} \tag{14}$$

$$\sigma^2_{total,0} = \sigma^2_{thermal} + 2qM^2_{APD}\left[R_{APD}\left(P_{R-solar}\right) + I_d\right]B_n \tag{15}$$

The SNR of the underwater-to-air OWC system is

$$SNR = \frac{\left[M_{APD}R_{APD}P_{R-signal}\left(1 - r_e\right)\right]^2}{\sigma^2_{total,1} + \sigma^2_{total,0}} \tag{16}$$

where r_e is the extinction ratio between optical power associated with bit '0' and '1', and the value is assumed as 0.1.

The performance of the underwater-to-air OWC system using OOK modulation can be expressed as [46]

$$BER = \frac{1}{2}erfc\left(\frac{\sqrt{SNR}}{2\sqrt{2}}\right) \tag{17}$$

where $erfc$ is the complementary error function.

III. RESULTS AND DISCUSSION

To quantify the effect of solar noise on the performance of the underwater-to-air OWC system, numerical results are presented for a range of scenarios, diverse oceanic conditions, varying receiver configurations, and atmospheric conditions. The parametric values for the transmitter and receiver used in our simulations are specified in Table 2. The selection of a green wavelength, specifically 515 nm, offers advantages for an UOWC system due to reduced absorption and enhanced signal transmission at this wavelength. This study employed the MC method using in-situ optical measurement data as the input parameters. Additionally, the HN model was integrated to account for bubble populations during the wave breaking events. In our simulations, the transmitter was situated 50 m below the sea surface and the receiver positioned 2 m above the sea surface. It was assumed that the transmitter is aligned with the receiver. In order to achieve a realistic wireless optical communication through the underwater-to-air system, it is necessary to analyze the impacts of air-sea interface and bubbles in the upper ocean layer.

The sea surfaces were modelled under different wind conditions, specifically at wind speeds of 3, 5 and 10 m s^{-1}. To generate these varied sea surfaces, The ECKV model was employed which accurately replicates the complex dynamics of ocean waves influenced by the varying wind speeds. The

spatial grid resolution for the sea surfaces generated in our simulations is an important consideration in the present study. When making the simplified assumption that the sea surface is perfectly flat, there are no spatial or temporal variations in its characteristics. Consequently, the power received by this flat surface remains constant regardless of the changes in time, wind speed or spatial location. Numerous studies have employed the Cox and Munk sea surface model to analyse the received power in wave surface conditions. However, it is important to note that this model does not provide a comprehensive explanation of the spatial and temporal dynamics of sea surfaces and wave shapes. When the model reveals variations in the received power with varying wind speeds, it is worth emphasising that for a single wind speed scenario, the received power remains constant. This suggests that the Cox and Munk model captures wind-dependent fluctuations in the received power without accounting for the intricate variations in the sea surface characteristics and waveforms that occur under these conditions.

In reality, sea surfaces exhibit a diverse range of wave shapes at different locations, which can encompass crests, troughs, and various random patterns. These complex waveforms introduce dynamic variations in the sea surface over time, making it a dynamic and ever-changing environment. Consequently, the received power from such dynamic sea surfaces can fluctuate considerably due to their temporal and spatial changes.

To investigate the influence of wave shape on the received power, the maximum wavelength (L_x and L_y) was divided into 500 cross-sectional segments for each wind speed. After travelling 50 m through the water, the optical beam passed through the segmented wave cross sections. Observed was a range of fluctuations in the laser beam's intensity at the receiver and this intensity variation was directly related to the specific wave shapes encountered on the sea surface. Consequently, the power received by the detector varied significantly depending on the specific characteristics of the encountered waves, highlighting the substantial impact of wave shape on the received power.

A. NORMALISED RECEIVED POWER

In our analysis, we examined the wind speeds of 3, 5, and 10 m s^{-1} and calculated the received power at the detector plane for each scenario by considering every cross section of the sea surface. The receiver aperture size FOV were considered as 4'' and 180^0 respectively. Our calculations revealed that the presence of waves can significantly impact the received power, potentially resulting in a reduction in the received power and consequently limiting the data transfer capability of the system.

In Fig. 11, we present a histogram depicting the fitting of normalised received power derived from the contributions of 500 distinct cross-sections under varying wind speeds. Our analysis revealed that the received power is not consistent for a specific wind speed, but it falls within a defined range that is influenced by the wind speed. When the wind speed reaches 10 m s^{-1}, the received power is observed to be lower compared to the cases with wind speeds 3 and 5 m s^{-1}. This observation suggests that with the increasing wind speed, the sea surface becomes rougher and leads to a more divergent orientation of the sea surface normal. Consequently, this variation of the sea surface roughness is directly reflected in the received power calculations, which highlight the sensitivity of the system's performance depending on the wind speed and sea surface conditions.

In addition, we investigated the received power variations in the presence of bubbles in the uppermost layers of the

TABLE 2. The Parameters used for MC simulations.

Parameter	Value
Transmitted beam power (P_{Tx})	50 mW
Transmitted beam divergence angle (θ)	1.5 mrad
Transmitted beam width (ω)	1 mm
Transmission beam wavelength (λ)	515 nm
Optical filter bandwidth ($\Delta\lambda$)	15 nm
Optical filter transmissivity (T_f)	1
Gain of APD (M_{APD})	50
TIA resistance (R_{TIA})	50 Ω
Responsivity of APD (R_{APD})	0.8 AW^{-1}
Receiver aperture	4 inches
Receiver FOV	90^0 - 180^0

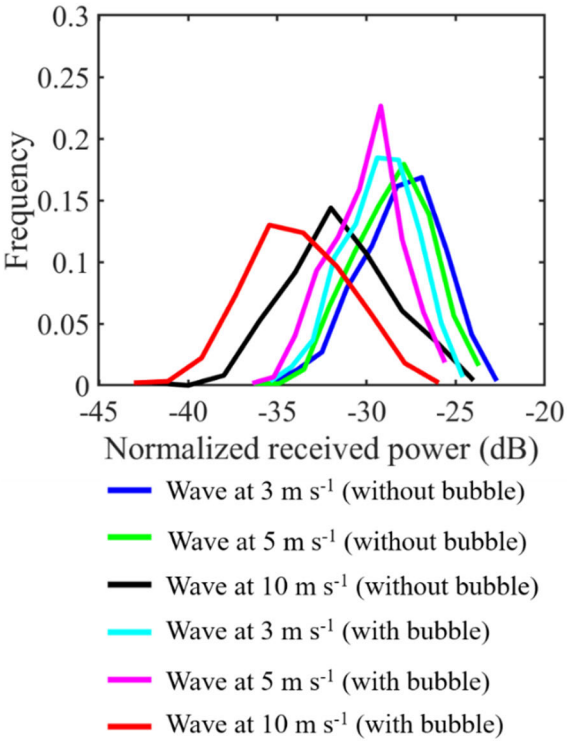

FIGURE 11. The histograms of the normalised received power (aperture: 5'', FOV: 180^0) for 500 sea surface cross-sections at various wind speeds.

sea surface. These bubbles penetrate into the subsurface layer depending on the wind speed. For the MC simulations, we determined the depth to which bubbles penetrated using an exponential decay model that considers the decreasing bubble concentrations with increasing water depth. Our analysis revealed that the wave-breaking-induced bubbles penetrate to water depths of 5, 7, and 10 m for wind speeds of 3, 5, and 10 m s^{-1} respectively.

Figure 11 shows the histograms of the normalised received power (with a 5'' aperture and a FOV 180^0) calculated based on the data collected from 500 different sea surface cross sections and all of which incorporated the bubbles. Our findings clearly demonstrate that the oceanic bubbles have a substantial impact on the normalised received power. When compared to the scenarios without bubbles, the received power significantly decreases under these conditions. Further observations revealed that the oceanic bubbles generated at various wind speeds introduce significant variations in the received power due to changes in the number density of bubbles according to wind speed fluctuations. The bubble number density fluctuation is of utmost importance for UOWC studies, as it directly influences both the scattering and attenuation coefficients. Specifically, at higher wind speeds, these coefficients are increased leading to the increased photon loss owing to a greater number of scattering events. A contributing factor to this phenomenon is that a photon scatters off a bubble at the higher angles when compared to other particulates in the water column. This scattering behaviour causes the optical beam to spread more quickly and widely, ultimately leading to a reduction in the received power intensity at the center of the beam.

B. UNDERWATER-TO-AIR OWC SYSTEM'S BER PERFORMANCE

This section presents a detailed analysis of numerical results to precisely quantify the influence of solar noise on the performance of a typical underwater-to-air OWC link operating in clear oceanic water conditions. We conducted a comprehensive assessment of the system's performance – specifically focusing on BER under various solar noise scenarios. These scenarios were dependent on the factors such as wind speeds, time of day, and bubbles in the upper ocean layer. It is important to note that our analysis assumes the ideal conditions, including perfect beam alignment and precise time synchronisation between the transmitter and the receiver. Data transmission is executed using NRZ-OOK modulation with a transmission speed of 500 Mbps, which allows us to rigorously evaluate the system's performance in realistic operational settings. In the system that employs NRZ-OOK modulation, the APD's bandwidth efficiency is set at 1 bit per second per hertz (1 bit/s/Hz). For this analysis, we have considered an APD receiver and the receiver parameters as provided in Table 2. In our study, we focused on a wavelength of 515 nm. To determine solar power for our analysis, we calculated it based on the solar spectrum specifically at this wavelength under investigation.

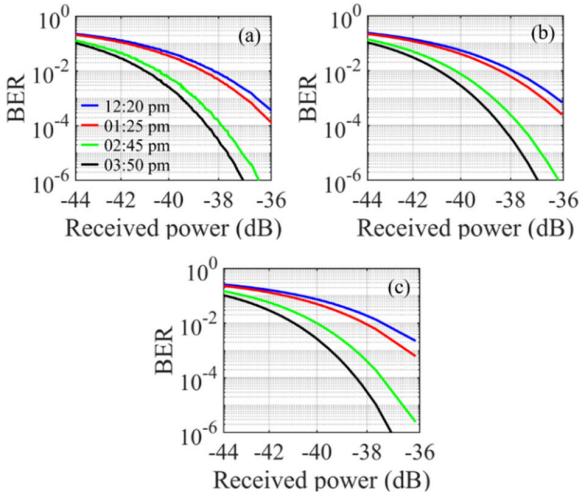

FIGURE 12. BER as a function of the received signal power with an APD receiver and the variations at different times of day and wind speeds (a) 3 m s^{-1}, (b) 5 m s^{-1}, and (c) 10 m s^{-1}.

1) THE IMPACT OF SOLAR NOISE ACROSS DIFFERENT TIMES OF THE DAY

As previously discussed, solar radiation exhibits varying intensities throughout the day. This fluctuation in solar intensity plays a crucial role in influencing the system BER performance in distinct ways at different times of the day. For this analysis, we assumed no bubbles present on the sea surface and performed the BER calculations with the different received signal power for particular wind speed conditions, which determine the shape of the surface waves and hence the solar power variations. Figure 12 presents the BER performance of an underwater-to-air OWC system. It demonstrates how the BER changes in response to the received signal power at different wind speeds and various times of the day. The simulations were executed using a receiver FOV value of 180^0. Our findings indicate that when the Sun passes through the zenith at noon, the BER exhibits poor performance across all wind speed conditions. This deterioration in BER performance is attributed to the increased collection of solar power around midday. As the sea surface wave shapes cause variations in the received signal power, it is imperative to identify the minimum power threshold as necessary to achieve the improved BER performance, aligned with the constraints of the Forward Error Correction (FEC) limit. According to our analysis, we have established specific minimum power requirements to achieve error-free data transmission at various times of the day. These requirements vary depending on the wind speed conditions, ensuring reliable communication in different scenarios.

2) THE IMPACT OF SOLAR NOISE IN THE PRESENCE OF SUN GLINT

The sun glint varies depending on its intensity at different wavelengths, Sun angle and sea surface conditions. In addition to the inherent solar noise from different sources, the sun glint radiation also interacts / interferes with the

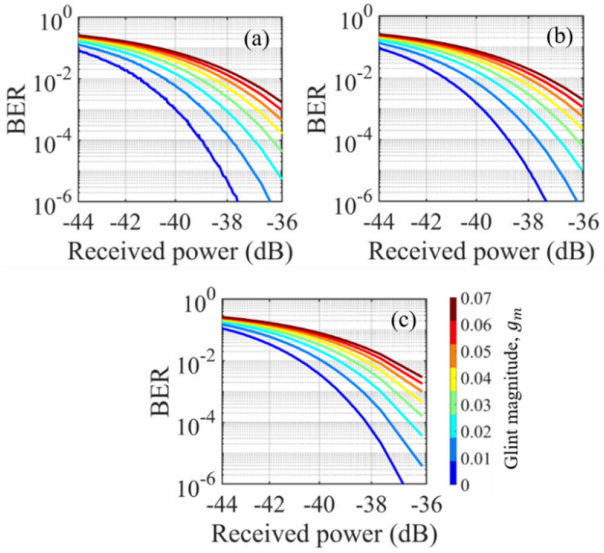

FIGURE 13. BER as a function of the received signal power around midday (noon time) with the varying glint intensities and wind speed conditions (a) 3 m s^{-1}, (b) 5 m s^{-1}, and (c) 10 m s^{-1}.

transmitted optical signal. This phenomenon of sun glint is particularly prominent when the Sun is around midday. In our study, we conducted a detailed analysis of the sun glint effect on the optical signal and system BER performance. For this analysis, the FOV was set at 90^0. Figure 13 shows the BER performance of the OWC system under various sun glint intensities when combined with the other sources of solar noise at wind speeds of 3, 5, and 10 m s^{-1}. The solid blue line on each graph represents the system's BER performance in the absence of sun glint and other solid lines of varying colors depict the BER performance at different sun glint intensities. Our results highlight the substantial impact of sun glint on the system's BER performance. It is noteworthy that if experiments or simulations are conducted on the conditions of maximum possible sun glint, it will become challenging to achieve error-free transmission at the lower received signal power and all wind speeds.

It should be noted that sun glint occurs throughout the day but exhibits higher intensities around midday (at high noon). Consequently, there are fluctuations in the system's BER performance due to the prevailing sun glint conditions. To avoid sun glint during the in-situ experiments in marine environments, one may consider scheduling these measurements during early morning or late afternoon hours when the sun is at a lower angle. Also to adjust the instrument angles and use polarising filters or anti-glare shields to minimise glare from the water's surface.

3) THE IMPACT OF SOLAR NOISE IN THE PRESENCE OF WAVE-INDUCED BUBBLES ON THE SEA SURFACE

Wave breaking is a common occurrence in the marine environments due to the prevailing winds. This oceanographic process generates bubbles in the upper ocean layer and hence it becomes virtually unavoidable to simulate the system's BER performance without accounting the oceanic bubbles.

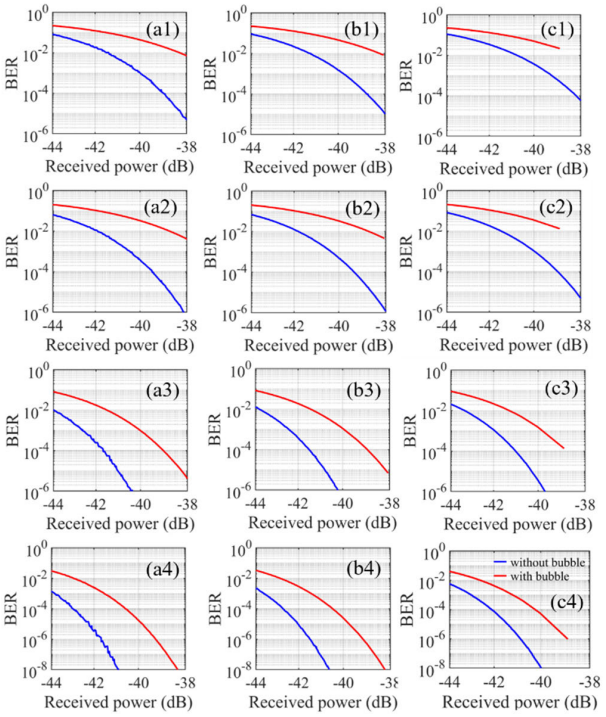

FIGURE 14. BER as a function of the received signal power at different times of the day and wind speeds with and without bubbles. Subplots (a1) through (a4) correspond to a wind speed of 3 m s^{-1}at 12:20 pm, 01:25 pm, 02:45 pm, and 03:50 pm, respectively. Subplots (b1) through (b4) correspond to a wind speed of 5 m s^{-1}, while subplots (c1) through (c4) represent a wind speed of 10 m s^{-1}.

In this study, we made a significant observation from our simulations. The presence of bubbles generated by wave breaking conditions results in distinct variations in the solar power collected at the receiver, in contrast to the scenarios in the absence of bubbles. In our measurements conducted at various times of the day, the wind speed was consistently observed around 5 m s^{-1} when making the measurements of upwelling solar radiance ($L_u\left(0^-\right)$). There were no $L_u\left(0^-\right)$ data collected for instances when bubbles were generated at wind speeds of 3 and 10 m s^{-1}. For these two wind speed conditions, we made the assumption that the solar radiation at the detector was similar to that at a wind speed of 5 m s^{-1}. Nevertheless, the transmittance parameter was taken into account that corresponds to the sea surfaces generated by wind speeds of 3 and 10 m s^{-1}. As a result, the solar noise reaching the detector differed from the condition at 5 m s^{-1} due to the variability of the transmittance parameter associated with the wind-generated sea surfaces. Figure 14 shows the BER performance of the underwater-to-air OWC system for two scenarios: with bubbles and without bubbles at different wind speeds, while considering a receiver FOV of 90^0. According to these simulations, the presence of bubbles in the uppermost ocean layer leads to a reduction in the transmitted power at the detector, and these bubbles have the effect of enhancing the solar radiation reaching the receiver. Consequently, the BER performance deteriorates when bubbles are present at the sea surface as compared to the system's performance in the absence of bubbles.

IV. CONCLUSION

A robust model was presented in this study for evaluating the performance of underwater-to-air OWC system using Monte Carlo technique. Using the simulation and experimental results, we comprehensively assessed the impact of solar noise on the system BER performance by taking into account the various marine environmental factors such as bubbles, wavy surface conditions, and solar noise under different atmospheric and marine conditions. To ensure an accurate simulation of the system's performance, we incorporated the in-situ optical measurements, including IOPs and solar radiance data obtained from Bay of Bengal waters. Additionally, the measurement data were collected from the Southern Ocean to derive and account for the bubble properties using the theoretical HN model. The modelling of wavy surface was achieved through the utilisation of the ECKV model, which incorporates both spatial and temporal dependencies in the generation of sea surfaces. This approach was crucial for our understanding of the optical signal behaviour when propagating through the air-sea interface. This study highlighted the significant influence of both sea wave shapes and bubbles on the received signal power of a laser beam at different wind speed conditions. The findings indicate that the received signal power varied depending on the wind speed and surface wave structure at the air-sea boundary. Additionally, the oceanic bubbles were found to decrease the received signal power as the wind speed increased. Finally, we analysed the system's BER performance under different times of the day, varying sun glint intensities, and different receiver setups. Our findings indicate that the BER performance is significantly deteriorated around midday (when the sun at noon) and improved at other times of the day. Additionally, we observed that the sun glint has a significant impact on the system's BER performance. The higher intensities of sun glint result in reduced BER performance, leading to an increased occurrence of data transmission errors. Additionally, our analysis revealed that the presence of bubbles in the upper ocean layer enhances the reception of solar signal power at the receiver. Consequently, this increase in solar power due to the oceanic bubbles leads to a reduction in the system's BER performance as compared to scenarios in the absence of bubbles. These findings offer essential guidance for system designers as they create and refine underwater-to-air OWC systems by taking into account the various marine and atmospheric conditions encountered in real-world applications.

BHOGESWARA RAO ANGARA received the B.Tech. degree in electronics and communication engineering (ECE) from Andhra University, Andhra Pradesh, India, in 2011, and the M.Tech. degree in control and instrumentation from Delhi Technological University (DTU), Delhi, India, in 2015. He is currently a Ph.D. Scholar with the Department of Ocean Engineering and Electrical Engineering, IIT Madras, Chennai, India. His research interest includes underwater wireless optical communications (UWOC).

PALANISAMY SHANMUGAM received the Ph.D. degree in optical remote sensing from Anna University, Chennai, India, in 2002.

He is currently a Professor with the Department of Ocean Engineering, IIT Madras, Chennai, India, where he is involved in the experimental and theoretical studies of the optical properties of natural water, air–sea interface, and subsea optical processes. He has been a principal investigator of several projects funded by the Government of India. His current research interests include developing models for ocean optical studies and retrieval algorithms for multispectral and hyperspectral remote sensing sensors, with an emphasis on applications to sediment dynamics, algal blooms, climate change, and marine environmental and coastal processes.

HARISHANKAR RAMACHANDRAN received the B.Tech. degree from IIT Bombay, in 1982, and the Ph.D. degree from the University of California at Berkeley, both in electrical engineering.

He was a Research Scientist with the Physics Department, University of California at Los Angeles, for five years before returning to India. He was a Scientist with the Institute for Plasma Research, Gandhinagar, from 1993 to 2001. In November 2001, he joined IIT Madras, where he is currently a Professor with the Department of Electrical Engineering. His research interests include optical link design and planning, nonlinear optics, computational optics, edge plasma physics, and computational plasma physics.

CHAVAPATI GOUSE SANDHANI received the B.Tech. degree in civil engineering from API-IIT Nuzvid, RGUKT University, Nuzvid, Andhra Pradesh, India, in 2015, and the M.Tech. degree in environmental engineering and management from IST, JNTUK University, Kakinada, Andhra Pradesh, in 2018.

He has been a Ph.D. Scholar with the Department of Ocean Engineering, IIT Madras, Chennai, India. His research work involves effect of bubble clouds on the remote sensing reflectance and deriving the water color products with and without bubble clouds.

Photonic Spin Hall Effect based AQI sensor: Effect of concentration of $PM_{2.5}$

Lokesh Ahlawat, Kamal Kishor, Monu Nath Baitha and Ravindra Kumar Sinha

***Abstract*—The current study proposes an Air Quality Index (AQI) sensor based on the Photonic Spin Hall Effect (PSHE). It senses the changes in AQI caused by the variations in the concentration of particulate matter ($PM_{2.5}$). The layered structure utilizes the Surface Plasmon Resonance (SPR) mechanism for PSHE shifting and enhancement. The present study reports an enhanced PSHE shift of 1888 μm. The proposed AQI sensor possesses a sensitivity of 42.0349°/RIU and a Figure of Merit (FOM) of 4.2×10^6/RIU. The PSHE shift ($\delta_{r\pm}^{H}$) also shows a switching response upon change in AQI range which may serve as an indicator of high pollution level.**

***Index Terms*— Refractive Index Sensor, Photonic Spin Hall Effect, Surface Plasmon Resonance, $PM_{2.5}$, Lorentz Lorenz Equation.**

I. Introduction

A family of Hall effects (Quantum Hall Effect, Anomalous Hall Effect, Spin Hall Effect) have been discovered with some winning Nobel Prizes (Integral QHE in 1985, Fractional QHE 1998). Photonic Spin Hall Effect (PSHE) is the most recent member of the Hall Effect family[1]. The PSHE manifest itself as a spin-dependent splitting of linearly polarized light into Right Circularly Polarized (RCP) and Left Circularly Polarized (LCP) components[2]. This splitting occurs due to spin-orbit coupling upon light-matter interaction[3].

Photons carry both Spin Angular Momentum (SAM)[3] and Orbital Angular Momentum (OAM)[4]. When a linearly polarized light is incident on an optical interface SAM is not conserved perpendicular to the incident plane. Therefore, RCP and LCP components of incident light splits up transversely to conserve the total angular momentum of light[5]. The splitting of RCP and LCP perpendicular to incident plane generates External Orbital Angular Momentum (EOAM). The EOAM leads to PSHE.

The PSHE is also explained in terms of the Rytov-Vladimirskii-Berry (RVB) Phase and the Panchratnam-Berry (PB) Phase[6]. When a light beam interacts with an optical interface one of two processes takes place either the change in direction of wavevectors upon reflection/refraction or a change in polarization of incident light. The variation in the wavevector's direction of incident light generates the RVB phase whereas the change in polarization of incident light is explained based on the PB phase. Polarization and trajectory ($\vec{k}$) of light are coupled by the transverse nature of light[7]. If wavevectors are represented as radii of a sphere in the momentum space (k-space) then the electric field ($\vec{E}$) is tangent to this sphere[8]. The change in the direction of the wavevector upon reflection/transmission leads to parallel transport of the electric field vector over the sphere in k-space. This parallel transport causes no local rotation to the electric field but adds a phase to it. The phase generated between the incident and reflected electric field vector due to parallel transport is referred to as the RVB phase (ϕ_B=-σ.θ)[9]. This geometric Berry phase is opposite for RCP (σ=+1) and LCP (σ=-1) because of their eigenvalues and hence causes them to split.

The PSHE is the flag bearer of spin photonics and is sometimes confused with the Imbert-Fedorov (IF) Shift[10] as both originated from Spin-Orbit Interaction (SOI) of light and are perpendicular to the incident plane. The IF shift is an overall centroid shift whereas the PSHE is the splitting of linearly polarized light into RCP and LCP components[5].

The PSHE shift being sensitive to optical parameters finds applications in precision metrology[5], edge detection[11], optical switches[12], sensors[2], mathematical operations[11], nanophotonics and much more. Along with unique applications come obstacles. The PSHE is a nanoscale phenomenon and difficult to observe directly. This limitation was addressed by enhancing the PSHE through various techniques like evaluation of the PSHE shift at Brewster angle[13] and resonance angle[14] which gave rise to Giant PSHE (G-PSHE)[15]. The PSHE has been observed in hyperbolic metamaterials[16], metasurfaces[17], photonic crystals[18], layered structures[19], zero index metamaterials[20], Moiré surfaces[21], [22]. Seeing the universality, wide-scale applicability and integrability makes PSHE an interesting area of exploration. PSHE being sensitive to optical parameters makes it an excellent choice for sensing. Sensors based on light-matter interaction find unique applications in temperature sensing[23], biosensing[24], gas sensing[25] etc. The PSHE sensing has been utilized to distinguish cancer cells from normal cells as well as detect their concentration[26], gas sensing[27], number of graphene layer

detection[28], haemoglobin sensing[2] and protein sensing[29].

In this paper, variation of concentration of Particulate Matter is studied based on Kretchmann Configuration[2]. Particulate matter i.e., $PM_{2.5}$ and PM_{10} are a type of aerosol (solid or liquid particles in air) having diameters less than 2.5 µm and 10 µm respectively. $PM_{2.5}$ can penetrate deep into the respiratory tract reaching the lungs and entering the bloodstream. Continuous monitoring of $PM_{2.5}$ is required to minimize the exposure of $PM_{2.5}$ to the human population. The AQI[30] serves as an indicator for measuring the concentration of particulate matter in air. The AQI sensors work on the principle of scattering of light by particulate matter. The scattering of light technique is size-dependent and works well for particle sizes greater than 500 nm[31]. Another technique used for characterizing particles is based on mass. In the present article theoretical AQI sensor is proposed. It works on the principle of reflection of light from a layered structure and is independent of the size of the particulate matter. The proposed layered structure utilizes the Krestchmann configuration[2], [12] for the generation of SPR to detect different concentrations of $PM_{2.5}$ (i.e., AQI). The occurrence of PSHE shift at a unique resonance angle for different AQIs gives the proposed design a high sensitivity of 42.0349º/RIU and a high FOM of 4.2×10^6/RIU. The PSHE shift reaches a value of 1888 µm for AQI 340. The proposed sensor is also compared different plasmonic sensors in Table.3 and to different PSHE-based sensors in Table.4.

II. Design and Modelling

To observe PSHE in the proposed structure, a plane-polarized Gaussian beam having a wavelength of 632.8 nm is considered. The prism in the Krestchmann configuration, depicted in Fig. 1, is made of Boron Nitride (BN) with a refractive index of 2.1. Beneath the prism, is a layer of gold with a thickness of 48.5 nm and a complex refractive index of 0.2166 + i3.2322.

At the interface of the prism-Au layer (i.e., $x = 0$), we consider a global Cartesian coordinate frame (x, y, z) attached to the structure. The incident (x_i, y, z_i) and reflected (x_r, y, z_r) beams are considered to have a Laboratory frame coordinate system affixed to them. z_i and z_r signify the direction of propagation of the incident and reflected light respectively. The y-axis points in the same direction for the incident and reflected light beams as shown in Fig.1.

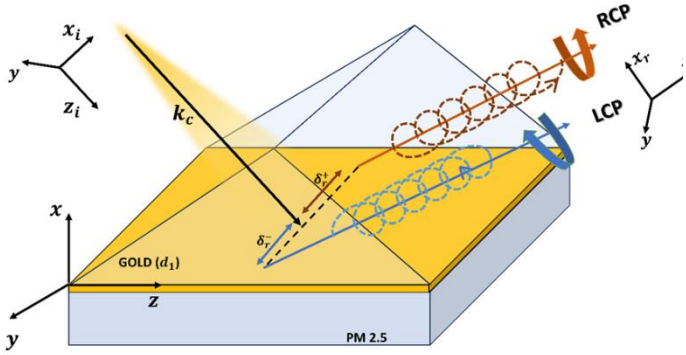

Fig. 1. **The transverse PSHE shift ($\pm\delta_r^+$) of RCP and LCP components of incident light in the Kretchmann configuration comprising of a prism, gold layer (with thickness d_1) and $PM_{2.5}$ layer as the substrate. k_c is the central wavevector of the incident Gaussian beam.**

III. Theory

A. Surface Plasmon Resonance

The leakage of light into the classically forbidden region i.e., from a higher index medium into a lower index medium is referred to as evanescent wave. When light is incident at an angle greater than the critical angle, it leads to the generation of an evanescent wave. This evanescent wave decays exponentially in the axial direction with respect to the interface of the two mediums[32]. Therefore, it can be localized up to a few hundred nanometres, which is the skin depth of the wave. This localized field generates surface selective excitations and is ideally suited for sensing applications. This fact has been utilized to study the variation of the concentration of $PM_{2.5}$ using the proposed layered structure shown in Fig.1.

The generation of evanescent waves, in the case of a dielectric-metal interface, extends into the phenomenon of SPR. The wave travelling along the metal-dielectric interface is known as the Surface Plasmon Polariton (SPP)[33], [34] and the evanescent field decays exponentially normal to the interface.

B. Photonic Spin Hall Effect

A linearly polarized electromagnetic wave is a superposition of RCP and LCP light. Therefore, the electric field vector associated with linearly polarized light can be decomposed into RCP and LCP components[2]. It can be written in the circular basis in the Ket form as:

$$\left|E_H^i\right\rangle = \frac{1}{\sqrt{2}}\left(E_{|+\rangle} + E_{|-\rangle}\right) \quad (1)$$

$$\left|E_V^i\right\rangle = \frac{i}{\sqrt{2}}\left(E_{|+\rangle} - E_{|-\rangle}\right) \quad (2)$$

where H stands for horizontally-polarized (in-plane polarization) which is same as p-polarized and V stands for vertical-polarized (out-of-plane polarization) which is same as light. The RCP and LCP Jones vectors are $E_{|+\rangle}$ and $E_{|-\rangle}$ respectively. The incident Gaussian beam is given as

$$\tilde{E}_{i|\pm\rangle} = \frac{w_0}{2\pi}\left(E_{|x\rangle} + i\sigma E_{|y\rangle}\right).e^{\frac{-w_0^2\left(k_{ix}^2+k_{iy}^2\right)}{4}}.e^{i(k_{iz}.z-\omega t)} \quad (3)$$

Upon interacting with an optical interface splits up transverse to the incident plane, where beam waist is represented by w_0. The eigenvalues of RCP and LCP are σ=±1 respectively. The x and y component of the electric field are denoted by $E_{|x\rangle}$ and $E_{|y\rangle}$ respectively. The x, y and z direction wavevectors are k_{ix}, k_{iy} and k_{iz} respectively with $k_{iz} \gg k_{ix}, k_{iy}$. The perpendicular shift in reflected light is given as:

This article has been accepted for publication in IEEE Sensors Journal. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/JSEN.2024.3412927

$$\langle \hat{y} \rangle = \frac{\langle \tilde{E}_H^r \left| \frac{i\partial}{\partial k_{ry}} \right| \tilde{E}_H^r \rangle}{\langle \tilde{E}_H^r | \tilde{E}_H^r \rangle} \quad (4)$$

where the electric field of the reflected p-polarized light is given by $\tilde{E}_H^r$. Also, $\tilde{E}_H^r$ is related to the incident Gaussian beam vector by the modified reflected Jones matrix as: -

The electric field profile associated with reflected Gaussian beam is represented as: -

$$\tilde{E}_H^r = \frac{r_p}{\sqrt{2}} \left[e^{(-ik_{ry}\delta_{r+}^H)} E_{|+\rangle} + e^{(ik_{ry}\delta_{r+}^H)} E_{|-\rangle} \right] \quad (6)$$

where,

$$\delta_{r\pm}^H = \mp \left(\frac{1}{k_0}\right) \left[1 + \frac{|r_s|}{|r_p|} cos(\varphi_s - \varphi_p) \right] cot\, \theta_i \quad (7)$$

The transverse shift of reflected p-polarized light into RCP and LCP components respectively is $\delta_{r\pm}^H$. The incident wavevector of light is k_0. The Fresnel reflection coefficients for s and p-polarized light are r_s and r_p respectively. The phase attained by the s and p-polarized light after reflection from the optical interface is φ_s and φ_p respectively. θ_i is the angle of incidence.

C. Lorentz Lorenz Equation and AQI sensing

The theoretical modelling of the proposed AQI sensor is based on the Lorentz-Lorenz equation. This equation relates the macroscopic properties of the medium i.e., refractive index and the concentration with the microscopic properties like the polarizability of the scattering particles present in the system. It serves as a bridge between the Maxwell equations and the theory of atomicity[35]. The interaction of the electromagnetic field with the dielectric medium ($PM_{2.5}$ layer in the present studies) leads to the modification of the applied field due to the polarization of the medium. The Lorentz-Lorenz equation is given as: -

$$\frac{4\pi N\alpha}{3} = \frac{n^2 - 1}{n^2 + 2} \quad (8)$$

where, N is the concentration of the particles in the dielectric medium ($PM_{2.5}$ particles for the present study), α is the polarizability and n is the refractive index of the medium.

The concentration of $PM_{2.5}$ particles and the AQI indices have been obtained from[36]. The value of α is taken as 3.75×10^{-9} m^3 (assumed to be constant throughout the range). The concentration values for $PM_{2.5}$ have been plugged into eqn. (8) for calculating the refractive index of the medium. The value of the refractive index of $PM_{2.5}$ varies between 1.3-1.8[37] and it has been taken as 1.8 for the calculation of α. Table.1 reflects the different ranges of AQI indices along with their risk assessment.

	AQI Colour Index	Concern	AQI	Air Quality Description
	Green	Good	0 to 50	Satisfactory air quality.
	Yellow	Moderate	51 to 100	Risk to people sensitive to air pollution.
	Orange	Unhealthy for Sensitive Groups	101 to 150	Risk to people sensitive to air pollution
	Red	Unhealthy	151 to 200	The sensitive group may experience serious health effects
	Purple	Very Unhealthy	201 to 300	Everyone is affected by air pollution level
	Maroon	Hazardous	301 and higher	Emergency situation

Table1. AQI colour index along with the level of risk proposed to different groups (adapted from[38])

IV. Result and Discussion

The incident light is considered to be a plane-polarized Gaussian beam, as seen in Fig.1, interacts with the layered structure. The variation in the concentration of $PM_{2.5}$ alters the refractive index of the substrate. These changes in $PM_{2.5}$ concentration are represented in terms of the AQI index as shown in Table.1. As seen from eqn. (8), an increase in the concentration of particles has a direct impact on the effective refractive index of the structure. Using eqn. (7), PSHE has been calculated for the reflected light in the layered structure for AQI classification. The generation of SPR in this layered structure plays a pivotal role in PSHE enhancement and in obtaining an excellent shift in the resonance angle.

At resonance angle, maximum absorption of incident light takes place in the proposed layered structure due to the generation of SPP and evanescent wave. This exponentially decaying evanescent wave is utilized for concentration detection of $PM_{2.5}$ near the gold layer. An increase in absorption corresponds to a decrease in the Fresnel reflection coefficient, r_p. As seen from eqn. (7), reduction in the r_p enhances the PSHE shift for p-polarized light. The Transfer Matrix Method (TMM)[15] has been utilized for the calculation of $|r_s|$ and $|r_p|$ for the proposed layered structure (Fig.1) in MATLAB.

A. SPR in the proposed structure

The proposed layered structure is depicted in 2D in Fig.2a where the uppermost cyan coloured layer depicts the Boron Nitride prism, the yellow middle layer is the metallic layer of gold and the bottom-most(grey coloured) layer i.e., the substrate has been taken as $PM_{2.5}$. Fig.2b shows the electric field profile at the Au- $PM_{2.5}$ (AQI 50) interface simulated in COMSOL. It illustrates the decaying evanescent wave normal to the Au-$PM_{2.5}$ interface. Here, the simulations depicted are for AQI 50 but similar results will be obtained for all other values of AQI owing to the same phenomenon as discussed above.

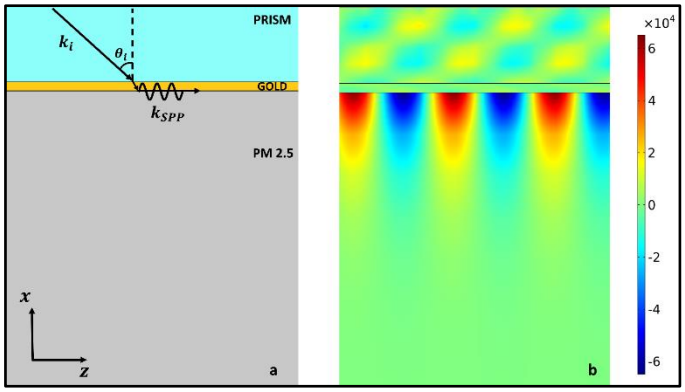

Fig. 2. **SPP at Au-$PM_{2.5}$ (AQI 50) interface for p-polarized light incident at 30.7259º**

The electric field profile corresponding to the decaying field intensity (Evanescent wave) of Fig.2b is shown in the graphical form (blue curve) in Fig.3. The exponentially decaying evanescent wave has a skin depth of 290.1 nm. The sinusoidally propagating electric field (SPP) along the Au- $PM_{2.5}$ interface (green curve) has a wavelength of 589.5 nm, which is less than the incident wavelength (632.8 nm) as expected.

SPR takes place when the horizontal component of incident light wavevector ($n_{Prism}k_0 \cos\theta_i$) matches SPP wavevector (k_{SPP}). Therefore, the Krestchmann configuration has been utilized in the present work which matches k_{SPP} ($(1.0653 \times 10^7\ m^{-1})$ for AQI 50 and horizontal the component of incident p-polarized light at resonance angle of 30.7251º.

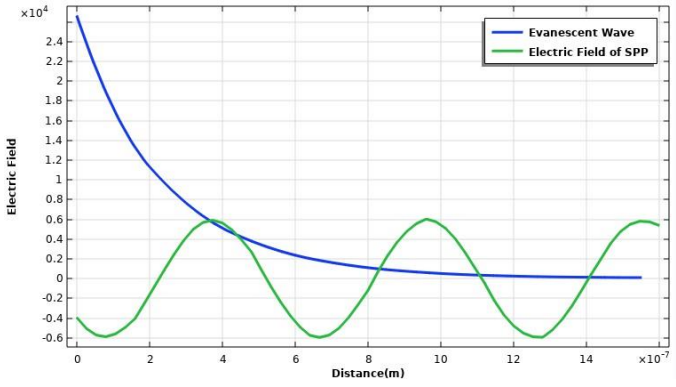

Fig. 3. **Evanescent wave and SPP for AQI 50 in the substrate region**

As shown in Fig.4, there is a sudden dip in the Fresnel reflection coefficient (r_p) because at resonance the absorption light incident on the structure is the largest. When the angle of incidence (θ_i) is greater than the critical angle (θ_C), it leads to the generation of the evanescent wave which penetrates the $PM_{2.5}$ substrates. This evanescent wave is concentrated at the Au- $PM_{2.5}$ interface at the resonance angle (θ_R). The evanescent wave interacts with the $PM_{2.5}$ substrate below the gold surface making the resonance angle sensitive to changes near the gold layer. Changes in the concentration of $PM_{2.5}$ in air lead to changes in the AQI and hence in the proposed structure's effective refractive index.

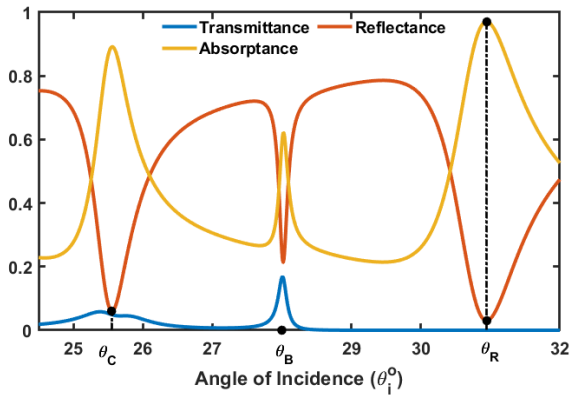

Fig. 4. **Brewster angle (θ_B), critical angle (θ_C) and resonance angle (θ_R) of proposed layered structure for AQI 50**

B. PSHE in the proposed structure

As depicted in Fig.5, the PSHE enhancement has been investigated in the green AQI (0-50) range. The shift in the reflected RCP takes place in the positive y-axis for the whole green range. This shift ($\delta_{r\pm}^H$) is different for different AQIs and occurs at different incident resonance angles owing to SPR. The maximum enhancement ($\delta_{r\pm}^H$= 251.66 µm) takes place for AQI 50 at θ_i= 30.7251º.

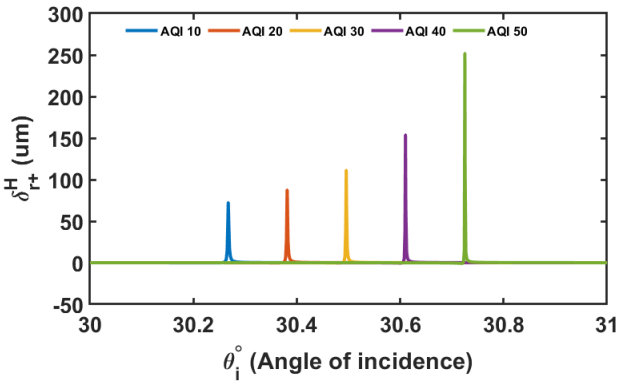

Fig. 5. **Shift in PSHE and resonance angle with change in AQI (10-50)**

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on July 01,2024 at 04:50:46 UTC from IEEE Xplore. Restrictions apply.

This article has been accepted for publication in IEEE Sensors Journal. This is the author's version which has not been fully edited and content may change prior to final publication. Citation information: DOI 10.1109/JSEN.2024.3412927

As seen from Fig.6, the PSHE shift has been investigated for the yellow AQI (60-100) range. The shift in the reflected RCP takes place in the negative y-axis for the whole yellow range. The PSHE shows a switching action in going from green AQI range to yellow AQI range. The PSHE shift ($\delta_{r\pm}^{H}$) is different for different AQIs and occurs at different incident resonance angles owing to SPR. The maximum enhancement ($\delta_{r\pm}^{H}$= 1314 μm) takes place for AQI 60 at θ_i=30.9320º.

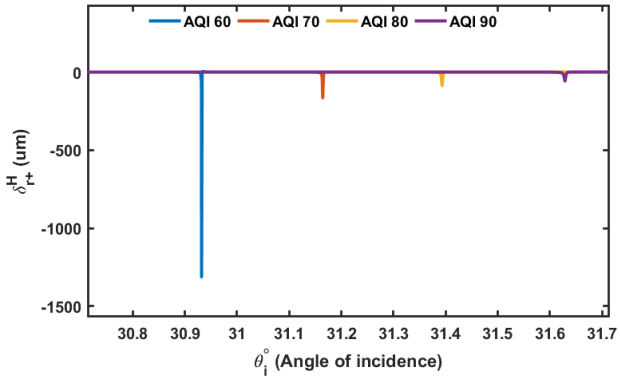

Fig. 6. **Shift in PSHE and resonance angle with change in AQI (60-90)**

As shown in Fig.7, the PSHE shift for the orange (110-150) AQI range has been evaluated. The shift in the reflected RCP takes place in the negative y-axis for the whole orange AQI range. Again, switching of δ_{r+}^{H} from positive y-axis in yellow AQI range to negative y-axis in orange AQI range has taken place. The shift in δ_{r+}^{H} is different for different AQIs and occurs at different incident resonance angles owing to SPR. The maximum enhancement (δ_{r+}^{H}= 36.59 μm) takes place for AQI 110 at θ_i=32.0501º.

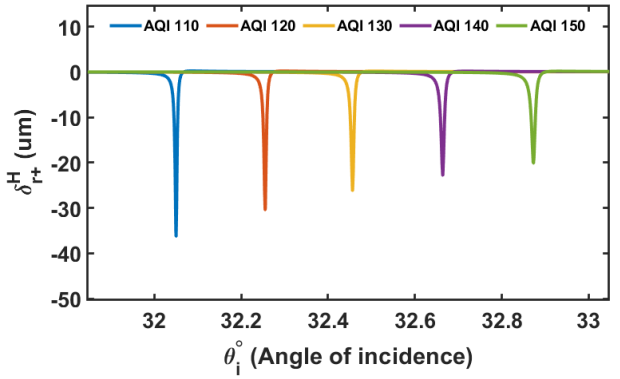

Fig. 7. **Shift in PSHE and resonance angle with change in AQI (110-150)**

The shift in PSHE, as shown in Fig.8, has been investigated for the red AQI (160-200) range. The shift in the reflected RCP takes place in the negative y-axis for the whole red range. This shift in $\delta_{r\pm}^{H}$ is different for different AQIs and occurs at different incident resonance angles owing to SPR. The maximum enhancement ($\delta_{r\pm}^{H}$= 13.38 μm) takes place for AQI 160 at θ_i=33.7794º.

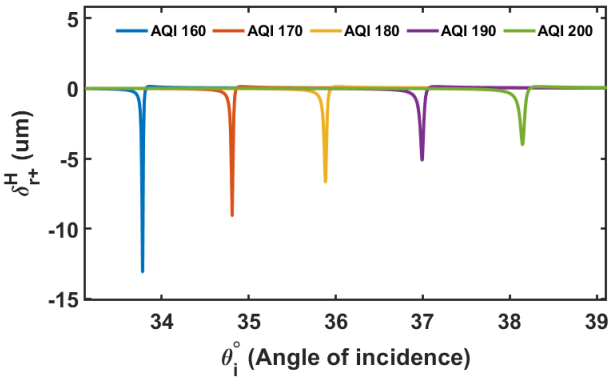

Fig. 8. **Shift in PSHE and resonance angle with change in AQI (160-200)**

As observed in Fig.9, the PSHE shift has been investigated for the purple range of AQI (210-300). The shift in the reflected RCP takes place in the negative y-axis for the whole green range. This shift in $\delta_{r\pm}^{H}$ is different for different AQIs and occurs at different incident resonance angles owing to SPR. The maximum enhancement ($\delta_{r\pm}^{H}$=3.86 μm) takes place for AQI 210 at θ_i=38.7055º.

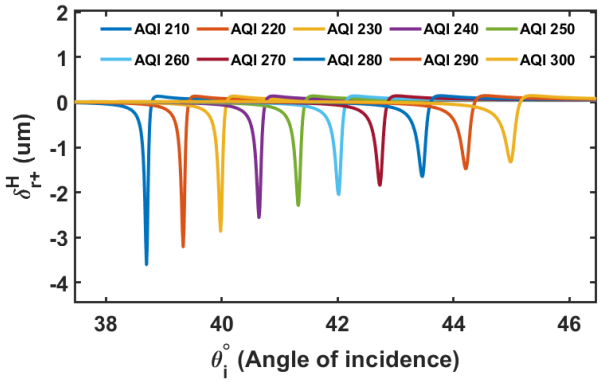

Fig. 9. **Shift in PSHE and resonance angle with change in AQI (210-300)**

As r in Fig.10, the shift in PSHE has been investigated for the maroon AQI (300+) range. The shift in the reflected RCP takes place in the positive y-axis for AQI 310-330 and in the negative y-axis from AQI 340-370. This switching in $\delta_{r\pm}^{H}$ takes place owing to modifications made in the proposed structure. The BN prism is replaced by InAs prism (n_{Prism}=3.966) and gold layer thickness is reduced from 48.5 nm to 46 nm. The modification has been made to observe the significant PSHE enhancement. After these modifications, resonance takes place at a smaller angle of incidence which is caused by increase in the refractive index of prism. The maximum enhancement ($\delta_{r\pm}^{H}$=1888 μm) takes place for AQI 340 at θ_i=23.1705º.

C. Sensitivity and Figure of Merit

Sensitivity (S)[39] for the present work is characterized by the ratio of variation in the resonance angle ($\Delta\theta_R$) corresponding to change (Δn) in the refractive index of $PM_{2.5}$ layer beneath the gold layer. The proposed sensor's sensitivity performance is evaluated using eqn. (9).

$$S = \frac{\Delta\theta_R}{\Delta n} \tag{9}$$

FOM characterizes the performance of the sensor relative to its alternatives and is calculated using eqn. (10).

$$FOM = \frac{S}{FWHM} \tag{10}$$

Here, FWHM stands for Full Width at Half Maximum.

Sensitivity of the proposed sensor is calculated from the slope of Fig.11 and is found to be 42.0349º/RIU. Table.2 summarizes the findings of the presented work. In Table.2, refractive indices for different AQIs and their PSHE enhancement and the performance of the sensor in terms of FOM is reported. AQI 60 and AQI 340 are found to have the same FWHM (i.e. 0.0001º) but different PSHE shift. The PSHE shift reaches its highest value of 1888 μm for AQI 340. The highest value of FOM (4.2×10^{6} RIU^{-1}) is found for AQI 60.

V. Conclusion

In summary, a PSHE based AQI sensor is proposed as a new class of AQI sensors. The proposed sensor utilizes Kretchmann configuration for the generation of SPR. The resonance occurs at unique angle of incidence for all AQIs. Unique resonance angle for each AQI gives our model a sensitivity of 42.0349º/RIU. An enhanced PSHE shift of 1888 μm is reported which is 12 times more than its previously reported results. The presented design possesses FOM of 4.2×10^6 /RIU which is several orders larger than other plasmonic sensors. The PSHE shift shows a switching action upon changing green AQI range to yellow AQI range and a similar switching is seen upon changing yellow AQI range to orange AQI range. This switching behaviour serves as an indicator of increase in pollution levels.

Abstract

In this study, crosslinked films of polyvinyl alcohol (PVA) were prepared using two dicarboxylic acids: saturated succinic acid (SA) and unsaturated maleic acid (MAL) as crosslinkers. The crosslinking capabilities of these acids were compared through physical, chemical, mechanical, morphological, thermal analysis, and swelling measurements to investigate their impact on the physicochemical properties of the resulting films. Attenuated total reflectance fourier transform infrared spectroscopy (FTIR) confirmed the occurrence of an esterification reaction between PVA and the dicarboxylic acids. Based on the degree of crosslinking and thermal properties, it was noted that the crosslinking achieved with maleic acid is more effective for PVA compared with succinic acid. The crosslinking degree of PVA-MAL was determined to be 6.47 times higher than that of the PVA-SA film. In terms of thermal stability, the decomposition temperature for crosslinked PVA-MAL was measured at 365.57°C, whereas PVA-SA exhibited a slightly lower decomposition temperature of 362.58°C. The findings indicate that the PVA-MAL film displays lower crystallinity and a higher contact angle (80.60°) in contrast to PVA-SA (76.0°) and PVA (30.4°). Atomic force microscopy analysis indicated that the PVA-SA film exhibited more surface roughness compared with the smoother PVA-MAL film. Also, crosslinked films displayed enhanced elasticity and resilience in comparison with neat PVA, which may be due to the difference in crosslinking density, disruption in intermolecular hydrogen bonding due to crosslinking, and incorporation of flexible crosslinkers.

Highlights

- PVA was crosslinked using SA and MAL.
- Unsaturated MAL exhibited superior crosslinking density over saturated SA.
- PVA-SA film exhibited a porous surface compared to PVA-MAL film.
- PVA crosslinked with unsaturated MAL showed higher thermal stability than SA.
- Both the films showed enhanced elasticity and resilience compared with neat PVA.

1 | INTRODUCTION

Polyvinyl alcohol (PVA) stands out as a highly promising semicrystalline polymer with a range of notable properties, including biocompatibility, water solubility, ready availability, low cost, non-toxicity, and biodegradability.[1–3] It is widely used for the production of thin films in the field of packaging,[4] drug delivery,[5] pervaporation,[6] tissue engineering,[7] and fuel cells.[8] However, PVA films face challenges due to their limited mechanical strength, and their hydrophilic characteristics contribute to poor moisture barrier properties and higher water sensitivity. To improve water resistance and material properties of PVA, a chemical modification that is crosslinking is required.[2,9,10]

Various crosslinkers are commonly utilized for this purpose, including dialdehydes,[11] boric acid,[12] genipin,[13] carboxylic acids,[14] and epoxy compounds.[15] Among them, carboxylic acids have emerged as promising crosslinkers due to their easy availability, environmental friendliness, cost-effectiveness, non-toxicity, biodegradability, and non-accumulative nature.[16,17] Furthermore, the crosslinking of PVA with carboxylic acids involves an esterification process, with water being the primary by-product. This aspect contributes to the overall environmental friendliness of both the crosslinkers and the process itself, as the reactions generate no hazardous or toxic by-products harmful to the environment. A recent review provides a comprehensive overview of the applications and properties associated with PVA crosslinked using carboxylic acids.[18]

While significant researches have been dedicated to the crosslinking of PVA using carboxylic acids, only a limited number of studies have explored the influence of their molecular structure on physicochemical properties.[19–22] These investigations revealed the crucial role played by the molecular structure of carboxylic acids in shaping the degree of crosslinking with PVA and, consequently, the resulting film properties. A comparative study involving suberic acid as aliphatic molecule and terephthalic acid as aromatic molecule revealed the greater compatibility of aliphatic molecules for crosslinking compared with aromatic ones and which in turn showed the elevated tensile strength and thermal properties.[9] In another study, the impact of carboxylic group positioning in the aliphatic chain was studied and it was found that the trans position of carboxyl group in fumaric acid exhibited enhanced crosslinking compared with maleic acid due to its ability to easily get fit in between the polymeric chains, which further influenced the pervaporation process.[22,23] Similarly, an examination of phthalic acid, isophthalic acid, and terephthalic acid elucidated that the para position in terephthalic acid proved most effective for crosslinking, whereas the ortho position was summarized as less suitable.[23] Furthermore, the research highlighted the role of carbon chain length in crosslinking, with succinic acid and adipic acid in the dicarboxylic series demonstrating that longer carbon chains create more space within the PVA matrix, facilitating increased water permeability.[21] These findings collectively emphasize the importance of considering molecular structure, carboxylic group positioning, and carbon chain length when selecting crosslinkers for specific applications to achieve desired properties in PVA films. While independent reports exist in the published literature regarding the properties of PVA crosslinked with saturated and unsaturated crosslinkers, but there is an absence of a comprehensive comparative study conducted under uniform experimental conditions.[24–27] Such a study is crucial for understanding the influence of saturated and unsaturated crosslinking agents on the physicochemical properties of PVA.

This experimental work is therefore intended to fill this gap and specifically aims to elucidate the impact of single and double bonds present in the crosslinking agents. For this investigation, two dicarboxylic acids, succinic acid (SA), and maleic acid (MAL) were chosen. Succinic acid features a saturated, linear chain containing four carbon, between, whereas maleic acid is characterized by an unsaturated chain containing four carbon atoms containing a double bond between two carboxylic acid groups. The study involves a comparative assessment of the chemical structure, hydrophilicity, swelling degree, thermal, tensile, and morphological properties of crosslinked PVA films using various techniques such as attenuated total reflectance (ATR)-FTIR, x-ray diffraction (XRD), scanning electron microscopy (SEM), atomic force microscopy (AFM), differential scanning calorimetry (DSC), tensile, swelling measurements, and sessile drop contact angle analysis. The detailed findings of these investigations are presented and correlated with the structure of the dicarboxylic acids.

2 | MATERIALS AND METHODS

2.1 | Materials

PVA of M.W. = 145,000, fully hydrolyzed was ordered from Sigma-Aldrich, USA. Dicarboxylic acids namely SA and MAL were purchased from Loba Chemie and used as received without any purification. Deionized water was used for all experiments. The molecular structure of acids is depicted in Figure 2.

2.2 | Methodology

The crosslinked PVA films were synthesized using the solution casting method, illustrated in Figure 1.

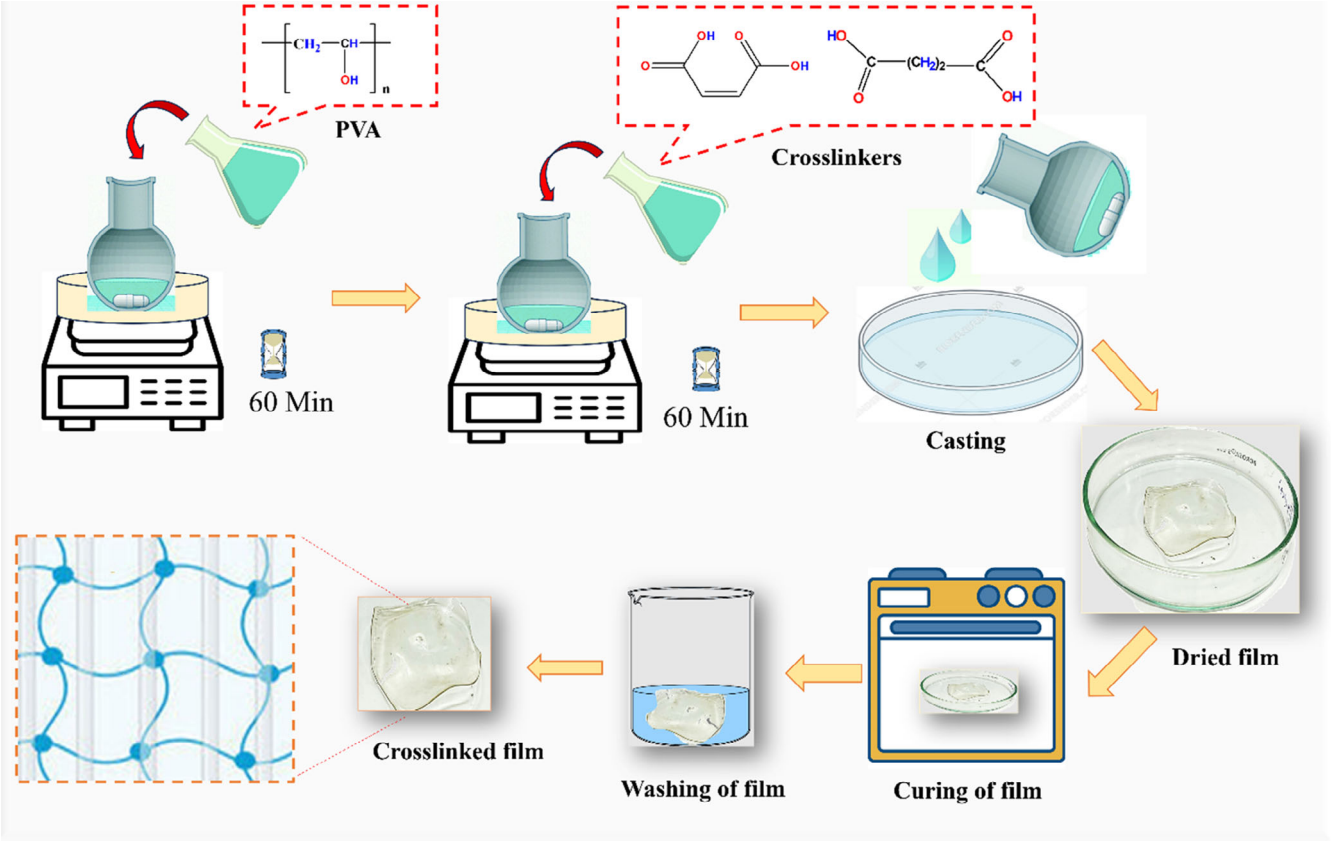

FIGURE 1 Schematic diagram of preparation of crosslinked polyvinyl alcohol (PVA) film.

TABLE 1 Compositions and formulation of crosslinked polyvinyl alcohol (PVA) films.

S. No.	Designation	PVA (mL)	Succinic acid (g)	Maleic acid (g)	Curing temperature (°C)	Curing time (Min)
1.	PVA-SA	20	0.48	-	100	90
2.	PVA-MAL	20	-	0.48	100	90

Abbreviations: MAL, maleic acid; SA, succinic acid.

Initially, an 8% w/v PVA solution was prepared by dissolving PVA in water under stirring at 80°C for approximately 1 h, ensuring the formation of a homogeneous and transparent solution. In the next step, 20 mL of the PVA solution was taken in a round bottom flask attached to a condenser, and 30% by weight of succinic acid and maleic acid, respectively, were added. The resulting solution was stirred in a water bath for 1 h at 80°C to achieve complete homogenization. The clear solution obtained was then poured into molds made of flat glass sheets for the complete evaporation of water under environmental conditions, forming the film. This process was repeated for each acid. The dried films were peeled off and subjected to curing at 100°C for 90 min to promote the crosslinking reaction. To eliminate any unreacted crosslinker, the cured films were washed several times by placing them in distilled water to remove extracted acids. The washed crosslinked films were air-dried at room temperature and subsequently stored in sealed plastic bags for further research. The films were named PVA-MAL and PVA-SA, and their composition and formulation details are provided in Table 1.

3 | CHARACTERIZATION OF THE CROSSLINKED FILMS

3.1 | ATR—FTIR spectroscopy

To confirm the presence of characteristic functional groups, ATR-FTIR analysis was conducted using the Brukeroptik Spectrum instrument. The FTIR spectra of the samples were recorded at resolution 4 cm^{-1}, and the number of scans was 48 in the range of 4000–500 cm^{-1}.

15482634, 0, Downloaded from https://4spepublications.onlinelibrary.wiley.com/doi/10.1002/pen.26806 by Delhi Technological University, Wiley Online Library on [11/06/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The obtained values were processed using Origin Lab software to generate and visualize the spectra.

3.2 | Swelling percentage and crosslinking density

Crosslinked PVA films, varying in dicarboxylic acids, were cut into 1.5 cm × 1.5 cm pieces, weighed, and submerged in deionized water (pH ∼ 7.0–7.2) at room temperature. At different intervals, the swollen films were removed from the water, weighed after gently wiping off excess water with filter paper, and promptly placed back into the water. Initially, measurements were taken hourly for the first 5 h, followed by a final measurement at the 24-h mark. The films were left in water for several additional days and were found to be stable, with the swelling percentage remaining constant as observed at the 24-h measurement. Therefore, we reported the values up to 24 h, considering it as the equilibrium value. The degree of swelling was determined using the following Equation (1).

$$\%S = \frac{W_S - W_D}{W_D} \times 100, \tag{1}$$

where, S, W_S, and W_D are the degree of swelling in percent, the weight of the films in the swollen state, and the weight of the film in dry states, respectively. The above study was performed in triplicate.

However, the swelling characteristics of the crosslinked films can be understood more by calculating parameters such as the number average molecular mass between crosslinks (M_c), crosslink density (ρ), and mesh size (ξ). To predict M_c, the Flory–Rehner equation provided below was used.[28–30]

$$\frac{1}{M_c} = -\frac{\frac{v}{V}[\ln 1 - \varphi] + \varphi + \chi\varphi^2}{\varphi^{1/3} - \frac{1}{2}\varphi}. \tag{2}$$

Here, V represents the molar volume of water ≃molar mass of water (18.1 g/mol). The Flory Huggins polymer–water interaction parameter, denoted as χ, ≃0.498. The specific volume of the polymer, v, is 0.788 cm^3/g. The polymer volume fraction in the swollen state, denoted as φ, was estimated from equilibrium swelling results using the provided relation.[29]

$$\varphi = \left[1 + \frac{d_p}{d_s}\left(\frac{m_a}{m_b}\right) - \frac{d_p}{d_s}\right]^{-1}. \tag{3}$$

To determine φ using Equation (3), the calculation involved the following parameters: mass of the film before swelling (m_b), the mass of the film after swelling (m_a), the density of the hydrogel (d_p), and the density of the solvent (d_s). The density of the films was calculated using Equation (4).

$$d_p = \frac{W}{S \times X} \tag{4}$$

In the given context, X denotes the average thickness of the film, S represents the cross-sectional area, and W corresponds to the weight of the film. The density (ρ) of the films was determined using the following equation.

$$\rho = \frac{1}{v \times M_c}. \tag{5}$$

The mesh size (ξ) was calculated using the Flory characteristic ratio of the polymer C by the following equation[28]:

$$\xi = \varphi^{\frac{-1}{3}}\left[c_n\left(\frac{M_c}{M_r}\right)\right]^{\frac{-1}{2}}.l \tag{6}$$

Here, C_n is the Flory ratio (with a value of 8.3), l represents the bond angle between the C—C bond (measured at 1.54 Å), M_r is the molecular weight of repeating units of PVA, and M_c represents the molecular weight of crosslinks.

3.3 | Water contact angle measurement

The hydrophilicity of the PVA crosslinked films was investigated by a Kruss advance 1.6.2.0 sessile drop contact angle Goniometer at ambient temperature. A deionized water droplet of 2 μL was dropped by a microsyringe onto the top surface of the films. For each film, a minimum of 5 points were measured to get the average water contact angle measurement (WCA).

3.4 | XRD analysis

To study the crystalline structure of the PVA crosslinked films, XRD patterns of all crosslinked films were recorded using the Rigaku Ultima IV diffractometer (Japan) [λ(Cu–Kα) = 1.54 A]. Scattered radiations were recorded in the range of 2θ ranging from 5° to 50° at a rate of 4 degrees/min.

3.5 | Field emission scanning electron microscopy

To observe the change in the morphology of the surface of the PVA, crosslinked films were examined using FEI Quanta 200 Field emission scanning electron microscopy

15482634, 0, Downloaded from https://4spepublications.onlinelibrary.wiley.com/doi/10.1002/pen.26806 by Delhi Technological University, Wiley Online Library on [11/06/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

(FESEM), Netherlands. The films were coated with gold–palladium and observed at a voltage of 5.0 kV.

3.6 | Atomic force microscopy

AFM images were recorded using asylum research MFP3D-BIO atomic force microscope to observe the 3-D image and to estimate the roughness of the films.

3.7 | Thermal gravimetric analysis

To observe the thermal stability and decomposition temperature of neat PVA and crosslinked PVA samples, thermal gravimetric analysis (TGA) and DTGA were recorded using PerkinElmer TGA 4000 with an N_2 atmosphere in the range of 30–700°C at the rate of 10°C/min.

3.8 | Differential scanning calorimetry

DSC analysis was performed to examine the change in heat evolved and melting point in the PVA crosslinked films. The heat flow measurement was recorded using the PerkinElmer model DSC8000 analyzer. The samples of nearly 10 mg mass of pure PVA and crosslinked PVA films were heated from 30 to 300°C at 10°C/min.

3.9 | Tensile strength

The tensile tests of the PVA and crosslinked films were performed on Zwick Roell Z010 according to ASTM D638 and ASTMD790, respectively. Three samples were tested for each set, and the mean value was reported.

3.10 | Rheological studies

Dynamic rheological studies of neat PVA and crosslinked PVA films were carried out using Anton Paar MCR-702, rheometer in torsional setup mode. Frequency-dependent data were collected at room temperature and a fixed strain ($\gamma = 0.3\%$) over a frequency range from 0.01 to 100 Hz.

4 | RESULTS AND DISCUSSION

4.1 | Formation of crosslinked films

Crosslinked PVA films, prepared at a 30% w/w concentration of SA and MAL, a curing temperature of 100°C, and a curing time of 90 min. The concentration, curing time, and temperature were determined based on preliminary studies, revealing that temperatures exceeding 100°C and curing times beyond 90 min resulted in the appearance of yellow color on the films. PVA films crosslinked with SA and MAL were obtained through an esterification crosslinking mechanism. Being difunctional acids, both SA and MAL may react with the hydroxyl groups of PVA chains, and this results in intermolecular-type and intramolecular-type ester linkages among them. Maleic acid or cis-butenedionic acid (MAL) consists of four carbon atoms. However, its molecular structure includes a carbon–carbon double bond (C═C), introducing rigidity in terms of group rotations around the C—C axis. This double bond restricts the rotation of the COOH groups about the C—C bond, restricting certain molecular motions.[31] In comparison, SA comprises only single bonds and has free rotations around the C—C axis, resulting in a comparatively more flexible structure than MAL. The best possible interaction of SA and MAL based on the information available in the literature is depicted in Figure 2. In our current study, homogeneous solutions of PVA and acids were dried at room temperature. During drying, the reactive functional groups of PVA and acid molecules aligned, potentially forming H-bonds and some of the ester bonds, as previously proposed by Larrañeta et al. and Liu et al.[29,32] To enhance the crosslinking reaction, the films were further cured by heating them in an oven at 100°C for 90 min. The supplied thermal energy during crosslinking facilitated the formation of more ester bonds between the previously aligned COOH and OH groups. Additionally, water evaporation occurred, promoting the esterification reaction in the forward direction and lowering the pH of the prepared films, thereby catalyzing esterification.[32] Washing the cured films in water helped leach out most of the unreacted acid, leaving behind ester-bonded and strongly H-bonded acids. The prepared films were further characterized by ATR-FTIR to prove the formation of ester bonds, discussed later.

4.2 | ATR—FTIR spectroscopy

The ATR-FTIR spectra and data of neat PVA, SA, MAL, and crosslinked PVA films are shown in Figure 3. From the graph, it is evident that when SA and MAL were used as crosslinkers with PVA, new peaks emerged in the FTIR spectrum at 1730 cm^{-1} for PVA-SA and 1720 cm^{-1} for PVA-MAL films. These peaks indicate that an esterification reaction has occurred between PVA and both acids. The peaks correspond to the C═O stretching frequency, confirming ester formation as a result of crosslinking.

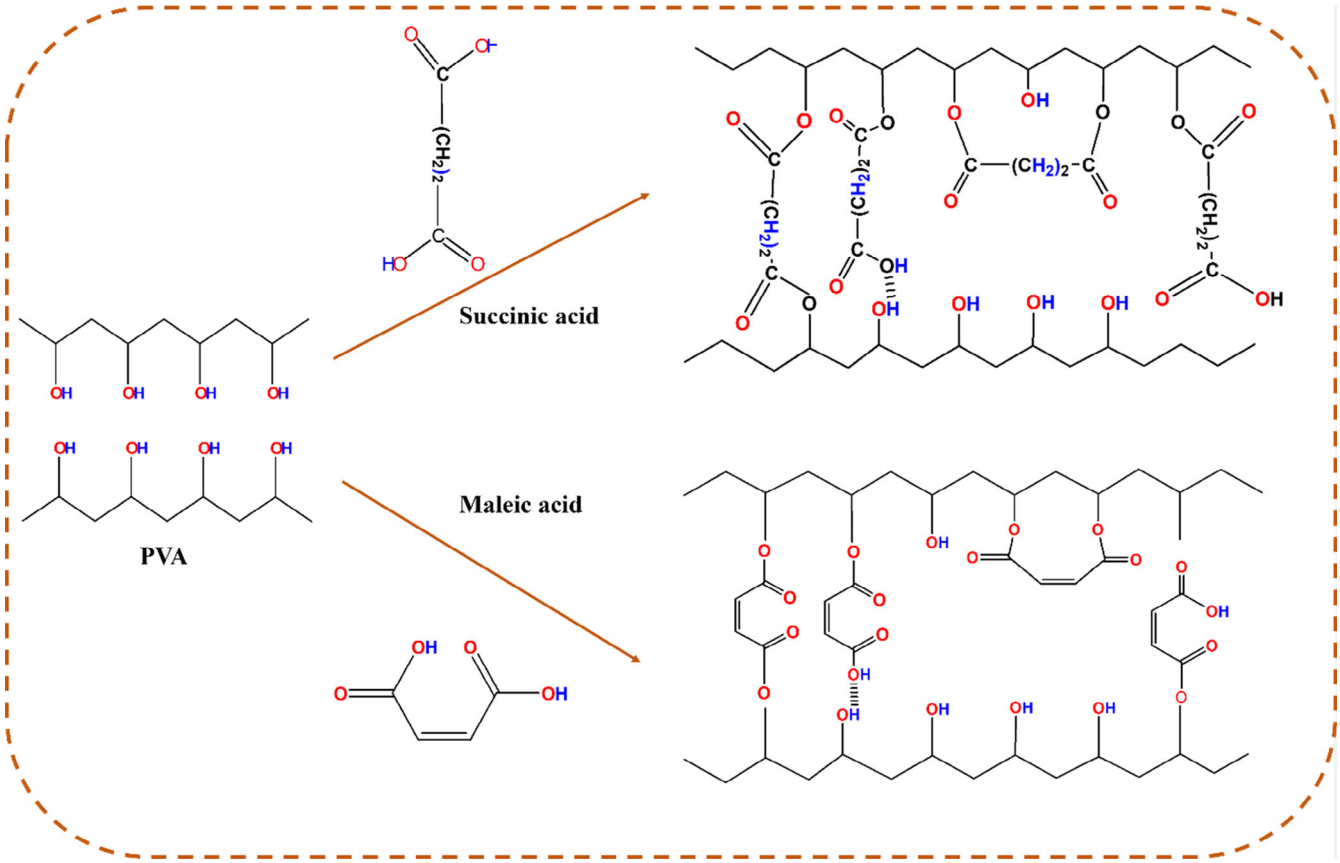

FIGURE 2 The molecular structures of the polyvinyl alcohol (PVA), crosslinkers, and schematics illustrating the modes of crosslinking with PVA.

In PVA-MAL, the C═O stretching is observed at slightly lower frequency, influenced by the conjugation with C═C bond.[33]

As the crosslinking process does not alter the existing methylene groups (1420 cm^{-1}) in the crosslinked films, the intensity of the methylene group peak remains constant. Therefore, the extent of crosslinking can be quantitatively determined using the band index method, which involves calculating the area ratio of the C═O (ester bond) peak to the CH_2 (methylene group) peak.[33] The results revealed that the ratio for the PVA-MAL film (0.63) film is higher than the PVA-SA (0.38). This observation suggests an increment in the carboxyl group content and further indicates more crosslinking in the PVA-MAL film. This could be due to the higher solubility of maleic acid than succinic acid and may be due to the cis orientation of carboxyl groups.[34]

4.3 | Swelling analysis

The swelling behavior of PVA is primarily influenced by the presence of available free OH groups that attract water molecules and the ease of diffusion of water molecules in the space present between the chains. Crosslinking of PVA with dicarboxylic acids, known for enhancing water resistance, involves the consumption of OH groups in esterification reactions. Additionally, crosslinking covalently binds PVA chains, reducing the available space for water molecules to come inside. Saturated and unsaturated dicarboxylic acids, when employed as crosslinkers, exhibit varying effects on the swelling behavior of PVA, as depicted in Figure 4. The intermolecular or intramolecular crosslinking generates numerous succinate and maleate ester groups, leading to a reduction in swelling percentage. Notably, the reduction in swelling percentage was found more pronounced in PVA-MAL compared with PVA-SA film. This may be due to the presence of double bonds present in MAL resulting in a more rigid structure of the crosslinked film and anticipated to allow less amount of water in comparison with the relatively flexible structure of SA molecule and may provide more space in between the PVA chains.

To go deeper into the analysis, the equilibrium swelling data were utilized to calculate the essential network parameters, including the average molecular weight between consecutive crosslinks (M_c), crosslinking density (ρ), and mesh size (ξ), as presented in Table 2.

15482634, 0, Downloaded from https://4spepublications.onlinelibrary.wiley.com/doi/10.1002/pen.26806 by Delhi Technological University, Wiley Online Library on [11/06/2024]. FIGURE 3 Fourier transform infrared spectroscopy (FTIR) analysis of the succinic acid (SA); maleic acid (MAL); polyvinyl alcohol (PVA); SA crosslinked film (PVA-SA); and MAL crosslinked film (PVA-MAL).

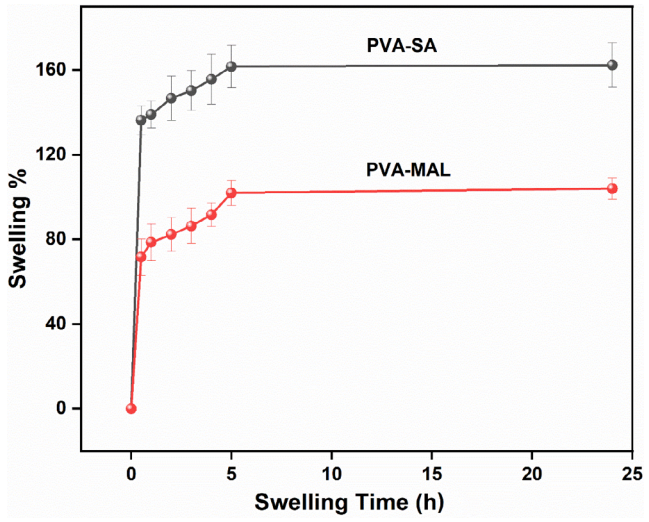

FIGURE 4 Swelling analysis of the dicarboxylic acids crosslinked polyvinyl alcohol (PVA) films; PVA-succinic acid (SA) and PVA-maleic acid (MAL).

The crosslinking density is particularly crucial in understanding swelling behavior, as a lower crosslinking density indicates greater distances between crosslinking points. Additionally, the mesh size provides insights into the available space for water molecules to permeate. As can be seen in Table 2, the average molecular weight between crosslinks and mesh size values was found proportional to the swelling capacity of the film. The M_c, ρ, and ξ values obtained for PVA-SA films were found aligned with swelling results.

4.4 | Water contact angle measurement

The WCA is an effective method for assessing the hydrophilicity/hydrophobicity of a surface. Figure 5 illustrates a reduction in the WCA of crosslinked films compared with neat PVA. The corresponding images reveal water droplets spreading differently on the film surfaces. PVA enhances water adhesion due to its polar OH groups, resulting in a lower contact angle. Crosslinking with SA and MAL acids removes numerous polar OH groups from the PVA chain, leading to higher contact angles.[22] The maximum contact angles for PVA, PVA-SA, and PVA-MAL were observed to be 30.40, 76.0, and 80.60, respectively. Through crosslinking, PVA films transition from a highly hydrophilic state to a moderately hydrophobic state.[35] These results demonstrated that PVA-MAL has the maximum contact angle, showing more effective crosslinking than PVA-SA. The above results are in agreement with FTIR and swelling results.

4.5 | XRD analysis

The XRD graphs of crosslinked films, namely PVA-SA and PVA-MAL were examined and compared with the XRD graph of pure PVA film Figure 6. PVA is recognized as a semicrystalline polymer, featuring both a crystalline phase and an amorphous matrix. The predominant peak observed at 19.28 in the XRD graph of PVA is attributed to its ordered arrangement and crystalline phase. Upon crosslinking, the characteristic peak intensity of PVA at 19.28° was noted to decrease in both PVA-SA and PVA-MAL films. This reduction in peak intensity signifies a decrease in the crystallinity of PVA after crosslinking.[23] The decrease in crystallinity is attributed to the incorporation of large dicarboxylic acid moieties into the structure through interactions with free hydroxyl groups in PVA, resulting in the formation of ester bonds. These changes not only indicate modifications in the crystalline phase of PVA but also suggest increasing molecular disarrangement in the PVA matrix. The relative percent

15482634, 0, Downloaded from https://4spepublications.onlinelibrary.wiley.com/doi/10.1002/pen.26806 by Delhi Technological University, Wiley Online Library on [11/06/2024]. FIGURE 5 Variation of contact angle of polyvinyl alcohol (PVA) and PVA crosslinked films with succinic acid (PVA-SA) and malonic acid (PVA-MAL).

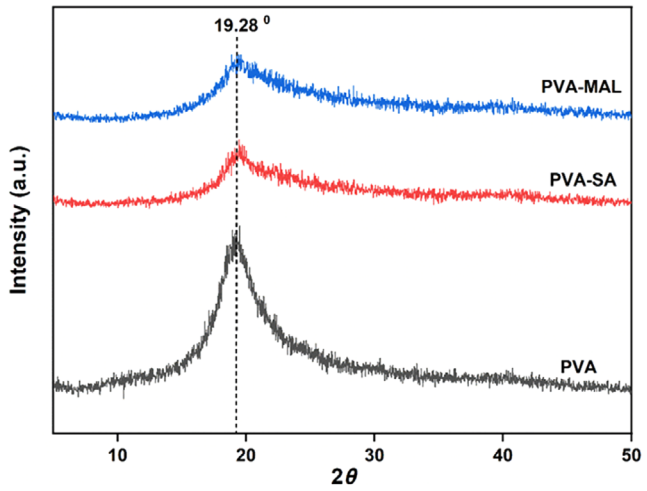

FIGURE 6 X-ray diffraction diffractograms of polyvinyl alcohol (PVA) and PVA crosslinked films with succinic acid (PVA-SA) and maleic acid (PVA-MAL).

TABLE 2 Network parameters of the crosslinked films.

Crosslinked film	φ	M_c (g/mL)	ρ (mol/cm^3)	ξ (Å)
PVA-SA	0.30	980.39	1.29×10^{-3}	95.29
PVA-MAL	0.36	151.97	8.35×10^{-3}	16.39

Abbreviations: MAL, maleic acid; PVA, polyvinyl alcohol; SA, succinic acid.

crystallinity of the crosslinked films was determined with respect to the 19.28 peak of PVA using the following equation.[21]

$$x\% = \frac{Ac}{Ac + A_A} \times 100,$$

where A_C is the crystalline area and A_A is the amorphous area. It was observed that the crystallinity of PVA-MAL (47%) film is lower compared with both PVA-SA (49%) and pure PVA (56%) films. These results regarding crystallinity are in agreement with the outcomes obtained from ATR-FTIR analysis, providing further support to the findings of the study.

4.6 | Field emission scanning electron microscopy

The surface morphology films crosslinked with succinic acid and maleic acid were investigated using FESEM images. Figure 7 illustrates the morphological distinctions between PVA-SA and PVA-MAL films. Notably, the PVA-MAL film displayed a dense structure and a higher level of uniformity and appeared homogenous and smooth which is somewhat similar to the dense layer morphology, suggesting effective dispersion of the crosslinker within the PVA matrix. By contrast, the surface of the PVA-SA film appeared rough, shrunk, and exhibited some pores. This observation signifies that, when subjected to identical processing conditions, the film morphology is significantly influenced by the structure of the crosslinker. The compact structure observed in the PVA-MAL film may be attributed to the effective interlocking of polymer chains, facilitated by the presence of a double bond in MAL.

4.7 | Atomic force microscopy

The 3-D AFM images of PVA and its crosslinked films, that is, PVA-SA and PVA-MAL were analyzed to characterize their surface properties, including roughness and height (Figure 8). The obtained data clearly reveal that the roughness parameters of crosslinked PVA films are greater than the neat PVA film. In the case of PVA, the AFM image reveals a smooth surface with low height (200 nm) and moderate average roughness. Upon crosslinking with SA and MAL, notable changes occurred. The height increases to 760 nm and 590 nm for PVA-SA and PVA-MAL films, respectively. Additionally, there is an increase in roughness values, confirming the occurrence of a chemical reaction during the crosslinking process.[36,37] For PVA, PVA-SA, and PVA-MAL, the increased R_a (average surface roughness) value follows the order of PVA (53 nm) < PVA-MAL (196 nm) < PVA-SA (245 nm). Notably, PVA-SA exhibits significantly higher roughness parameters compared with PVA-MAL also the surface displays distinct humps and grooves, suggesting the formation of voids. The above result matches the findings of SEM analysis.

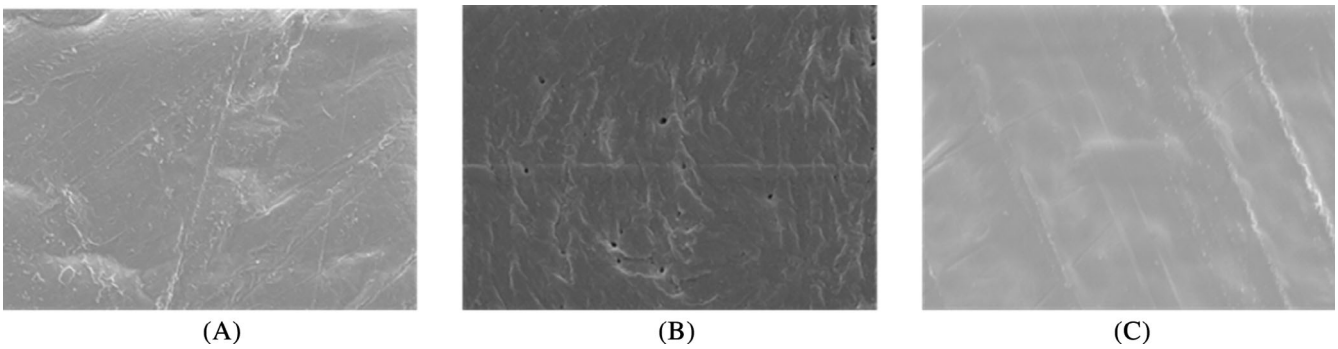

FIGURE 7 Surface field emission scanning electron microscopy images polyvinyl alcohol (PVA) crosslinked films: (A) PVA; (B) succinic acid (PVA-SA); (C) maleic acid (PVA-MAL).

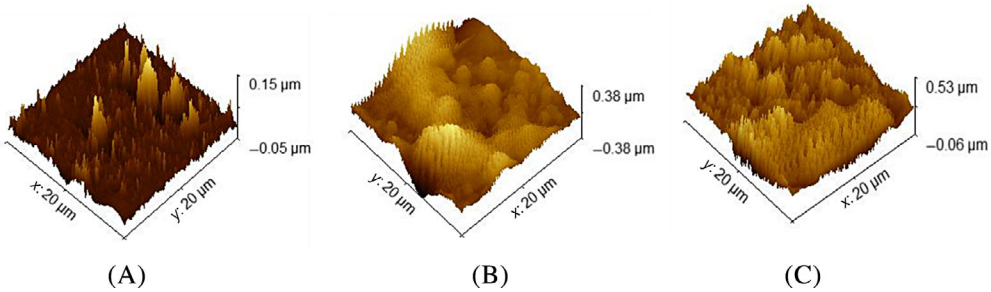
FIGURE 8 Atomic force microscopy images of polyvinyl alcohol (PVA) and PVA crosslinked films: (A) PVA; (B) succinic acid crosslinked film (PVA–SA); (C) maleic acid crosslinked film (PVA-MAL).



Also, the obtained roughness values can be further used to validate the swelling analysis. It was noted that the crosslinked films treated with MAL exhibited relatively less roughness and consequently showed less swelling. This consistency in results could be related to the fewer surface irregularities that restrict water absorption, facilitating a more controlled swelling process.[36,38]

4.8 | Thermal gravimetric analysis

The TGA and DTG thermogram of the pure PVA and crosslinked films are shown in Figure 9A.

All TGA graphs show three-stage degradation. For PVA, initial mass loss is observed due to the moisture evaporation (30–200°C, 8% loss). The main degradation starts from the second stage (263–498°C, 85.5% loss) due to the removal of hydroxyl groups in the form of water and the formation of polyene macromolecules.[5] The third stage (502–689°C, 5%) is because of the overall decomposition of the backbone of PVA.[35] For crosslinked films, the first stage that corresponds to a minimal mass loss is due to the removal of moisture and the second stage at elevated temperatures (269–481°C), which may be due to the breakage of ester linkage or decarboxylation of free carboxylic acids present in the film. The third stage should be the result of the degradation of the backbone of crosslinked films.[35] Additionally, there is a difference in decomposition rates of PVA-SA and PVA-MAL films, which can be attributed to the different crosslinking degrees. At 350°C, PVA-MAL film retains 72% of its original weight whereas PVA-SA and PVA have 71% and 52%. The PVA-MAL film also showed a slightly higher residue left at 700°C than the other two films. In the DTG analysis, Figure 9B, it was observed that the PVA-MAL film exhibited a higher maximum decomposition temperature compared with PVA-SA and PVA. The decomposition temperature for PVA film was recorded at 344.78°C, whereas for PVA-SA and PVA-MAL, the decomposition temperatures were noted at 362.58 and 365.57°C, respectively. These findings indicate that the PVA-MAL films demonstrate enhanced thermal stability compared with the PVA-SA film.

4.9 | Differential scanning calorimetry

The DSC curves of the pure PVA and crosslinked films are shown in Figure 9C.

In the DSC curves, the endothermic peak around 145°C is associated with the evaporation of bound water (T_e), representing the energy needed to vaporize water bound within the films. Another endothermic peak at approximately 229°C corresponds to the crystalline melting (T_m) of the PVA film, with the peak area (ΔH_m) in the melting region indicating the crystallinity of the

15482634, 0, Downloaded from https://4spepublications.onlinelibrary.wiley.com/doi/10.1002/pen.26806 by Delhi Technological University, Wiley Online Library on [11/06/2024]. FIGURE 9 (A) Thermal gravimetric analysis, (B) differential thermogravimetry analysis, (C) differential scanning calorimetry graphs of polyvinyl alcohol (PVA) and PVA crosslinked films. MAL, maleic acid; SA, succinic acid.

films. The addition of SA and MAL results in a reduction of the T_e value, indicative of a chemical crosslinking effect.[39,40] This implies that PVA films crosslinked with SA and MAL exhibit reduced hydrophilicity compared with pure PVA. Crosslinking induces disruption in the crystalline region, leading to an increase in the amorphous region and, consequently, a decrease in T_m.[41] Pure PVA, being semicrystalline with a more ordered structure, exhibits a higher melting temperature and a sharp endothermic curve. By contrast, PVA-MAL and PVA-SA show lower melting temperatures and broadened peaks, confirming effective crosslinking. The melting temperature (T_m) and ΔH_m values of the crosslinked PVA films are lower than those of pure PVA, following the order: PVA (229°C, 141.68 J/g) > PVA-SA (211°C, 129.77 J/g) > PVA-MAL (209°C, 21.811 J/g). This indicates that the addition of a crosslinker has diminished the overall crystallinity of the films,[40] matching with the previously discussed XRD results. Consequently, the discussion leads to the conclusion that the PVA-MAL film exhibits the highest thermal stability among the three, consistent with the trends observed in swelling and FTIR results.

4.10 | Tensile properties

The typical tensile stress–strain curves of the PVA, PVA-SA, and PVA-MAL films are shown in Figure 10. Neat PVA film exhibited higher tensile strength than PVA-SA and PVA-MAL films. The tensile strength values follow the order PVA-MAL (30.41 ± 9.02 MPa) < PVA-SA (35.85 ± 3.33 MPa) < PVA (42.77 ± 3.145 MPa).

15482634, 0, Downloaded from https://4spepublications.onlinelibrary.wiley.com/doi/10.1002/pen.26806 by Delhi Technological University, Wiley Online Library on [11/06/2024]. FIGURE 10 Typical stress–strain curve of polyvinyl alcohol (PVA) and PVA crosslinked films: succinic acid crosslinked film (PVA-SA); and maleic acid crosslinked film (PVA-MAL).

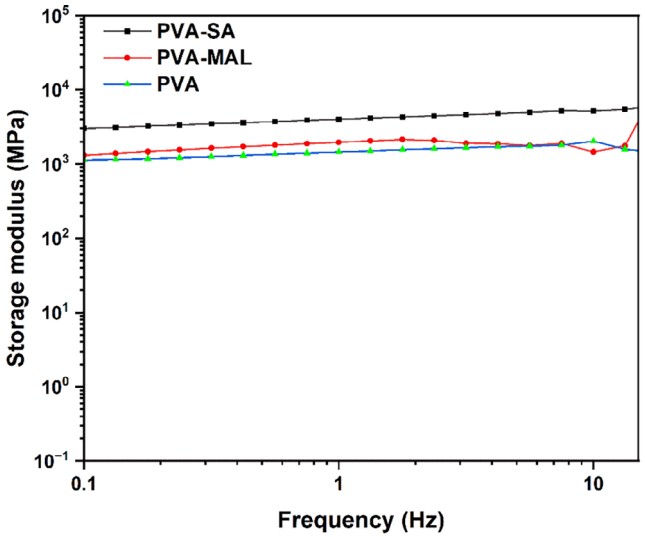

FIGURE 11 Storage modulus of polyvinyl alcohol (PVA) and PVA crosslinked films: Succinic acid crosslinked film (PVA-SA); and maleic acid crosslinked film (PVA-MAL).

The higher tensile strength observed in PVA can be attributed to its crystalline phase and inherent rigidity resulting from strong hydrogen bonding. The decline in tensile strength in crosslinked films may be linked to a reduction in crystallinity and rigidity caused by the introduction of SA and MAL as crosslinkers.[32] The inclusion of crosslinkers, significantly weakens hydrogen bonding and interrupts crystallinity, resulting in lower rigidity and the formation of amorphous regions, which further leads to the reduction in the tensile strength.[42] The higher recorded crosslinking density in PVA-MAL films may be used to explain their lower tensile strength compared with PVA-SA films. Similar results have been reported in some of the studies.[19] Notably, despite the reduction in tensile strength, the crosslinked films exhibit greater elongation when compared to the neat PVA, with % values of 145.06% ± 2.93%, 210.07% ± 4.53%, and 151.41% ± 1.09% for PVA, PVA-SA, and PVA-MAL, respectively. The increased elongation may be associated with the flexible structure of four carbons present in both crosslinkers. However, MAL, with its double bond, promotes more interlocking of chains, resulting in lower elongation for PVA-MAL compared with PVA-SA. It can be concluded that both the crosslinking density and flexibility of the crosslinker affect the mechanical properties of the crosslinked films.

4.11 | Rheological studies

Rheological measurements were carried out to determine the viscoelastic behavior of the PVA, PVA-SA, and PVA-MAL films. Frequency-dependent viscoelastic response of storage modulus (G') is shown in Figure 11. It is well known that the storage modulus of crosslinked polymeric material depends on factors like the extent of crosslinking and crystallinity.[32,42] When a crosslinker is introduced into a semicrystalline polymer, such as the PVA chain, it induces crosslinking but also affects the existing crystallinity. The obtained findings can be explained by focusing on the above two competitive factors during the crosslinking process. From the graph, it is evident that the inclusion of a crosslinker has a significant impact on the storage modulus values of PVA-SA and PVA-MAL films, which are both higher than those of neat PVA. This confirms that effective crosslinking has occurred in both types of films.

Interestingly, the storage modulus (G') of the PVA-SA film is higher than that of the PVA-MAL film, despite the PVA-SA film having a lower crosslinking density. This discrepancy can be attributed to the higher crystallinity observed in the PVA-SA film compared with the PVA-MAL film. The DSC and XRD findings support this observation by showing a greater reduction in crystallinity in the PVA-MAL film relative to the PVA-SA film. The more significant reduction in crystallinity in the PVA-MAL film effectively offsets the impact of its higher crosslinking density, resulting in a lower storage modulus when compared to the PVA-SA film.

5 | CONCLUSION

The study aimed to compare the effect of saturation (single bond) of SA and unsaturation (double bond) of maleic acid as crosslinkers on the properties of PVA

15482634, 0, Downloaded from https://4spepublications.onlinelibrary.wiley.com/doi/10.1002/pen.26806 by Delhi Technological University, Wiley Online Library on [11/06/2024]. films. The crosslinked films were synthesized without the use of any catalyst, highlighting a catalyst-free approach. The calculated crosslinking density of the PVA-MAL film was noticed to be 6.47 times higher than that of the PVA-SA film. Consequently, PVA-MAL films exhibited minimal swelling. Morphological analysis further revealed that PVA-MAL films displayed smoother surfaces than PVA-SA films, which gives an idea of better dispersion of MAL over SA as crosslinker. In thermal analysis, the PVA-MAL film demonstrated superior properties compared with the PVA-SA film. The maximum decomposition temperature recorded for maleic acid crosslinked PVA samples was 365.57°C, higher than succinic acid crosslinked PVA samples (362.58°C) and neat PVA (344.78°C).

XRD results indicated that crosslinking led to a decrease in the overall crystallinity of PVA films, resulting in lower percentages of crystallinity for both crosslinked films, whereas from DSC results, it was seen that PVA-MAL film has less crystallinity % than PVA-SA film. Additionally, a more significant reduction in hydrophilicity was observed in the PVA-MAL film compared with both PVA-SA and neat PVA films. Also, crosslinked films displayed enhanced elasticity and resilience in comparison with neat PVA, with the order of elongation being PVA-SA (210.07% ± 4.53%) > PVA-MAL (151.41% ± 1.09%) > PVA (145.06% ± 2.93%), which may be due to the difference in crosslinking density, disruption in intermolecular hydrogen bonding due to crosslinking, and incorporation of flexible crosslinkers.

Succinic acid and maleic acid crosslinked PVA films can be used for different applications such as food packaging, reverse osmosis membranes for waste water treatment, hydrophilic pervaporation membranes for hydrophobic/hydrophilic separation, fuel cell, wound dressing, drug delivery, etc.[18] The collective findings of this study emphasize that crosslinkers with double bonds can create dense networks, resulting in less swelling. Additionally, double bonds improve the thermal behavior and surface properties of PVA more effectively than single bond containing crosslinkers. These considerations are crucial for tailoring PVA films to achieve specific properties for diverse applications of PVA films but also contribute significantly to the comprehension of green crosslinking processes.

The most exigent call of the United Nations' 17 sustainable goals is to end poverty everywhere by 2030. Unlike in the past, when poverty was measured based on data collected through ground-level surveys, the new technology adopted by many developing and developed countries is to estimate the poverty index using remote sensing satellite images with the help of machine learning techniques. Our approach demonstrates the prediction of cluster wealth score and establishes the relationship between wealth score obtained from Demographic and Health Survey (DHS) data and remote sensing satellite images of India by calculating Pearson's correlation coefficient (r^2). The implementation results have been analyzed in four phases. Phase 1 comprises four regression models (RMs): Ridge, RANSAC, Lasso, and k-nearest neighbor for feature extraction from a pre-trained convolutional neural network model using daylight & nightlight images. Here, the Lasso RM outperforms the others and is best suited for predicting the wealth score. Phase 2 categorizes daylight images with DHS data, where the Lasso RM efficiently generates the cluster wealth score. Phase 3 focuses on images of specific regions of Delhi, Tamil Nadu, Maharashtra and Telangana, using the Lasso RM, as it emerged as the best predictor of cluster wealth score in the previous two phases. Phase 4 compares the results attained through our proposed model with existing results.

Keywords: convolutional neural network, Demographic and Health Survey Data, Inception V3, transfer learning.

1. Introduction

The word poverty comes from the old Latin word *pauper*, which means *poor* in English. According to the World Bank, poverty can be regarded as the deprivation of well-being, including low income and the inability to acquire the basic goods and services essential for survival with dignity. The eradication of extreme poverty in all its forms is the major goal of the world's leading organizations, such as the United Nations (UN), the World Bank, etc. The mission of eliminating poverty is rooted in all the analytical, operational and united work in more than 145 client countries. Despite significant strides in reducing extreme poverty, the rate of reduced poverty remains high in low-income countries and those affected by conflict and political instability. Progress has been marked in reducing poverty, which is the first of the world's Sustainable Development Goals (SDGs) as mentioned by the UN [1].

As India is a developing nation, poverty is declining in the country with each passing day. According to Brookings reports, it is estimated that "India may become the third-largest economy by 2030 and poverty will fall below 10 percent by 2025". The reported data also showed that India will be out of the list of top 10 countries in terms of extreme poverty by 2030 [8]. The most common method used in India to estimate poverty is typically based on income or consumption levels, and if either parameter falls below the given minimum level, the person is considered to be in debt or living below the poverty line.

The government and its numerous bodies run several programs and implement different policies to alleviate poverty. Economists and intellectuals have different opinions regarding the estimation of poverty, which has led to divergent views and confusion in the country. In India, the earlier method used to estimate poverty involved collecting survey data on the ground, which was not always accurate, was a costly method of data collection, and consumed a lot of time [2]. The most novel approach used nowadays to estimate the poverty index is using techniques such as machine learning (ML) and deep learning (DL) combined with remote sensing satellite data. This method effectively overcomes the shortcomings of traditional data collection and is able to project poverty at a large scale in developing countries. The scheme has been successfully implemented and has yielded better outcomes in several African countries like Nigeria, Uganda, Tanzania and Rwanda.

In this paper, we have effectively used a pre-trained convolutional neural network (CNN) model on daylight satellite images for predicting the wealth score of different regions. We have also observed that there is a strong correlation between predictions obtained through daylight images with nightlight images and daylight images labelled using household survey data. The contributions of this paper are as follows:

1. Exploring the role of recent developments in ML for predicting the wealth score of regions in any country. This is prerequisite for utilizing limited available resources to reduce poverty in the most affected regions. It will help in attaining the most significant SDG of the UN, emphasizing the importance of addressing this problem and exploring its solutions.
2. Analyzing CNN's performance along with four different RMs: Ridge, Lasso (least absolute shrinkage and selection operator), RANSAC (random sample consensus) and KNN (k-nearest neighbor) for identifying the correlation of wealth score obtained from household survey data with high-resolution satellite images (daylight and nightlight) of various regions of India.
3. Learning robust features from daylight images categorized using nightlight images or survey data as available, using a pre-trained Inception V3 model. Transfer learning (TL) solves the problem of availability of insufficient labeled data and reduces the computational efforts of training a network from scratch.
4. As we know, collecting household data through ground-level surveys is very expensive and time-consuming, the use of TL has been encouraged by combining a CNN with different RMs to predict wealth score utilizing satellite images, thus reducing the role of survey data.
5. Forecasting wealth score will help government policy makers and NGOs to effectively allocate resources to regions with deficiencies and improve their economic conditions.

2. Literature survey

The scarcity of data concerning livelihood, social, health and environmental issues produces unreliable information regarding economic livelihoods in the developing world [3]. Due to the low number of surveys, developing countries have very little data to make significant decisions. In contrast, developed countries have a lot of data to measure poverty. In the list of SDGs released by the UN, poverty is the first of the 17 objectives to be eradicated by 2030 [8]. Traditionally, the major source for measuring poverty was collecting data from ground-level surveys such as household consumption and wealth surveys. However, these methods were inaccurate, tedious, and costly. The living standard measurement survey (LSMS) was initially used in the context of ground-level surveys. Household expenditure was measured using LSMS approach. The limitation of LSMS surveys was that they did not provide comprehensive information needed to accurately calculate the poverty in a particular region [4, 5].

The use of mobile data and digital footprint has also emerged as a method to calculate poverty. Frequent data on societal, economic, and livelihood conditions is required to track SDGs and target poverty-related information. New technologies such as ML and data science have now evolved as new measures to predict poverty. Researchers have begun to develop these techniques to calculate poverty [6]. One of the most highly structured, easily available, and inexpensive data sources is remote sensing data, such as satellite imagery. Using satellite imagery makes it easier to minimize the data gap between actual values and predicted values. For this purpose, a CNN is trained to estimate poverty levels using satellite imagery [7, 8]. With ML techniques, it is also possible to establish the relationship of predicting poverty over several years. These techniques learn visual features from satellite imagery which indicate the poverty levels in a region.

Several experiments also suggest that poverty prediction from different and multiple parameters gives more accurate results compared to using a single parameter [9]. Object identification, image segmentation and labelling of satellite images help to identify visual features to estimate poverty. The United States Government's Landsat 7 program was used to acquire publicly available satellite imagery. The model is pre-trained on one of the datasets, and further, this model can be trained to predict nightlight intensity corresponding to daylight satellite imagery. Daytime satellite imagery can be used to estimate local per capita outcomes [4]. Features learned from one model can be used to train other models. This technique is known as transfer learning (TL). A Google Geocoding API is employed to predict the location of a place's center as well as latitude and longitude. Multi-task learning involves learning multiple tasks simultaneously by analyzing the similarities and differences among the tasks [10, 11]. The suitable input image size for a model is 1920×1920 pixels. For predicting wealth, nightlight images serve as a good proxy. Socio-economic indicators can be best extracted with the help of raw satellite images. There is a need for more frequent data that can learn features from the TL approach to monitor the range of issues covered by 17 goals and 169 targets [12]. The TL approach not only predicts the nightlight intensity corresponding to daylight satellite images but also helps in mapping the poverty level.

The ultimate goal of TL approach is to transfer the knowledge from daylight satellite imagery to the target problem for predicting nightlight intensity. TL is highly scalable and does not require human annotation. However, nightlight intensity faces difficulties in distinguishing between densely populated, poor and sparsely populated areas, making it unsuitable for estimating per capita consumption [13]. The multitask model can be used for predicting poverty and at the same time evaluating the similarities and differences among the tasks. The multitask fully convolutional model comprises convolutional layer,

ReLU activation layer, batch normalization layer, pooling layer, and a dropout layer [14].

The model is able to establish the relationship between specific graphic structures and growth factors. These features reflect the relationship between ground-truth values and predicted values. Pearson's correlation coefficient (PCC) calculation is used to assess model accuracy. Differences in the relationship between household data and remote sensed data are evident at the community level [8]. The prediction of household-level wealth in a particular area can be visualized with the help of a classification tree. To check whether the TL model improves with nightlights, 210 trials of 10-fold cross-validation were conducted. Another model to predict poverty is the Wikipedia embedding model, trained using the mean squared error loss function and Adam optimizer. The Wikipedia learning model outperforms using nightlights only [31]. The poor performance of the model is due to the limitations of the nightlight baseline. To forecast poverty predictions across years and determine their accuracy a recurrent neural network can be integrated on top of a CNN.

To revolutionize social science, remote sensing data presents new potential, especially with the night-time light dataset that provides night-time luminosity from 1993 to 2013 [17]. It evaluates the night-time light data against the rural electrification data from the 2011 Census of India. The results suggest that these night-time satellite images are accurate for estimating rural electrification. The accuracy is improved with better GIS maps, basic geoprocessing tools, and night-time luminosity aggregation [6]. The nighttime satellite images and census data were also used to correlate light intensity from images with state-wise poverty, population, GDP, and forest cover. The ARIMA model is used for forecasting the census data. The output is measured in terms of PCC with r^2 value of four states of India namely [19]:

1. Uttar Pradesh (0.68),
2. Himachal Pradesh (0.68),
3. Jharkhand (0.37) and
4. Gujarat (0.25).

The summary of literature survey is shown in Table 1. As seen in the literature survey of different countries, we conclude that wealth score of any area can be predicted with the help of satellite images such as daylight and nightlight images. There are several other methods also to predict the poverty of any area such as LSMS Surveys, Object Identification, UN Govt. Landsat's Program, Wikipedia Embedding Model, and Tracking of Mobile Call Records. Other technologies involved the use of ARIMA model. But the best among all that we have seen in the literature survey is the use of daylight and nightlight images that accurately predicts the wealth score or poverty of any area.

3. Proposed method

The Phase 1 model, presented in Figs. 1 and 2, initiates with Demographic and Health Survey (DHS) data, i.e., household data (containing records for everyone) and geographical data (DHS data linked with health and infrastructure). By processing these two files, cluster and household data are generated, which contain wealth score, cluster wealth, latitude, and longitude for different locations. The raw survey data is then used to produce the more refined cluster and household data, containing wealth score, nightlight intensity, number of households, household ID, and cluster ID. The extracted cluster data is managed to store files that hold the values of each cluster size and the values of nightlight. Daylight images are downloaded from the signed URL of the HERE Maps API, sized at 400×400 pixels using generated image coordinates. Later, the size is reduced to 299×299 pixels, and the files generated contain the downloaded dataset locations. Similarly, from the DMSP-OLS, the nightlight images are downloaded at size $43\,201 \times 18\,801$ pixels.

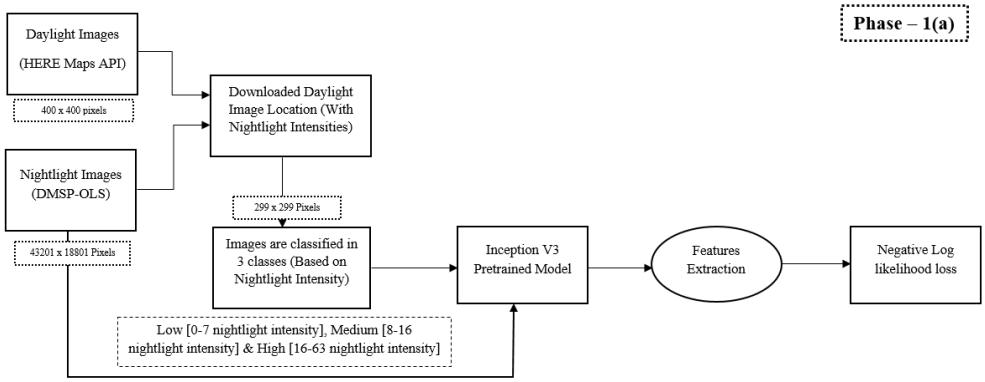

Fig. 1. Phase 1(a) for the training model with TL.

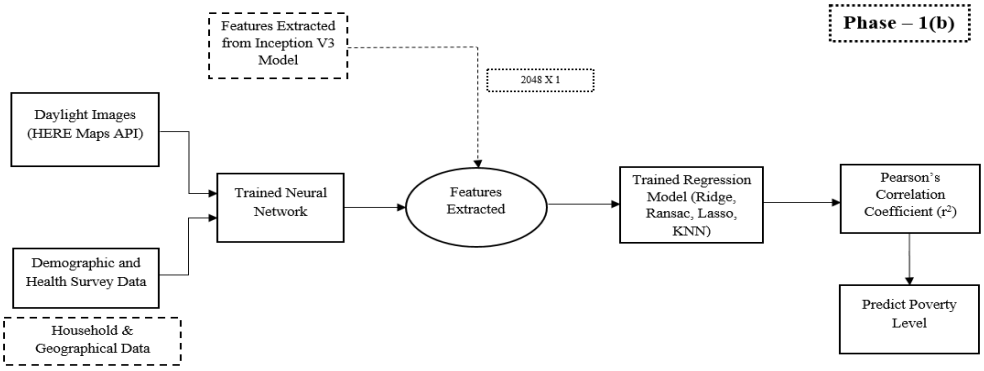

Fig. 2. Phase 1(b) for the regression model and predicting poverty.

The downloaded daylight images are then divided into three classes: low, medium, and high. With the help of the pre-trained Inception V3 model, we train our CNN that establishes the relationship between training, testing loss and accuracy. The features of satellite images are now extracted with the help of the trained model along with latitude and longitude values. Regression models such as Lasso, Ridge, RANSAC and KNN are trained using features generated from the trained CNN model and DHS data. We can use this DHS data to plot a single-panel regression value graph between model prediction and actual assets value for all four RMs. In the end, confusion matrices with normalization and without normalization are plotted for the trained model.

Similarly, in Phase 2 depicted in Fig. 3, the model initiates with daylight images only to predict poverty. These daylight images are classified and trained with the help of a pre-trained network, and different regression models are then applied to the daylight images only to predict poverty using PCC (r^2).

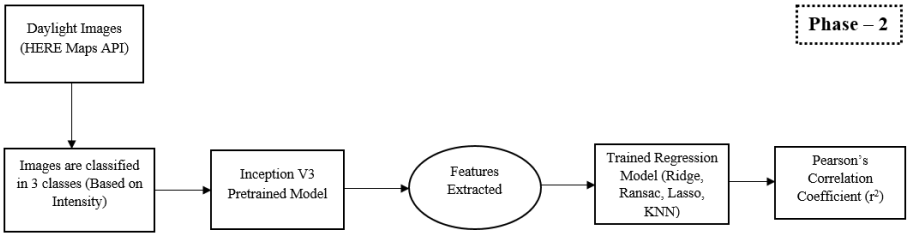

FIG. 3. Phase 2 for the training, regression and prediction of poverty.

The Phase 3 model proposes a method for the prediction of poverty, where daylight images and nightlight images of Delhi/ NCR, Tamil Nadu, Maharashtra, and Telangana regions are considered. The locations of images are identified with the help of latitude and longitude values generated. These images are then divided into three categories: low, medium, and high, based on their nightlight intensity. These images are then processed through the Inception V3 pre-trained model for feature extraction. To predict poverty in all three regions, their images will be trained with the Lasso RM using PCC (r^2).

3.1. Regression models

3.1.1. The Ridge regression model (Ridge RM). It is a technique for handling multiple regression data that suffer from multicollinearity issues. When multicollinearity occurs, least squares estimates are unbiased, but their variances are large so they may be far from the true value. By adding a degree of bias to the regression estimates, ridge regression reduces the standard errors. It is hoped that the net effect will give estimates that are more reliable. The cost function for ridge regression is shown in Eq. (1):

$$\sum_{i=1}^{M}(y_i-\widehat{y}_i)^2=\sum_{i=1}^{M}\left(y_i-\sum_{j=0}^{p}w_j*x_{ij}\right)^2+\lambda\sum_{j=0}^{p}w_j^2, \tag{1}$$

where x – the predictor variable, y – the response variable, $\widehat{y}_i$ – the predicted value of y for the i-th instance, M – the number of instances in the dataset, λ – the regularization penalty, p – the number of features, and w – the number of coefficients.

In ridge regression, the cost function is transformed by penalty term that is equal to the sum of squared coefficients multiplied by a tuning parameter λ. It puts a limitation on the coefficients in such a way that a penalty is imposed on the coefficient function if it takes large values. With ridge regression, the value of coefficients is minimized and the complexity of the model is reduced. If the value of λ becomes 0, the cost function of ridge regression reduces to the linear model cost function [27].

3.1.2. The Lasso regression model (Lasso RM). Lasso RM is very similar to Ridge regression. While Ridge regression penalizes the sum of squared coefficients (L2 penalty), Lasso penalizes the absolute value sum (L1 penalty) for non-zero coefficients. The loss function for Lasso regression is shown in Eq. (2):

$$\sum_{i=1}^{M}(y_i-\widehat{y}_i)^2=\sum_{i=1}^{M}\left(y_i-\sum_{j=0}^{p}w_j*x_{ij}\right)^2+\sum_{j=0}^{p}|w_j|. \tag{2}$$

Equation (2) differs from Eq. (1) in that Lasso regression uses the magnitude of coefficients in place of the square of coefficients. This means that many coefficients may be disregarded. Lasso RM helps in feature selection as well as reducing overfitting [27].

3.1.3. The RANSAC regression model (RANSAC RM). It is a learning technique used to estimate model parameters for observed data through random sampling. If a dataset contains both inliers and outliers, RANSAC RM finds the optimal fitting result by using a voting scheme [28].

3.1.4. The KNN regression model (KNN RM). It is used for both classification and regression problems. To predict the value of new points of data, the concept of feature similarity is used. The new value of the data point is assigned based on the closest point in the training data [29].

3.1.5. Pearson's correlation coefficient (PCC). PCC is a statistical measure used to compute the linear correlation between two variables: X and Y. The

value for PCC ranges between 1 and −1, where +1 is total positive linear correlation, 0 is no linear correlation and −1 is total negative linear correlation. PCC is calculated as the covariance of the two variables X and Y divided by their standard deviations. The formula for PCC is given in Eq. (3)

$$\rho_{X,Y} = \frac{E\left[XY\right] - E\left[X\right]E\left[Y\right]}{\sqrt{E\left[X^2\right] - \left[E\left[X\right]\right]^2}\sqrt{E\left[Y^2\right] - \left[E\left[Y\right]\right]^2}}, \tag{3}$$

where $E[X]$ – the mean of X scores, $E[Y]$ – the mean of Y scores, and $E[XY]$ – the mean of the product of paired score.

3.2. Inception V3 architecture

Inception V3 is a CNN trained on an ImageNet dataset [26] to enhance image analysis and object detection. This ImageNet Dataset is comprised of more than 14 000 000 images. The size of each input image in the dataset is 299×299 pixels. Inception V3 model is a well-designed convolutional module that produces discriminative features and reduces the number of parameters. The inception module is composed of several convolutional layers, pooling layers, and fully connected layers. This model consists of a total of 32 convolutional layers of different sizes, 5 (3 avg and 2 max) pooling layers, and 5 fully connected layers with different numbers of neurons, including 2048, 2048 and 210. The base network of Inception V3 is formed with the combination of convolutional and pooling layers [18].

The output of the Inception V3 network consists of 210 classes. The layer-wise classification of the Inception V3 model is given above in Table 2.

Table 2. Inception V3 architecture [18].

Model	nCLs	Filter sizes	nPLs	Filter sizes	nFCs	No. of neurons
Inception V3	15	1×1				
	7	3×3				
	3	1×7	3 (avg)	3×3	3	2048, 2048, 210
	3	7×1	2 (max)	3×3		
	1	1×3				
	3	3×1				

3.3. Dataset description

3.3.1. Daylight images. The daylight satellite images used in the paper are downloaded from the HERE Maps API, where the dimension of each image

is 400×400 pixels, and there are 60 000 images. The obtained latitudes and longitudes help to download the images from the HERE Maps API [10].

3.3.2. Nightlight intensities. The nightlight images are used to obtain the nightlight intensities. These nightlight images are taken from DMSP-OLS data source accessible from 1990s to the present. Each image is of size $43\,201 \times 16\,801$ pixels [4].

3.3.3. Cluster wealth score. The wealth index is calculated as an integral part of the inspection of goods. An inquiry is made into questions about the ownership of common items such as bicycles, televisions, and materials used for house construction. These parameters are normalized for each country and therefore we do not need further generalizations [5].

4. Implementation and results

We tested the same concept with a fixed learning rate (LR) value of 0.001 and 0.0001. We predicted the accuracy of the model on a pre-trained model (true and false) with these two LR values. Ridge RM was tested for predicting the accuracy and cluster value. With an LR value of 0.001 and pre-trained set to true, the best test accuracy achieved was 78.54%.

System configuration used for implementing the proposed approach is shown in Table 3.

Table 3. System configuration.

Python	3.8.1
Jupyter notebook	6.0.3
R	3.6.2
Processor	I7-9750H CPU (9th Gen)
RAM	16 GB DDR4
GPU	4GB GTX 1650

4.1. Phase 1: daylight + nightlight images

Table 4 presents the results of training the model with the help of daylight and nightlight Images. The model is trained with LR values set to 0.02, 0.42, and 0.89, and the momentum and epoch are kept at 0.9 and 20, respectively. The Inception V3 retrain model is used to train our model, and RMs are trained to predict the wealth score. As shown in Table 4, accuracy and loss analysis

Table 4. Accuracy and loss analysis for different values of learning rate.

Daylight + nightlight images						
Model	Accuracy and loss					
	Batch size = 64					
Pre-trained	Momentum/Epoch	Learning rate	Training accuracy	Training loss	Test accuracy	Test loss
True	0.9/20	0.02	99.1	0.35	80.1	1.7
		0.42	94.7	0.51	75.3	1.16
		0.89	88.7	1.16	76.9	1.11
	0.9/30	0.001	99.9	0.35	78.5	92.8
		0.0001	65.7	1.11	64.2	77.4
False	0.9/30	0.001	55.1	1.28	58.7	87.1
		0.0001	49.5	1.38	50.5	96.3

is done on different values of LR, i.e., 0.02, 0.42, and 0.89, revealing that the training test accuracies are higher when the LR value is low.

The value of test loss decreases with decreasing LR in some cases, However, this is not consistent across all LRs. We infer from the table that training and testing accuracy are higher when the value of LR is low. The results for LR values of 0.001 and 0.0001 for both pre-trained = true and pre-trained = false were also included [2].

LR is a hyper-parameter that controls the weights of the neural network with respect to the loss gradient. It defines how quickly the neural network updates the concept it has learned. Adaptive LR allows the training algorithm to monitor the performance of the model and automatically adjust the LR for the best performance. Neural networks with the help of adaptive LR can usually outperform those fixed values of LR.

4.1.1. Learning rate: 0.02. As shown in Fig. 4, the training loss gradually degraded from the 1st to the 7th iteration, then slightly curved down from the 6th to the 8th iteration before reaching a saturation state after the 9th iteration. The test loss shows frequent fluctuations until the 7th iteration, after which it starts to increase gradually and reaches saturation after the 13th iteration. On the other hand, the training accuracy gradually increased from the very first iteration until the 7th iteration and after the 7th iteration, it remained constant due to the fixed LR.

The test accuracy shows repeated fluctuations from different iterations and stabilizes from the 7th iteration without further deflection. Figure 5 presents the training of the model with the help of four different RMs: Ridge, RANSAC,

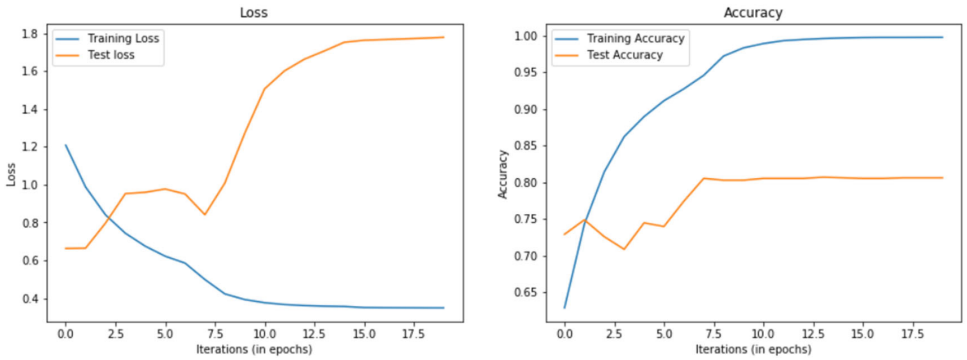

FIG. 4. Iteration vs. loss and accuracy graph.

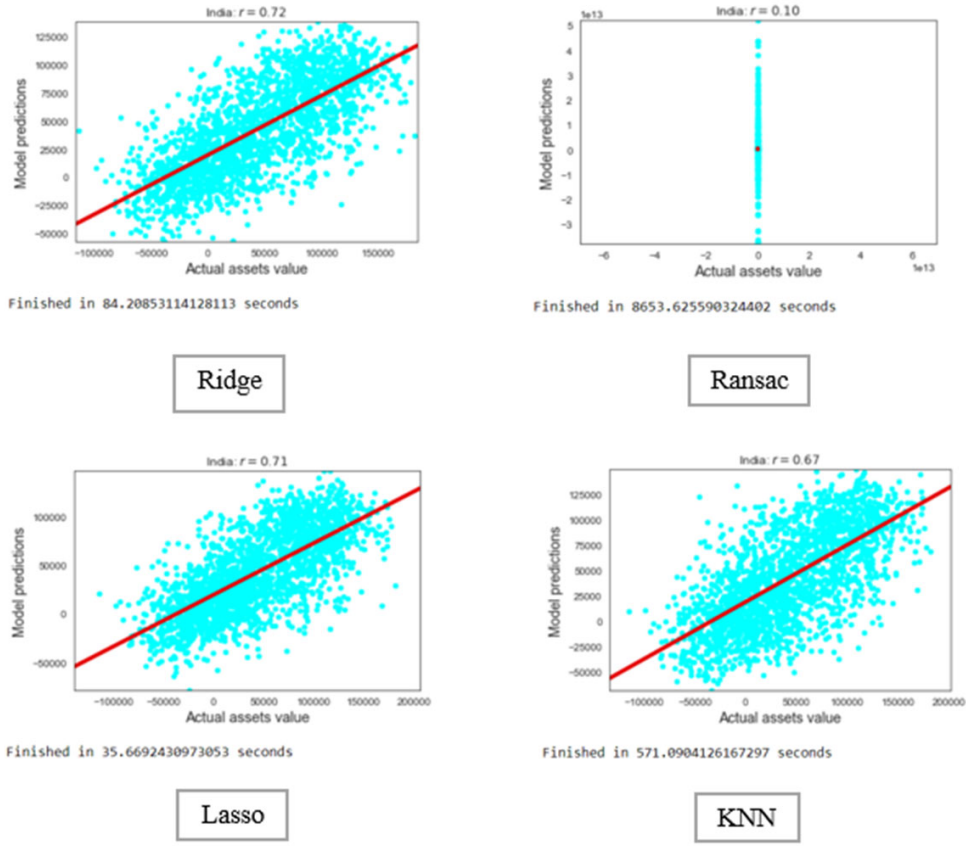

FIG. 5. Comparison of clusters with different RMs for predicting wealth score.

Lasso and KNN, where the Lasso RM requires significantly less time to train the model, achieving an r^2 value of 0.71.

For all three class labels (low, medium and high), confusion matrices with and without normalization are shown above in Figs. 6a and 6b.

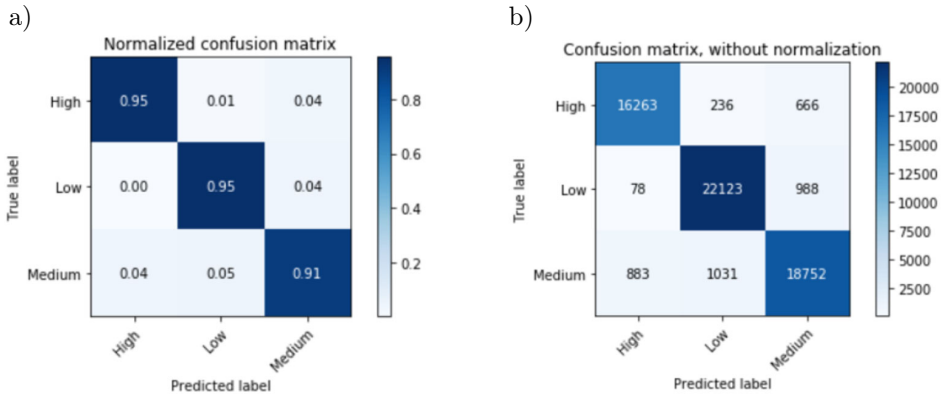

FIG. 6. Confusion matrices with standardization (a) and without standardization (b).

4.1.2. Learning rate: 0.42. As presented in Fig. 7, the training loss o starts from a very high value and then decreases after experiencing a sharp downward deflection at the 6th iteration, reaching saturation after the 11th iteration. Contrarily, the test loss starts with a value of 1 and without showing very much deflection it starts increasing very slowly after the 12th iteration. At the same time, the training accuracy starts from a very low value and exponentially increases from the very first iteration until the last iteration.

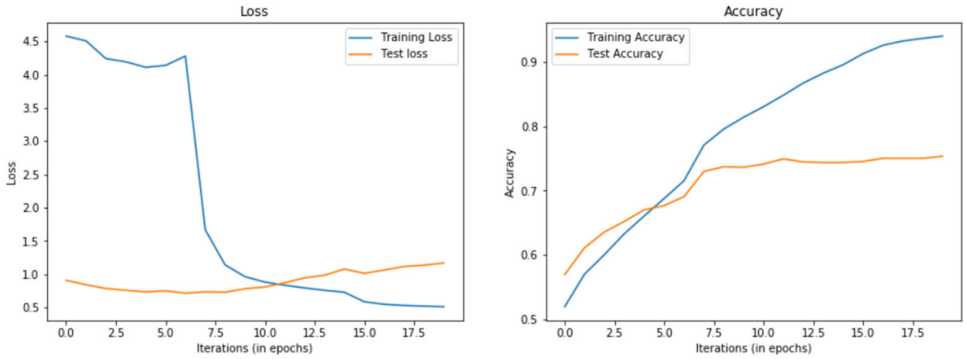

FIG. 7. Iteration vs. loss and accuracy graph.

Conversely, the test accuracy gradually increases at the beginning but shows some deflection due to the slowly decreasing LR and fixed momentum between the 5th and 10th iterations, after which the test accuracy saturates from the 11th iteration onward.

The results depicted below in Fig. 8 show the performance differences between various RM with the LR set at 0.42. The PCC (r^2) for Ridge, Lasso, RANSAC and KNN RMs is 0.62, 0.65, −0.01 and 0.61, respectively. A negative PCC here signifies that the straight-line model through the data explains $0.01^2 = 0.0001 = 0.99\%$ of the data variance, and the (–) signifies that the slope of the graph is negative.

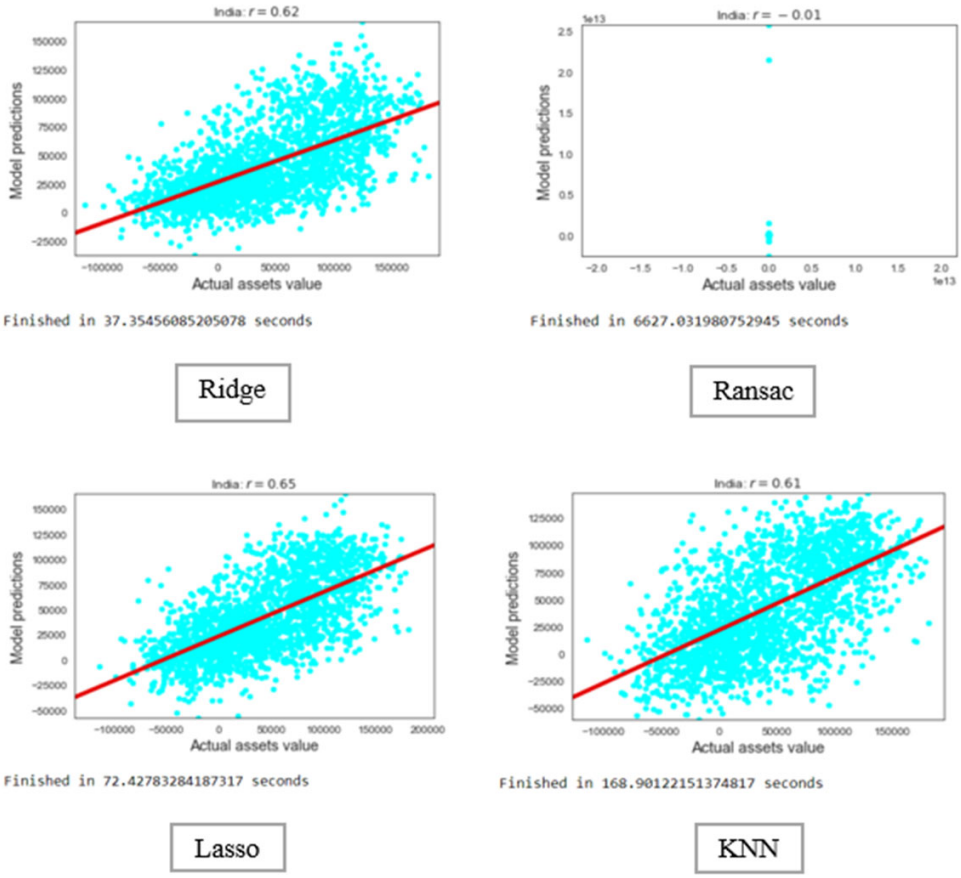

FIG. 8. Comparison of clusters with different RMs for predicting wealth score.

Here, the Lasso RM outperforms the other RMs, achieving the highest accuracy of the model with an r^2 value of 0.65.

Confusion matrices for three output classes (low, medium, and high) are shown in Figs. 9a and 9b.

4.1.3. Learning rate: 0.89. As shown in Fig. 10, the training loss deflects sharply and frequently initially, followed by sharp decrease from the 6th iteration, and reaching a saturation state after the 8th iteration onward.

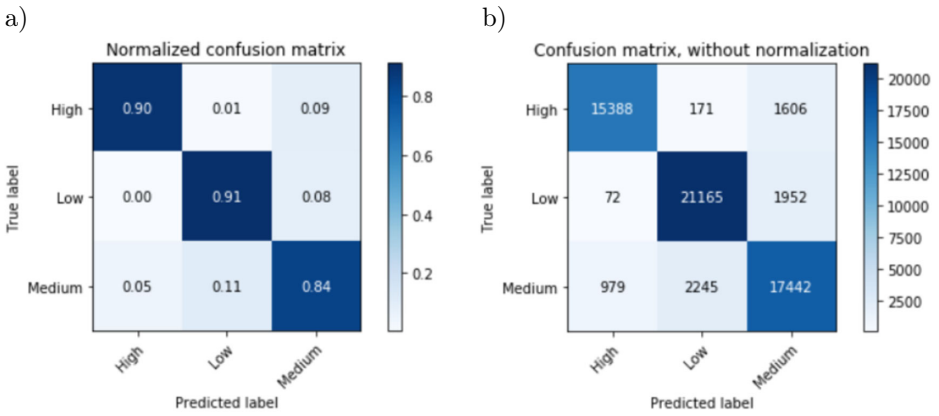

FIG. 9. Confusion matrices with standardization (a) and without standardization (b).

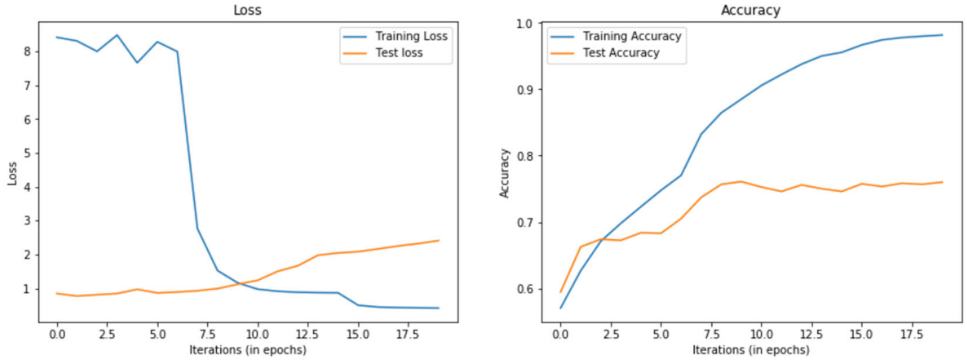

FIG. 10. Iteration vs. loss and accuracy graph.

This is due to the fast-paced training of the model with high LR of 0.89. Conversely, the test loss starts increasingly very smoothly from the very first iteration, and by the 13th iteration, it reaches a saturation state with some deflection. Additionally, the training accuracy exponentially increases from the very first iteration to the last iteration. However, the test accuracy shows repeated fluctuations with each iteration. It keeps on changing its values regardless of the fixed LR and momentum.

Figure 11 shows performance difference in four RMs with an LR value of 0.89. The PCC (r^2) is 0.64, 0.66, −0.02, and 0.61 for Ridge, Lasso, RANSAC, and KNN RMs, respectively. Among these, Lasso RM with LR 0.89 proved to be the best RM that predicted the best accuracy on the dataset provided. RANSAC RM again shows a negative correlation coefficient, indicating that an increase in the LR value leads to a decrease in the PCC value of the provided dataset.

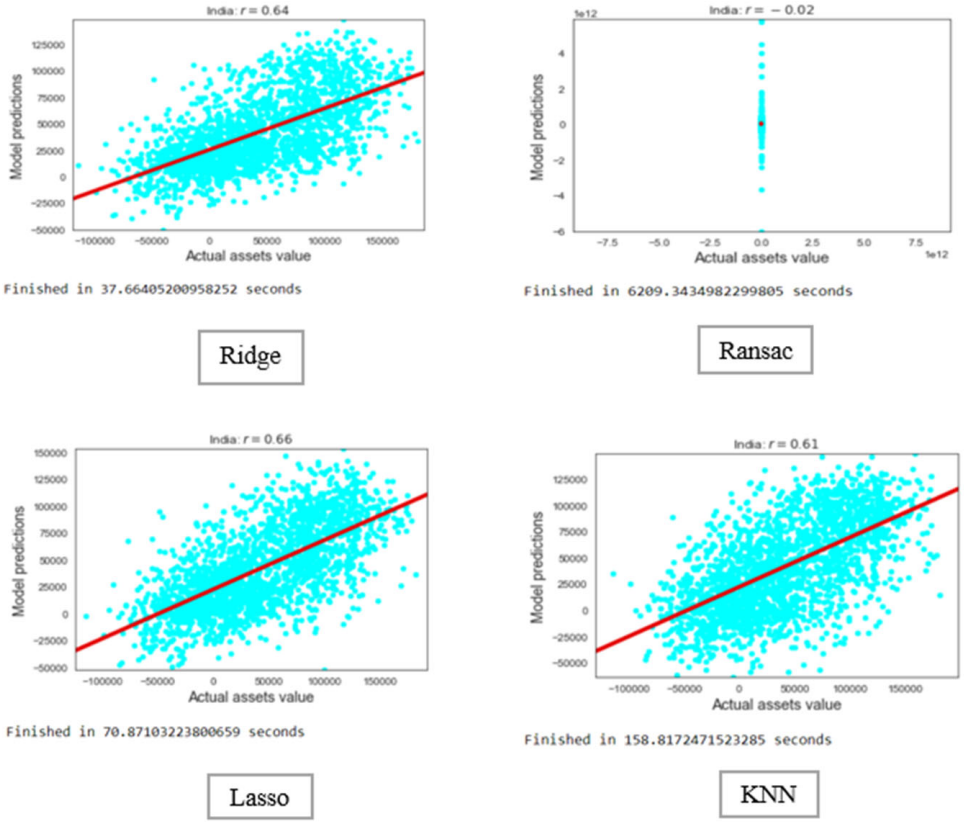

Fig. 11. Comparison of clusters with different RMs for predicting wealth score.

Confusion matrices with and without normalization are once again displayed for LR value of 0.89 and low, medium and high classes in Figs. 12a and 12b.

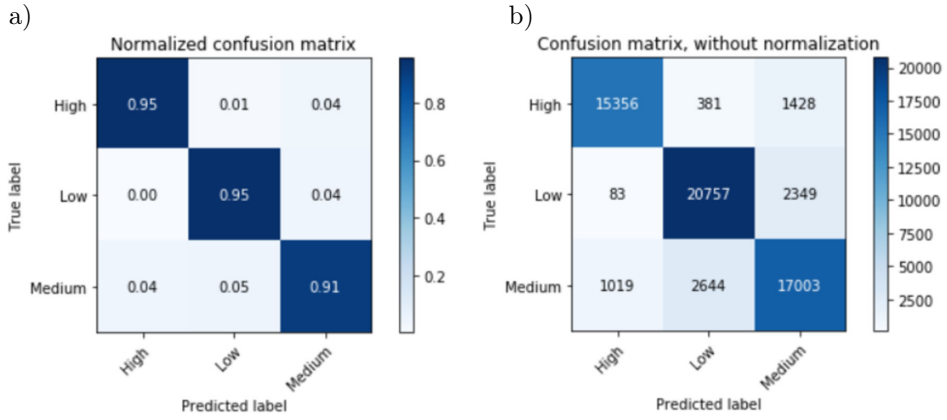

Fig. 12. Confusion matrices with standardization (a) and without standardization (b).

4.2. Phase 2: daylight images only

In this phase, the model is trained with the help of daylight images only. The locations of the images are identified with the help of latitude and longitude obtained from the Household and Geographical Survey Data. Table 5 shows the analysis of accuracy and loss with different LR values. It is observed that the training accuracy and test accuracy are highest for lower values. It is also observed that train loss decreases when we decrease LR. The momentum and number of epochs taken here are set to 0.9 and 20, respectively. The results are obtained using the daylight images only.

TABLE 5. Accuracy and loss analysis with various values of LR.

Daylight + nightlight images						
Model	Accuracy and loss					
	Batch size = 64					
Pre-trained	Region	Momentum/Epoch	Learning rate	Training accuracy	Training loss	Test accuracy
True	Delhi/NCR	0.9/20	0.02	0.958	0.294	0.777
	Tamil Nadu	0.9/20	0.02	0.967	0.471	0.841
	Maharashtra	0.9/20	0.02	0.877	0.605	0.866

4.2.1. Learning rate: 0.02. Figure 13 shows the graph plotting the training and testing loss/accuracy vs. iteration. The training loss degrades from the very 1st iteration and saturates after the 10th iteration.

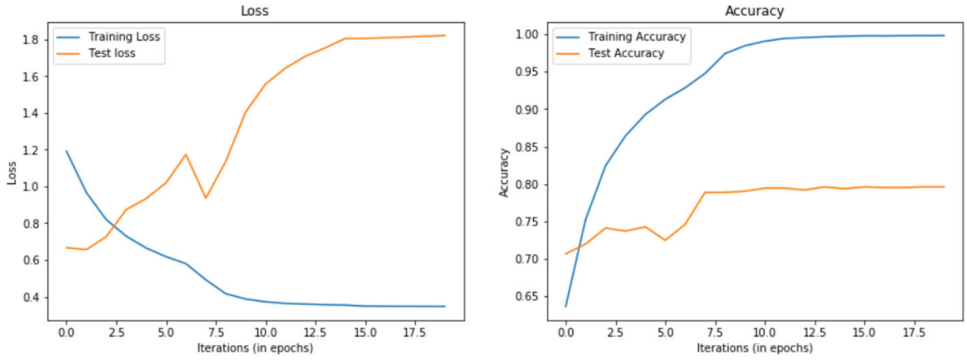

FIG. 13. Iteration vs. loss and accuracy graph.

The testing loss turns sharply at the 6th iteration and again at the 7th iteration. Next, it exponentially increases after the 7th iteration due to the LR decrement by a factor of 10. Meanwhile, the training accuracy exponentially

increases from the very first iteration and saturates as LR decreases gradually. The test accuracy shows frequent deflections before the 7th iteration and then stabilizes after the 7th iteration.

Figure 14 shows the performance comparison of four different RMs-Ridge, Lasso, RANSAC and KNN, where the Lasso RM outperforms all the other RMs with a PCC value of 0.72, completing the process in 35.42 sec. This indicates that with LR of 0.02, Lasso RM gives a better output on daylight images.

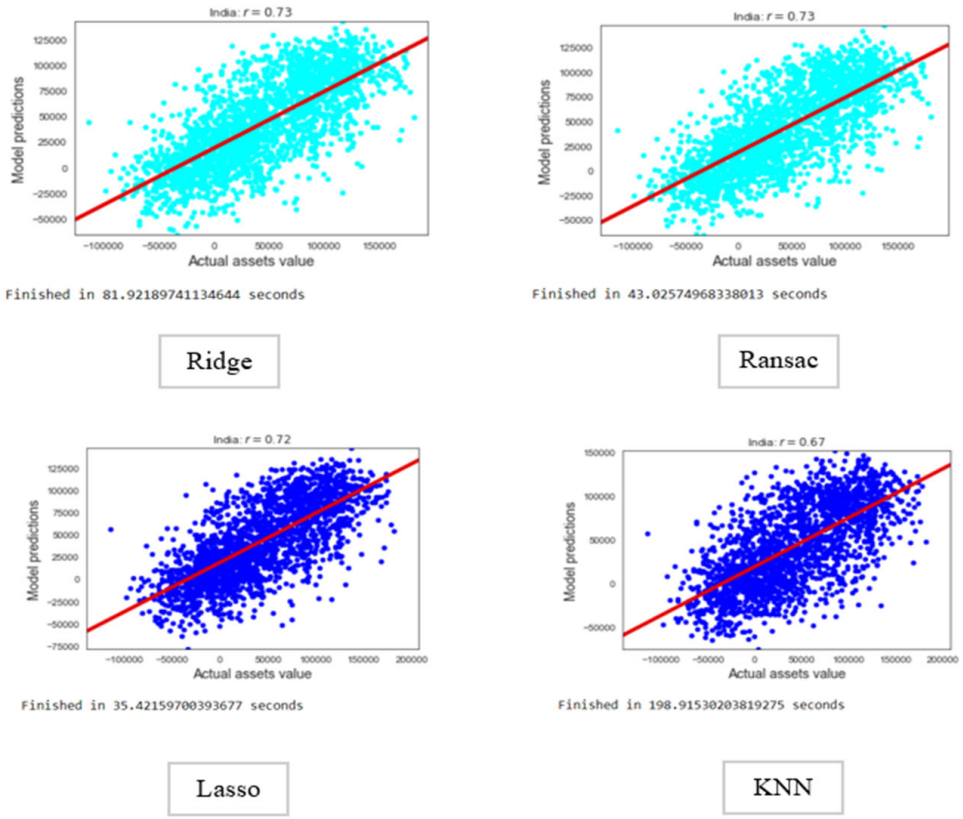

Fig. 14. Comparison of clusters with different RMs for predicting wealth score.

Confusion matrices with normalization and without normalization for LR = 0.02 are given in Figs. 15a and 15b.

4.2.2. Learning rate: 0.42. The training loss starts with a high value from the very 1st iteration and shows frequent deflections until the 6th iteration, then gradually decreases and saturates after the 8th iteration due to changes in LR. In contrast, the test loss starts with a very low value and maintains a single value throughout the iterations. Both training and testing accuracy exponen-

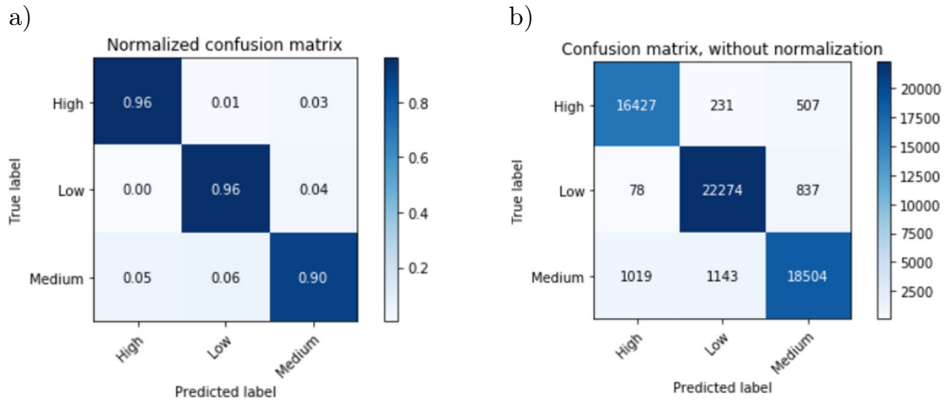

FIG. 15. Confusion matrices with standardization (a) and without standardization (b).

tially increase from the very 1st iteration and converge at the 7th iteration due to a single fixed value of LR, as shown in Fig. 16.

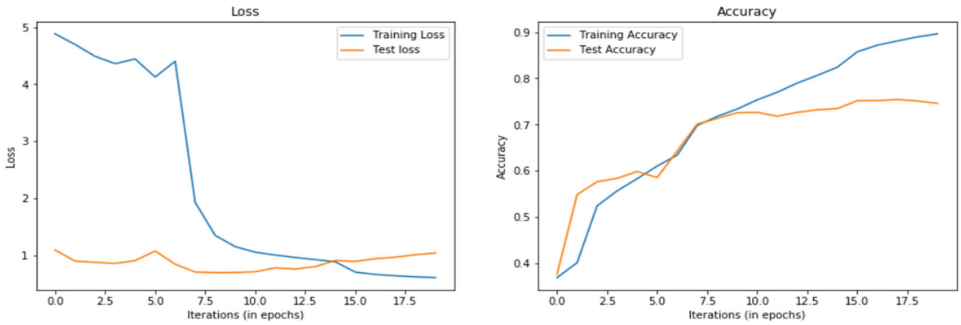

FIG. 16. Iteration vs. loss and accuracy graph.

As shown in Fig. 17, the four RMs are trained on daylight images with LR value = 0.42. Here, with this LR value, the RANSACRM outperforms all three models with an r^2 value of 0.62 and a total processing time of 161.7 sec, which is comparatively faster than the other three models (Ridge, Lasso and KNN).

Confusion matrices with normalization and without normalization for LR = 0.02 are given in Figs. 18a and 18b, respectively.

4.2.3. Learning rate: 0.89. The training loss, shown in Fig. 19, demonstrates a slight transformation at the 2nd iteration before exponentially falling after the 6th iteration and reaching saturation after the 8th iteration due to the higher LR value. Consecutively, the test loss remains constant throughout all iterations. Both training accuracy and testing accuracy start increasing simultaneously from the 1st iteration, and have the same value from the 3rd iteration to the 6th

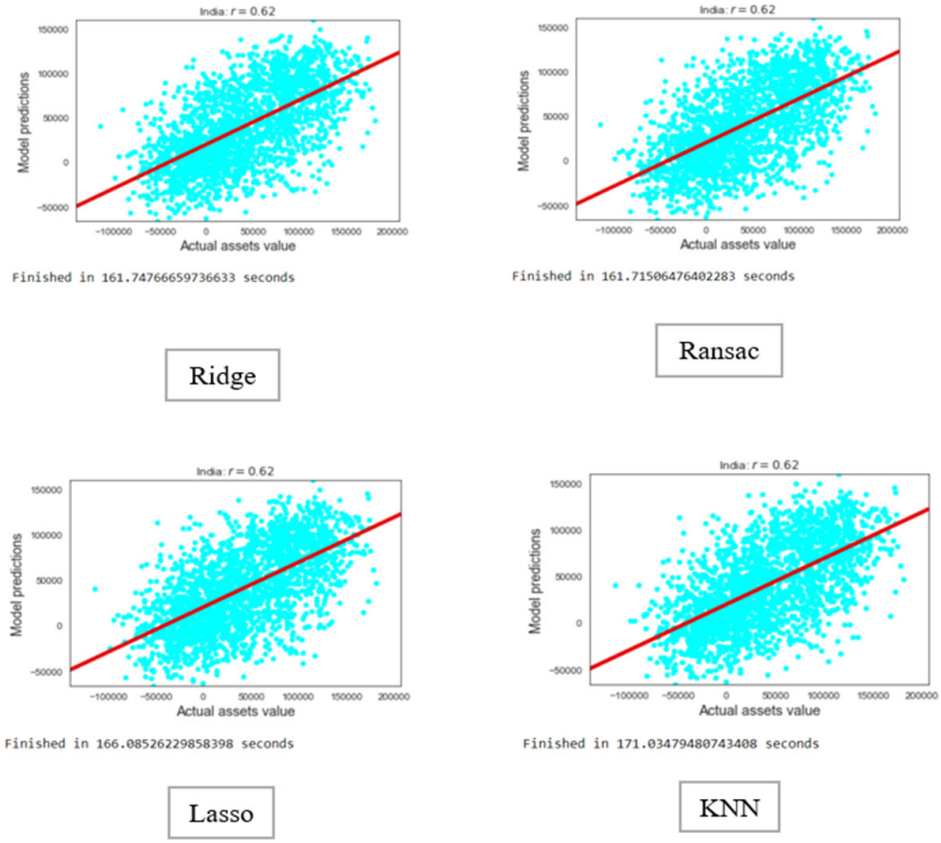

Fig. 17. Comparison of cluster with different RMs for predicting wealth score.

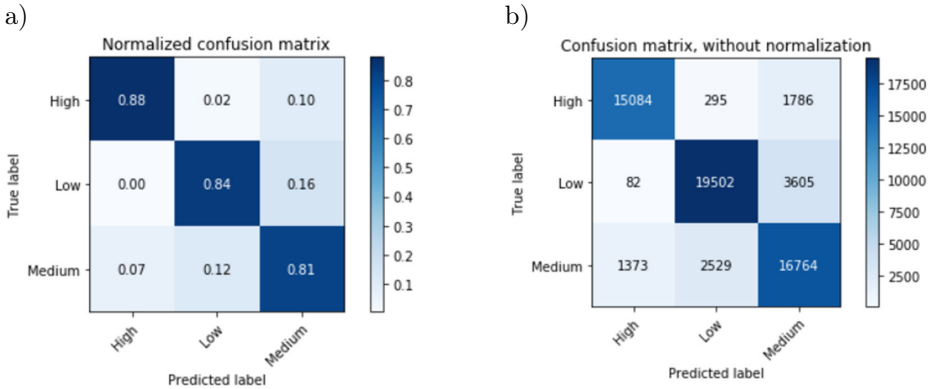

Fig. 18. Confusion matrices with standardization (a) and without standardization (b).

iteration, after which training accuracy increases rapidly while testing accuracy saturates from the 6th iteration.

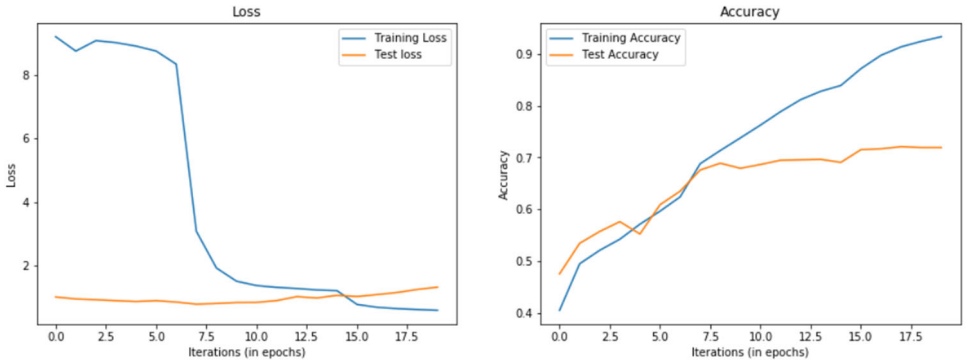

FIG. 19. Iteration vs. loss and accuracy graph.

The four regression models trained on daylight images are shown in Fig. 20, which clearly identifies that Lasso RM with an r^2 value = 0.63 is the best regression model for estimating PCC. Although the other TMs perform better at some points, Lasso RM predicts the coefficient with less processing time and fewer coefficient values.

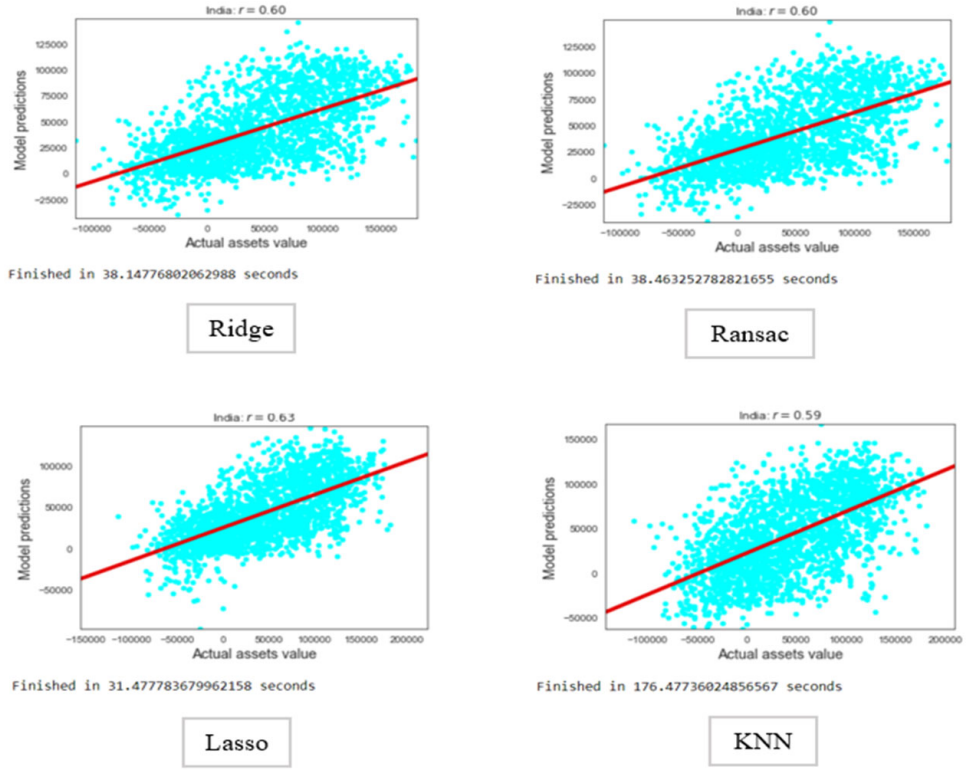

FIG. 20. Comparison of cluster with different RMs for predicting wealth score.

Confusion matrices with normalization and without normalization for LR = 0.02 are given in Figs. 21a and 21b, respectively.

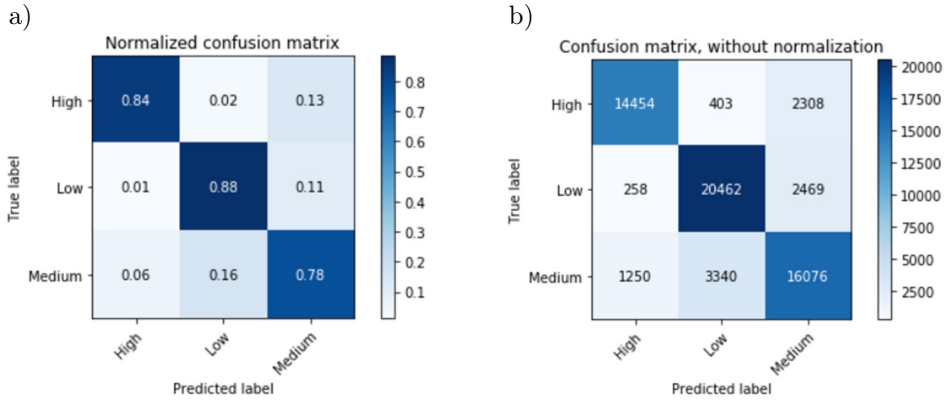

FIG. 21. Confusion matrices with standardization (a) and without standardization (b).

4.3. Phase 3

Table 6 shows the accuracy and loss analysis of training/testing conducted on daylight and nightlight images in the regions of Delhi/NCR, Tamil Nadu, and Maharashtra. The results are obtained using a single value of LR = 0.02, and the test accuracy for Delhi/NCR, Tamil Nadu, Maharashtra, and Telangana is 77.7, 84.1, 86.6 and 66.6, respectively.

TABLE 6. Accuracy and loss analysis for different regions.

Daylight + nightlight images							
Model	Accuracy and loss						
	Batch size = 64						
Pre-trained	Region	Momentum/ Epoch	Learning rate	Training accuracy	Training loss	Test accuracy	Test loss
True	Delhi/NCR	0.9/20	0.02	0.958	0.294	0.777	1.06
	Tamil Nadu	0.9/20	0.02	0.967	0.471	0.841	1.21
	Maharashtra	0.9/20	0.02	0.877	0.605	0.866	0.675
	Telangna	0.9/20	0.02	0.672	1.01	0.666	0.988

4.3.1. Delhi/NCR region (daylight + nightlight images). In this phase, we focus particularly on predicting poverty in the Delhi/NCR, Tamil Nadu, and Maharashtra regions of India. We filtered the images of these regions with the help of latitude and longitude values and trained the model for prediction with the help of the Lasso RM because it gave the best output with less time and

less coefficient value when trained with both daylight + nightlight images, as well as with daylight images alone. Sample images of the Delhi/NCR region are presented in Figs. 22 and 23.

FIG. 22. Sample image 1 [10].

FIG. 23. Sample image 2 [10].

The model is trained with the help of the Inception V3 pre-trained model with LR = 0.02, and momentum and number of epochs are kept at 0.9 and 20, respectively. The test accuracy of the model was determined to be 77.7%. Features extracted from the model were passed on to the and a comparison was made between PCC and DHS data.

Figure 24 presents the graph of training/testing loss and accuracy against iterations, where the training loss decreases exponentially until the 7th iteration before the saturation due to the constant LR value and parameters involved in the pre-training model, By contrast, the test loss shows frequent deflections until the 8th iteration and saturates after the 9th iteration. Training accuracy increases exponentially and saturates after the 3rd iteration, while test accuracy sharply increases until the 2nd iteration and saturates after the 7th iteration.

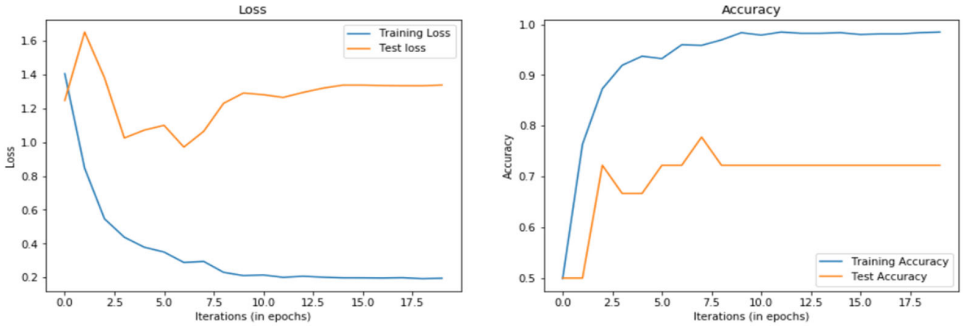

FIG. 24. Iteration vs. loss and accuracy graph.

The trained model is passed to the Lasso RM, which predicts PCC as 0.69 and takes 37.28 seconds. The prediction of the result is fairly accurate, considering

that cluster locations of DHS have eruption fused, upholding the invisibility of the survey in Fig. 25.

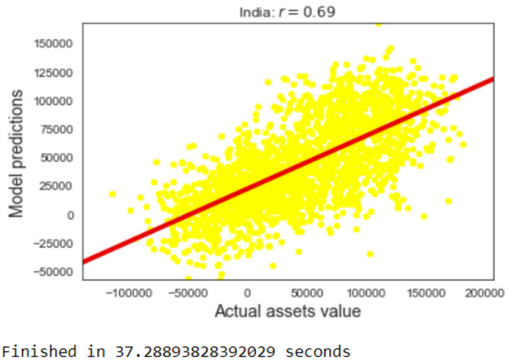

Fig. 25. Clusters for prediction of wealth score on daylight images.

Confusion matrices for the Delhi/NCR region (daylight + nightlight images) for low, medium and high classes are shown in Figs. 26a and 26b.

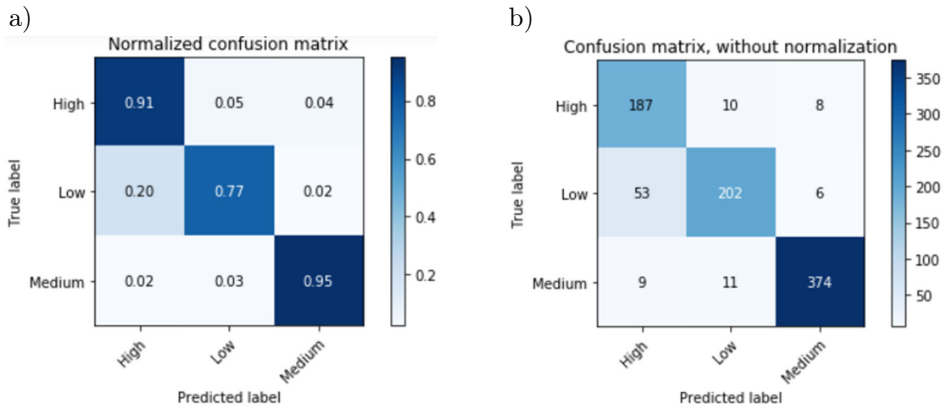

Fig. 26. Confusion matrices with standardization (a) and without standardization (b).

4.3.2. Tamil Nadu region (daylight + nightlight images). Sample images of the Tamil Nadu region are provided in Figs. 27 and 28.

As shown in Fig. 29, both test loss and training loss start with the same magnitude due to a fixed value of LR and momentum value, and the test loss shows frequent and sharp deflections until the 13th iteration before coming to a saturation state. The training loss continuously decreases with each iteration and saturates after the 12th iteration. The test accuracy with initial iteration shows very sharp deflection and then stabilizes during the iterations before finally saturating after the 13th iteration. The training accuracy gradually increases with each iteration.

FIG. 27. Sample image 1 [10].

FIG. 28. Sample image 2 [10].

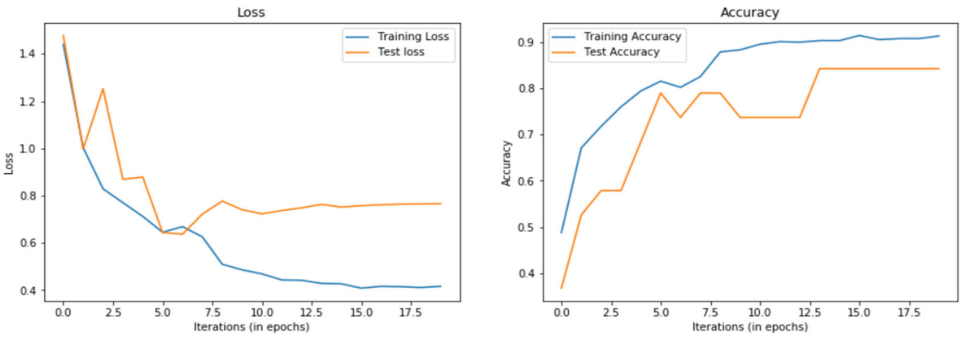

FIG. 29. Iteration vs. loss and accuracy graph.

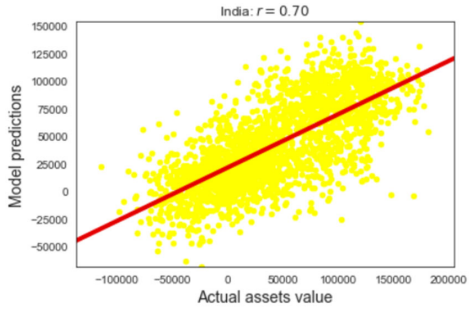
The Lasso RM predicts PCC as 0.70 and takes 36.10 seconds. The prediction is quite accurate, considering that cluster locations of DHS have eruption fused maintaining the survey's invisibility, as shown in Fig. 30.



```
Finished in 36.107677936553955 seconds
```

FIG. 30. Clusters for prediction of wealth score on daylight images.

Confusion matrices for the Tamil Nadu region (daylight + nightlight images) for low, medium and high classes as shown in Figs. 31a and 31b.

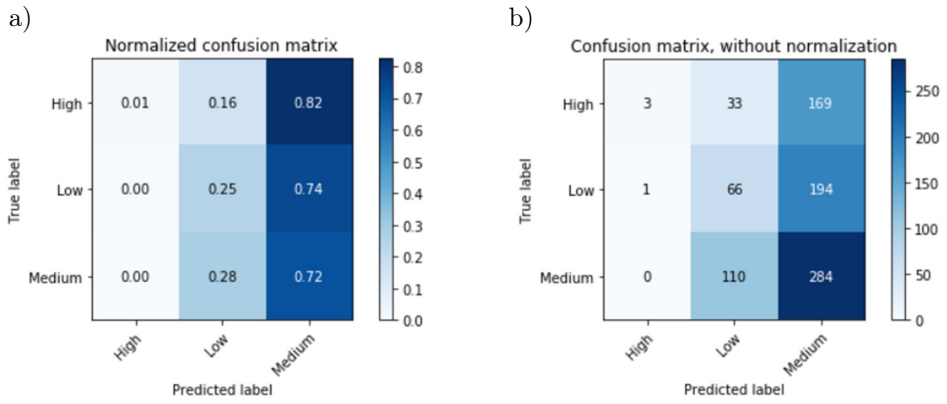


Fig. 31. Confusion matrices with standardization (a) and without standardization (b).

4.3.3. Maharashtra region (daylight + nightlight images). The third module deals with predicting the poverty index in the region of Maharashtra. Sample images of the Maharashtra region are given in Figs. 32 and 33.

Fig. 32. Sample image 1 [10].

Fig. 33. Sample image 2 [10].

As shown in Fig. 34, the test loss starts with a low value and exhibits sharp deflection from the 2nd to the 4th iteration before saturating after the 8th iteration. The training loss starts with a high magnitude and decreases gradually before coming to a saturation state after the 10th iteration. Test accuracy shows sharp variations before the 8th iteration and saturates after the 8th iteration. Training accuracy gradually increases with each iteration and shows no deflection after the 3rd iteration.

The model for the Maharashtra region is trained with Lasso regression, which predicts the value of r^2 as 0.69 and takes 76.10 seconds. The prediction is quite accurate considering that cluster locations of DHS have eruption fused that maintains the invisibility of the survey, as shown in Fig. 35.

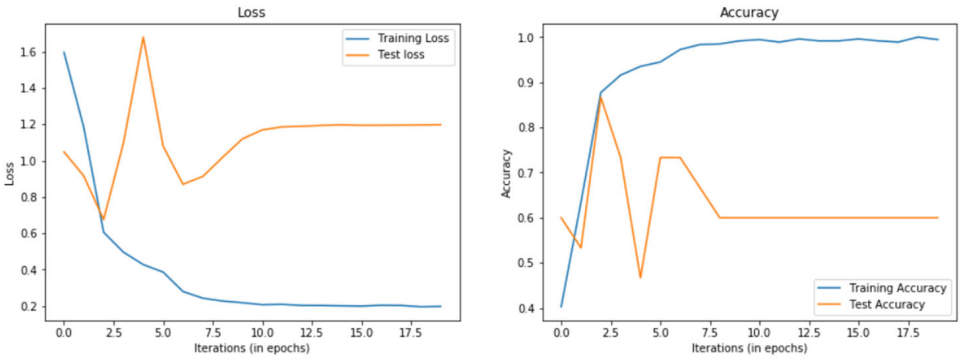

FIG. 34. The graph of iteration vs. loss and accuracy.

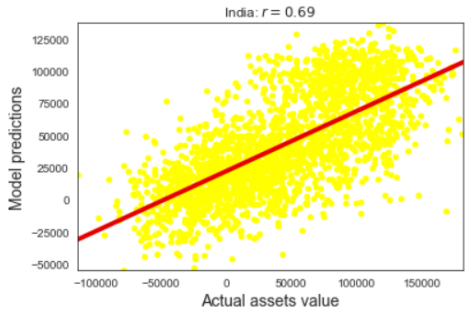

```
Finished in 76.10032796859741 seconds
```

FIG. 35. Clusters for prediction of wealth score on daylight images.

Confusion matrices for the Maharashtra region (daylight + nightlight images) for low, medium and high classes are shown in Figs. 36a and 36b.

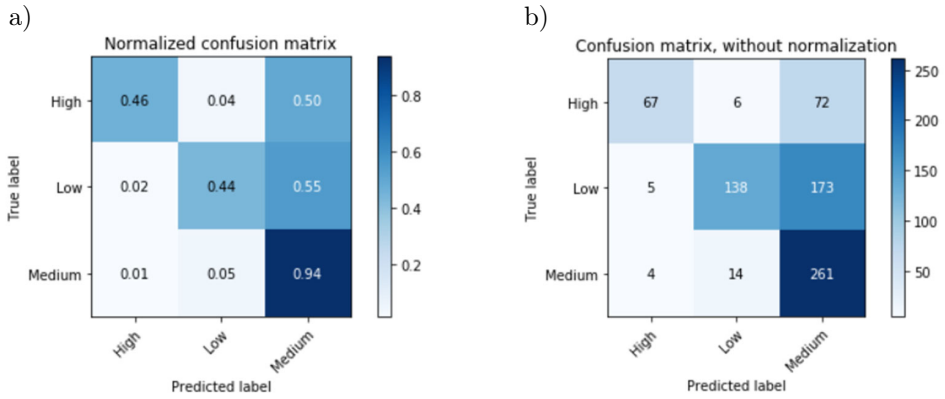

FIG. 36. Confusion matrices with standardization (a) and without standardization (b).

4.3.4. Telangana region (daylight + nightlight images). The sample images for the Telangana region are displayed in Figs. 37 and 38.

FIG. 37. Sample image 1 [10].

FIG. 38. Sample image 2 [10].

In Fig. 39, the training loss shows sharp deflections before the 5th iteration. After the 5th iteration, it starts increasing gradually and saturates after the 15th iteration. The test loss, on the other hand, stars with a very high value and degrades continuously until the 12th iteration before saturating after the 13th iteration. This is due to the very low value of LR and fixed value of momentum.

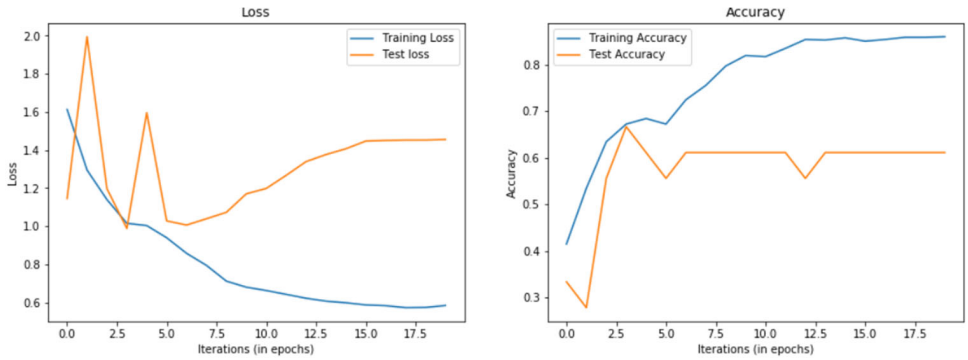

FIG. 39. Iteration vs. loss and accuracy graph.

Training accuracy gradually increases without significant variation in values, and saturates after the 13th iteration. Test accuracy, conversely, initially attains a very high value and decreases before the 5th, reaching a saturation status after the 6th iteration.

The model, trained with Lasso RM, yields an r^2 value of 0.68 and completes in 51.47 seconds. This suggests that the result obtained for the cluster score closely resembles the result obtained from the DHS survey, as shown in Fig. 40.

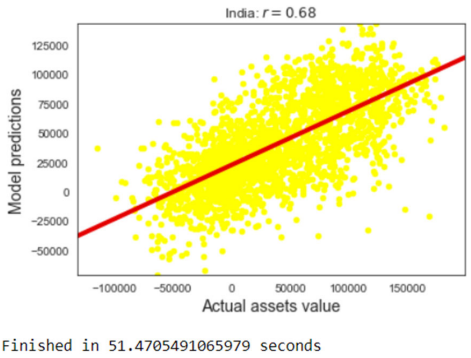

FIG. 40. Clusters for prediction of wealth score on daylight images.

Confusion matrices for the Telangana Region (daylight + nightlight images) for low, medium and high classes are shown in Figs. 41a and 41b.

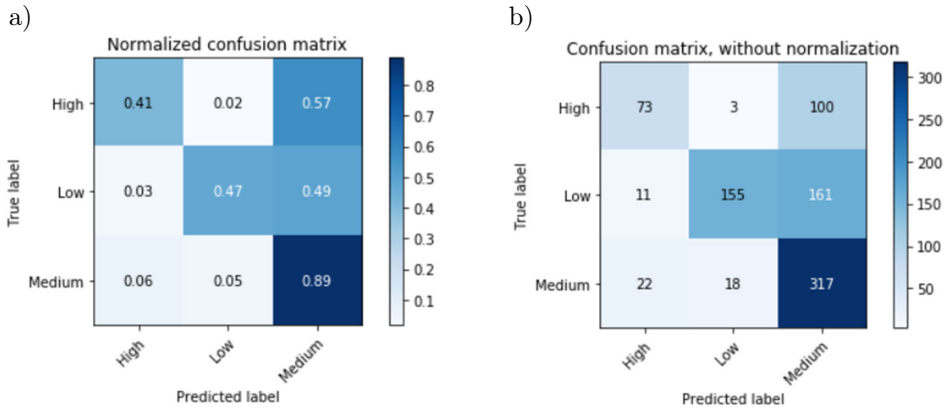

FIG. 41. Confusion matrices with standardization (a) and without standardization (b).

4.4. Phase 4: Comparison of results

As shown in Table 7, we have compared the results obtained from Phases 1 and 2 with respect to training and testing loss, accuracy and the coefficient of determination (R^2). Training accuracy remains the same in both phases and does not show much change in the values. The test loss also does not show much variance in the values. They remain close to 1 in both phases. We observed that the training loss decreases when using daylight images only. The coefficient of determination also improves when using daylight images only. The value of R^2 for daylight + nightlight images is 0.72 whereas for daylight images only, it is 0.73. This shows that using smaller data will improve the model's predictive performance.

Table 7. Comparison of results of different phases.

Comparison of results						
Momentum = 0.9, epoch = 20, batch size = 64						
Phases	Learning rate	Training accuracy	Training loss	Test accuracy	Test loss	R^2 (coefficient of determination)
1) Daylight + nightlight images	0.02	99.1	0.35	80.1	1.7	0.72
	0.42	94.7	0.51	75.3	1.16	
	0.89	88.7	1.16	76.9	1.11	
2) Daylight images only	0.02	99.8	0.34	79.6	1.8	0.73
	0.42	88.09	0.62	75.1	0.96	
	0.89	91.8	0.63	72.9	1.14	

The comparison of computation time is shown in Table 8, where the time taken by different RMs in Phases 1 and 2 is provided. We observed that the computation time for ridge RM does not show a significant difference for LR. However, a notable difference was observed in the case of the RANSAC RM, which required considerably more computation time when trained with both daylight and nightlight images compared to when trained with daylight images only required less time. Additionally, the computation time for the KNN RM shows a substantial difference when trained with LR of 0.02 and not much difference when trained with LR of 0.42 and 0.89. Notably, It was observed that Lasso RM takes shorter times compared to the other three RMs.

Table 8. Comparison of computation time.

Computation time [in seconds]					
Momentum = 0.9, epoch = 20, batch size = 64					
Phases	Learning rate	Ridge regression	Lasso regression	RANSAC regression	KNN regression
1) Daylight + nightlight images	0.02	84.2	35.6	8653.6	571
	0.42	37.3	72.4	6627	168.9
	0.89	37.6	70.8	6209.3	158.8
2) Daylight images only	0.02	81.9	35.4	43	198.9
	0.42	161.7	166	161.7	171
	0.89	38.1	31.4	38.4	176

As shown in Table 9, the results of our paper are compared with those of other papers in the same domain. The locations considered in other papers include India and several countries in Africa. The results obtained in our paper gave better results when compared with the results of several countries in Africa.

Table 9. Comparison of results of different research papers.

Parameter	Paper title	Location (value)
R^2 (coefficient of determination)	Multi-task DL for predicting poverty from satellite images [13]	India (0.82)
	Temporal poverty prediction in developing countries [16]	Africa: Malawi (0.55), Nigeria (0.68), Tanzania (0.57), Uganda (0.69)
	Combining satellite imagery and ML to predict poverty [3]	Rwanda (0.75)
	Socioecologically informed use of remote sensing data to predict the rural household poverty [20]	Sauri (Western Kenya) (0.62)
	Predicting city poverty using satellite imagery [22]	Chile: Santiago (0.52) USA: Los Angeles (0.56), Chicago (0.36), Boston (0.37), Houston (0.327), Philadelphia (0.46)
	Mapping poverty using mobile phones and satellite data [23]	Bangladesh (0.78)
	Identifying a slum degree of deprivation from VHR images using CNN [9]	India: Banglore (0.75)
	Predicting wealth score from remote sensing satellite images and household survey data using deep learning – current study	India (0.72) (daylight + nightlight) India (0.73) (daylight images) Delhi/NCR (0.69), Tamil Nadu (0.70), Maharashtra (0.69), Telangana (0.68)

Additionally, we provide a comprehensive comparison for both the entire area of India and four specific states – Delhi/NCR, Tamil Nadu, Maharashtra and Telangana.

5. Conclusion

We have exhaustively reviewed the literature to understand how ML techniques can help predict the socioeconomic parameter (poverty index) using remote sensing satellite images, household and geographical survey data. This review led us to analyze the use of satellite images and pre-trained models to predict poverty levels. We established a strong correlation between the results obtained from satellite images and DHS Data. In Phase 1, we considered both daylight and nightlight images. The poverty index was determined to be 0.72 using the Lasso RM. In Phase 2, we predicted the labels of the daylight images using survey data. Fine-tuning of the CNN improved the extraction of features, and the poverty index increased to 0.73. In both phases, Lasso RM outperformed

Ridge, RANSAC and KNN RMs. Considering the results obtained in Phases 1 and 2 using Lasso RM, we trained the model again in Phase 3 with images only from the Delhi/NCR, Tamil Nadu, Maharashtra and Telangana regions of India. The calculated wealth scores for these regions were 0.69, 0.70, 0.69, and 0.68, respectively. Phase 4 compared these results with existing data. Future prospects that can be considered include:

- Using the Google Maps API instead of the HERE Maps API to download the daylight images;
- Using DHS Data for 2019-20 for more refined results.

Acknowledgements

We would like to thank HERE Maps for providing the dataset for daylight satellite images and for their guidance on how to access these images for training of our model. We are also grateful to the DHS Program and the DMSP-OLS data source for granting us permission to use the DHS Survey data for 2015–2016 and nightlight images, respectively.

Abstract

The present study elucidates a photonic crystal-based pressure sensor exploiting the change in refractive index with pressure and the corresponding structural deformation of the dielectric material. The stress-sensitive refractive indices of the constituent materials of the photonic crystal have been considered to study the effect of applied pressure on the photonic bandgap characteristics of the structure. The designed pressure sensor, proposed using a two-dimensional hexagonal lattice arrangement of air holes in a dielectric slab, operates in the high-pressure range of 1-6 GPa. A comparative study of the photonic bandgap characteristics with the application of high pressure has been reported for three semiconducting materials- GaAs, Ge and Si, used for the dielectric slab in the proposed structure. GaAs is found to exhibit the highest sensitivity to pressure variations and shows more pronounced shifting of the midgap wavelength with pressure in comparison to Ge and Si. The largest photonic bandgap is seen in the Ge-based structure, closely followed by the GaAs and Si-based structures. The proposed structure is suitable for high-pressure sensing applications.

Keywords

Pressure, photonic bandgap (PBG), gap-to-midgap ratio, sensor, photonic crystal (PhC)

1. Introduction

Optical sensors have shown supremacy over conventional sensors owing to the crucial advantages that they offer [1]**.** Optical sensors have exhibited great capacity in sensing physical quantities such as chemical concentration [2], humidity [3], gases [4], bio-analytes [5] etc. Photonic crystals (PhCs) have been used for various sensing applications

Accepted Manuscript

like gas sensing [6], chemical sensing [7], temperature sensing [8,9], biosensing [9–11], etc. due to their high sensitivity over the slightest change in refractive index. Photonic crystals (PhCs) are characterized by one, two or three-dimensional periodic variations in the dielectric constant on the scale of an optical wavelength. The trapping of light within a PhC structure is driven by the photonic bandgap (PBG) effect, which prevents a specific spectral band from propagating through the structure. The tunable PBG makes PhCs more appealing for manipulation of the light propagation characteristics and the radiation fields. Notably, introducing a defect layer disrupts the periodicity, resulting in the creation of strongly localized allowed states within the PBG [12]. The PBG functions as a reflection band, causing the defect mode to manifest as a sharp passband within the PBG [13,14].

PhC sensors are lucrative due to their high sensitivity, low response time, small size, no-label detection, anti-interference ability, high resolution and easy integration with their optical and electronic counterparts [14,15]. PhCs have also been commonly used for mechanical sensing. Force [16–18], displacement [19] and strain sensors [20] based on PhCs have been widely reported. Another form of mechanical sensing where PhCs are used is pressure sensor [21]. Photoelasticity gives a competent tool to design pressure sensors, where the application of stress or pressure leads to change in refractive index and consequently the optical performance of the material [22].

Electrostrictive stress is linked to electric field components through photo-elastic constants, which are proportional to the fourth power of the refractive index. This relationship makes materials with high refractive indices, such as silicon (Si), germanium (Ge), and gallium arsenide (GaAs), particularly significant for optomechanical applications[23,24]. Moreover, using high refractive index materials can also help reduce radiation losses [25]. Additionally, the high refractive index offered by GaAs, Si and Ge provides a considerable refractive index contrast in the air holes in a slab type of PhC structure. Due to this high index contrast, the structure offers a large photonic bandgap which also makes it suitable for wide band applications.

Further, Si, Ge and GaAs are key the intrinsic semiconductors extensively used in electronic devices. Silicon is crucial for most electronic circuits due to its cost-effectiveness, supported by the IC industry, and its superior properties, including high thermal conductivity, an optical damage threshold ten times greater than that of GaAs, a Raman effect 1000 times stronger, and a Kerr effect 100 times larger than that of silica fiber [26,27]. Additionally, silicon is favored for its low-loss waveguides, uniformity, and compact size in photonic devices [28]. GaAs, the second most common semiconductor, is utilized in laser diodes, solar cells, and microwave frequency integrated circuits, boasts of superior

Accepted Manuscript

electrical properties such as higher electron saturation velocity and a direct bandgap. These attributes result in less noise at high frequencies and higher power operation compared to Si [29]. Nevertheless, Si remains dominant due to its abundance, natural oxide (SiO_2) insulator, and ability to form CMOS gates with both P and N transistors, while GaAs is preferred for pressure sensing applications due to its higher sensitivity and better sensing parameters [30]. Advancements in miniaturization and high dielectric systems have made Ge a viable replacement for Si as a channel material [31], offering benefits such as direct CMOS compatibility[32], a high refractive index (~4), and minimal dispersion over a wide temperature range. These properties make Ge excellent for photodetectors in on-chip data distribution [33,34] and valuable for emitters[35], lasers [36], and solar cells. Additionally, existing literature shows that ultrafast optical reflectivity measurements of Si, Ge and GaAs have been carried out using sub-picosecond pulses as pump and broadband 340-780 nm ultrafast pulses as probe [37]. Such intriguing results open avenues for cutting-edge research on photonic devices based on these semiconductors.

Pressure sensors have been reported which work in the megapascals (MPa) or lesser range [38–42]. These sensors are based on the principle of cantilever and higher pressure applied on these leads to permanent deformation. The other class of pressure sensors exploit the variation in refractive index of the PhC material due to applied pressure, leading to shift in the resonant wavelength. Several two-dimensional PhC sensors have been reported in literature which demonstrate shift in resonant wavelength with increase in pressure [30]. These sensors can operate in a comparatively high-pressure range (i.e., GPa).

Table 4 summarizes various PhC structures employed for pressure and force sensing applications, highlighting their design specifications, sensing ranges, sensitivities and simulation platforms. Triangular and square lattice PhCs of dielectric rods in air, as well as 2D PhCs with holes or defect rings, are commonly used, often simulated using finite-difference time-domain (FDTD) or finite element method (FEM) platforms. The PhC-based micro-ring resonator (MRR) structures and hexagonal/triangular lattice hole type PhCs show considerably high sensitivities across different force and pressure ranges. Notably, these PhC based sensor designs need to have a finite structures design with specific boundary conditions in order to deliver the reported results. The plane wave expansion method (PWEM) offers a simpler way to numerically analyse the photonic bandgap with variations in pressure. The PWE simulations, available through means of open source softwares like MPB, assume an infinite PhC structure without the need for any defects/ resonant cavities. This propels the need for a simple and easy to fabricate PhC structure analysed using PWE which

Accepted Manuscript

exploits high index materials – GaAs, Ge, Si; with a comparative study of their PBG properties based on the electrical, semiconducting, optical and photo-elastic properties of the three materials.

The proposed study theoretically analyzes the pressure dependence of the bandgap characteristics and midgap wavelength of a hexagonal lattice photonic crystal of air holes in a semiconducting slab. The study draws a comparison on the effect of pressure variations of the order of GPa on the PhC structure for three semiconductors- GaAs, Si and Ge- used as the dielectric slab. The stress-optic effect, wherein changes in refractive index occur due to application of pressure, has been exploited for the three semiconductors. The changes in the gap-to-midgap ratio and the midgap wavelength with variation in applied pressure have been analyzed for the GaAs, Si and Ge-based PhC structures. GaAs shows the highest-pressure sensitivity owing to maximum change in its refractive index per unit change in pressure, followed by Ge and the least sensitive to pressure variations being Si. The largest PBG is exhibited by Ge followed by GaAs, with Si showing a smaller bandgap than both Ge and GaAs. The reliable and easy to fabricate design positions the proposed structure as a highly promising approach for high pressure sensing applications.

2. Theoretical Design

The proposed structure consists of air holes in a dielectric slab, designed in a hexagonal lattice arrangement. The lattice constant (a) for proposed arrangement has been taken as 485 nm with the radius of air holes (r) taken as 0.45a. The optimization of these parameters is conducted to obtain a large bandgap approximately within the wavelength range of 1300 nm to 1400 nm for the three semiconductors- GaAs, Si and Ge- used for the slab. The precise values of the geometrical parameters are optimized so that the GaAs based PhC yields maximum PBG at the maximum value of applied pressure (6 GPa) such that midgap wavelength at this pressure is ~ 1350 nm. The optimized parameters have been listed in Table 1.The proposed PhC structure has been depicted in Fig. 1. A hexagonal lattice arrangement is used since it can give a bandgap for both TM and TE polarizations. This is because the hexagonal arrangement provides a structure with high-dielectric regions that are both practically isolated and linked by narrow veins [8]. This leads to a connected structure which has channels along which the field can propagate [43].

Accepted Manuscript

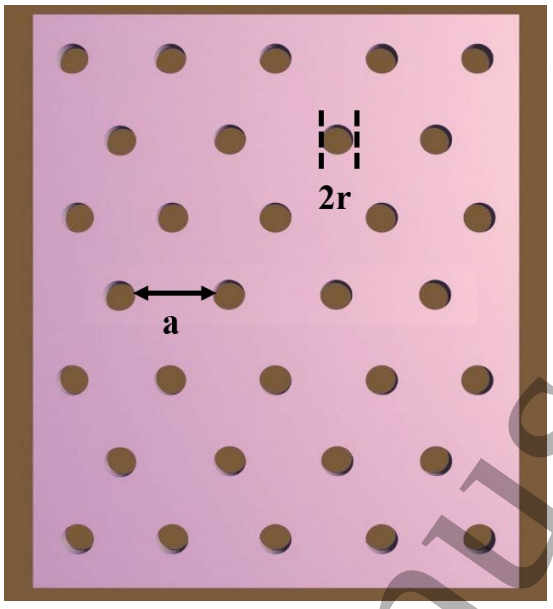

Fig. 1. Schematic of the proposed PhC with hexagonal lattice

Apart from the fact that the proposed design is an infinite PhC structure without any defects, it should also be pointed out that Si, Ge and GaAs have different refractive indices and thus offer a different value of index contrast in the proposed air hole in slab type of geometry. Hence, all the three materials yield maximum PBG at different wavelengths. This leads to the assumption of an approximate optimization wavelength (~1350 nm) common to all the three materials for the purpose of an objective comparison.

S. No.	**Parameters**	**Designation**
1.	Lattice structure	Hexagonal lattice
2.	Configuration	Air holes in dielectric slab
3.	Lattice constant (a)	485 nm
4.	Radius of the air holes (r)	0.45*a
5.	RI of slab (without the applied pressure)	$n_{GaAs} \sim 3.43$; $n_{Ge} \sim 4$; $n_{Si} \sim 3.42$
6.	Operating wavelength range (for all the three-semiconductor based PhCs)	1290-1400 nm

9.	Simulation platform	MIT- Photonic Bands (MPB)
10.	Defects and Dimensions	No defects; infinite PhC structure (for PWE based PBG calculations in MPB)

Table 1. Design specifications of the proposed air holes in slab type PhC sensor

2D PhCs can provide a full PBG (not in a strict sense), not possible in case of 1D PhCs which are limited to one-dimension in terms of the dielectric periodicity, and they are simpler to fabricate than 3D PhCs [44]. The air holes in slab kind of structure has very low losses [30]. Hence, the proposed 2D PhC is appealing for the current research work. The proposed design is reliable and simple to be integrated into various detection applications and optical devices such as filters, splitters, cavities, multiplexers/demultiplexers, sensors, etc [45]. This hole type PhC structure has better pressure detection ability and easier to fabricate compared to the rod type structure [46] and is useful for high pressure measurement applications. The 2D PhC-based structure can be realized by etching holes in the higher dielectric material periodically in two dimensions. The etching methods have been used for semiconductors, where the marking of unwanted areas is done on the surface of a semiconductor, using a lithographic technique such as electron beam lithography. The marked areas are then etched to create holes [47].

3. Pressure dependance of refractive index

The stress-strain relation and the photo-elastic effect dictate the relation between refractive index and stress, which takes a tensor form as follows [48]:

$$\boldsymbol{\Delta}\left(\frac{\mathbf{1}}{\mathbf{n^2}}\right) = \sum \mathbf{p_{ij}}\,\boldsymbol{\sigma_j} \qquad (\mathbf{1})$$

Here, $\mathbf{n}$ is the refractive index of the slab material, $\mathbf{p_{ij}}$ are the strain-optic coefficients and $\boldsymbol{\sigma_j}$ is the component of stress. Following the assumption that the pressure is applied in one direction only with the medium being isotropic, equation $(\mathbf{1})$ takes a simplified form [49]:

$$\mathbf{n} = \mathbf{n_0} - (\mathbf{c_1} + \mathbf{2c_2})\boldsymbol{\sigma} \qquad (\mathbf{2})$$

Accepted Manuscript

Where, $\mathbf{n}$ is the refractive index of the sensor plate matrix and $\mathbf{n_0}$ is the refractive index of the slab without application of pressure. $\mathbf{c_1}$ and $\mathbf{c_2}$ are the strain-optic constants defined as [49]:

$$\mathbf{c_1} = \frac{\mathbf{n_0^3}\,(\mathbf{p_{11}} - \mathbf{2Vp_{12}})}{\mathbf{2E}} \quad (3)$$

$$\mathbf{c_2} = \frac{\mathbf{n_0^3}\,[\mathbf{p_{12}} - \mathbf{V}(\mathbf{p_{11}} + \mathbf{p_{12}})]}{\mathbf{2E}} \quad (4)$$

Here, $\mathbf{p_{11}}$ and $\mathbf{p_{12}}$ are the strain-optic coefficients, $\mathbf{V}$ is the Poisson's ratio and $\mathbf{E}$ is the Young's modulus. The strain-optic constants for GaAs and Si are given in Table 2 [50]. Thus, GaAs and Si exhibit a stress-optic effect which is linear, as shown in Fig. 2.

Material	$\mathbf{n_0}$	$\mathbf{c_1}$ ($\mathbf{10^{-12}/Pa}$)	$\mathbf{c_2}$ ($\mathbf{10^{-12}/Pa}$)
Si	3.42	-11.35	3.65
GaAs	3.43	-18.39	-10.63

Table 2. Strain-optic constants

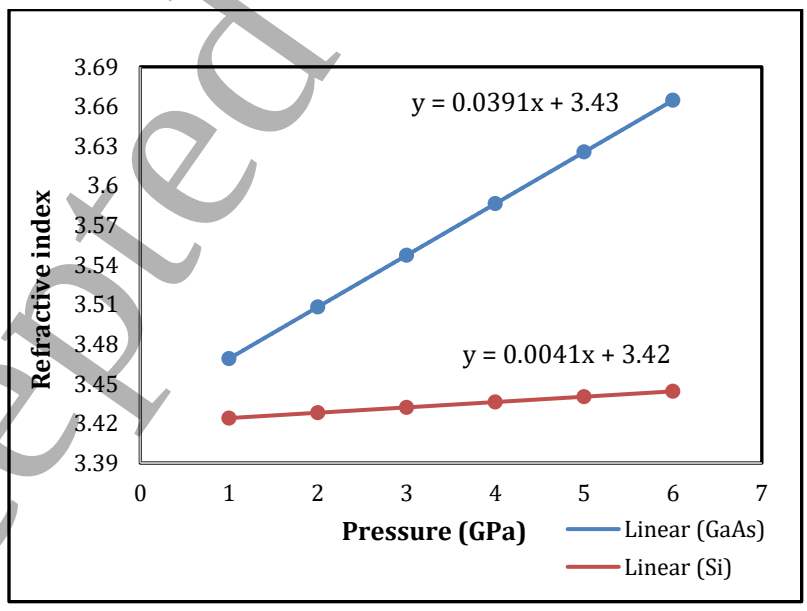

Fig. 2. Refractive index profile of GaAs and Si with variation in applied pressure

Accepted Manuscript

Another material exhibiting the stress-optic effect is germanium (Ge). The variation of refractive index of Ge n_{Ge} on application of hydrostatic pressure P to its surface [51] is given by:

$$n_{Ge} = \sqrt{15.94 - 0.36P + 0.014\,P^2} \quad (5)$$

This relation is used to obtain the variation of refractive index of Ge with pressure varying in the range 0 – 10 GPa, as shown in Fig. 3.

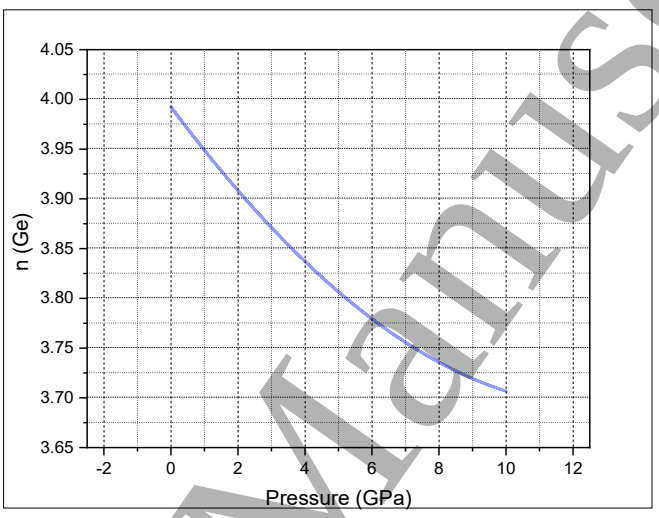

Fig. 3. Refractive index of Ge as a function of pressure

4. Results and Discussion

The MIT Photonic Bands (MPB) software has been employed to compute the frequency eigenstates of the Maxwell's equation using the plane wave expansion (PWE) method. The eigen-frequencies for each wavevector (or k-point) gives the band structure of the proposed PhC design. The photonic band structure calculations have been performed for the three different semiconducting materials- GaAs, Ge and Si, used as the dielectric slab keeping all the structural parameters unchanged. The output frequency values are normalized in units of c/a, where c and a represent the speed of light and lattice constant of the structure respectively. The corresponding wavelengths are determined by employing the optimized value of the lattice constant in the normalized output. The design and geometry have been optimized to obtain wide bandgaps, since large band structures find utility in sensing applications.

Accepted Manuscript

4.1 GaAs

The bandgap calculations performed for the proposed PhC design with the dielectric slab composed of GaAs show the existence of a wide photonic bandgap (PBG) for the TE mode (~ 48.87 %) and a much smaller PBG for the TM mode (~ 9.71 %). The calculations have been performed for various values of pressure in the range 1 GPa - 6 GPa. For this pressure range, the TE bandgap, gap-to-midgap ratio and the band-edge wavelengths have been computed for different values of applied pressure. The GaAs based structure shows are a large bandgap for the TE mode ~ 48.87 % at 1GPa pressure between bands 1 and 2, as can be seen from Fig. 4.

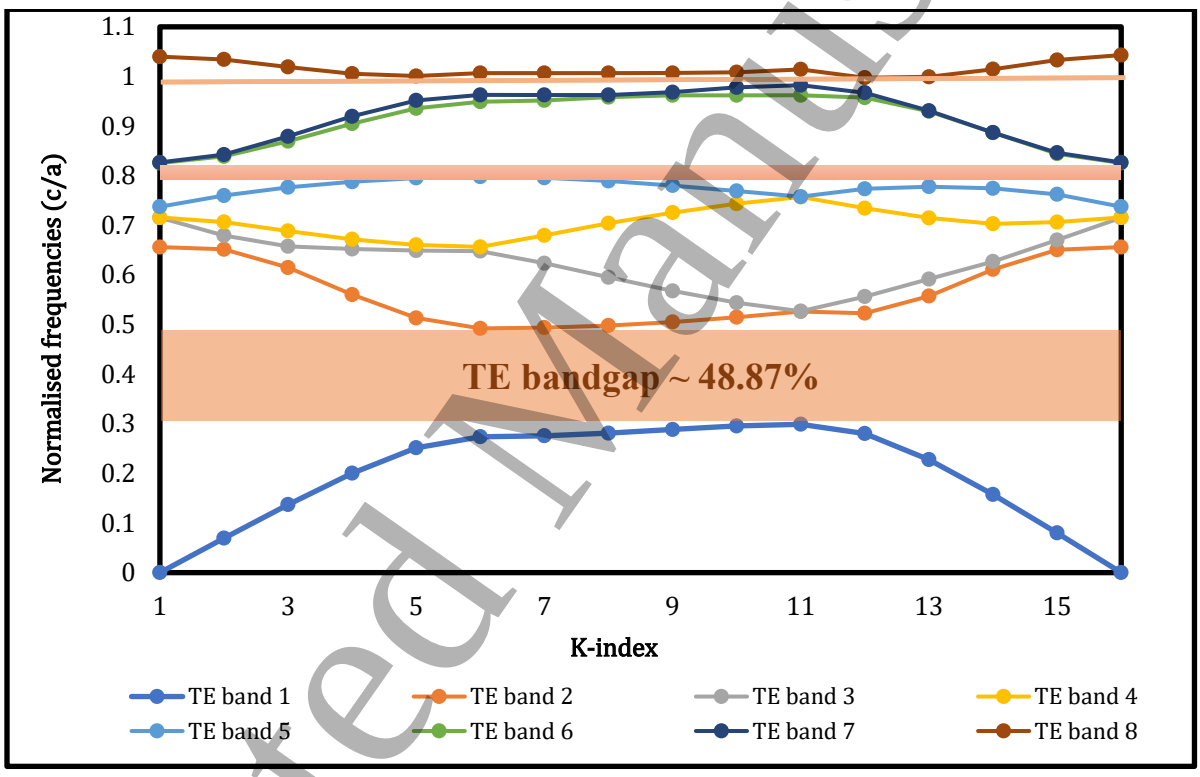

Fig. 4. Photonic band structure of the GaAs-based PhC for the TE mode at 1GPa pressure

The central wavelength of the photonic bandgap, i.e., the midgap wavelength of the structure, has been evaluated at different values of applied pressure P in the range 1 GPa -6 GPa, using the corresponding band-edges, as per the following equation:

$$\lambda(\mathrm{P})_{\mathrm{midgap}} = \frac{\lambda(\mathrm{P})_{\mathrm{upper\ band\ edge}} + \lambda(\mathrm{P})_{\mathrm{lower\ band\ edge}}}{2} \quad (6)$$

The midgap wavelength increases linearly with increase in applied pressure, as depicted in Fig. 5. Hence, the midgap wavelength is sensitive to changes in applied pressure and can be tuned with pressure. The pressure

Accepted Manuscript

sensitivity, S_p , is calculated as the ratio of the change in midgap wavelength ($\Delta\lambda$) to the change in applied pressure (ΔP) , measured in units of nm/GPa.

$$S_p = \frac{\Delta\lambda}{\Delta P} = \frac{\Delta\lambda}{\Delta n}\frac{\Delta n}{\Delta P} \tag{7}$$

The GaAs-based PhC structure shows a pressure sensitivity of 9.294 nm/GPa and can be used for high pressure sensing applications. Here, $\Delta\lambda/\Delta P > 0$ i.e., the central wavelength increases for every 1 GPa increase in pressure.

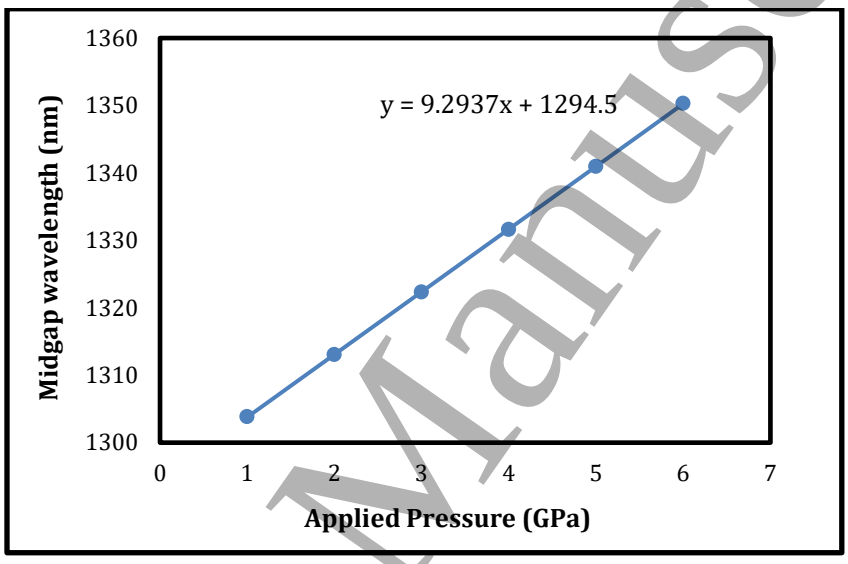

Fig. 5. Midgap wavelength of the GaAs-based PhC as a function of applied pressure

The gap-to-midgap ratio, determined for different values of applied pressure in the range 1 GPa – 6 GPa, has been shown in Fig. 6. It is seen to increase linearly with increase in pressure. This is expected, owing to the fact that the refractive index of the GaAs slab increases with increasing pressure (as seen in Fig. 2 as per equation (2)). This increase in refractive index leads to an increase in the dielectric contrast between the slab and the air holes of the PhC structure, causing the PBG to increase with applied pressure. This consequently is responsible for the increase in gap-to-midgap ratio with applied pressure.

Accepted Manuscript

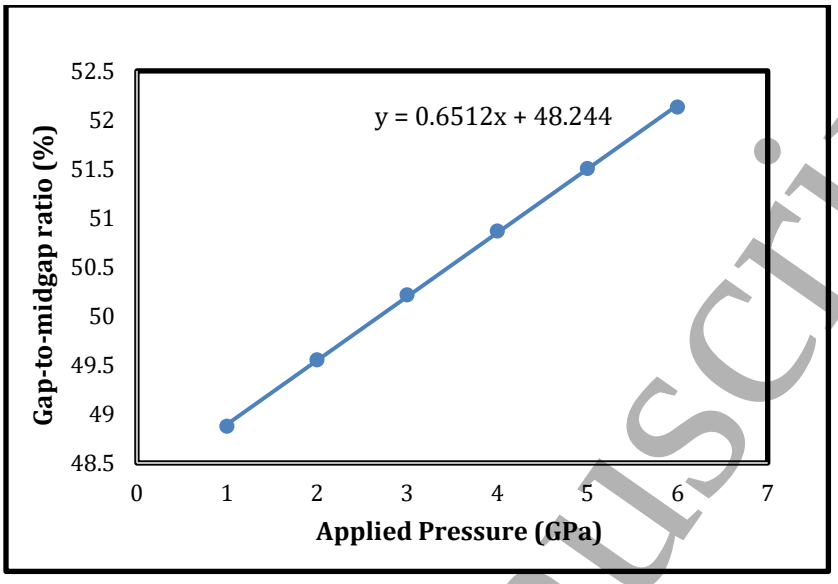

Fig. 6. Change in the gap-to-midgap ratio with variation of applied pressure for the GaAs-based PhC

4.2 Ge

The bandgap calculations for the Ge-based PhC reveal the existence of a large TE bandgap (~ 56.31 %) between bands 1 and 2 along with a small TM bandgap (~ 11.76 %) between bands 2 and 3 at 1 GPa pressure. The photonic band structure along with the bandgap for the TE mode has been shown in Fig. 7.

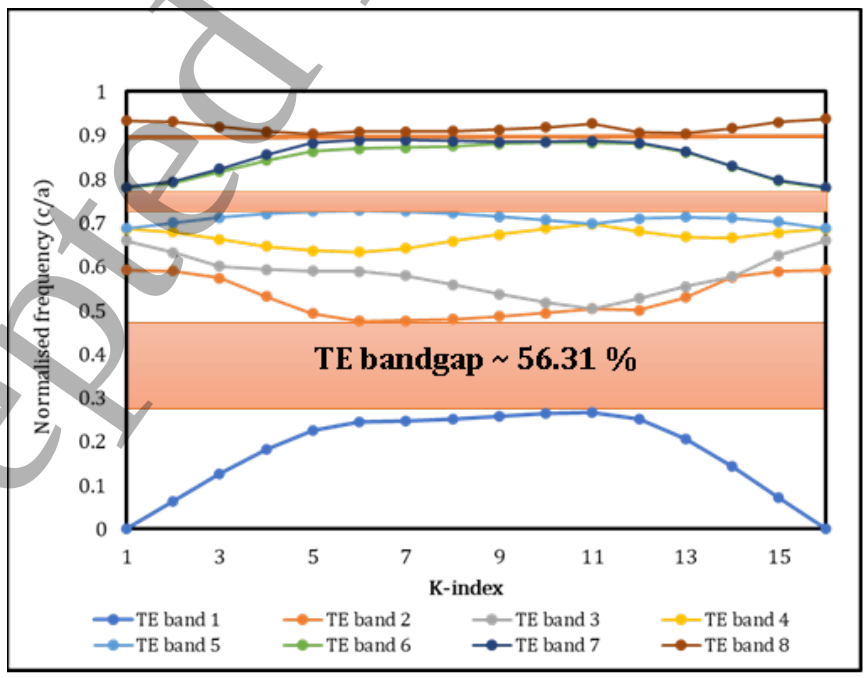

Fig. 7. Photonic band structure of the Ge-based PhC for the TE mode at 1GPa

Accepted Manuscript

The midgap wavelength of the Ge-based PhC is determined for different pressure values in the range 1 GPa to 6 GPa as per equation (**6**) by using the corresponding values of the band-edge wavelengths as at that particular pressure. The midgap wavelength exhibits a linear decrease with increase in pressure as shown in Fig. 8. The pressure sensitivity of the structure, calculated as per equation (**7**), is observed to be -8.295 nm/GPa. Here, the negative sign is indicative of the decrease in the central wavelength for every 1 GPa increase in pressure (i.e., $\boldsymbol{\Delta\lambda/\Delta P < 0}$).

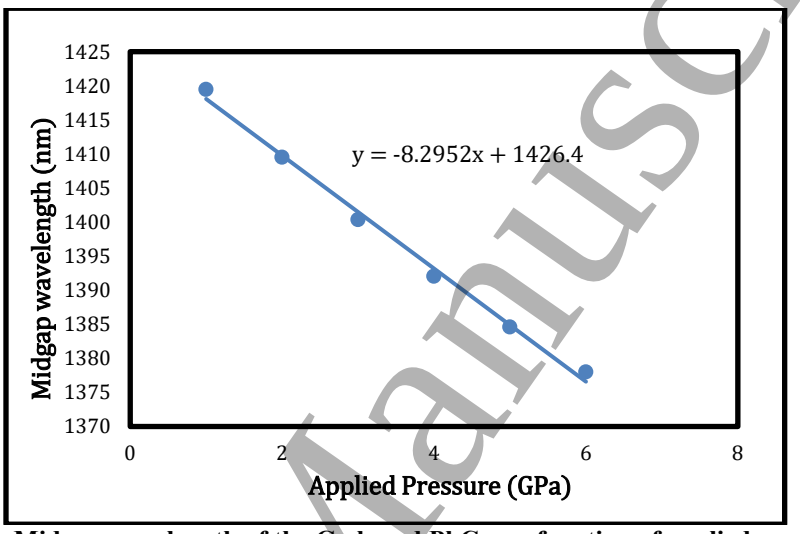

Fig. 8. Midgap wavelength of the Ge-based PhC as a function of applied pressure

The variation of the gap-to-midgap ratio with pressure, applied in the range 1 GPa – 6 GPa, has been shown in Fig. 9 for the Ge-based PhC. The gap-to-midgap ratio decreases linearly with increase in applied pressure. This is because the refractive index of the Ge slab decreases with increasing pressure (as seen in Fig. 3 as per equation (**5**)). This decrease in refractive index causes a decrease in the dielectric contrast between the slab and the air holes leading to a decrease in the PBG and the gap-to-midgap ratio of the Ge-based PhC.

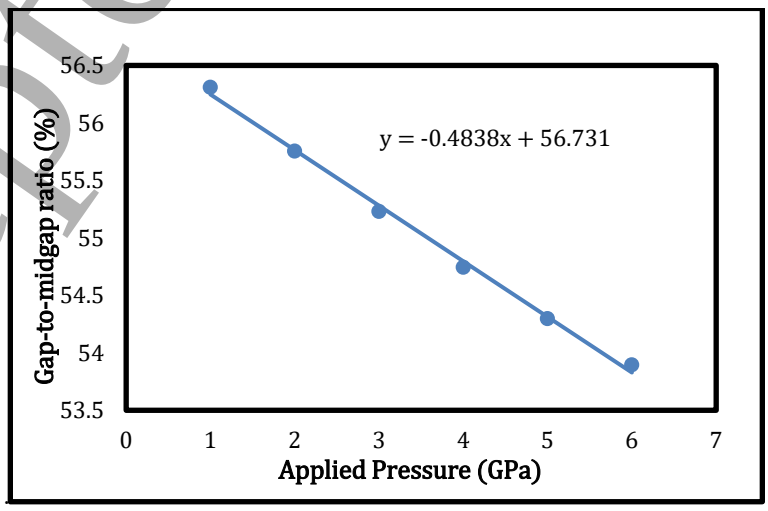

Fig. 9. Change in the gap-to-midgap ratio with applied pressure for the Ge-based PhC

Accepted Manuscript

4.3 Si

The PBG calculations performed for the Si-based PhC shows the existence of a large TE bandgap (~ 48.07 %) between bands 1 and 2 and a much narrower gap for the TM mode (~ 9.47 %) between bands 2 and 3. The TE bandgap for the Si-based PhC is depicted in the TE band structure diagram in Fig. 10.

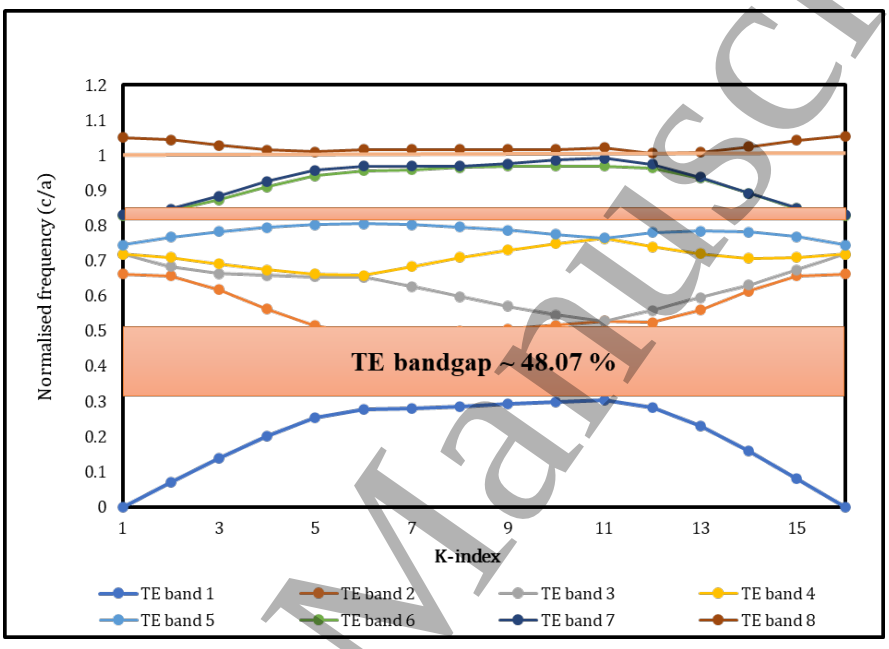

Fig. 10. Photonic band structure of the Si-based PhC for the TE mode at 1GPa pressure

For different values of pressure in the range 1 GPa – 6 GPa, the midgap wavelength of the Si-based structure is calculated as per equation (6). The midgap wavelength is observed to increase linearly with increase in applied pressure as seen in Fig. 11. The pressure sensitivity of the structure, as per equation (7), is calculated to be 0.9502 nm/GPa. The positive value of the slope in Fig. 8, i.e., $\Delta\lambda/\Delta P > 0$ is indicative of the increase in the central wavelength of the TE PBG for every 1 GPa increase in applied pressure.

Accepted Manuscript

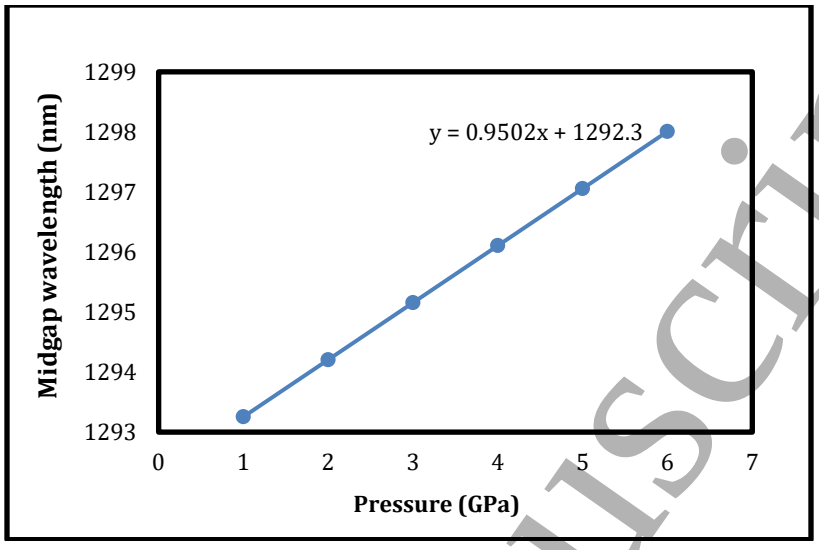

Fig. 11. Midgap wavelength of the Ge-based PhC as a function of applied pressure

The gap-to-midgap ratio of the Si-based PhC determined for various values of applied pressure from 1 GPa – 6 GPa shows a linear increase with pressure as seen from Fig. 12. This is owing to the increase in refractive index of the Si slab with increase in applied pressure. This causes an increase in the refractive index contrast between the Si slab and the air holes, leading to an increase in the bandgap, which in turn is responsible for the increase in the gap-to-midgap ratio of the structure.

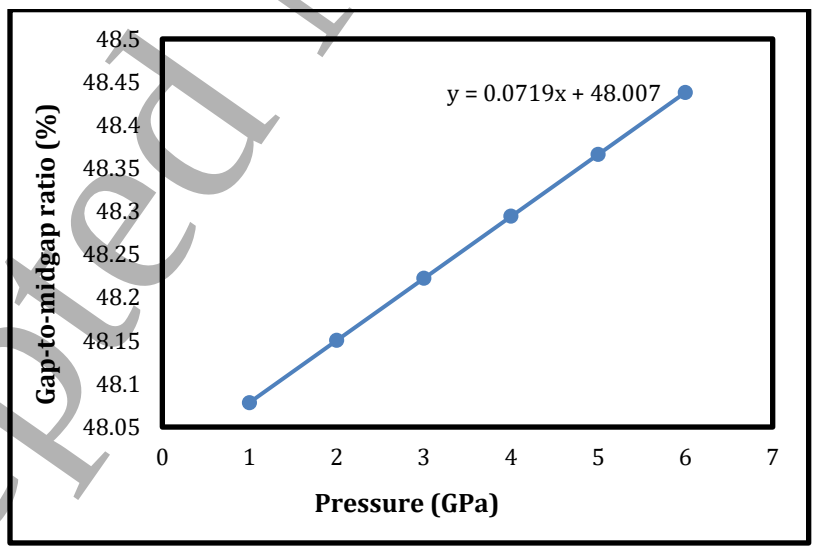

Fig. 12. Gap-to-midgap ratio as a function of applied pressure for the Ge-based PhC

Accepted Manuscript

4.4 Comparative analysis of the GaAs, Ge and Si-based structures

The proposed PhC design has been realized using three different semiconducting materials- Si, Ge and GaAs for the dielectric slab. Si and Ge are monocrystalline semiconductors i.e., they have a repeating crystal structure. On the other hand, GaAs is a compound semiconductor i.e., composed of one or more semiconducting materials with different atomic structures.

Semiconducting slab material	**Young's Modulus (E)**	**Δ n for Δ P = 1GPa**	**Pressure sensitivity (S_p)**	**Normalised sensitivity (S_n)**	**Refractive index at 1 GPa**	**PBG at 1 GPa**
GaAs	85.5 GPa	0.0391	9.294 nm/GPa	0.006884222 /GPa	3.4691	48.87%
Ge	100 GPa	0.0355	-8.295 nm/GPa	0.006144444 /GPa	3.9489	56.31 %
Si	165 GPa	0.0041	0.9502 nm/GPa	0.000703852 /GPa	3.4241	48.07 %

Table 3. Parameters for comparisons of the three PhC structures

The refractive index of GaAs and Si increases linearly with increase in pressure whereas the refractive index of Ge exhibits a non-linear decrease with increase in pressure as seen in Fig. 2 and Fig. 3. The pressure applied induces a certain strain and stress in the material. The major reason for a significant change in the refractive index of the material is the strain-induced change of the energy bandgap or the absorption coefficients [52,53].

The calculated pressure sensitivity is lowest for Si and highest for GaAs as seen from Table 3. This is a consequence of the fact that the change in refractive index for 1 GPa change in pressure is highest for GaAs and lowest for Si among the three semiconducting materials as shown in Table 3. The Young's modulus of Si is the highest and the of GaAs is the lowest among the three materials. Hence, Si offers the most rigid structure with the least deformations as compared to the other two structures. GaAs, on the other hand, exhibits more strain for the same value of applied pressure. This strain-induced change of energy bandgap causes change in the refractive

Accepted Manuscript

index which is most significant in GaAs. Thus, GaAs shows the highest variation of refractive index with pressure and consequently, is the most sensitive to changes in applied pressure.

For a more objective comparison of sensitivity of the proposed PhC sensors, normalised sensitivity has been evaluated. The normalised sensitivity is defined as ratio of the pressure sensitivity to the operating wavelength of the defect mode. Since the proposed structure is an infinite PhC without any defects, the operating wavelength is taken to be the average wavelength (~1350 nm approx.) of the wavelength range (~ 1300 -1400 nm) around which the PhC's geometrical parameters have been optimized for the three semiconductors. Additionally, due to the different RIs of GaAs, Si and Ge, they offer maximum PBG at different wavelengths. This leads to the assumption of an approximate optimization wavelength common to all the three materials for the purpose of comparison. Hence, the normalised sensitivity (S_n) has been calculated and tabulated in Table 3 using the following equation:

$$S_n = \frac{\text{Pressure sensitivity}}{\text{Operating wavelength}} = \frac{S_P}{\lambda_{optimisation}} \tag{8}$$

where, $\lambda_{optimisation}$ is approximated to 1350 nm for normalised sensitivity calculations. As is expected on the basis of the pressure sensing performance, the normalised sensitivity is highest for the GaAs based PhC sensor, followed by Ge, with the Si based PhC exhibiting the lowest sensitivity to pressure variations as interpreted from Table 3.

GaAs is a direct bandgap semiconductor having a zincblende structure whereas Si and Ge are indirect bandgap semiconductors with a diamond structure. This causes GaAs to have a greater electronic bandgap than Si and Ge. Being indirect bandgap semiconductors, Si and Ge need phonon emission or absorption, hence the efficiency of a device based on these will be effectively lesser than that of GaAs. Due to greater resistance of GaAs as compared to Si and Ge, there are a large number of localized states available in GaAs. Therefore, on application of pressure the atoms have larger number of possible states that they can occupy in GaAs. As pressure is applied, the atoms acquire a configuration in which they are closer to each other and hence the refractive index increases considerably [54]. The greater increase in refractive index leads to larger shifts in the midgap wavelength for the GaAs-based PhC. Si, on the other hand, has fewer localized states available and therefore, shows a lesser increase in refractive index. This is responsible for the greater sensitivity of the GaAs based PhC pressure sensor as

Accepted Manuscript

compared to Ge and Si. The largest photonic bandgap, however, is seen in the Ge-based PhC structure, followed by the GaAs and then the Si-based PhC structures. This is a consequence of the fact that Ge shows the largest change in refractive index for every 1 GPa change in pressure applied to its surface as compared GaAs and Si (as seen from Table 3).

A comparative study has been conducted to draw a contrast between the pressure sensing performances of the proposed PhC sensor and similar PhC based pressure sensing structures previously reported in literature. The comparative analysis has been summarized in Table 4. It can be observed that the proposed work is the only one that employs PWE and doesn't contain any defects/resonant cavity. Yet it offers a considerably high sensitivity over a good enough sensing range. This hole type PhC structure has better pressure detection ability compared to the rod type structure [46]. It is is easy to fabricate, reliable and simple to be integrated into various high pressure detection applications.

5. Conclusion

This paper presents an optical platform for pressure sensing based on a hexagonal lattice photonic crystal of air holes in a dielectric slab. The pressure detection characteristics are theoretically analyzed based on the Plane Wave Expansion method. The study draws comparison of the effect of pressure variations on the photonic bandgap characteristics of the proposed PhC design for three semiconductors- GaAs, Ge and Si- used for the dielectric slab. GaAs and Si show an increase in refractive index and hence, increase in the photonic bandgap of their corresponding PhC structures with increase in applied pressure. Ge, on the other hand, shows decrease in its refractive index and

Accepted Manuscript

hence decrease in bandgap with increasing values of pressure. The change in the midgap wavelength and the gap-to-midgap ratio with applied pressure for the three PhC structures reveal that GaAs exhibits the highest-pressure sensitivity of 9.294 nm/GPa, followed by Ge with 8.295 nm/GPa and the least sensitive being Si with a sensitivity of only 0.9502 nm/GPa. The largest PBG is shown by the Ge-based PhC followed by the GaAs and Si based structures. Since the proposed PhC sensor has been analyzed for the range 1- 6 GPa, it is suitable for high pressure sensing applications such as downhole application [64], quantification of pressure levels during the testing of energetic materials [65].

Abstract
In many game theoretic environments, the precise crisp values of payoffs are not always easy to gather as real-life decision-making problems are not inevitably precise and symmetrically distributed in nature. Hence, there is a need to explore matrix games having unbalanced probabilistic linguistic information. To fill this research gap, this study proposes a concept of probabilistic multiplicative unbalanced linguistic (PM-UL) game in which the players express their responses in terms of PM-UL term. This type of PM-UL game is a useful technique for multiple criteria analysis. Further, to thoroughly capture the uncertainty involved in payoffs of such games, they are converted to probabilistic unbalanced linguistic clouds (PULCs) that describe the uncertainties of qualitative payoffs by implementing the uncertain transformation between PM-UL payoffs and quantitative values. The PULCs are represented by three numerical characteristics, i.e. expectation, entropy and hyper-entropy. Hence, this model overcomes the inherent limitation of existing linguistic games where only the fuzziness of concepts is evaluated, by providing a PULC strategy and PULC value of the game. This procedure overcomes the loss of information occurring in the process of transformation of payoff values into quantitative ones. The defined methodology is implemented on a real-life working problem to demonstrate the effect and applicability in decision-making circumstances.

1 Introduction

Game theory has already proved its tremendous potential for conflict resolution problems in decision-making problems. Decision making is a social activity that is characterized by inherent uncertainty and ambiguous information communicated in day-to-day language. When a game theoretic approach is implemented to solve any decision-making problem, it is necessary to analyse which concept should be implemented to solve that particular problem. The results and methods of a problem are not always realistic and do not always match a real-life phenomenon. The ambiguity present in a concept make it difficult to assess a decision-making problem in a particular way. Hence, it is necessary to consider the uncertainty pertaining in a decision maker's (DM's) judgement to solve a problem underlying in a fuzzy environment. The development of fuzzy set theory [49] made it possible to deal with imprecise information explicitly. Several academics have looked into matrix games with payoffs that are fuzzy numbers [7, 8, 10, 14, 22, 25, 32] in order to reflect the uncertainty in the context of payoffs and goals. Also, the fuzzy programming approach plays a vital role in managing the group decision-making problems [35–38].

Although fuzzy games have provided phenomenal results in literature, these are still incapable of addressing games having qualitative information as the best expression in strategic forms occurs in the form of natural language only. Thus linguistic variables [50] play an important role in real-life decision making. Arfi [1, 2] introduced game theory based on fuzzy linguistic logic, which is a more straightforward and adaptable way to define payoffs in terms of linguistic labels. The utility of linguistic concepts implies a broad outlook in the current specialized literature on Computing with Words (CWW)-related methodologies. Also, a number of linguistic computational models based on balanced [17, 18] as well as unbalanced linguistic data [6, 9, 15, 28, 44, 52] are developed in existing literature to avoid information loss occurring in the process of CWW. For example, Herrera et al. [19] defined a computational model based on hierarchical structure to manage unbalanced linguistic information. Zhang et al. [54] revised the Herrera's model to define a simplified computational model to fuse multi-granular unbalanced linguistic terms. In fact, some authors have focused on developing linguistic computation models to managing multigranular unbalanced hesitant fuzzy linguistic information [53] in multi-attribute large-scale group decision making. Further, it is also necessary to model DMs' personalized individual semantics (PISs) in linguistic group decision making [55]. Zhang and Li's [51] work focuses on developing some PIS-based consistency control and consensus reaching models for this purpose. Furthermore, the DMs have extended the use of balanced as well as unbalanced linguistic information to deal with matrix games having such linguistic information [12, 13, 33, 34].

However, to deal with the ambiguity involved in the qualitative concepts, it is sometimes not possible to express the information with the help of a single particular term, or there are probabilities of occurrence of a qualitative term attached with them. For example, if $\mathbb{LT} = \{\text{Good}, \text{Very Good}\}$ is a linguistic term set, then it might be possible that the player expresses his linguistic information as "50%

chances of being good", then we might say that the linguistic term “Good" has a probability attached as “Good (0.5)". For expressing such type of information, there is a need to use probabilistic linguistic term sets (PLTS) introduced in [31]. The PLTS enables the players or DMs to evaluate using numerous linguistic terms rather than a single term, more efficiently by giving each term a weight through probability. Moreover, a PLTS may be transformed into linguistic distribution so that each and every term of the original linguistic set is present in the final evaluation by the DMs [45]. A lot of research has been carried out based on PLTSs [3, 20, 46–48] as these types of sets allow the DMs to use more than one linguistic term with associated probabilities. Mi et al. [30] put forward this extensive and comprehensive way of expressing information in matrix games taking PLTS as input of matrix game. However, this PLTS consists of symmetrically distributed linguistic terms only. As it is well known that the real-life decision-making problems are not just based on symmetric data sets. Rather, a practical decision-making problem considers terms that are irregularly distributed. In order to deal with unbalanced linguistic information, Han et al. [16] established probabilistic unbalanced linguistic term set (PULTS), in which the authors proposed a computational model based on copula and co-copula. However, an additive scale set is still used to represent the data, therefore the term “unbalanced” does not retain its literal meaning. This is the first research gap in the literature that is addressed in the present study.

To handle unbalanced linguistic probabilistic information, Malhotra and Gupta [27] introduced a probabilistic multiplicative ULTS (PM-ULTS) that takes into account the irregular distribution of probabilistic linguistic terms and is sufficient enough to deal with all types of ULTSs. Further they have solved matrix games that have payoffs in terms of PM-ULTS. By the concept “PM-UL payoffs”, it is meant that the players of the game express their responses in the form of linguistic terms that are distributed asymmetrically and are multiplicative in their distribution with some attached probabilities. Moreover, the set consisting of such types of linguistic terms is referred to as probabilistic multiplicative unbalanced linguistic term set. However, despite such study of PM-UL game, the methodology defined by [27] also has a limitation that it handles only one kind of uncertainty, i.e. fuzziness. The two most significant uncertainties in natural language, however, are randomness and fuzziness that have received a lot of attention in the field of artificial intelligence. It is typically exceedingly challenging to ascertain precise information or define the bounds of extensions if we only take fuzziness into account. For instance, there is no specific value that can be used to describe the concept’s distinct border when we define the linguistic term “old". This is the second research gap addressed in the current study. In general, it is always possible for a linguistic variable to take on distinct meanings for different people, and even for the same person, to have different interpretations in different circumstances due to the abstractness and generality of notions. As a result, some notions frequently include randomness as well. Many linguistic terms have both randomness and fuzziness at the same time, despite the fact that they are of very different kinds. For instance, the linguistic terms “about", “maybe", “probably", etc., although represent random thoughts, also exhibit the fuzziness due to the vague boundary of the extension. In the light of this, it seems more practical for a formal

representation model of concepts to simultaneously account for both randomness and the fuzziness. Li et al. [21] presented a cloud model that can synthetically express the concept of randomness and fuzziness of decision information at the same time to formally characterize the underlying relationship between randomness and fuzziness and effectively integrate both uncertainties. The cloud models use EX (expectation), EN (entropy), and HE (hyperentropy) to illustrate a linguistic concept. Since the development of cloud models, numerous academics have dedicated their efforts to advance cloud-specific studies [23, 24, 26, 29, 39–42]. Although existing cloud models are believed to be able to preserve the original information, they are still unable to accurately represent labels that are asymmetrically distributed. To solve this problem, Wang et al. [43] proposed an Asymmetric Trapezoidal Clouds (ATCs) model as a solution to this problem.The EN and HE of the ATCs differ on the left and right sides in this model, and the authors expressed the expectation as an interval rather than a specific number. To address multiplicative unbalanced linguistic information, Chauhan et al. [11] have developed an accurate and innovative cloud decision support model. Here, in the present paper, we solve two-person matrix games having payoffs in the form of PM-ULTS by dealing with both randomness and fuzziness of the linguistic concepts. Further, the operational laws used to aggregate the payoffs in the paper [27] are based on probabilistic linguistic terms, while in present paper, well-defined cloud aggregation operators are used that are already well established in literature and do not follow any complex representation. This is the third research gap to be addressed in the current paper.

To fill all the discussed research gaps, the following contributions are offered in this paper:

- The matrix games having payoffs in the form of PM-ULTS are considered and solved using the defined methodology. These PM-ULTSs are able to handle all types of regular as well as irregular distribution of the linguistic concepts. Moreover, the defined methodology is able to deal with the most important uncertainties, i.e. randomness and fuzziness underlying in a qualitative information.
- An unbalanced linguistic cloud model is used to transform the probabilistic multiplicative data into its numerical form without making any significant loss of information. The probabilistic multiplicative unbalanced linguistic variables that are used as payoffs of a game problem are transformed into probabilistic unbalanced linguistic clouds (PULCs), i.e. the clouds generated from the probabilistic unbalanced linguistic terms, to effectively capture the uncertainty of the probabilistic linguistic payoff.
- The dispersion of cloud drops is measured by standard deviation S.D. defined in the paper that suggests the relative stability distribution of the linguistic term. Also, the score function is defined to compare different PULCs.
- To address the practical issues, the defined approach is then applied to address matrix games having probabilistic multiplicative unbalanced linguistic payoffs. The values of the players are defined in terms of PULCs. Also, the proposed method provides more accurate results by providing the values and strategies of the game in terms of expectation, entropy and hyperentropy. The expectation is the most representative and typical sample of the qualitative concept,

while entropy represents the randomness and fuzziness extent of the cloud drop. Hyperentropy reflects the uncertainty degree of entropy.

The paper is organized in the following manner. Section 2 reviews the basic concepts related to PM-ULTS, unbalanced linguistic cloud model and two-person matrix games that are required in the present paper. Section 3 provides the transformation of probabilistic multiplicative unbalanced linguistic variables to PULCs and operational laws. In Sect. 4, the application of PULC model in two-person constant sum matrix games is illustrated by first defining a PM-ULC game (PM-ULCG) along with the methodology for solving PM-ULCG followed by a numerical problem. Some analysis of results obtained and comparison with other defined methodologies, along with discussion, is provided in Sect. 5. Section 6 concludes the paper along with future scope.

2 Preliminaries

This section reviews some basic concepts that are required in this paper. The PM-ULTS defined in Sect. 2.1 consists of unbalanced linguistic terms having probabilities associated with them. Section 2.2 discusses the unbalanced linguistic cloud model based on which the payoffs are aggregated in this paper. In Sect. 2.3, the fundamentals of two-person matrix games are discussed.

2.1 Probabilistic multiplicative unbalanced linguistic term set (PM-ULTS)

Definition 1 [27] Let $\mathbb{LS} = \{t_{a^i} | i = -n, \ldots, 0, \ldots, m\}$ be a ULTS, where n and m may or may not be equal, $a > 1$. Then, a probabilistic multiplicative ULTS is defined as

$$\mathbb{LS}(p) = \{t_{a^i}{}^k(p^k) | k = 1, 2, \ldots, \#\mathbb{LS}(p)\}$$

where $t_{a^i}{}^k \in \mathbb{LS}$, $p^k \geq 0$, $\sum_{k=1}^{\#\mathbb{LS}(p)} p^k$ may or may be not be equal to 1 and $\#\mathbb{LS}(p)$ is the cardinality of all the given distinct multiplicative unbalanced linguistic terms in $\mathbb{LS}(p)$. The term $t_{a^i}{}^k(p^k)$ is interpreted as unbalanced linguistic term $t_{a^i}{}^k$ associated with the probability p^k.

Note If $\sum_{k=1}^{\#\mathbb{LS}(p)} p^k < 1$ or $\sum_{k=1}^{\#\mathbb{LS}(p)} p^k > 1$, then the probability information within the set is incomplete and we normalize the incomplete PM-ULTS to transform the set into complete PM-ULTS using the following process.

1. Normalize the probability. If $\sum_{k=1}^{\#\mathbb{LS}(p)} p^k \neq 1$, then the given PM-ULTS is defined as $\widetilde{\mathbb{LS}}(p) = \{t_{a^i}{}^k(\bar{p}^k) | \sum_{k=1}^{\#\mathbb{LS}(p)} \bar{p}^k = 1\}$, where $\bar{p} = \frac{p^k}{\sum_{k=1}^{\#\mathbb{LS}(p)} p^k}$, $t_{a^i} \in \mathbb{LS}$, $p^k \geq 0$, $k = 1, \ldots, \#\mathbb{LS}(p)$;

2. Normalize the granularity. If $\mathbb{LS}_1(p)$ and $\mathbb{LS}_2(p)$ are two PM-ULTS. If $\#\mathbb{LS}_1(p) < \#\mathbb{LS}_2(p)$, add $\#\mathbb{LS}_2(p) - \#\mathbb{LS}_1(p)$ multiplicative unbalanced linguistic terms to $\mathbb{LS}_1(p)$

Definition 2 [27] Let $\mathbb{LS}(p) = \{t_{a^i}{}^k(\bar{p}^k)|k = 1, \ldots, \#\mathbb{LS}(p)\}$ be a normalized PM-ULTS. The negation of $\mathbb{LS}(p)$ is defined as $Neg(\mathbb{LS}(p)) = \{neg(t_{a^i}{}^k)(\bar{p}^k)|k = 1, \ldots, \#\mathbb{LS}(p)\}$.

Definition 3 [27] Let $\mathbb{LS}_1(p_1) = \{t_{a^i}{}^k(p^k)|k = 1, 2, \ldots, \#\mathbb{LS}_1(p_1)\}$ and $\mathbb{LS}_2(p_2) = \{t_{a^j}{}^k(p^k)|k = 1, 2, \ldots, \#\mathbb{LS}_2(p_2)\}$, $i,j = -n, \ldots, m$ be any two ordered PM-ULTS. Then, the operational laws are given as follows:

1. $\mathbb{LS}_1(p_1) \oplus \mathbb{LS}_2(p_2) = \{t^k_{a^i \oplus a^j}(\bar{p}^k_1 \oplus \bar{p}^k_2)|k = 1, 2, \ldots, \#\mathbb{LS}_1(p_1)\}$
2. $\mathbb{LS}_1(p_1) \otimes \mathbb{LS}_2(p_2) = \{t^k_{a^i \otimes a^j}(\bar{p}^k_1 \otimes \bar{p}^k_2)|k = 1, 2, \ldots, \#\mathbb{LS}_1(p_1)\}$
3. Let $\lambda \in (0, 1)$ be any arbitrary scalar, $\lambda \odot \mathbb{LS}(p) = \{t^k{}_{\lambda \odot a^i}(\bar{p}^k)|k = 1, 2, \ldots \mathbb{LS}(p)\}$
4. $(\mathbb{LS}(p))^\lambda = \{t^k_{a^{\lambda i}}(\bar{p}^k)|k = 1, 2, \ldots \#\mathbb{LS}(p)\}$

2.2 Unbalanced linguistic cloud model

Definition 4 [11] Let $\mathbb{LS} = \{t_{a^i}|i = -n, \ldots, 0, \ldots, m\}$, $a > 1$ (n and m may or may not be equal) be any finite ordered multiplicative unbalanced LT set. The linguistic scale function (LSF) converting a linguistic term t_{a^i} to a certain number δ_{a^i}, $(i = -n, \ldots, 0, \ldots, m)$ can be expressed as follows:

$$\widetilde{\mathfrak{g}} : t_{a^i} \to \delta_{a^i} \, (i = -n, \ldots, 0, \ldots, m)$$

where

$$\delta_{a^i} = \begin{cases} \left(\frac{b^n - b^{-i}}{2b^n - 2}\right)\frac{1}{\log a}, & -n \le i \le 0 \\ \left(\frac{b^n + b^i - 2}{2b^n - 2}\right)\frac{1}{\log a}, & 0 < i \le n \end{cases} \tag{1}$$

Here, $\delta_{a^i} \in [0, 1/\log a] \subseteq [0, 1]$ is a numeric value. The value of the parameter b can be obtained through experiments such as $b \in [1.36, 1.4]$ [4]. In this paper, we take $b = 1.4$ without any loss of generality.

The next definition introduces the process of generating cloud droplets based on the rational transformation method of unbalanced linguistic variables into clouds.

Definition 5 [11] Let $t_{a^i} \in \mathbb{LS}$ be any arbitrary unbalanced linguistic term corresponding to the cloud drop $(EX_{a^i}, EN_{a^i}, HE_{a^i})$. Then, the working cloud generation procedure is given as follows:

1. Calculate δ_{a^i} using Eq. 1.
2. Calculate EX_{a^i}.

$$EX_{a^i} = X_{\min} + \delta_{a^i}(X_{\max} - X_{\min})$$

3. Calculate EN_{a^i}.

$$3EN'_{a^i} = \max(X_{\max} - EX_{a^i}, EX_{a^i} - X_{\min})$$

Because of $EN' \sim N(EN, HE^2)$, EN_{a^i} may be considered the mean value of EN'_{a^i} corresponding to the clouds in consideration and their adjacent clouds.

$$EN_{a^{-i}} = EN_{a^i} = \frac{EN'_{a^{i-1}} + EN'_{a^i} + EN'_{a^{i+1}}}{3\log a} \text{ for } |i| = 0, 1, \ldots, n-1, \tag{2}$$

and for $|i| = n$,

$$EN_{a^{-n}} = EN_{a^n} = \frac{EN'_{a^n} + EN'_{a^{n-1}}}{2\log a} \tag{3}$$

These calculations may be rewritten as the following formulas:

$$EN'_{a^i} = \begin{cases} \frac{(1-\delta_{a^i})(X_{\max}-X_{\min})}{3\log a}, & -n \le i \le 0 \\ \frac{\delta_{a^i}(X_{\max}-X_{\min})}{3\log a}, & 0 < i \le n \end{cases} \tag{4}$$

$$EN_{a^{-i}} = EN_{a^i} = \begin{cases} \frac{(\delta_{a|i-1|}+\delta_{a|i|}+\delta_{a|i+1|})(X_{\max}-X_{\min})}{9\log a}, & 0 < |i| < n-1 \\ \frac{(\delta_{a|i|}+\delta_{a|i-1|})(X_{\max}-X_{\min})}{6\log a}, & |i| = n \\ \frac{(\delta_{a^i}+2\delta_{a^{i+1}})(X_{\max}-X_{\min})}{9\log a}, & i = 0 \end{cases} \tag{5}$$

4. Calculate HE_{a^i}. Due to $EN'_{a^i} \sim N(EN_{a^i}, {HE_{a^i}}^2)$, the hyperentropy satisfies the 3σ principle. In particular,

$$HE_{a^{-i}} = HE_{a^i} = \frac{EN'^{+} - EN_{a^i}}{3\log a} \tag{6}$$

where, $EN'^{+} = \sup_k\{EN'_k\}$.

Note It should be noted that the point-based cloud-generating procedure described above can be used in scenario $n \neq m$ if dummy variables are added to the multiplicative unbalanced linguistic term set in a way that $n = m$.

2.3 Matrix games

Definition 6 [5] A crisp two-player zero-sum matrix game is represented as a triplet (S^r, S^s, A), where S^r is the set of 'r' possible strategies of Player I, S^s is the set of 's' possible strategies of Player II, $[A]_{r\times s}$ is the payoff matrix of order of Player I corresponding to Player II, and $neg(A)$ refers to the matrix consisting of payoffs of Player II.

Definition 7 [5] A matrix game having $A = (a_{ij})_{r\times s}$ as the matrix of payoffs has the lower value

$$v^- = \max_{i=1,\ldots,r} \min_{j=1,\ldots,s} a_{ij}$$

and the upper value

$$v^+ = \min_{j=1,\ldots,s} \max_{i=1,\ldots,r} a_{ij}$$

The upper value v^+ is the guaranteed maximum that Player II may lose, while the lower value v^- is the guaranteed minimum that Player I is guaranteed to get. If $v^+ = v^-$, we say that the game has a value of v.

Definition 8 [5] If no pure strategies exist, a mixed strategy is a vector where $\Phi = (\phi_1, \phi_2, \ldots, \phi_r)$ for Player I and $\Psi = (\psi_1, \psi_2, \ldots, \psi_s)$ for Player II, where

$$\phi_i \geq 0, \sum_{i=1}^{r} \phi_i = 1 \quad \& \quad \psi_j \geq 0, \sum_{j=1}^{s} \psi_j = 1.$$

Player I's probability of utilizing row 'i' and Player II's probability of using column 'j' are each represented by ϕ_i and ψ_j. We represent the collection of mixed strategies having 'k' components as

$$S^k = \left\{ (z_1, z_2, \ldots, z_k) | \, z_r \geq 0, r = 1, 2, \ldots, k, \sum_{r=1}^{k} z_r = 1 \right\}.$$

Given a choice of mixed strategy $\Phi = (\phi_1, \phi_2, \ldots, \phi_r)$ for Player I and $\Psi = (\psi_1, \psi_2, \ldots, \psi_s)$ for Player II, selected autonomously, the expected payoff of Player I is

$$\begin{aligned} E(\Phi, \Psi) &= \sum_{i=1}^{r} \sum_{j=1}^{s} \phi_i a_{ij} \psi_j \\ &= \Phi A \Psi^T \end{aligned}$$

3 Transformation of PM-UL variables to PULCs and operational laws

In this section, we present how to transform a PM-UL variable to its corresponding PULC, and a numerical example is shown. Further, the operational laws and score function of PULCs are defined.

3.1 Method for transformation of probabilistic unbalanced linguistic variables to probabilistic unbalanced linguistic clouds (PULCs)

Definition 9 Let $\mathbb{LS} = \{t_{a^i} | i = -n, \ldots, 0, \ldots, m\}$ be a ULTS where n and m may or may not be equal and $a > 1$. Suppose p_i be any probability associated with the unbalanced linguistic term t_{a^i} such that $\mathbb{LS}(p) = \{t_{a^i}(p_i) | i = -n, \ldots, m\}$ denotes the linguistic set representing linguistic terms having attached probabilities.

Consider a valid universe $X = [X_{\min}, X_{\max}]$. Now to represent the linguistic terms of the set $\mathbb{LS}(p)$, the procedure is as given below.

- First transform the linguistic terms into their corresponding cloud using the method given in Definition 4 and 5, i.e.

* Find the value of the LSF δ_{a^i}, $(i = -n, \ldots, 0, \ldots, m)$
* Calculate EX_{a^i} as $EX_{a^i} = X_{\min} + \delta_{a^i}(X_{\max} - X_{\min})$.
* Compute EN_{a^i}.
* Calculate HE_{a^i}.

Note. The above-mentioned procedure is used in the scenario $n = m$. In case $n \neq m$, then we add a dummy linguistic term with probability $\}0'$ in $\mathbb{LS}(p)$ so that $n = m$, where the linguistic term is added on the side of $\min(m, n)$.

- Now consider the attached probabilities with the linguistic terms by multiplying these probabilities with the above-obtained cloud. Hence, a cloud corresponding to a linguistic term $t_{a^i}(p_i)$ is given as $\mathbb{Y}_i(p_i EX_{a^i}, p_i EN_{a^i}, p_i HE_{a^i})$.

$$\therefore t_{a^i}(p_i) \longrightarrow (p_i EX_{a^i}, p_i EN_{a^i}, p_i HE_{a^i})$$

Example 1 Given the universe $[X_{\min}, X_{\max}] = [0, 7]$, let $\mathbb{LS} = \{t_{2^{-2}} : \text{Terrible}, t_{2^{-1}} : \text{Poor}, t_{2^0} : \text{Middle}, t_{2^1} : \text{Satisfactory}, t_{2^2} : \text{Good}, t_{2^3} : \text{Excellent}\}$. As $n \neq m$, we add a dummy linguistic term on the left hand side of $\mathbb{LS}$ with probability $\}0'$. Consider $\mathbb{LS}(p) = \{t_{2^{-3}}(0), t_{2^{-2}}(0), t_{2^{-1}}(0.1), t_{2^0}(0.4), t_{2^1}(0), t_{2^2}(0.2), t_{2^3}(0.3)\}$. By following the steps mentioned above, the cloud is generated as follows. Setting $b = 1.4$.

1. First we calculate δ_{a^i} for each t_{a^i}. $\delta_{2^{-3}} = 0 \quad \delta_{2^{-2}} = 0.7467 \quad \delta_{2^{-1}} = 1.2801$ $\delta_{2^0} = 1.6611 \quad \delta_{2^1} = 2.0421 \quad \delta_{2^2} = 2.5755 \quad \delta_{2^3} = 3.3222$
2. $EX_{2^{-3}} = 0 \quad EX_{2^{-2}} = 5.22718 \quad EX_{2^{-1}} = 8.9607 \quad EX_{2^0} = 11.6277 \quad EX_{2^1} = 14.2947$ $EX_{2^2} = 18.0285 \quad EX_{2^3} = 23.2557$
3. $EN'_{2^{-3}} = 7.7519 \quad EN'_{2^{-2}} = 1.9632 \quad EN'_{2^{-1}} = -2.1715 \quad EN'_{2^0} = -5.125$ $EN'_{2^1} = 15.8308 \quad EN'_{2^2} = 19.9652 \quad EN'_{2^3} = 25.7538 \therefore \max EN'_{a^i} = 25.7538$ Next, $EN_{2^{-3}} = EN_{2^3} = 22.8595 \quad EN_{2^{-2}} = EN_{2^2} = 20.5164 \quad EN_{2^{-1}} = EN_{2^1} = 16.2241$ $EN_{2^0} = 14.8457$
4. $HE_{2^{-3}} = HE_{2^3} = 20.9258 \quad HE_{2^{-2}} = HE_{2^2} = 23.9762 \quad HE_{2^{-1}} = HE_{2^1} = 26.7236$ $HE_{2^0} = 21.944$

Hence, the probabilistic multiplicative unbalanced clouds corresponding to each linguistic term of the set $\mathbb{LS}(p)$ are given as: $t_{2^{-3}}(0) \longrightarrow (0, 0, 0) \quad t_{2^{-2}}(0) \longrightarrow (0, 0, 0)$ $t_{2^{-1}}(0.1) \longrightarrow (0.89607, 1.6224, 2.6723) \quad t_{2^0}(0.4) \longrightarrow (4.651, 5.9382, 8.777) \quad t_{2^1}(0) \longrightarrow$ $t_{2^1}(0) \longrightarrow (0, 0, 0) \quad t_{2^2}(0.2) \longrightarrow (3.6057, 4.1032, 4.7952) \quad t_{2^3}(0.3) \longrightarrow (6.9767,$ $6.8578, 6.2777)$ These probabilistic multiplicative unbalanced linguistic clouds are represented in Fig. 1.

In the graph, the dispersing extent of cloud drops is depicted by entropy and the hyperentropy EN and HE, respectively. It is also the measurement of fuzziness, representing the scope of the universe that can be accepted by the concept.

3.2 Operations and score functions of probabilistic unbalanced linguistic clouds

In this section, we define some operational laws for probabilistic unbalanced linguistic clouds based on the operators defined for normal clouds.

Definition 10 Given the PULCs $\mathbb{Y}_i = (p_i EX_{a^i}, p_i EN_{a^i}, p_i HE_{a^i})$, the basic operations are developed as follows:

1. $\sum_{i=-n}^{m} (p_i EX_{a^i}, p_i EN_{a^i}, p_i HE_{a^i}) = \left(\sum_{i=-n}^{m} p_i EX_{a^i}, \sqrt{\sum_{i=-n}^{m} \left(p_i EN_{a^i}\right)^2}, \sqrt{\sum_{i=-n}^{m} \left(p_i HE_{a^i}\right)^2} \right)$
2. $\lambda(p_i EX_{a^i}, p_i EN_{a^i}, p_i HE_{a^i}) = (\lambda p_i EX_{a^i}, \lambda p_i EN_{a^i}, \lambda p_i HE_{a^i})$, where λ is any real scalar.
3. Let $\mathbb{Y}_i(p_i EX_{a^i}, p_i EN_{a^i}, p_i HE_{a^i})$, $i = -n, \ldots, m$ be a collection of PULCs with associated weights $\omega_i \in [0, 1]$ and $\sum_{i=-n}^{m} \omega_i = 1$. Then, their aggregated value with use of the weighted average (WA) operator is still a cloud and is denoted as follows:

$$WA(Y_{-n}, \ldots, Y_m) = \left(\sum_{i=-n}^{m} \omega_i p_i EX_{a^i}, \sqrt{\sum_{i=-n}^{m} \omega_i \left(p_i EN_{a^i}\right)^2}, \sqrt{\sum_{i=-n}^{m} \omega_i \left(p_i HE_{a^i}\right)^2} \right) \quad (7)$$

The score function is a crucial tool for obtaining the ranking results during the decision-making process. For the normal clouds, a number of score functions have previously been defined. Here, we define the score function for PULCs. Before

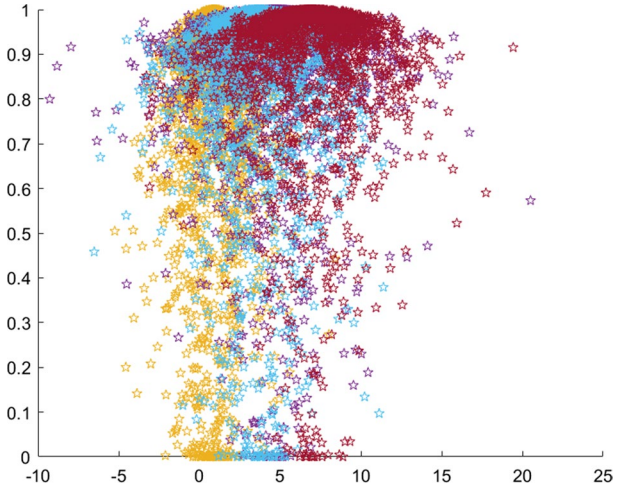

Fig. 1 Representation of probabilistic multiplicative unbalanced linguistic clouds with respect to linguistic terms having attached probabilities based on 1000 droplets

presenting the new function, we first introduce an important concept, the variance of a normal cloud, which is developed by Li et al. [30].

Definition 11 Let $(p_iEX_{a^i}, p_iEN_{a^i}, p_iHE_{a^i})$ be a PULC with $n+m+1$ generated cloud drops, and the variance of these cloud drops can be computed as

$$V = \left(p_iEN_{a^i}\right)^2 + \left(p_iHE_{a^i}\right)^2 \tag{8}$$

Hence, the standard deviation follows $S.D. = \sqrt{V}$.

The standard deviation ($S.D.$), which can be used to express the ambiguity and fluctuation of a quantitative notion, is used to measure the dispersion of cloud drops. A low standard deviation indicates that the distribution of the linguistic term is reasonably steady. A high standard deviation suggests stability even when the linguistic concept has a high degree of ambiguity and volatility. In this case, the relationship between EX and $S.D$ can be seen as the expected utility and utility dispersion of the utility theory. Therefore, the choice for an option (alternative) can be expressed as a linear trade-off between expected utility and utility dispersion. In response to this approach, we construct a score formula below to compare PULCs.

Definition 12 Given a PULC $(p_iEX_{a^i}, p_iEN_{a^i}, p_iHE_{a^i})$, then a score function of PULC is defined as

$$\hat{S} = p_iEX_{a^i} - \gamma S.D. \tag{9}$$

where $S.D.$ is the standard deviation of a PULC, $\gamma \in [0, 1]$ refers to a coefficient to capture the attitude towards the standard deviation. The value of γ can be chosen based on actual decision-making circumstances. $\gamma = 0$ signifies that the DMs do not

care about the uncertainty and fluctuation of the assessment information and simply take into account the average level, which is the expectation *EX*. The greater the value of γ, the greater the weight given to *S.D*.

The score function $\hat{S}$ is monotonically increasing w.r.t. *EX* while monotonically decreasing w.r.t. *EN* and *HE*. On the basis of score function, two PULCs may be compared in the following manner.

Definition 13 Let $\mathbb{Y}_1$ and $\mathbb{Y}_2$ be two PULCs, and $\hat{S}_1$ and $\hat{S}_2$ denote their score functions, respectively, then

- If $\hat{S}_1 > \hat{S}_2$, then we prefer $\mathbb{Y}_1$ over $\mathbb{Y}_2$ and denote it as $\mathbb{Y}_1 > \mathbb{Y}_2$.
- $\hat{S}_1 = \hat{S}_2$ represents that both the PULCs are equally preferred and are denoted as $\mathbb{Y}_1 = \mathbb{Y}_2$.
- $\max\{\mathbb{Y}_i | i = -n, \ldots, m\} = \mathbb{Y}_{\max}$ such that $\hat{S}(\mathbb{Y}_{\max}) \geq \hat{S}(\mathbb{Y}_i)\ \forall\, i$.
- $\min\{\mathbb{Y}_i | i = -n, \ldots, m\} = \mathbb{Y}_{\min}$ such that $\hat{S}(\mathbb{Y}_{\min}) \leq \hat{S}(\mathbb{Y}_i)\ \forall\, i$.

Example 2 Consider the problem given in Example 1, the set consisting of linguistic terms with attached probabilities is $\mathbb{LS}(p) = \{t_{2^{-3}}(0),\ t_{2^{-2}}(0),\ t_{2^{-1}}(0.1),\ t_{2^0}(0.4), t_{2^1}(0), t_{2^2}(0.2),\ t_{2^3}(0.3)\}$. The PULCs obtained from these probabilistic unbalanced linguistic terms are

$$\mathbb{Y}_1(0,0,0) \quad \mathbb{Y}_2(0,0,0) \quad \mathbb{Y}_3(0.89607, 1.6224, 2.6723) \quad \mathbb{Y}_4(4.651, 5.9382, 8.777)$$

$$\mathbb{Y}_5(0,0,0) \quad \mathbb{Y}_6(3.6057, 4.1032, 4.7952) \quad \mathbb{Y}_7(6.9767, 6.8578, 6.2777)$$

Using the definition of score function, we find scores of these PULCs for some random values of γ and provide their rankings in Table 1.

Now, from the aspect of information representation form, the PM-UL information is a flexible tool for CWW. Also, the unbalanced linguistic cloud model has provided wonderful results to deal with uncertainty of a linguistic concept. But in the framework of game theory, it is still not investigated how to solve a game problem whose payoffs are of the form PM-UL by capturing the randomness and fuzziness involved in the payoffs. In this regard, Sect. 4 presents the definition of a PM-UL game (PM-ULG) and a methodology is given to solve such type of game by converting its payoffs to PULCs and treating it as a PM-UL cloud game (PM-ULCG).

Table 1 PULC rankings based on scores for different values of γ

Value of γ	$\hat{S}(\mathbb{Y}_1)$	$\hat{S}(\mathbb{Y}_2)$	$\hat{S}(\mathbb{Y}_3)$	$\hat{S}(\mathbb{Y}_4)$	$\hat{S}(\mathbb{Y}_5)$	$\hat{S}(\mathbb{Y}_6)$	$\hat{S}(\mathbb{Y}_7)$	Score ranking	PULC ranking
0	0	0	0.896	4.651	0	3.605	6.277	$\hat{S}(\mathbb{Y}_7) > \hat{S}(\mathbb{Y}_4) > \hat{S}(\mathbb{Y}_6) >$ $\hat{S}(\mathbb{Y}_3) > \hat{S}(\mathbb{Y}_1) = \hat{S}(\mathbb{Y}_2) = \hat{S}(\mathbb{Y}_5)$	$\mathbb{Y}_7 > \mathbb{Y}_4 > \mathbb{Y}_6 >$ $\mathbb{Y}_3 > \mathbb{Y}_1 = \mathbb{Y}_2 = \mathbb{Y}_5$
0.1	0	0	0.583	3.591	0	2.974	6.046	$\hat{S}(\mathbb{Y}_7) > \hat{S}(\mathbb{Y}_4) > \hat{S}(\mathbb{Y}_6) >$ $\hat{S}(\mathbb{Y}_3) > \hat{S}(\mathbb{Y}_1) = \hat{S}(\mathbb{Y}_2) = \hat{S}(\mathbb{Y}_5)$	$\mathbb{Y}_7 > \mathbb{Y}_4 > \mathbb{Y}_6 >$ $\mathbb{Y}_3 > \mathbb{Y}_1 = \mathbb{Y}_2 = \mathbb{Y}_5$
0.2	0	0	0.27	2.531	0	2.343	5.117	$\hat{S}(\mathbb{Y}_7) > \hat{S}(\mathbb{Y}_4) > \hat{S}(\mathbb{Y}_6) >$ $\hat{S}(\mathbb{Y}_3) > \hat{S}(\mathbb{Y}_1) = \hat{S}(\mathbb{Y}_2) = \hat{S}(\mathbb{Y}_5)$	$\mathbb{Y}_7 > \mathbb{Y}_4 > \mathbb{Y}_6 >$ $\mathbb{Y}_3 > \mathbb{Y}_1 = \mathbb{Y}_2 = \mathbb{Y}_5$

4 Two-person probabilistic multiplicative unbalanced linguistic cloud games (PM-ULCG)

In uncertain situations, the probabilistic unbalanced linguistic matrix game with payoffs as clouds is introduced in this section to model uncertain cloud payoff values. The payoff matrix $\widetilde{A}$ with probabilistic unbalanced linguistic information can be denoted as:

Player I	Player II			
	Strategy 1	Strategy 2	$\cdots$	Strategy s
Strategy 1	$\widetilde{a}_{11}$	$\widetilde{a}_{12}$	$\cdots$	$\widetilde{a}_{1s}$
Strategy 2	$\widetilde{a}_{21}$	$\widetilde{a}_{12}$	$\cdots$	$\widetilde{a}_{2s}$
$\vdots$	$\vdots$	$\vdots$	$\vdots$	$\vdots$
Strategy r	$\widetilde{a}_{r1}$	$\widetilde{a}_{r2}$	$\cdots$	$\widetilde{a}_{rs}$

where each $\widetilde{a}_{ij} \in LS(p)$ is a probabilistic unbalanced linguistic term.

4.1 PM-ULCG: definition and meaning

A two-person constant sum probabilistic multiplicative unbalanced linguistic cloud game is defined as $(S^r, S^s, \mathbb{LS}(p), \widetilde{A})$ where S^r and S^s are the strategy sets of Player I and Player II, respectively. $\mathbb{LS}(p)$ is the set of PM-UL terms having associated probabilities. Now to deal with the uncertainties like randomness and fuzziness underlying the PM-UL terms $\widetilde{a}_{ij}$, we first convert the payoffs in the form of PULC. Hence, finally, $\widetilde{A}$ is the payoff matrix of Player I corresponding to Player II given as

$$\widetilde{A} = \begin{pmatrix} \widetilde{a}_{11} & \widetilde{a}_{12} & \cdots & \widetilde{a}_{1s} \\ \widetilde{a}_{21} & \widetilde{a}_{22} & \cdots & \widetilde{a}_{2s} \\ \vdots & \vdots & \ddots & \vdots \\ \widetilde{a}_{r1} & \widetilde{a}_{r2} & \cdots & \widetilde{a}_{rs} \end{pmatrix}$$

where each $\widetilde{a}_{ij} = (p_t EX_{a^t}, p_t EN_{a^t}, p_t HE_{a^t})$ is a PULC. On the contrary, $neg(\widetilde{A})$ is the payoff matrix of Player II, where $neg(\widetilde{A}) = neg(\widetilde{a}_{ij})_{r\times s}$, where $neg(\widetilde{a}_{ij})$ is as defined in Definition 10.

Conventionally, Player I is the row player and wants to maximize his payoff, while column player II wants to minimize row player's payoff so as to maximize his own payoff. The rows are pure strategies for Player I and columns for Player II.

$$v^- = \max_{i=1,\ldots,r} \min_{j=1,\ldots,s} \widetilde{a}_{ij}$$

called the lower value of the game, and is the minimum amount that Player I is guaranteed to receive. Here $\widetilde{a}_{ij}$ is a PM-UL term. On the other hand,

$$\omega^- = \max_{i=1,\ldots,r} \min_{j=1,\ldots,s} neg(\widetilde{a}_{ij})$$

is the minimum amount that Player *II* is guaranteed to receive. Obviously,

$$\upsilon^+ = neg(\omega^-) = \min_{j=1,\ldots,s} \max_{i=1,\ldots,r} \widetilde{a}_{ij}$$

is the upper value of the game and is the guaranteed maximum amount that Player *II* can lose. The game is said to have a value $\upsilon = (EX_{a^i}, EN_{a^i}, HE_{a^i})$ if $\upsilon^- = \upsilon^+ = \upsilon$, also called the saddle point in pure strategies. However, in most two-person zero sum games a saddle point in pure strategies will not exist because that would interpret that the players must always play in a similar manner. But that is not always possible as in such case, the opposing player will be able to figure out the player's strategy in advance.

Definition 14 A mixed cloud strategy is a vector $\varrho = (\varrho_1, \varrho_2, \ldots, \varrho_r)$ for Player *I* and $\varphi = (\varphi_1, \varphi_2, \ldots, \varphi_s)$ for Player *II*, where

$$\varrho_i \geq 0, \varrho_i = (EX_{a^i}, EN_{a^i}, HE_{a^i}) \text{ so that } \sum_{i=1}^{r} \varrho_i = 1 \implies \sum_{i=1}^{r} EX_{a^i} = 1,$$

$$\sqrt{\sum_{i=1}^{r} {EN_{a^i}}^2} = 1, \text{ and } \sqrt{\sum_{i=1}^{r} {HE_{a^i}}^2} = 1$$

and,

$$\varphi_j \geq 0, \varphi_j = (EX_{a^j}, EN_{a^j}, HE_{a^j}) \text{ so that } \sum_{j=1}^{s} \varphi_j = 1 \implies \sum_{j=1}^{s} EX_{a^j} = 1,$$

$$\sqrt{\sum_{j=1}^{s} {EN_{a^j}}^2} = 1, \text{ and } \sqrt{\sum_{j=1}^{s} {HE_{a^j}}^2} = 1$$

The set of mixed strategies having k components is denoted as

$$S^k = \left\{ (z_1, z_2, \ldots, z_k) | z_i \geq 0, \sum_{i=1}^{k} EX_{a^i} = 1, \sqrt{\sum_{i=1}^{k} {EN_{a^i}}^2} = 1, \text{ and } \sqrt{\sum_{i=1}^{k} {HE_{a^i}}^2} = 1 \right\}$$

such that $\varrho \in S^r$ and $\varphi \in S^s$.

Since it is mentioned that a PM-ULCG has a saddle point in pure strategies if $\upsilon^- = \upsilon^+$. However, in practical real-life scenarios, this is not always the case that saddle point exists. Hence in that case, the following inequality holds in general.

Theorem 1 *Suppose v^- and v^+ be the lower and upper values of a PM-ULCG, respectively, and let both the values exist. Then $v^- \leq v^+$.*

Proof For any column j, we know that for any fixed row i, by Definition 13

$$\min_{j=1,\ldots,s} \widetilde{a}_{ij} \leq \widetilde{a}_{ij}$$

Taking max over $i = 1, \ldots, r$ both the sides,

$$v^- = \max_{i=1,\ldots,r} \min_{j=1,\ldots,s} \widetilde{a}_{ij} \leq \max_{i=1,\ldots,r} \widetilde{a}_{ij}$$

This is true for any column $j = 1, \ldots, s$. The LHS is just a number independent of i and j and is smaller than RHS for any j. This means that $v^- \leq \min_{j=1,\ldots,s} \max_{i=1,\ldots,r} \widetilde{a}_{ij} = v^+$. This proves the theorem. □

In crisp games, the expected payoff of the player is presented in the form of mathematical expectation; but the uncertainty pertaining in the PM-ULCG does not allow the expected payoffs to be defined simply as in crisp games. Thus, it is necessary to define PM-UL cloud expected payoffs.

Definition 15 Let $\varrho \in S^r$ and $\varphi \in S^s$ be the mixed strategies associated with Player *I* and Player *II*, respectively. Then, the PM-UL cloud expected payoff of Player *I* is defined as:

$$E(\varrho, \varphi) = \bigoplus_{i=1}^{r} \left(\varrho_i \left(\bigoplus_{j=1}^{s} \widetilde{a}_{ij} \varphi_j \right) \right)$$

where $\widetilde{a}_{ij} = (p_t EX_{a^t}, p_t EN_{a^t}, p_t HE_{a^t})$, $t = -n, \ldots, m$ is a PULC.

$$\implies E(\varrho, \varphi) = \left(\sum_{i=1}^{r} \sum_{j=1}^{s} \varrho_i \varphi_j p_t EX_{a^t}, \sqrt{\sum_{i=1}^{r} \sum_{j=1}^{s} \varrho_i \varphi_j \left(p_t EN_{a^t} \right)^2}, \sqrt{\sum_{i=1}^{r} \sum_{j=1}^{s} \varrho_i \varphi_j \left(p_t HE_{a^t} \right)^2} \right) \tag{10}$$

and this expected payoff is further a PULC. Similarly, the PM-UL cloud expected payoff of Player *II* is given by $Neg(E(\varrho, \varphi))$.

4.2 PM-ULCG: methodology and solution

This section discusses the probabilistic unbalanced linguistic cloud linear programming (PULCLP) method for solving matrix games problems having payoffs in the form of PM-UL terms.

Suppose $\mathbb{LS}(p) = \{t_{a^i}(p_i) | i = -n, \ldots, m\}$ where n and m are positive integers and $a > 1$ be the linguistic set having PM-UL terms with probabilities

associated with them; $\widetilde{A} = [\widetilde{a}_{rs}]$ be the PULC matrix so that each $\widetilde{a}_{ij}$ represents a PULC written as $\widetilde{a}_{ij} = (p_t EX_{a^t}, p_t EN_{a^t}, p_t HE_{a^t})$. Let υ^- refers to the lower value of the game corresponding to Player I and let $\varrho \in S^r$ be the mixed strategies of Player I. Now, the PM-UL cloud expected payoff of Player I for s^{th} strategy of Player II is the weighted average of $\widetilde{a}_{ij}$, i.e. $\bigoplus_{j=1}^{s} \left(\varrho_i \widetilde{a}_{ij}\right)$ where $\widetilde{a}_{ij} = (p_t EX_{a^t}, p_t EN_{a^t}, p_t HE_{a^t})$, $t = -n, \ldots, m$ is a PULC such that $i = 1, 2, \ldots, r$. Analogously, υ^+ is the maximum expected payoff of Player II, $\varphi \in S^s$ is its mixed strategy, and its expected payoff against Player I's r^{th} strategy is given by $\bigoplus_{i=1}^{r} \left(\varphi_i \widetilde{a}_{ij}\right)$ where $j = 1, 2, \ldots, s$.

For finding the expected payoffs and values of both the players in terms of PULCs, we first convert each PM-UL payoff to a PULC.

Hence, the PULCLP for Player I can be given as

$$\max \upsilon^- \tag{P1}$$

$$\text{s.t.} \begin{cases} \bigoplus_{i=1}^{r} \widetilde{a}_{ij} \varrho_i \geq \upsilon^- \; j = 1, 2, \ldots, s \\ \text{where} \\ \varrho_i \geq 0, \; \sum_{i=1}^{r} \varrho_i = 1. \end{cases}$$

and for Player II, the problem is

$$\max \omega^- \tag{P2}$$

$$\text{s.t.} \begin{cases} \bigoplus_{j=1}^{s} neg(\widetilde{a}_{ij}) \varphi_j \geq \omega^- \; i = 1, 2, \ldots, r \\ \text{where} \\ \varphi_j \geq 0, \; \sum_{j=1}^{s} \varphi_j = 1. \end{cases}$$

In above problems, each $\widetilde{a}_{ij}$ is a PULC. Further, simplifying P2 and using the properties of negation operator, the problem for Player II becomes

$$\begin{array}{l} \min \quad \upsilon^+ \\ \text{s.t.} \begin{cases} \bigoplus_{j=1}^{s} \widetilde{a}_{ij} \varphi_j \leq \upsilon^+ \; i = 1, 2, \ldots, r \\ \text{where} \\ \varphi_j \geq 0, \; \sum_{j=1}^{s} \varphi_j = 1. \end{cases} \end{array} \tag{P3}$$

A unified mechanism for solving a probabilistic unbalanced linguistic game for Player I is given below in the form of a computation procedure.

Step 1: First normalize the payoff matrix for the row player (i.e. normalize the payoff entries row-wise) so that the sum of probabilities in each row is 1.

Step 2: Convert each payoff to a PULC using the procedure given in Sect. 3.1 to deal with uncertainty in a better way.

Step 3: Since each payoff is a PULC now, suppose the expected value of Player I be $\upsilon^- = (v_{EX}{}^-, v_{EN}{}^-, v_{HE}{}^-)$ such that the PULCLP becomes

$$\max \quad \upsilon^{-} \implies (\max \upsilon_{EX}{}^{-}, \min \upsilon_{EN}{}^{-}, \min \upsilon_{HE}{}^{-})$$
$$\text{s.t.} \begin{cases} \bigoplus_{i=1}^{r} \widetilde{a}_{ij} \varrho_i \geq \upsilon^{-} \; j = 1, 2, \ldots, s \\ \text{where} \\ \varrho_i \geq 0, \sum_{i=1}^{r} \varrho_i = 1. \end{cases} \tag{P4}$$

Here each $\widetilde{a}_{ij} = (p_t EX_{a^t}, p_t EN_{a^t}, p_t HE_{a^t})$.

Step 4: From here, the PM-ULCG splits into three individual games, called the expectation game, entropy game, and hyperentropy game given as: Expectation Game

$$\max \quad \upsilon_{EX}{}^{-}$$
$$\text{s.t.} \begin{cases} \sum_{i=1}^{r} (p_t EX_{a^t})_{ij} \varrho_i \geq \upsilon_{EX}{}^{-} \; j = 1, 2, \ldots, s \\ \text{where} \\ \varrho_i \geq 0, \sum_{i=1}^{r} \varrho_i = 1. \end{cases} \tag{EX:1}$$

Entropy Game

$$\min \quad \upsilon_{EN}{}^{-}$$
$$\text{s.t.} \begin{cases} \sqrt{\sum_{i=1}^{r} [(p_t EN_{a^t})_{ij}]^2} \varrho_i \leq \upsilon_{EN}{}^{-} \; j = 1, 2, \ldots, s \\ \text{where} \\ \varrho_i \geq 0, \sum_{i=1}^{r} \varrho_i = 1. \end{cases} \tag{EN:1}$$

Hyperentropy Game

$$\min \quad \upsilon_{HE}{}^{-}$$
$$\text{s.t.} \begin{cases} \sqrt{\sum_{i=1}^{r} [(p_t HE_{a^t})_{ij}]^2} \varrho_i \leq \upsilon_{HE}{}^{-} \; j = 1, 2, \ldots, s \\ \text{where} \\ \varrho_i \geq 0, \sum_{i=1}^{r} \varrho_i = 1. \end{cases} \tag{HE:1}$$

Step 5: Proceeding further, Expectation Game Setting $X_i = \frac{\varrho_i}{\upsilon_{EX}{}^{-}}$ and letting $V_{EX} = \frac{1}{\upsilon_{EX}{}^{-}}$, the transformed linear programming problem becomes

$$\min \quad V_{EX} = \sum_{i=1}^{r} X_i$$
$$\text{s.t.} \begin{cases} \sum_{i=1}^{r} (p_t EX_{a^t})_{ij} X_i \geq 1 \; j = 1, 2, \ldots, s \\ \text{where } X_i \geq 0 \end{cases} \tag{EX Game PI}$$

Entropy Game Squaring both sides of the constraints and letting $(\upsilon_{EN}{}^{-})^2 = \upsilon_{EN}{}'$. Further setting $Y_i = \frac{\varrho_i}{\upsilon_{EN}{}'}$, and letting $V_{EN}{}' = \frac{1}{\upsilon_{EN}{}'} \upsilon_{EN}{}^{-} = \sqrt{\upsilon_{EN}{}'} = \frac{1}{\sqrt{V_{EN}{}'}}$
$\therefore \min \upsilon_{EN}{}^{-} \equiv \max \sqrt{V_{EN}{}'}$ $V_{EN}{}'$ being a positive quantity, we maximize $V_{EN}{}'$ instead of $\sqrt{V_{EN}{}'}$ and square the value later on. Thus, the final entropy linear programming problem becomes

$$\begin{aligned} &\max \quad {V_{EN}}' = \sum_{i=1}^{r} Y_i \\ &\text{s.t.} \begin{cases} \sum_{i=1}^{r} \left[(p_t EN_{a^t})_{ij}\right]^2 Y_i \le 1,\ j = 1, 2, \ldots, s \\ \text{where } Y_i \ge 0 \end{cases} \end{aligned} \tag{EN Game PI}$$

Hyperentropy Game Similar to entropy game, squaring both sides and letting $(\upsilon_{HE})^2 = {\upsilon_{HE}}'$. Further setting $Z_i = \frac{\varrho_i}{{\upsilon_{HE}}'}$, and suppose ${V_{HE}}' = \frac{1}{{\upsilon_{HE}}'} {\upsilon_{HE}}^- = \sqrt{{\upsilon_{HE}}'} = \frac{1}{\sqrt{{V_{HE}}'}} \therefore \min {\upsilon_{HE}}^- \equiv \max \sqrt{{V_{HE}}'}\ {V_{HE}}'$ being a positive quantity, we maximize ${V_{HE}}'$ instead of $\sqrt{{V_{HE}}'}$ and square the value later on. Thus, the final hyperentropy linear programming problem becomes

$$\begin{aligned} &\max \quad {V_{HE}}' \\ &\text{s.t.} \begin{cases} \sum_{i=1}^{r} \left[(p_t HE_{a^t})_{ij}\right]^2 Z_i \le 1,\ j = 1, 2, \ldots, s \\ \text{where } Z_i \ge 0 \end{cases} \end{aligned} \tag{HE Game PI}$$

Step 6: After the formulation of final LPPs each for expectation, entropy and hyperentropy, we solve them to get the PULC strategies and PULC value of each game. Combining all three, we get Lower value of the game: $\upsilon^- = ({\upsilon_{EX}}^-, {\upsilon_{EN}}^-, {\upsilon_{HE}}^-)$ and mixed strategies ϱ_i for each game such that $\sum_{i=1}^{r} \varrho_{i_{EX}} = 1,\ \sqrt{\sum_{i=1}^{r} \varrho_{i_{EN}}^2} = 1,\ \sqrt{\sum_{i=1}^{r} \varrho_{i_{HE}}^2} = 1$

Step 7: Substituting back to the original variables, we get the final results. Also, the final strategy to be played by the player may be decided by using score of each strategy. The higher the score, the better (optimum) is the strategy.

Figure 2 demonstrates the process of evaluation of a PM-ULCG problem for the row player.

The exact same procedure is to be followed for Player *II*, where the payoffs are $neg(\widetilde{a}_{ij})$. The expected value of Player *II* would be $\upsilon^+ = ({\upsilon_{EX}}^+, {\upsilon_{EN}}^+, {\upsilon_{HE}}^+)$ such that as per P3, the PULCLP becomes

$$\begin{aligned} &\min \quad \upsilon^+ \implies (\min {\upsilon_{EX}}^+, \max {\upsilon_{EN}}^+, \max {\upsilon_{HE}}^+) \\ &\text{s.t.} \begin{cases} \bigoplus_{j=1}^{s} \widetilde{a}_{ij} \varphi_j \le \upsilon^+ \ i = 1, 2, \ldots, r \\ \text{where} \\ \varrho_j \ge 0,\ \sum_{j=1}^{s} \varphi_j = 1. \end{cases} \end{aligned} \tag{P5}$$

and thus, the PULCLP splits into three problems given as: Expectation Game

$$\begin{aligned} &\min \quad {\upsilon_{EX}}^+ \\ &\text{s.t.} \begin{cases} \sum_{j=1}^{s} (p_t EX_{a^t})_{ij} \varrho_j \le {\upsilon_{EX}}^+ \ i = 1, 2, \ldots, r \\ \text{where} \\ \varrho_j \ge 0,\ \sum_{j=1}^{s} \varphi_j = 1. \end{cases} \end{aligned} \tag{EX Game PII}$$

Entropy Game

$$\max \quad {v_{EN}}^{+}$$
$$\text{s.t.} \begin{cases} \sqrt{\sum_{j=1}^{s} \left[(p_t EN_{a^t})_{ij}\right]^2 \varrho_j} \geq {v_{EN}}^{+} \; i = 1, 2, \ldots, r \\ \text{where} \\ \varrho_j \geq 0, \; \sum_{j=1}^{s} \varphi_j = 1. \end{cases} \qquad \text{(EN Game PII)}$$

Hyperentropy Game

$$\max \quad {v_{HE}}^{+}$$
$$\text{s.t.} \begin{cases} \sqrt{\sum_{j=1}^{s} \left[(p_t HE_{a^t})_{ij}\right]^2 \varrho_j} \geq {v_{HE}}^{+} \; i = 1, 2, \ldots, r \\ \text{where} \\ \varrho_j \geq 0, \; \sum_{j=1}^{s} \varphi_j = 1. \end{cases} \qquad \text{(HE Game PII)}$$

Then, solving just as in Step 5 mentioned above, we combine the strategies and values obtained from all three games so that we get upper value of the game, i.e. $v^{+} = ({v_{EX}}^{+}, {v_{EN}}^{+}, {v_{HE}}^{+})$.

We illustrate the defined methodology using an example.

4.3 Numerical illustration

Example 3 An investor wishes to invest his money in the stocks of some IT companies. He does so by analysing the average stock closing values for the past 6 years 2017–2022. The possible alternatives under consideration are the five IT companies: Infosys, Wipro, TCS, HCL Technologies, and Larsen & Toubro Infotech. The following linguistic variables represent the stock values:

$$LS = \{t_{2^{-2}} : \text{Very Low (VL)}, t_{2^{-1}} : \text{Low (L)}, t_{2^{0}} : \text{Average (Avg)}, t_{2^{1}} : \text{High (H)}, t_{2^{2}} : \text{Very High (VH)}\}$$

Table 2 provides the values of stocks of the IT companies for the financial years 2017-2022. These data are taken from https://www.moneycontrol.commoneycontrol.

Based on the values listed in Table 2, the variations that occurred in the stock values of different IT companies are evaluated in terms of PM-ULTS (just an interpretation). The interpretation here is done by supposing that the values less than 300 assume the linguistic term “VL”, 300–900 assume “L”, 900–1500 as “Avg”, 1500–2100 as “H” and greater than 2100 assume the linguistic term “VH”. Also, the probabilistic values are interpreted based on the deviation of numeric values from the original linguistic terms. Thus, the probabilistic unbalanced linguistic stock data for the years 2017–2022 for the above-mentioned IT companies are provided in the following “IT company versus year" matrix:

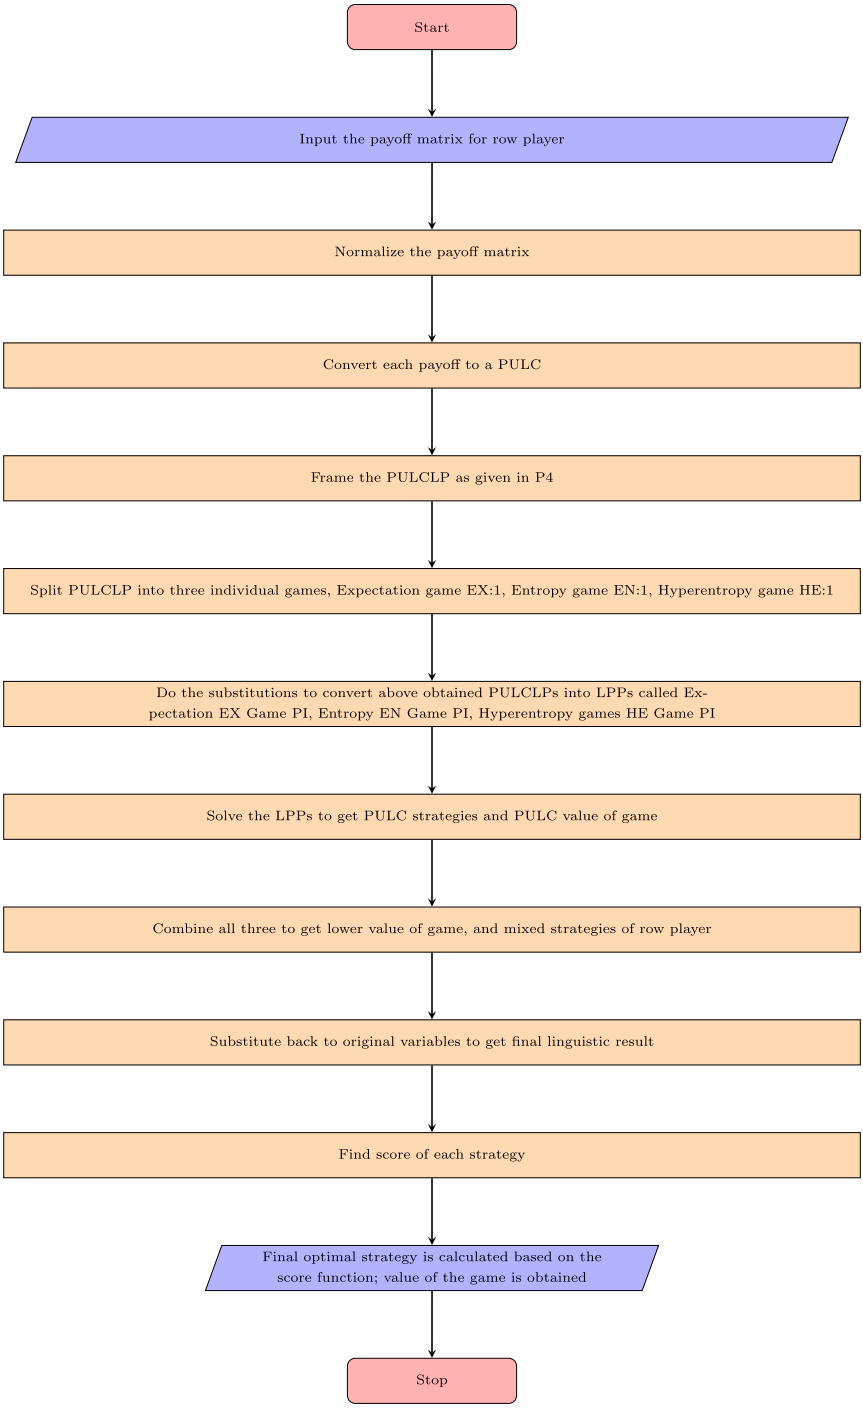

Fig. 2 Flowchart for evaluation of PM-ULCG problem for row player

$$\widetilde{A} = \begin{array}{c} \\ \text{Infosys} \\ \text{Wipro} \\ \text{TCS} \\ \text{HCL Technologies} \\ \text{Larsen \& Toubro Infotech} \end{array} \begin{array}{c} \begin{array}{cccccc} 2017 & 2018 & 2019 & 2020 & 2021 & 2022 \end{array} \\ \begin{bmatrix} t_{2^{-1}}(0.4) & t_{2^{-1}}(0.6) & t_{2^{-1}}(0.7) & t_{2^0}(0.6) & t_{2^1}(0.7) & t_{2^1}(0.1) \\ t_{2^{-2}}(0.2) & t_{2^{-2}}(0.2) & t_{2^{-2}}(0.2) & t_{2^{-1}}(0.2) & t_{2^{-1}}(0.7) & t_{2^{-1}}(0.2) \\ t_{2^0}(0.7) & t_{2^1}(0.7) & t_{2^2}(0.1) & t_{2^2}(0.2) & t_{2^2}(0.4) & t_{2^2}(0.4) \\ t_{2^{-1}}(0.3) & t_{2^{-1}}(0.4) & t_{2^{-1}}(0.5) & t_{2^0}(0.1) & t_{2^0}(0.7) & t_{2^0}(0.4) \\ t_{2^0}(0.4) & t_{2^1}(0.4) & t_{2^1}(0.5) & t_{2^2}(0.4) & t_{2^2}(1) & t_{2^1}(0.8) \end{bmatrix} \end{array}$$

The payoff $\widetilde{a}_{ij}$ of Player *I* represents the response to strategy *i* of Player *I* for the case when Player *II* selects strategy *j* in order to win the game. Also, a probabilistic linguistic payoff signifies that any strategy played by a player can be evaluated on an unbalanced linguistic scale.

Next, we apply our methodology to deal with PM-UL information to analyse which company has had a higher growth in share market from financial year 2017 to 2022. On the basis of this analysis, one can interpret which company to invest in, for future purpose. Now first we normalize the payoff matrix. So, the normalized payoff matrix may be given as:

$$\widetilde{A} = \begin{array}{c} \\ \text{Infosys} \\ \text{Wipro} \\ \text{TCS} \\ \text{HCL Technologies} \\ \text{Larsen \& Toubro Infotech} \end{array} \begin{array}{c} \begin{array}{cccccc} 2017 & 2018 & 2019 & 2020 & 2021 & 2022 \end{array} \\ \begin{bmatrix} t_{2^{-1}}(0.13) & t_{2^{-1}}(0.194) & t_{2^{-1}}(0.225) & t_{2^0}(0.194) & t_{2^1}(0.225) & t_{2^1}(0.032) \\ t_{2^{-2}}(0.118) & t_{2^{-2}}(0.118) & t_{2^{-2}}(0.118) & t_{2^{-1}}(0.118) & t_{2^{-1}}(0.41) & t_{2^{-1}}(0.118) \\ t_{2^0}(0.28) & t_{2^1}(0.28) & t_{2^2}(0.04) & t_{2^2}(0.08) & t_{2^2}(0.16) & t_{2^2}(0.16) \\ t_{2^{-1}}(0.125) & t_{2^{-1}}(0.167) & t_{2^{-1}}(0.208) & t_{2^0}(0.041) & t_{2^0}(0.292) & t_{2^0}(0.167) \\ t_{2^0}(0.114) & t_{2^1}(0.114) & t_{2^1}(0.144) & t_{2^2}(0.114) & t_{2^2}(0.286) & t_{2^1}(0.228) \end{bmatrix} \end{array}$$

The ambiguity and volatility of stock values are represented by the dispersion of cloud droplets. So we convert the probabilistic unbalanced linguistic terms to PULCs so as to choose a specific alternative. Hence, we use the procedure given in Sect. 3.1 to convert the payoffs to PULCs, and thus, the PULC payoff matrix is given as:

$$\widetilde{A}_{PULC} = \begin{array}{c} \\ \text{Infosys} \\ \text{Wipro} \\ \text{TCS} \\ \text{HCL Technologies} \\ \text{Larsen \& Toubro Infotech} \end{array} \begin{array}{c} \begin{array}{cccccc} 2017 & 2018 & 2019 & 2020 & 2021 & 2022 \end{array} \\ \begin{bmatrix} (0.6298, 1.76033, 0.6987) & (0.9399, 2.6269, 1.0427) & (1.0901, 3.0467, 1.2093) & (1.6112, 2.2799, 1.42706) & (2.6473, 3.0467, 1.2093) & (0.3765, 0.4333, 0.172) \\ (0, 1.854, 0.3506) & (0, 1.854, 0.3506) & (0, 1.854, 0.3506) & (0.5717, 1.5978, 0.6342) & (1.9864, 5.5518, 2.203) & (0.5717, 1.5978, 0.6342) \\ (2.3255, 3.2907, 2.0596) & (3.2944, 3.7914, 1.505) & (0.6284, 0.6284, 0.1188) & (1.2569, 1.2569, 0.2376) & (2.5139, 2.5139, 0.4753) & (2.5139, 2.5139, 0.4753) \\ (0.6056, 1.6926, 0.6718) & (0.8091, 2.2613, 0.8976) & (1.0077, 2.8165, 1.118) & (0.3405, 0.4818, 0.3015) & (2.4252, 3.4317, 2.1479) & (1.387, 1.9626, 1.2284) \\ (0.9468, 1.3397, 0.8385) & (1.3413, 1.5436, 0.6127) & (1.6943, 1.9499, 0.774) & (1.7911, 1.7911, 0.3387) & (4.4936, 4.4936, 0.8497) & (2.6826, 3.0873, 1.2255) \end{bmatrix} \end{array}$$

Solving this game problem for Player *I*, i.e. for “IT companies", we get three separate games as expectation game, entropy game and hyperentropy game given as:

Expectation Game

Table 2 Closing stock prices of IT companies for different financial years

	2017	2018	2019	2020	2021	2022
Infosys	521.03	658.95	731.15	1255.8	1887.75	1508.2
Wipro	235.69	248.14	245.8	386.25	715.35	392.75
TCS	1350.6	1893.05	2161.7	2862.75	3738.35	3256.7
HCL Technologies	445.25	482.18	568.1	946.15	1319.1	1039.3
Larsen & Toubro Infotech	1118.85	1731.2	1750.5	3659.5	7332	2085.8

$$\max \quad {v_{EX}}^{-}$$
$$\text{s.t.} \begin{cases} 0.6298\varrho_1 + 0\varrho_2 + 2.3255\varrho_3 + 0.6056\varrho_4 + 0.9468\varrho_5 \geq {v_{EX}}^{-} \\ 0.9399\varrho_1 + 0\varrho_2 + 3.29448\varrho_3 + 0.8091\varrho_4 + 1.3413\varrho_5 \geq {v_{EX}}^{-} \\ 1.0901\varrho_1 + 0\varrho_2 + 0.6284\varrho_3 + 1.0077\varrho_4 + 1.6943\varrho_5 \geq {v_{EX}}^{-} \\ 1.6112\varrho_1 + 0.5717\varrho_2 + 1.2569\varrho_3 + 0.3405\varrho_4 + 1.7911\varrho_5 \geq {v_{EX}}^{-} \\ 2.6473\varrho_1 + 1.9864\varrho_2 + 2.5139\varrho_3 + 2.4252\varrho_4 + 4.4936\varrho_5 \geq {v_{EX}}^{-} \\ 0.3765\varrho_1 + 0.5717\varrho_2 + 2.5139\varrho_3 + 1.387\varrho_4 + 2.6826\varrho_5 \geq {v_{EX}}^{-} \\ \text{where } \varrho_i \geq 0,\ \sum_{i=1}^{5} \varrho_i = 1 \end{cases}$$

Setting $X_i = \frac{\varrho_i}{{v_{EX}}^{-}}$, the problem becomes

$$\min \quad V_{EX} = X_1 + X_2 + X_3 + X_4 + X_5$$
$$\text{s.t.} \begin{cases} 0.6298X_1 + 0X_2 + 2.3255X_3 + 0.6056X_4 + 0.9468X_5 \geq 1 \\ 0.9399X_1 + 0X_2 + 3.29448X_3 + 0.8091X_4 + 1.3413X_5 \geq 1 \\ 1.0901X_1 + 0X_2 + 0.6284X_3 + 1.0077X_4 + 1.6943X_5 \geq 1 \\ 1.6112X_1 + 0.5717X_2 + 1.2569X_3 + 0.3405X_4 + 1.7911X_5 \geq 1 \\ 2.6473X_1 + 1.9864X_2 + 2.5139X_3 + 2.4252X_4 + 4.4936X_5 \geq 1 \\ 0.3765X_1 + 0.5717X_2 + 2.5139X_3 + 1.387X_4 + 2.6826X_5 \geq 1 \\ \text{where } X_i \geq 0,\ i = 1, \ldots, 5 \end{cases}$$

Solving the above LPP, we get the solution as: $X_1 = 0$, $X_2 = 0$, $X_3 = 0.223$, $X_4 = 0$, $X_5 = 0.508$, $V_{EX} = 0.731$. Substituting back to the original variables, we get the optimal solution of the expectation game problem as: ${v_{EX}}^{-} = \frac{1}{V_{EX}} = 1.36$, $\varrho_1 = 0$, $\varrho_2 = 0$, $\varrho_3 = 0.305$, $\varrho_4 = 0$, $\varrho_5 = 0.695$. Hence, the strategies are (0, 0, 0.305, 0, 0.695) and expectation value is 1.36. Entropy Game

$$\min \quad {v_{EN}}^{-}$$
$$\text{s.t.} \begin{cases} \sqrt{(1.7603)^2\varrho_1 + (1.854)^2\varrho_2 + (3.2907)^2\varrho_3 + (1.6926)^2\varrho_4 + (1.3397)^2\varrho_5} \leq {v_{EN}}^{-} \\ \sqrt{(2.6269)^2\varrho_1 + (1.854)^2\varrho_2 + (3.7914)^2\varrho_3 + (2.2613)^2\varrho_4 + (1.5436)^2\varrho_5} \leq {v_{EN}}^{-} \\ \sqrt{(3.0467)^2\varrho_1 + (1.854)^2\varrho_2 + (0.6285)^2\varrho_3 + (2.8165)^2\varrho_4 + (1.95)^2\varrho_5} \leq {v_{EN}}^{-} \\ \sqrt{(2.2799)^2\varrho_1 + (1.5978)^2\varrho_2 + (1.2569)^2\varrho_3 + (0.482)^2\varrho_4 + (1.791)^2\varrho_5} \leq {v_{EN}}^{-} \\ \sqrt{(3.0467)^2\varrho_1 + (5.5518)^2\varrho_2 + (2.5139)^2\varrho_3 + (3.4317)^2\varrho_4 + (4.4936)^2\varrho_5} \leq {v_{EN}}^{-} \\ \sqrt{(0.4333)^2\varrho_1 + (1.5978)^2\varrho_2 + (2.5139)^2\varrho_3 + (1.9626)^2\varrho_4 + (3.0873)^2\varrho_5} \leq {v_{EN}}^{-} \\ \text{where } \varrho_i \geq 0,\ i = 1, \ldots, 5\ \sum_{i=1}^{5} \varrho_i = 1 \end{cases}$$

Squaring both sides, and letting $({v_{EN}}^{-})^2 = {v_{EN}}'$, we get

$$\min \quad \sqrt{{v_{EN}}'} \equiv \min {v_{EN}}'$$

$$\text{s.t.} \begin{cases} 3.0987\varrho_1 + 3.4374\varrho_2 + 10.8287\varrho_3 + 2.8649\varrho_4 + 1.7948\varrho_5 \le {v_{EN}}' \\ 6.9\varrho_1 + 3.437\varrho_2 + 14.375\varrho_3 + 5.113\varrho_4 + 2.382\varrho_5 \le {v_{EN}}' \\ 9.282\varrho_1 + 3.437\varrho_2 + 0.395\varrho_3 + 7.933\varrho_4 + 3.802\varrho_5 \le {v_{EN}}' \\ 5.198\varrho_1 + 2.553\varrho_2 + 1.579\varrho_3 + 0.232\varrho_4 + 3.208\varrho_5 \le {v_{EN}}' \\ 9.282\varrho_1 + 30.822\varrho_2 + 6.319\varrho_3 + 11.653\varrho_4 + 20.192\varrho_5 \le {v_{EN}}' \\ 0.187\varrho_1 + 2.553\varrho_2 + 6.319\varrho_3 + 3.851\varrho_4 + 9.531\varrho_5 \le {v_{EN}}' \\ \text{where } \varrho_i \ge 0,\ i = 1, \ldots, 5 \sum_{i=1}^{5} \varrho_i = 1 \end{cases}$$

Setting $Y_i = \frac{\varrho_i}{{v_{EN}}'}$ and ${V_{EN}}' = \frac{1}{{v_{EN}}'}$, hence the final entropy LPP becomes

$$\max \quad {V_{EN}}' = Y_1 + Y_2 + Y_3 + Y_4 + Y_5$$

$$\text{s.t.} \begin{cases} 3.0987Y_1 + 3.4374Y_2 + 10.8287Y_3 + 2.8649Y_4 + 1.7948Y_5 \le 1 \\ 6.9Y_1 + 3.437Y_2 + 14.375Y_3 + 5.113Y_4 + 2.382Y_5 \le 1 \\ 9.282Y_1 + 3.437Y_2 + 0.395Y_3 + 7.933Y_4 + 3.802Y_5 \le 1 \\ 5.198Y_1 + 2.553Y_2 + 1.579Y_3 + 0.232Y_4 + 3.208Y_5 \le 1 \\ 9.282Y_1 + 30.822Y_2 + 6.319Y_3 + 11.653Y_4 + 20.192Y_5 \le 1 \\ 0.187Y_1 + 2.553Y_2 + 6.319Y_3 + 3.851Y_4 + 9.531Y_5 \le 1 \\ \text{where } Y_i \ge 0,\ i = 1, \ldots, 5 \end{cases}$$

Solving the above LPP, the solution comes out to be $Y_1 = 0.08968$, $Y_2 = 0$, $Y_3 = 0.0265$, $Y_4 = 0$, $Y_5 = 0$. Further, ${V_{EN}}' = 0.1162$. $\therefore {v_{EN}}^- = 2.93$ and the strategies are (0.7717, 0, 0.2282, 0, 0). On a similar note, Hyperentropy Game

$$\min \quad {v_{HE}}^-$$

$$\text{s.t.} \begin{cases} \sqrt{(0.6987)^2\varrho_1 + (0.3506)^2\varrho_2 + (2.0596)^2\varrho_3 + (0.6718)^2\varrho_4 + (0.8385)^2\varrho_5} \le {v_{HE}}^- \\ \sqrt{(1.0427)^2\varrho_1 + (0.3506)^2\varrho_2 + (1.505)^2\varrho_3 + (0.8976)^2\varrho_4 + (0.6127)^2\varrho_5} \le {v_{HE}}^- \\ \sqrt{(1.2093)^2\varrho_1 + (0.3506)^2\varrho_2 + (0.1188)^2\varrho_3 + (1.118)^2\varrho_4 + (0.774)^2\varrho_5} \le {v_{HE}}^- \\ \sqrt{(1.427)^2\varrho_1 + (0.6342)^2\varrho_2 + (0.2376)^2\varrho_3 + (0.3015)^2\varrho_4 + (0.3387)^2\varrho_5} \le {v_{HE}}^- \\ \sqrt{(1.2093)^2\varrho_1 + (2.203)^2\varrho_2 + (0.4754)^2\varrho_3 + (2.1479)^2\varrho_4 + (0.8479)^2\varrho_5} \le {v_{HE}}^- \\ \sqrt{(0.172)^2\varrho_1 + (0.6342)^2\varrho_2 + (0.4754)^2\varrho_3 + (1.2284)^2\varrho_4 + (1.2255)^2\varrho_5} \le {v_{HE}}^- \\ \text{where } \varrho_i \ge 0,\ i = 1, \ldots, 5 \sum_{i=1}^{5} \varrho_i = 1 \end{cases}$$

Squaring both sides and letting $({v_{HE}}^-)^2 = {v_{HE}}'$

$$\min \quad \sqrt{{\upsilon_{HE}}'} \equiv \min {\upsilon_{HE}}'$$
$$\text{s.t.} \begin{cases} 0.4882\varrho_1 + 0.1229\varrho_2 + 4.2423\varrho_3 + 0.4513\varrho_4 + 0.7031\varrho_5 \le {\upsilon_{HE}}' \\ 1.0872\varrho_1 + 0.1229\varrho_2 + 2.265\varrho_3 + 0.8056\varrho_4 + 0.3755\varrho_5 \le {\upsilon_{HE}}' \\ 1.4624\varrho_1 + 0.1229\varrho_2 + 0.0141\varrho_3 + 1.2499\varrho_4 + 0.599\varrho_5 \le {\upsilon_{HE}}' \\ 2.036\varrho_1 + 0.4022\varrho_2 + 0.0564\varrho_3 + 0.0909\varrho_4 + 0.1147\varrho_5 \le {\upsilon_{HE}}' \\ 1.4624\varrho_1 + 4.8532\varrho_2 + 0.226\varrho_3 + 4.6134\varrho_4 + 0.7219\varrho_5 \le {\upsilon_{HE}}' \\ 0.029\varrho_1 + 0.4022\varrho_2 + 0.226\varrho_3 + 1.5089\varrho_4 + 1.5018\varrho_5 \le {\upsilon_{HE}}' \\ \text{where } \varrho_i \ge 0,\ i = 1, \ldots, 5\ \sum_{i=1}^{5} \varrho_i = 1 \end{cases}$$

Setting $Z_i = \frac{\varrho_i}{{\upsilon_{HE}}'}$ and ${V_{HE}}' = \frac{1}{{\upsilon_{HE}}'}$, the final hyperentropy LPP becomes

$$\max \quad {V_{HE}}'$$
$$\text{s.t.} \begin{cases} 0.4882Z_1 + 0.1229Z_2 + 4.2423Z_3 + 0.4513Z_4 + 0.7031Z_5 \le 1 \\ 1.0872Z_1 + 0.1229Z_2 + 2.265Z_3 + 0.8056Z_4 + 0.3755Z_5 \le 1 \\ 1.4624Z_1 + 0.1229Z_2 + 0.0141Z_3 + 1.2499Z_4 + 0.599Z_5 \le 1 \\ 2.036Z_1 + 0.4022Z_2 + 0.0564Z_3 + 0.0909Z_4 + 0.1147Z_5 \le 1 \\ 1.4624Z_1 + 4.8532Z_2 + 0.226Z_3 + 4.6134Z_4 + 0.7219Z_5 \le 1 \\ 0.029Z_1 + 0.4022Z_2 + 0.226Z_3 + 1.5089Z_4 + 1.5018Z_5 \le 1 \\ \text{where } Z_i \ge 0,\ i = 1, \ldots, 5 \end{cases}$$

Solving the above LPP, solution come out as $Z_1 = 0.3514$, $Z_2 = 0, Z_3 = 0.0883$, $Z_4 = 0$, $Z_5 = 0.6458$, ${V_{HE}}' = 1.0854$. Substituting back to original variables, the hyperentropy value ${\upsilon_{HE}}^- = 0.96$, and the strategies are (0.3237, 0, 0.08135, 0, 0.5949). Summarizing and writing collectively, the strategies in terms of PULC are: ${\varrho_1}^* = (0, 0.7717, 0.3237)$, ${\varrho_2}^* = 0, {\varrho_3}^* = (0.305, 0.2283, 0.0813), {\varrho_4}^* = 0, {\varrho_5}^* = (0.695, 0, 0.5949)$ and the PULC value of the game is $\upsilon^- = (1.36, 2.93, 0.96)$. Further, the probabilistic unbalanced linguistic value of the game can be calculated and is equal to $\widetilde{v}^-(p) = \{t_{2^0}(0.4612), t_{2^1}(0.5388)\}$.

Similarly, solving the game problem for Player *II*, i.e. for "Year", the expectation, entropy and hyperentropy games are as given below: Expectation Game

$$\min \quad {\upsilon_{EX}}^+$$
$$\text{s.t.} \begin{cases} 0.6298\varphi_1 + 0.9399\varphi_2 + 1.0901\varphi_3 + 1.6112\varphi_4 + 2.6473\varphi_5 + 0.3765\varphi_6 \le {\upsilon_{EX}}^+ \\ 0\varphi_1 + 0\varphi_2 + 0\varphi_3 + 0.5717\varphi_4 + 1.9864\varphi_5 + 0.5717\varphi_6 \le {\upsilon_{EX}}^+ \\ 2.3255\varphi_1 + 3.2944\varphi_2 + 0.6284\varphi_3 + 1.2569\varphi_4 + 2.5139\varphi_5 + 2.5139\varphi_6 \le {\upsilon_{EX}}^+ \\ 0.6056\varphi_1 + 0.8091\varphi_2 + 1.0077\varphi_3 + 0.3405\varphi_4 + 2.4252\varphi_5 + 1.387\varphi_6 \le {\upsilon_{EX}}^+ \\ 0.9468\varphi_1 + 1.3413\varphi_2 + 1.6943\varphi_3 + 1.7911\varphi_4 + 4.4936\varphi_5 + 2.6826\varphi_6 \le {\upsilon_{EX}}^+ \\ \text{where } \varphi_j \ge 0,\ \sum_{j=1}^{6} \varphi_j = 1 \end{cases}$$

Solving by doing required substitutions, we get the optimal solution as: ${\upsilon_{EX}}^+ = 1.36$, and the strategies are (0.4359, 0, 0.564, 0, 0, 0). Entropy Game

$$\max \quad {\upsilon_{EN}}^{+}$$
$$\text{s.t.} \begin{cases} \sqrt{(1.7603)^2\varphi_1 + (2.6269)^2\varphi_2 + (3.0467)^2\varphi_3 + (2.2799)^2\varphi_4 + (3.0467)^2\varphi_5 + (0.4333)^2\varphi_6} \geq {\upsilon_{EN}}^{+} \\ \sqrt{(1.854)^2\varphi_1 + (1.854)^2\varphi_2 + (1.854)^2\varphi_3 + (1.5978)^2\varphi_4 + (5.5518)^2\varphi_5 + (1.5978)^2\varphi_6} \geq {\upsilon_{EN}}^{+} \\ \sqrt{(3.2907)^2\varphi_1 + (3.7914)^2\varphi_2 + (0.6284)^2\varphi_3 + (1.2569)^2\varphi_4 + (2.5139)^2\varphi_5 + (2.5139)^2\varphi_6} \geq {\upsilon_{EN}}^{+} \\ \sqrt{(1.6926)^2\varphi_1 + (2.2613)^2\varphi_2 + (2.8165)^2\varphi_3 + (0.482)^2\varphi_4 + (3.4317)^2\varphi_5 + (1.9626)^2\varphi_6} \geq {\upsilon_{EN}}^{+} \\ \sqrt{(1.3397)^2\varphi_1 + (1.5436)^2\varphi_2 + (1.9499)^2\varphi_3 + (1.7911)^2\varphi_4 + (4.4936)^2\varphi_5 + (3.0873)^2\varphi_6} \geq {\upsilon_{EN}}^{+} \\ \text{where } \varphi_j \geq 0,\ j = 1, \ldots, 6\ \sum_{j=1}^{6} \varphi_j = 1 \end{cases}$$

Solving just as for Player *I*, we obtain result for entropy game as (0, 0.2839, 0, 0, 0.716, 0) and value ${\upsilon_{EN}}^{+} = 2.93$. Similarly for hyperentropy, Hyper-entropy Game

$$\max \quad {\upsilon_{HE}}^{+}$$
$$\text{s.t.} \begin{cases} \sqrt{(0.6987)^2\varphi_1 + (1.0427)^2\varphi_2 + (1.2093)^2\varphi_3 + (1.427)^2\varphi_4 + (1.2093)^2\varphi_5 + (0.172)^2\varphi_6} \geq {\upsilon_{HE}}^{+} \\ \sqrt{(0.3506)^2\varphi_1 + (0.3506)^2\varphi_2 + (0.3506)^2\varphi_3 + (0.6342)^2\varphi_4 + (2.203)^2\varphi_5 + (0.6342)^2\varphi_6} \geq {\upsilon_{HE}}^{+} \\ \sqrt{(2.0596)^2\varphi_1 + (1.505)^2\varphi_2 + (0.1188)^2\varphi_3 + (0.3015)^2\varphi_4 + (2.1479)^2\varphi_5 + (1.2284)^2\varphi_6} \geq {\upsilon_{HE}}^{+} \\ \sqrt{(0.6718)^2\varphi_1 + (0.8976)^2\varphi_2 + (1.118)^2\varphi_3 + (0.3015)^2\varphi_4 + (2.1479)^2\varphi_5 + (1.2284)^2\varphi_6} \geq {\upsilon_{HE}}^{+} \\ \sqrt{(0.8385)^2\varphi_1 + (0.6127)^2\varphi_2 + (0.774)^2\varphi_3 + (0.3387)^2\varphi_4 + (0.8497)^2\varphi_5 + (1.2255)^2\varphi_6} \geq {\upsilon_{HE}}^{+} \\ \text{where } \varphi_j \geq 0,\ j = 1, \ldots, 6\ \sum_{j=1}^{6} \varphi_j = 1 \end{cases}$$

The solution comes out as: (0.173, 0, 0, 0, 0.5669, 0.2598) and ${\upsilon_{HE}}^{+} = 0.96$. Hence, collectively the optimal PULC strategies and PULC value of Player *II* are: ${\varphi_1}^* = (0.4359, 0, 0.173)$, ${\varphi_2}^* = (0, 0.2839, 0)$, ${\varphi_3}^* = (0.564, 0, 0)$, ${\varphi_4}^* = 0$, ${\varphi_5}^* = (0, 0.716, 0.5669)$, ${\varphi_6}^* = (0, 0, 0.2598)$ Value $\upsilon^{+} = (1.36, 2.93, 0.96)$. Hence, $\upsilon^{-} = \upsilon^{+} = \upsilon =$ Value of the game. Further, the scores of strategies may be evaluated to finalize which strategy should a player use to win the game. For that, we may find different score function values for different values of γ. Without loss of generality, we fix the value of $\gamma = 0.5$ for current calculations.

For Player *I*, $\hat{S}({\varrho_1}^*) = -0.4184$, $\hat{S}({\varrho_2}^*) = 0$, $\hat{S}({\varrho_3}^*) = 0.3825$, $\hat{S}({\varrho_4}^*) = 0$, $\hat{S}({\varrho_5}^*) = 0.3975$. Thus, based on the score values, the IT company Larsen & Toubro would be the best to invest the money in. Thus, based on the above-obtained results, the DM can also plan where to invest in the future. Also, the trend of increment of stock prices may be determined by finding the score values of Player *II*, i.e. "Year".

Note. The above problem is solved for the case when the DMs record only a single linguistic term as a payoff entry. The same procedure may be followed for the case when multiple linguistic terms consist a payoff or the case when the payoffs are of a set type. In that case, we could break the individual term of the set and then form separate PULCLP for each broken term set.

5 Analysis and discussion

This section includes the analysis of numerical results obtained in previous section along with the comparison of proposed approach with the formerly defined literature.

5.1 Numerical discussion

For the numerical example 3, the matrix $\widetilde{A}$ corresponds to the first player, i.e. "IT Company" and based on the calculations, the DM is supposed to analyse which IT company is the best to invest in. For this purpose, the original problem is divided into three individual games, namely expectation, entropy and hyperentropy game. Solving the three games, it can be concluded that the optimal strategies are $\varrho_1{}^* = (0, 0.7717, 0.3237), \varrho_2{}^* = 0, \varrho_3{}^* = (0.305, 0.2283, 0.0813), \varrho_4{}^* = 0, \varrho_5{}^* = (0.695, 0, 0.5949)$ and the PULC value of the game is $\upsilon^- = (1.36, 2.93, 0.96)$. The score of the strategies may be evaluated as $\hat{S}(\varrho_1{}^*) = -0.4184, \hat{S}(\varrho_2{}^*) = 0, \hat{S}(\varrho_3{}^*) = 0.3825, \hat{S}(\varrho_3{}^*) = 0.3975$. Thus, based on the score values, the IT company Larsen & Toubro would be the best to invest the money in.

Similar task can be done for the second player, i.e. "Year" that can be used to investigate which year was the best year for investment in a particular IT company. For that purpose, similar expectation, entropy and hyperentropy game problems are constituted and solved.

5.2 Comparative analysis and discussion

This section provides a comparison analysis of the proposed methodology with the existing studies that involve game theoretic models using PULCs.

The idea of probabilistic linguistic term set (PLTS) was first proposed by Pang et al. [31], which allows the players or DMs to evaluate situations more effectively by using multiple terms rather than just one, by giving each term a probability-based weight. Apart from this, there are other variants of PLTS, such as [3, 46, 51]. In the paper [3], the authors have defined a concept "Interval-valued probabilistic linguistic term sets" that can describe two attributes of an object: possible linguistic term sets and their associated interval numbers. The former provides an assessment, such as "perfect" or "low". The latter describes the hesitancy for the given assessment and denotes the interval-valued probabilistic distribution or membership degrees with respect to the former. Xie et al. [46] extended the analytic hierarchy process to the situations with the probabilistic linguistic information. Zhai et al. [51] focus on improving the accuracy of the multi-granular linguistic recommender system by supporting customers to find out the most eligible items according their own preferences. For this purpose, they propose a probabilistic linguistic vector-term sets to promote the application of multi-granular linguistic information. However, despite having several practical applications, these PLTSs have the limitation that all of them use symmetric and balanced information for decision analysis. Further, this

symmetric information inculcated in these PLTSs is also used in matrix game theory in the paper [30]. The theory defined by Mi et al. [30] uses triangular membership function to represent probabilistic linguistic information. This information is defuzzified using the triangular membership function, and the calculated games values are then retranslated to probabilistic data by using linear interpolation method. This process is limited in its form as the defuzzification, and then, retranslation process causes major loss of information. Also, Mi et al. [30] study the cloud model in game problems where the responses of players belong to a symmetrically distributed linguistic set. To overcome the problem of symmetric probabilistic linguistic information, Han et al. [16] defined a probabilistic unbalanced linguistic term set (PULTS) that makes use of unbalanced linguistic data to represent probabilistic linguistic information. But this method uses the unbalanced linguistic model defined by [19] which is computationally very expensive method. Thus, in the paper [27], the authors solve linguistic matrix games that have probabilistic unbalanced linguistic data that comes from a probabilistic multiplicative unbalanced linguistic set defined by Malhotra & Gupta [28]. Table 3 summarizes the above-mentioned comparison analysis in tabular form.

The theory defined in our paper is useful for solving matrix games having the same probabilistic multiplicative linguistic information, but with a different point of view. The authors in [27] only considered the fuzziness involved in a linguistic concept. However, in our paper, the linguistic concept is analysed in the way that both randomness and fuzziness are omitted from the qualitative concept. The present paper uses cloud model [11] to thoroughly capture the intrinsic fuzziness and vagueness of decision information present in matrix game problems. Apart from that, the game problem considered in this paper consists of payoffs that are randomly irregularly distributed in a multiplicative manner. Such linguistic data address all types of linguistic information. This preserves the literal meaning of unbalanced linguistic matrix games. The suggested approach not only prevents data loss, it also studies different types of uncertainties lying in the linguistic information of matrix game problems. Also, the loss of information occurring in [30] due to the retranslation process is well handled in this paper as the probabilistic information is first converted into PULCs and the PULC data are then solved using cloud aggregation operators. Also, the retranslation process in this paper is done using the bijective operators that overcome the information loss. Furthermore, the methodology defined in this paper converts the probabilistic unbalanced payoff into a PULC in a way that it forms three independent easy-to-solve games, namely Expectation game, Entropy game and Hyperentropy game, which are basically three independent PULLPs. These PULLPs are converted into LPPs using required substitution and are then solved as a classical LPP. The objective function of these PULLPs runs into $\mathcal{O}(n)$ time, where n is the cardinality of the PULTS.

The novelty of this paper lies in the fact that it allows the DMs to study the underlying uncertainty in the information of an uncertain game problem and still solve a decision-making problem just as a classical problem without any loss of information. Unlike existing matrix game problems, this study captures the intrinsic randomness and fuzziness present in a qualitative concept of a matrix game which is based on a PM-ULTS.

Table 3 Comparison of the defined methodology with some existing research

Paper	Nature of information	Distribution of linguistic terms	Application in game	Nature of uncertainty of payoffs
[31]	Probabilistic	Symmetric	No	N/A
[3]	Probabilistic	Symmetric	No	N/A
[46]	Probabilistic	Symmetric and Asymmetric	No	N/A
[30]	Probabilistic	Symmetric	Yes	Fuzziness
[16]	Probabilistic	Asymmetric	No	N/A
[27]	Probabilistic	Asymmetric	Yes	Fuzziness
This paper	Probabilistic	Asymmetric	Yes	Randomness & Fuzziness

6 Conclusion

This study proposed and investigated the two-person matrix games having probabilistic multiplicative unbalanced linguistic information. This allows the theory of games to accept incomplete information as players' response as an input. The uncertain payoffs are dealt with by PULCs, and then, cloud aggregation operators are applied to aggregate the probabilistic cloud information. Then, the game problem is converted into three independent games, i.e. expectation game, entropy game and hyperentropy game. The LPPs of each game are individually solved to get cloud value of the game. The significance of transforming the unbalanced linguistic payoffs to PULCs is that the cloud model studies the uncertainty lying in a qualitative concept by thoroughly encapsulating the underlying randomness and fuzziness of the unbalanced payoff. The results of all three LPPs are collected to form a single strategy and single value, that further form a cloud value. The cloud value of the game provides the dispersion of cloud droplets using entropy value. Further, the hyperentropy studies the uncertainty of entropy. Thus, this methodology is advantageous as it provides more accurate results than other existing methodologies to solve matrix game problems having probabilistic linguistic information, in which only one kind of uncertainty is dealt. The more uncertainty is dealt, the more we proceed towards the preciseness of a certain result. Afterwards, this methodology is applied to solve a real-time decision problem of investment in stock of different IT companies.

As for future research directions, one can extend this methodology towards interval clouds as this methodology maps a qualitative information to a certain precise value. On the other hand, interval provides a more generalized range, thus reducing the loss of information. Further, one can work towards developing a more simpler theory for the case where the payoff information is in the form of multiple probabilistic linguistic terms.

Abstract

We consider the excitation of terahertz (THz) electromagnetic fields by interaction of radially polarized laser pulses of diverse profiles with a homogenous plasma density slab. We utilize the properties of the laser pulse to generate THz fields in a plasma slab. It is shown that the radial ponderomotive force exerted by laser imparts an oscillatory velocity to plasma electrons and drives a nonlinear current in azimuthal direction exciting THz electromagnetic fields in the plasma slab. The dependence of the excited radial electric field and azimuthal magnetic field on axial and radial parameters of the plasmas lab, as well as on the slab thickness and laser pulse width size, is investigated. It is demonstrated that the terahertz fields are generated most efficiently with a frequency close to the plasma frequency. It is also shown that the intensity of the excited fields may be optimized and controlled by the plasma slab and laser pulse parameters. Rectangular-triangular, super-Gaussian, and sinusoidal lasers exhibit a significantly steeper radial gradient of ponderomotive potential in comparison with other laser profiles, and excite intense radial electric fields and generate azimuthal magnetic fields in plasma slab. The numerical results closely follow the scaling laws and match with previous experimental and simulation results.

1 | INTRODUCTION

Laser-plasma interaction is an important process in the generation of electromagnetic fields and relativistic particles. The process is driven by the interaction of high-intensity laser pulses with a plasma. The laser energy creates an electric current in the plasma, which in turns generates a magnetic field. Recent studies have shown that the laser-plasma interaction can be enhanced by using a thin plasma slab for better control and improved absorption of the laser beam.[1,2] When the laser frequency exceeds the plasma frequency, the plasma becomes transparent, as the laser photons are able to travel through the plasma without being absorbed. As a result, the tunneling of the laser energy may take place through the plasma slab. Intense magnetic fields of several megagauss (MG) are self-generated in this regime of interaction. Such magnetic fields in plasma find numerous applications in magnetic field reconnection research,[3,4] strong electron acceleration,[5] fast ignition transport studies,[6,7] generation of shock waves in collision-less plasmas,[8] etc. The generation of terahertz (THz) electric fields using laser-induced plasma slabs is a well-established technique in the field of ultrafast optics and

THz spectroscopy. This method relies on the interaction of intense femtosecond laser pulses with a gas or solid target, which generates a plasma that can emit or modulate THz radiation. Electromagnetic terahertz (THz) radiations are utilized in many powerful applications, such as in imaging,[9] biomedical,[10] food processing,[11–13] communication,[14] development of future generation devices,[15,16] and military applications.[17]

The state of laser's polarization impacts the optical behavior, focus, and reflectance of laser. A radically polarized laser can accelerate electrons to relativistic energies by trapping the electrons via azimuthal magnetic field and radial electric field components and accelerating them via axial component of electric field. The electromagnetic fields are excited inside and outside the plasma slab by the ponderomotive forces of laser radiation. The shape and polarization of the laser pulse affects the efficiency of THz emission. An oscillatory velocity to the plasma electrons is exerted by the nonlinear ponderomotive force. The coupling of the velocity at the plasma-vacuum interface produces a rotational current, which is primarily responsible to excite electromagnetic radiation, which in turn produces waves of wakefield oscillations.[18–20] The influence of this ponderomotive force on plasma behavior has been extensively explored in a comprehensive review authored by Lundin and Guglielmi.[21] Their analysis delves into how this force is affected by several key factors, including wave amplitude, variations in the ambient magnetic field, wave non-stationarity, the specific wave mode employed, and various other parameters related to both the plasma and the wave. Electric fields in the THz range can be excited in radial and axial directions by interaction of a linearly polarized (s-polarized, p-polarized), circularly polarized or radially polarized laser pulse with plasma.[22,23] However, magnetic fields can be exerted only in an inhomogeneous plasma or with asymmetric laser pulses. The intensity of the laser can become inhomogeneous due to small plasma gradient, self-modulation of pulse wavefront, laser backscattering, or plasma refractive index disparity.[24]

Recently, several authors have performed investigations on self-generated magnetic fields driven by a laser in plasma experimentally[25–27] as well as theoretically.[28–31] An axial magnetic field in Megagauss (MG) range has been observed due to inverse Faraday effect from relativistic laser interactions with an underdense plasma. Scientists have made substantial advancements in the field of laser-plasma interactions for creating broadband THz sources in theoretical[32–42] as well as experimental[43–58] researches. Malik et al.[59] passed a triangle laser beam across a plasma with a ripple density and an external magnetic field and were able to produce a tunable THz source. THz radiation resulted from this interaction, highlighting the significance of perfect plasma management. Bakhtiari et al.[60] studied to maximize the efficiency of THz generation for real-world applications and their study methodically investigated variables like laser intensity and plasma density. By utilizing phase matching techniques and optical mixing with two-color lasers in a plasma medium with ripple density, Kumar and Tripathi were able to generate resonant THz waves.[61] The development of THz sources for spectroscopy, imaging, and communications is advanced by this work. In conclusion, these contributions advance the development of THz sources by accurate plasma regulation, parameter optimization, and cutting-edge methods with prospective applications in numerous sectors. The terahertz radiation emission from laser-irradiated objects inside a typically inhomogeneous plasma has been thoroughly investigated by the authors. Their investigation demonstrates that this emission is caused by linear mode conversion, offering an important explanation for this puzzling phenomenon.

In our continuing research, we analyze the establishment of radial and axial THz electric fields and self-generated magnetic field in an homogeneous plasma using the ponderomotive force based method. This force, which outcomes from the spatial imperfections in the laser pulse, is essential for producing an azimuthal magnetic field during interactions with homogeneous plasma. The objective is to explore novel methods for generating terahertz (THz) radiations at the interface between plasma and vacuum environment. This investigation delves into the intricate realm of laser beam shapes, specially sinusoidal, Gaussian, cosh-hyperbolic, super-Gaussian, triangular, and rectangular-triangular beams deployed both within the plasma slab and in the vacuum region. Our approach hinges on the meticulous application of continuity equations and boundary conditions at the critical juncture where plasma and vacuum converge. Within this framework, we model the intricate interaction between the diverse laser beam shapes and the plasma slab, delving into wave equations, nonlinear plasma responses and the perturbations these beams induce in the electron density. Our ultimate aim is to decipher the mechanisms underlying THz radiations generation stemming from these laser-plasma interactions. This investigation further extends to the magnetic fields produced by these distinct profiles, also presenting how the viewing angle affects the resultant model. By means of advanced simulations, we construct three-dimensional waveforms that delineate intricate correlations within the radial and axial dimensions, in conjunction with the electric and magnetic fields arising from diverse laser profiles, both within the confines of plasma and in vacuum. We meticulously gauge the intensities of these magnetic and electric fields, undertaking a rigorous evaluation of their respective THz field strengths. Furthermore, "surf" plots serve as instrumental tools for the graphical representation and in-depth scrutiny of the disparate behaviors exhibited by various waveforms when immersed in a uniform plasma environment. The authors have also undertaken research pertaining to flattened laser beams, with a primary objective of quantifying the generation

of THz radiation through the phenomenon known as phase matching resonance.[62] The radial direction of electric field and the azimuthal direction of magnetic field are focused on in both 2D and 3D contour plots to investigate the intensity of corresponding fields using simulations. By comparing the observed results with the provided experimental and theoretical framework, the concept is convincingly illustrated. The final section of this article offers a brief summary of the research findings.

2 | MATHEMATICAL ANALYSIS

We propose a technique for producing THz field in the range of MV/cm by the interaction of laser with the plasma slab. We have taken into account a moderate density plasma slab of nonlinear material of width 2 L in the z-direction with its dimensions ranging from $-L < z < L$. Vacuum regions are selected along both sides of the plasma slab. The presence of a vacuum-plasma interface is an established and viable phenomenon within the realm of plasma physics, a field where high-energy electron beams or laser pulses intersect with plasmas. This boundary between the vacuum and the plasma is fundamental and plays a pivotal role in numerous plasma physics experiments and practical applications that are still used in many research areas. When laser beam interacts the slab boundary, it excites the radial E_r and axial E_z components of electric field and azimuthal B_ϕ component of magnetic field. Various laser beam profiles have been studied in this paper for these constituents of fields.

The density of the plasma slab is rendered in such a way that the electron number density remains constant within the slab along the z-direction. The density is a constant step function whose value is constant in the plasma, that is, $-L\langle z\langle L$ and is 0 outside the slab, that is, $z \leq -L \& z \geq L$ (in vacuum). We visualize the electron plasma density as μ. In the current scenario, the pulse propagates through the plasma slab without being fully transmitted. This is due to the fact because $\omega_o/\omega_p > 1$. When the laser's frequency surpasses that of the plasma, a remarkable phenomenon occurs—the plasma becomes translucent, allowing laser photons to traverse it without being absorbed. Consequently, the laser's energy can tunnel through the plasma slab, offering intriguing possibilities in various scientific and practical domains, such as laser-driven fusion and advanced particle acceleration. The general equation of electric field for the input laser profile is a function of r, z, and t which can be written as

$$E_{\text{input}} = E_{\text{ol}} e^{(-i\omega_o t + ik_z z)} f(r)_{\text{profile}}, \tag{1}$$

where $E_{\text{ol}} = 10^7\ \text{V cm}^{-1}$ is the maximum laser amplitude, $\omega_o = 2.0 \times 10^{14}\text{Hz}$ is the incident laser frequency, and $k_z = \frac{\omega_o}{c}\text{cm}^{-1}$ is the wave number of laser beam in the z-direction.

In this study, we have investigated a range of laser radial profiles, including Gaussian, sinusoidal, cosh-hyperbolic, super-Gaussian, triangular, and rectangular-triangular. Each of these profiles introduce variations in the function denoted as $f(r)$, which in turn influences the parameter $k_\perp$ specific to each profile. The laser beam imparts an oscillatory velocity to electrons and exerts a nonlinear ponderomotive force on them. The interaction of electron velocity with sharp density gradients, particularly at the plasma-vacuum interface, gives rise to a rotational current. Consequently, the abrupt density changes at the interfaces between the vacuum and plasma play a pivotal role in exciting electromagnetic radiation. The ponderomotive force acting on plasma electrons is defined by a mathematical equation given as

$$\varphi = \frac{eE_{\text{ol}}^2 |f(r)|^2}{4m_e\omega_o^2}, \tag{2}$$

where $e = 4.8032 \times 10^{-10}$ statcoulomb is the charge of electron and $m_e = 9.109 \times 10^{-28}\text{g}$ is the mass of electron.

The transverse wave number, abbreviated as "$k_\perp$" is not steady but changes depending on the profile and adjusts as the input laser beam's shape alters. Below are listed the wave numbers for the ponderomotive potential at various radial distances "r" for the distinct profiles under study.

For sinusoidal laser beam:

$$f(r) = \sin\left(\frac{\pi r}{b_w}\right), \tag{3}$$

$$k_\perp \varphi = 2E_{\text{ol}}^2 f(r)\left(\frac{e^2}{4m_e\omega_o^2}\right)\left(\frac{\pi}{b_w}\right)\cos\left(\frac{\pi r}{b_w}\right). \tag{4}$$

15213986, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ctpp.202400020 by Delhi Technological University, Wiley Online Library on [13/06/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

For Gaussian and Super-Gaussian laser beam:

$$f(r) = e^{-\left(\frac{r^2}{b_w^2}\right)^n}, \tag{5}$$

$$k_\perp \varphi = \frac{-4nr}{b_w^2}\left(\frac{eE_{ol}^2}{4m_e\omega_o^2}\right)e^{-2\left(\frac{r^2}{b_w^2}\right)^n}\left(\frac{r^2}{b_w^2}\right)^{n-1}. \tag{6}$$

For triangular and rectangular-triangular laser beam,

$$f(r) = 1 - \left|\frac{r}{b_w}\right|^s, \tag{7}$$

$$k_\perp \varphi = 2\left[1 - \left|\frac{r}{b_w}\right|^s\right]\left(\frac{eE_{ol}^2}{4m_e\omega_o^2}\right)\left(\frac{-s}{b_w}\right)\left|\frac{r}{b_w}\right|^{s-1}. \tag{8}$$

For cosh-hyperbolic laser beam:

$$f(r) = \cosh\left(\frac{br}{b_w}\right)e^{\left(-\frac{r^2}{b_w^2}\right)}, \tag{9}$$

$$k_\perp \varphi = \left(\frac{eE_{ol}^2}{2m_e\omega_o^2}\right)e^{\left(-\frac{r^2}{b_w^2}\right)}\left[\left(\frac{-2r}{b_w^2}\right)\cosh^2\left(\frac{br}{b_w}\right) + \left(\frac{b}{2b_w}\right)\sinh\left(\frac{2br}{b_w}\right)\right]. \tag{10}$$

Within the aforementioned equations, the variable "n" serves as the form factor. The curvature of the curve intensifies as the value of "n" rises. Precisely, when "n" equals 1, the waveform adopts a Gaussian profile, while for "n" greater than 1 (such as 7), the waveform evolves into a super-Gaussian shape. These adjustments in the "n" parameter hold substantial sway over the waveform's attributes and overall appearance. The parameter "s" represents the order or index of the laser beam. As "s" increases in value, the curve exhibits a greater degree of steepness. To provide specifics, when s equals 1, the waveform assumes a triangular shape, while for values of s such as 4 (typically when s exceeds 2), the waveform transforms into a rectangular-triangular pattern. These variations in "s" have a substantial impact on the shape and characteristics of the laser beam. The parameter "b" serves as a measure of the degree of decentering, and its values encompass a range from 0 to 2. In our specific study, we have chosen to focus on two distinct values of "b," namely $b = 1.2$ and $b = 2$. These particular values have been selected because they exhibit significant disparities in their profile shapes, gradients, and slopes, making them particularly relevant for our investigation. The term "b_w" signifies the beam width of the input laser waveform, which spans from an initial value of 0 and extends up to 40 μm.

Terahertz electromagnetic radiation generation can be described by the hydrodynamic equations and Maxwell's equations averaged over low-frequency laser oscillations for electrons in plasma, and can be expressed as:

$$\frac{\partial}{\partial t}\vec{v} = \frac{e}{m_e}\vec{E} - \frac{e}{m_e}(\nabla\varphi), \tag{11}$$

$$\nabla \times \vec{E} = -\frac{1}{c}\frac{\partial}{\partial t}\vec{B}, \quad \left(a_o = \frac{eE_{ol}}{m_e c\omega}\right), \tag{12}$$

$$\nabla \times \vec{B} = \frac{1}{c}\frac{\partial}{\partial t}\vec{E} + \frac{4\pi e}{c}\vec{J}. \tag{13}$$

Here, $E(r,t)$, $B(r,t)$, and $v(r,t)$ are the electric fields, magnetic fields, and the averaged electron velocities, all altering slowly over the laser field period and c is the velocity of light. Here, $\vec{J} = e\mu\vec{v}$ is the electron current density in plasma produced due to varying electric and magnetic field over a period of time in the region $(-L < z < L)$, and $\vec{v}$ is the normalized velocity of electrons.

The time varying electric and magnetic field equations of the input laser beam can be derived from the Maxwell equations using Equations (11–13), which can be delineated as

15213986, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ctpp.202400020 by Delhi Technological University, Wiley Online Library on [13/06/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

$$\frac{\partial^2 \vec{E}}{\partial t^2} + \omega_p^2 \vec{E} + c^2(\nabla \times \nabla \times \vec{E}) = \omega_p^2(\nabla\varphi) \tag{14}$$

$$\frac{\partial^2 \vec{B}}{\partial t^2} + \omega_p^2 \vec{B} - c^2\left(\nabla^2 \vec{B}\right) = 4\pi ec(\nabla n) \times \vec{v}, \tag{15}$$

where $\varphi = \left(\frac{eE_{ol}^2|f(r)^2|}{4m_e\omega_o^2}\right)$ is the averaged ponderomotive potential of laser which is applied on plasma electrons, $\omega_p = \sqrt{\frac{4\pi ne^2}{m_e}}$ is the plasma electron frequency, and n is the number density of electrons in plasma slab with respect to z-direction. In Equation (15), the right side of the equation acts as the originating factor for the generation of THz radiation. Substituting $\partial/\partial t$ by $(-i\omega)$ and ∇ by $\left(ik_\dagger\right)$ in Equation (15) for the azimuthal component of magnetic field, we get

$$(-i\omega)^2 \vec{B}_\phi + \omega_p^2 \vec{B}_\varphi - \left(c^2 \frac{\partial^2}{\partial r^2} \vec{B}_\varphi + \frac{\partial^2}{\partial z^2} \vec{B}_\varphi\right) = 4\pi ec(\nabla n) \times \vec{v}, \tag{16}$$

$$\left(\omega_p^2 - \omega^2\right)\vec{B}_\varphi - c^2\left(k_\dagger^2 \vec{B}_\varphi + \frac{\partial^2}{\partial z^2} \vec{B}_\varphi\right) = 4\pi ec(\nabla n) \times \vec{v}, \tag{17}$$

where $k_\dagger^2 = \frac{\omega}{c}\sin(\theta)$ is the perpendicular wave number and "θ" is the angle at which resultant fields are viewed. In order to assess the power of terahertz radiation produced and determine the electric and magnetic field intensities for varying incident laser beam profiles, it becomes imperative to ascertain the precise angle in question.

The radial component of velocity experienced by the electrons in the plasma due to altering fields is obtained from Equation (11) as

$$(-i\omega_o)\vec{v_r} = -\frac{e}{m_e}\vec{E_r} - \frac{e}{m_e}(k_\perp \varphi), \tag{18}$$

$$\vec{v_r} = \frac{ek_\perp}{im_e}\varphi + \frac{e}{im_e\omega_o}\vec{E_r}. \tag{19}$$

In order to calculate the second-order time varying differential equation for B_φ, we first must conclude V_r in terms of B_φ. To calculate E_r in terms of B_φ, we use Equation (13). The electric field of the laser beam is oriented in the radial (r) direction, which produces the magnetic field aligned with azimuthal-axis, which gives rise to the equation:

$$E_r = \frac{c}{i\omega_o}\frac{\partial B_\varphi}{\partial z}. \tag{20}$$

Substituting Equation (20) in Equation (19), we get radial velocity in terms of B_φ which yields Equation (7) as

$$v_r = \frac{ek_\perp}{\omega_o m_e}\varphi + \frac{ec}{m_e\omega_o^2}\frac{\partial}{\partial z}B_\varphi. \tag{21}$$

The n, that is, the number density varies along the axial direction while the v_r as discussed in Equation (21) varies along the radial direction, which yields the result along azimuthal direction stated as

$$-\omega^2 \vec{B}_\phi + \omega_p^2 \vec{B}_\varphi - c^2\left(k_\dagger^2 \vec{B}_\varphi + \frac{\partial^2}{\partial z^2} \vec{B}_\varphi\right) = \left(\frac{4\pi e^2 c\vec{k_\perp}\varphi}{\omega_o m_e}\right) - \left(\frac{4\pi ec^2}{\omega_o^2 m_e}\frac{\partial n}{\partial z}\frac{\partial B_\varphi}{\partial z}\right). \tag{22}$$

Equating Equations (17) and (22), we obtain the second order differential equation of B_φ as

$$\frac{\partial^2 B_\varphi}{\partial z^2} - \left(\frac{4\pi e^2 N_{oe}}{\omega_o^2 m_e}\frac{\partial B_\varphi}{\partial z}\right) - \left(k_\dagger^2 - \frac{\omega^2}{c^2} + \frac{\omega_p^2}{c^2}\right)B_\varphi + \left(\frac{4\pi e^2 k_\perp \varphi \nabla n}{\omega_o c m_e}\right) = 0. \tag{23}$$

The laser frequency "ω_o" is in the order of 10^{14} Hz, which fabricates the constant term of $\frac{\partial B_\varphi}{\partial z}$ almost negligible. In the context of a plasma slab featuring sharp boundaries, there is a surface current responsible for causing a discontinuity in the magnetic field. It is worth noting that this discontinuity in the magnetic field, while present, is typically of lesser

15213986, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ctpp.202400020 by Delhi Technological University, Wiley Online Library on [13/06/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

significance when contrasted with the discontinuity in $\frac{\partial B_\varphi}{\partial z}$, which often leads to its omission in calculations. Equation (23) reduces to the form

$$\frac{\partial^2 B_\varphi}{\partial z^2} - \left(k_\dagger^2 - \frac{\omega^2}{c^2}\varepsilon_z\right)B_\varphi + \left(\frac{4\pi e^2 k_\perp \varphi(\nabla \mu)}{\omega_o c m_e}\right) = 0. \tag{24}$$

On solving Equation (23) in vacuum ($z < -L, z > L$) and in plasma ($-L < z < L$), and by applying the continuity conditions for the radial and azimuthal components of electric and magnetic fields respectively, at the interface between the plasma and vacuum, we can determine the characteristics of the low-frequency electromagnetic field across the entire columns of space. The wave entering from the left side of the slab and running away toward the right side of the slab provides us with the equations mentioned as

$$B_\varphi = C_3 e^{(\lambda_o\{z+L\})}, \quad (z < -L), \tag{25}$$

$$B_\varphi = C_4 e^{(-\lambda_o\{z-L\})}, \quad (z > L), \tag{26}$$

$$B_\varphi = C_1 e^{\lambda z} + C_2 e^{-\lambda z} + \frac{4\pi e^2 k_\perp \varphi}{K^2 \omega_o c m_e}\nabla n, \quad (-L < z < L), \tag{27}$$

where $K^2 = \left(k_\dagger^2 - \frac{\omega^2}{c^2}\varepsilon_z\right)$, and C_1, C_2, C_3, and C_4 are constants.

In order to calculate the boundary conditions for Equation (14), that is, "E_r" for the plasma-vacuum interface, we use

$$\nabla \times \nabla \times \vec{E} = -\frac{i\omega_o}{c}\frac{\partial B_\varphi}{\partial z}. \tag{28}$$

Substituting Equation (28) in Equation (14), we get E_r in terms of B_φ as

$$E_r = \frac{-ic}{\omega_o \varepsilon_z}\left(\frac{\omega_p^2 k_\perp \varphi}{\omega c} + \frac{\partial B_\varphi}{\partial z}\right). \tag{29}$$

Applying the continuity conditions and boundary conditions at the above equation, we receive the equations in plasma and in vacuum of the form:

$$E_r = \frac{-c\lambda_o}{\omega} C_3 e^{(-\lambda_o\{z+L\})} \text{for } (z < -L), \tag{30}$$

$$E_r = \frac{c\lambda_o}{\omega} C_4 e^{(\lambda_o\{z-L\})} \text{for } (z > L), \tag{31}$$

$$E_r = \frac{-ic}{\omega\varepsilon_z}\left[\frac{\omega_p^2 k_\perp \varphi}{\omega c} + C_1\lambda e^{\lambda L} - C_2\lambda e^{-\lambda L} - \frac{16\pi^2 e^4 k_\perp}{\omega_o c^3 m_e^2 \lambda^4}(\nabla n)^2\right] \text{for } (-L < z < L). \tag{32}$$

Equating Equations (30) and (32) as well as Equations (25) and (27) at the left side of the plasma-vacuum interface, and Equations (31) and (32) as well as Equations (26) and (27) at the right side of the plasma-vacuum interface, we obtain the values of constants as

$$C_3 = C_1 e^{-\lambda L} + C_2 e^{\lambda L} + \frac{4\pi e^2 k_\perp \varphi \nabla n}{\omega_o c m_e}, \tag{33}$$

$$C_4 = C_1 e^{\lambda L} + C_2 e^{-\lambda L} + \frac{4\pi e^2 k_\perp \varphi \nabla n}{\omega_o c m_e}. \tag{34}$$

Equating the constants C_3 and C_4 for both radial component of electric field and azimuthal component of magnetic field, we obtain relations

15213986, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ctpp.202400020 by Delhi Technological University, Wiley Online Library on [13/06/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

$$C_1(\lambda + i\lambda_o\varepsilon_z)e^{-\lambda L} - C_2(\lambda - i\lambda_o\varepsilon_z)e^{\lambda L} + \varphi\left[\frac{\omega_p^2 k_\perp}{\omega c} + i\lambda_o c - \frac{16\pi^2 e^4 k_\perp}{\omega_o c^3 m_e^2 \lambda^4}(\nabla n)^2\right], \tag{35}$$

$$C_1(\lambda - i\lambda_o\varepsilon_z)e^{\lambda L} - C_2(\lambda + i\lambda_o\varepsilon_z)e^{-\lambda L} + \varphi\left[\frac{\omega_p^2 k_\perp}{\omega c} - i\lambda_o c - \frac{16\pi^2 e^4 k_\perp}{\omega_o c^3 m_e^2 \lambda^4}(\nabla n)^2\right]. \tag{36}$$

Adding and subtracting Equations (35) and (36) simultaneously, we obtain

$$\begin{aligned} &C_1\left[(\lambda + i\lambda_o\varepsilon_z)e^{-\lambda L} + (\lambda - i\lambda_o\varepsilon_z)e^{\lambda L}\right] - C_2\left[(\lambda - i\lambda_o\varepsilon_z)e^{\lambda L} + (\lambda + i\lambda_o\varepsilon_z)e^{-\lambda L}\right] \\ &\quad + 2\varphi\left[\frac{\omega_p^2 k_\perp}{\omega c} + \frac{16\pi^2 e^4 k_\perp}{\omega_o c^3 m_e^2 \lambda^4}(\nabla n)^2\right] = 0, \end{aligned} \tag{37}$$

$$\begin{aligned} &C_1\left[(\lambda + i\lambda_o\varepsilon_z)e^{-\lambda L} - (\lambda - i\lambda_o\varepsilon_z)e^{\lambda L}\right] - C_2\left[(\lambda - i\lambda_o\varepsilon_z)e^{\lambda L} - (\lambda + i\lambda_o\varepsilon_z)e^{-\lambda L}\right]. \\ &\quad + 2\varphi(i\lambda_o\varepsilon_z) = 0 \end{aligned} \tag{38}$$

Within these mathematical expressions, the terms represented along with "C_1" and "$C2$" are typically recognized as "T_s" and "T_a" respectively, given as

$$C_1 = \left[\frac{\omega_p^2 k_\perp}{\omega c} - \frac{16\pi^2 e^4 k_\perp}{\omega_o c^3 m_e^2 \lambda^4}(\nabla n)^2\right]\left(\frac{-\varphi}{T_s}\right) + i\lambda_o\varepsilon_z\left(\frac{\varphi}{T_a}\right), \tag{39}$$

$$C_2 = \left[\frac{\omega_p^2 k_\perp}{\omega c} - \frac{16\pi^2 e^4 k_\perp}{\omega_o c^3 m_e^2 \lambda^4}(\nabla n)^2\right]\left(\frac{-\varphi}{T_s}\right) - i\lambda_o\varepsilon_z\left(\frac{\varphi}{T_a}\right), \tag{40}$$

$$T_s = (\lambda + i\lambda_o\varepsilon_z)e^{(-\lambda L)} + (\lambda - i\lambda_o\varepsilon_z)e^{(\lambda L)}, \tag{41}$$

$$T_a = (\lambda - i\lambda_o\varepsilon_z)e^{(\lambda L)} - (\lambda + i\lambda_o\varepsilon_z)e^{(-\lambda L)}. \tag{42}$$

The terms "T_s" and "T_a" correspond to the excitation of the plasma slab's electromagnetic eigenmodes (symmetric and antisymmetric), as they would appear in denominators of electric field (Equations 30–32) and magnetic field expressions (Equations 25–27). The dispersion relationship governing the symmetric electromagnetic mode within a plasma slab can be formulated when a particular condition is met which is determined by $T_s = 0$. This condition yields the following dispersion relationship:

$$\frac{\lambda}{\varepsilon}\tanh(\lambda L) + i\lambda_o = 0. \tag{43}$$

Similarly, the antisymmetric electromagnetic mode within a plasma slab can be formulated when $T_a = 0$. This yields the following dispersion relation for antisymmetric mode given by:

$$\frac{\lambda}{\varepsilon}\coth(\lambda L) + i\lambda_o = 0. \tag{44}$$

Equation (44) describes the dispersion relation for a symmetric mode that travels within a plane characterized by uniform plasma density, which exponentially diminishes as one moves away from the plasma boundary. This equation is a crucial mathematical expression used to understand how this specific mode behaves under these unique conditions. It helps us grasp the intricate relationship between the mode's propagation properties, the consistency of plasma density, and the rapid decay of plasma characteristics as we move away from its edge. Analyzing this equation can provide essential insights into the wavelength, frequency, and phase velocity of the mode in question, contributing to the understanding of wave-plasma interactions and their relevance in various scientific and technological contexts.

3 | RESULTS AND DISCUSSION

We estimate terahertz radiation field for typical parameters of laser-plasma experiments. A femtosecond laser pulse with intensity 10^{12}–10^{16} W/cm^2 is incident on a 80-μm thick plasma slab having electron number density of 10^{17}–10^{19} cm^{-3}.

15213986, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ctpp.202400020 by Delhi Technological University, Wiley Online Library on [13/06/2024]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

The laser beam is incident on the left boundary of plasma slab at $z = -40\,\mu m$. The laser propagates through the plasma slab and tunnels out of the right boundary of the slab at $z = 40\,\mu m$. We observe the THz field pattern and intensity for all the laser profiles under study and for all the three regions of laser propagation, that is, $z < -L$, $z > L$, and $-L < z < L$, where $L = 40\,\mu m$, and L is also varied to observe the THz field variation with plasma slab thickness. The gradient of the laser field (spatial variation) plays a crucial role in generating the electric radial field. When the laser intensity varies spatially within the plasma slab, it creates spatial gradients in the ponderomotive potential. These gradients lead to forces on charged particles within the plasma, causing them to move and generate the radial electric field. Essentially, the particles are pushed by the ponderomotive force associated with the gradient of the laser field.

Figure 1 shows the variation of normalized electric field as a function of radial distance r, for different spatially polarized profiles viz. Gaussian, super-Gaussian, cosh-hyperbolic, sinusoidal, triangular, and rectangular-triangular waveforms. Due to varying profile envelopes, the amplitude of incident laser varies with radial distance. The field amplitude of laser is also different for different profiles and is maximum for cosh-hyperbolic waveform. All other profiles have the same maximum amplitude value of $10^6\,V\,cm^{-1}$, while cosh-hyperbolic laser beam has two maximum points of $1.3 \times 10^6\,V\,cm^{-1}$ each on either side of $r = 0$ symmetrically. The amplitude at these two points depends on the value of decentered parameter "b" of laser beam profile. The laser propagates through the plasma and imparts an oscillatory velocity to the plasma electrons, which exerts a ponderomotive force on them, pushing them forward until it behaves as the space charge force. Since the laser beam is radially polarized, therefore the electrons experience a radial ponderomotive force and drive a nonlinear current in azimuthal direction.

We have plotted the variation of ponderomotive potential "ϕ" with radial distance "r" in Figure 2. The ponderomotive potential, influenced by laser intensity, mirrors the laser's spatial pattern as it is a quiver energy that describes how charged particles respond to the time-averaged laser field. When the laser intensity varies, the ponderomotive potential also varies accordingly. As the ponderomotive potential oscillates, it imparts kinetic energy to charged particles in the plasma, causing them to oscillate and contribute to the electric radial field. This potential, experienced by charged particles in a plasma, is proportional to the laser's power per unit area. Its gradient induces electric field excitation both within and outside the plasma slab accordingly to Equations (30–32). This phenomenon plays a pivotal role in shaping charged particle trajectories in laser-plasma interactions. The understanding of ponderomotive potential and it is associated dynamics is crucial in various applications, such as laser-driven fusion research and particle acceleration.

The nonlinear current excites a magnetic field in azimuthal direction. The variation of the self-generated magnetic field along the direction of laser propagation and the gradient of ponderomotive potential in radial direction, together contribute to the radial component of electric field. The axial component of the excited electric field is also related to the azimuthal magnetic field and is directly proportional to it is radial gradient. In Figure 3, we have plotted the normalized radial electric field within the plasma slab as a function of radial variable "r" in 2-D for all the laser

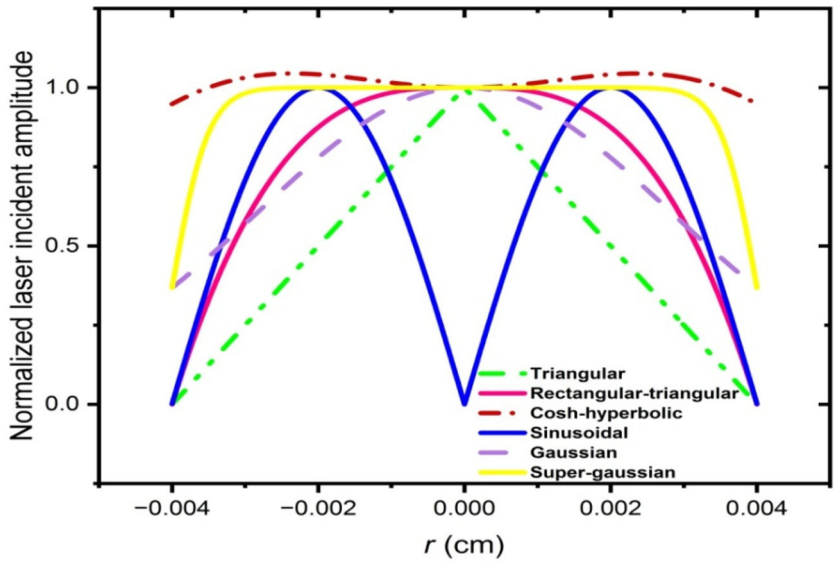

FIGURE 1 Normalized incident laser field amplitude as a function of "r" for rectangular-triangular, triangular, cosh-hyperbolic, sinusoidal, Gaussian, and super-Gaussian profiles.

15213986, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ctpp.202400020 by Delhi Technological University, Wiley Online Library on [13/06/2024]. FIGURE 2 Ponderomotive potential as a function of "r" for different laser profiles.

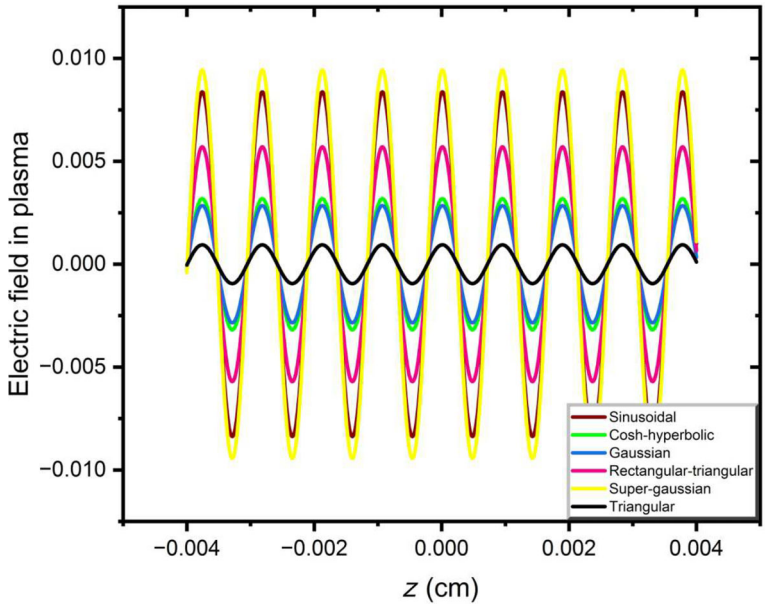

FIGURE 3 Normalized radial electric field "E_r" in plasma slab for different laser profiles.

profiles under consideration. It can be seen that normalized electric field is maximum for Super-Gaussian laser profile beam, which is then followed by rectangular-triangular, sinusoidal, cosh-hyperbolic, and triangular profiles. This variation maybe understood on comparing Figures 2 and 3, which indicate that the radial electric field is maximum where the slope of the ponderomotive potential versus r graph is maximum.

To get an insight of the variation of radial electric field with both spatial coordinates "r" and "z", we have simulated the 3D contour plots of the excited field within the plasma slab for limits $-L < z < L$ and outside the slab, on both sides in vacuum for all the laser beam profiles. Figure 4 shows the contour plots of normalized electric field within the plasma slab as a function of spatial variables "r" and "z," for sinusoidal, triangular, rectangular-triangular, cosh-hyperbolic ($b = 1.2$), cosh-hyperbolic ($b = 2.0$), Gaussian, and super-Gaussian laser pulse profiles, respectively. The gradient of the

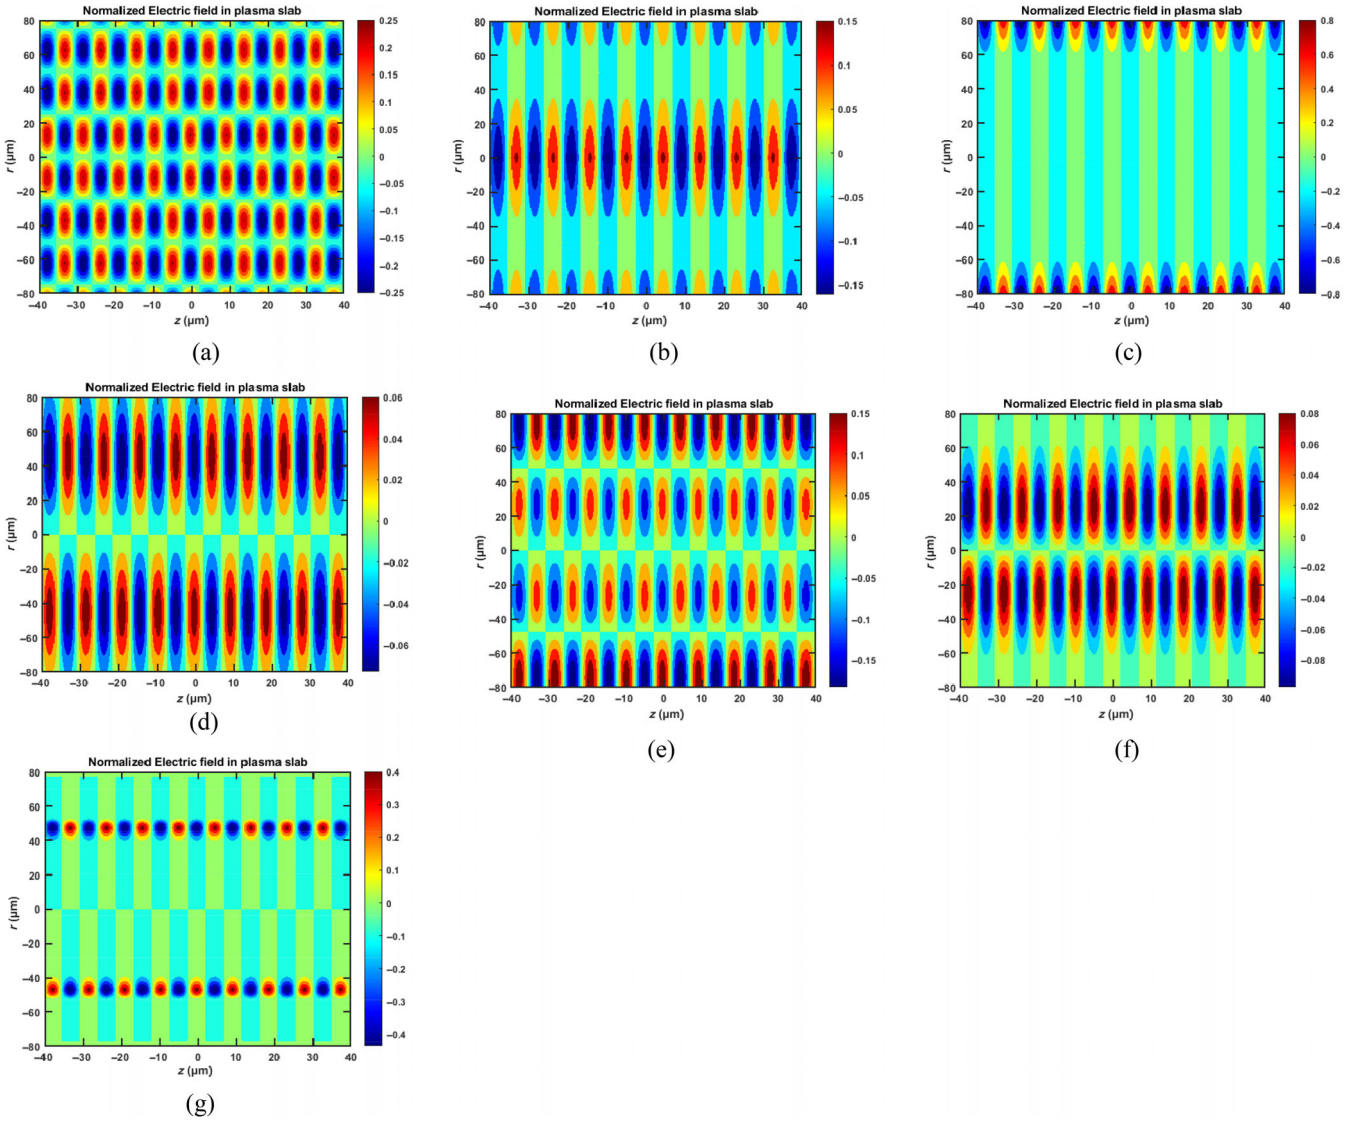

FIGURE 4 Normalized radial electric field "E_r/E_{ol}" in plasma slab for (a) sinusoidal, (b) triangular, (c) rectangular-triangular, (d) cosh-hyperbolic ($b = 1.2$), (e) cosh-hyperbolic ($b = 2.0$), (f) Gaussian, and (g) super-Gaussian laser profiles. Other parameters are $n_e = 1.3 \times 10^{19}$ cm^{-3}, $L = 40$ μm, $E_{ol} = 10^8$ V/cm, $\omega_o = 2 \times 10^{15}$ rad/s, $\omega = 2.07 \times 10^{14}$rad/s, $\theta = 10°$, and $b_w = 50$ μm.

laser field within the plasma slab leads to spatial variations in the ponderomotive potential, which in turn, results in forces on charged particles. These forces cause the particles to oscillate and generate the electric radial field. The normalized radial electric field (E_r/E_{ol}) in a plasma slab for different laser profiles varies in shape and magnitude, with Gaussian profiles producing a Gaussian E_r distribution, rectangular-triangular profiles yielding a more uniform E_r within the beam's central region, and other profiles exhibiting unique E_r patterns, all subject to the specific laser-plasma interaction physics involved. The rectangular-triangular laser ($s = 3$) generates maximum peak electric field of 0.8×10^8 V/cm due to it is flat-top pattern, succeeded by super-Gaussian laser ($n = 4$) with peak value of electric field as 0.4×10^8 V/cm, followed by sinusoidal laser with 0.25×10^8 V/cm, cosh-hyperbolic laser ($b = 2$) with 0.15×10^8 V/cm, triangular laser with 0.15×10^8 V/cm, Gaussian laser with 0.08×10^8 V/cm, and the least peak electric field for cosh-hyperbolic laser ($b = 1.2$) with 0.06×10^8 V/cm. Such a variation is justified as the rectangular-triangular and super-Gaussian lasers have steep radial gradient of ponderomotive potential as compared with other profiles. Hematizadeh et al.[63] and Gupta et al.[64] have also reported that top-hat laser beams and flattened Gaussian laser beams produce a stronger ponderomotive force and an enhanced THz field strength. Super-Gaussian and rectangular triangular beams can generate higher radial electric fields in laser-plasma interactions as they have a flatter central region compared with other beam profiles, which means that they can deliver more laser energy to a smaller, well-confined spatial area.

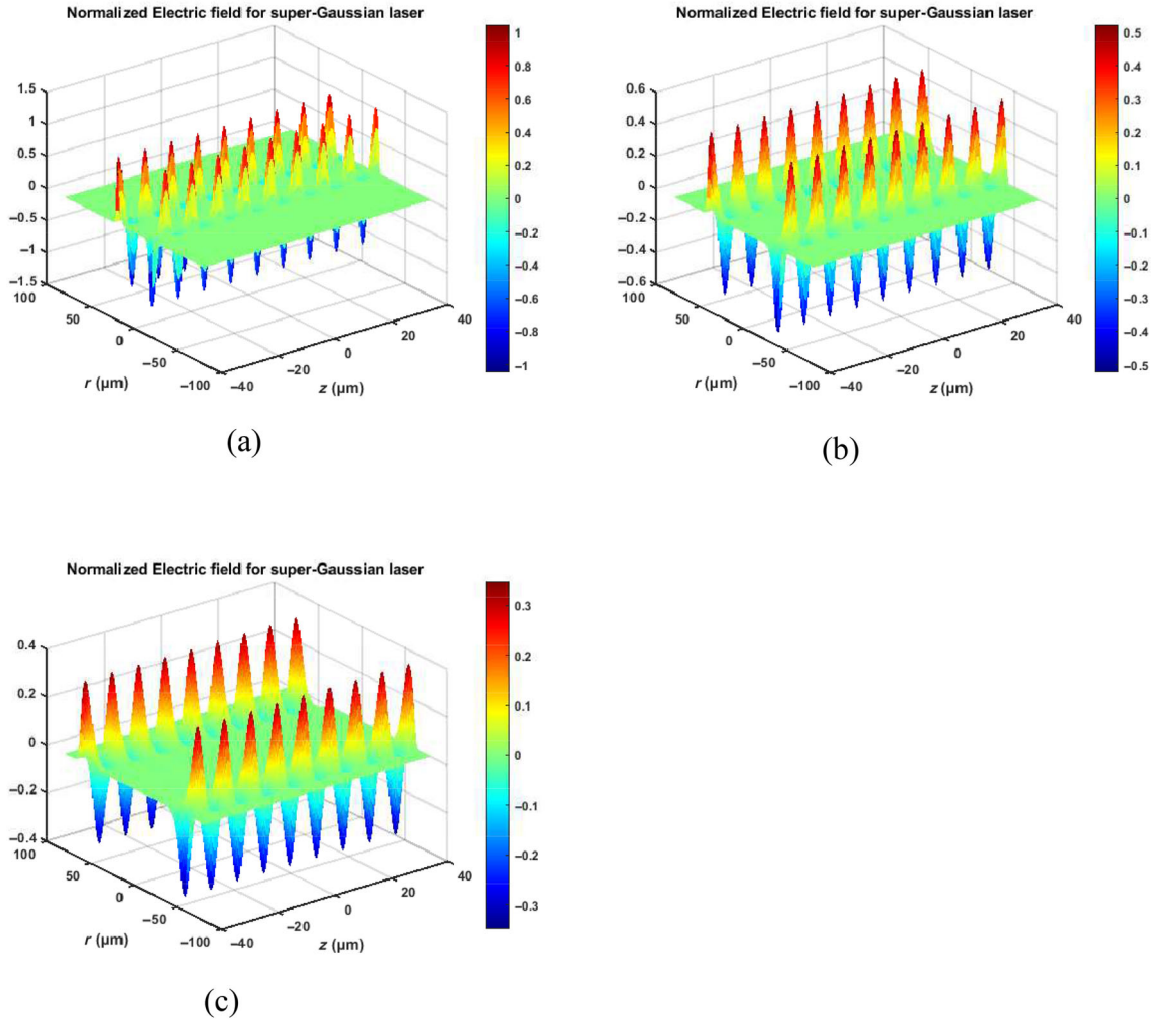

FIGURE 5 Variation of normalized electric field in plasma slab for super-Gaussian laser profile beam with "r" and "z" for different laser pulse width: (a) $b_w = 20\,\mu m$, (b) $b_w = 40\,\mu m$, and (c) $b_w = 60\,\mu m$.

Figure 5 illustrates the three-dimensional variation of normalized THz electric field with spatial coordinates, for different values of laser beam width $b_w = 20$, 40, and 60 μm, with rest of the parameters same as in Figure 4. The laser profile chosen here is super-Gaussian. One sees that the excited radial THz field is more focused and higher for lower values of beam width. A two-fold enhanced THz field is obtained when beam width is halved. Figure 5a depicts a highly focused beam for $b_w = 20\,\mu m$ as compared with a less focused beam for $b_w = 60\,\mu m$ in Figure 5c. It follows from the fact that for a laser pulse of small beam width, the characteristic wavenumber "$k_\perp$" which is inversely proportional to beam width b_w, is fairly large, and therefore, the waves propagate primarily in the radial direction. Thus, a decrease in the beam width enhances the efficiency of excitation in radial direction. Frolov[65] also reported that mainly surface waves are excited, when a laser pulse with tight focus falls on a plasma half-space boundary and therefore the waves predominantly propagate in radial direction.

Figure 6 shows the behavior of normalized THz electric field with frequency for varying plasma slab thickness, that is, $L = 25$, 35, 45, and 55 μm with laser frequency taken as $w_o = 2 \times 10^{14}$ rad/s and $n_e = 1.3 \times 10^{17}\ cm^{-3}$. The excited radial electric fields are emitted at THz frequencies and increase with decreasing slab thickness. Though the intensity of THz field decreases, but the field spectrum increases with the increase in value of L, and the frequency of maxima also increases lying within the range 15 to 20 THz. A 2D plot of THz electric field as a function of frequency, for different laser beam widths is shown in Figure 7 with the same parameters as taken for Figure 6. Reduction in beam width increases the intensity of emitted THz radiation but the frequency of maxima remains almost same for all values of beam width, which is comparable with the plasma frequency. As the plasma pulse width decreases, the area under the curve increases, indicating a wider spectrum with more intense excited electric field. The results are in conjunction with the 3D plots shown in Figure 5.

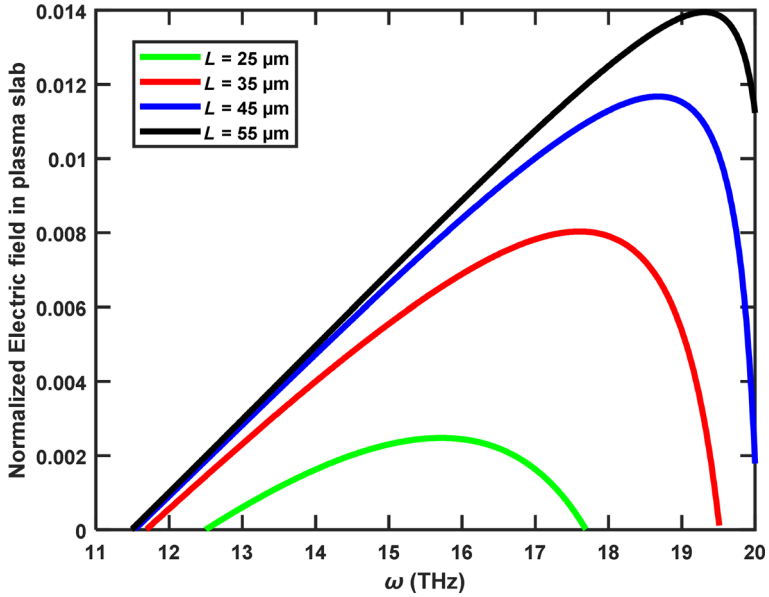

FIGURE 6 Normalized electric field in plasma slab for sinusoidal laser waveform as a function of THz frequency for different slab thickness $L = 25$, 35, 45, and 55 μm.

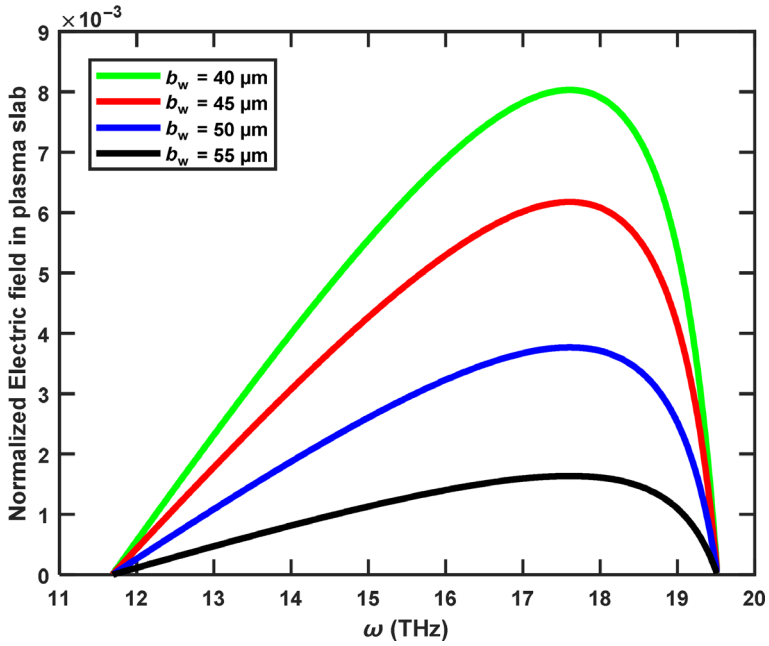

FIGURE 7 Normalized electric field as a function of THz frequency for varied laser beam widths for a sinusoidal waveform laser.

As a result of complex plasma currents, the plasma slab borders behave like antennas and produce electromagnetic radiation in a conical form. Therefore, we have also studied the angular distribution of THz field inside the plasma slab and in vacuum. Figure 8 shows normalized THz field as a function of frequency for different viewing angles. Maximum THz field is observed at a perspective angle of 45° to the laser propagation direction. For angles less than 45°, an increase in the view angle increases the intensity as well as spectrum of THz field and the frequency of maximum intensity field remains close to the plasma frequency at about 17 THz. For angles more than 45°, an increase in the view angle, decreases the emitted THz field intensity but the THz spectrum expands with view angle. These observations are specifically for Gaussian laser pulse profile. For other laser profiles also, a similar pattern of variation is observed. It is shown from

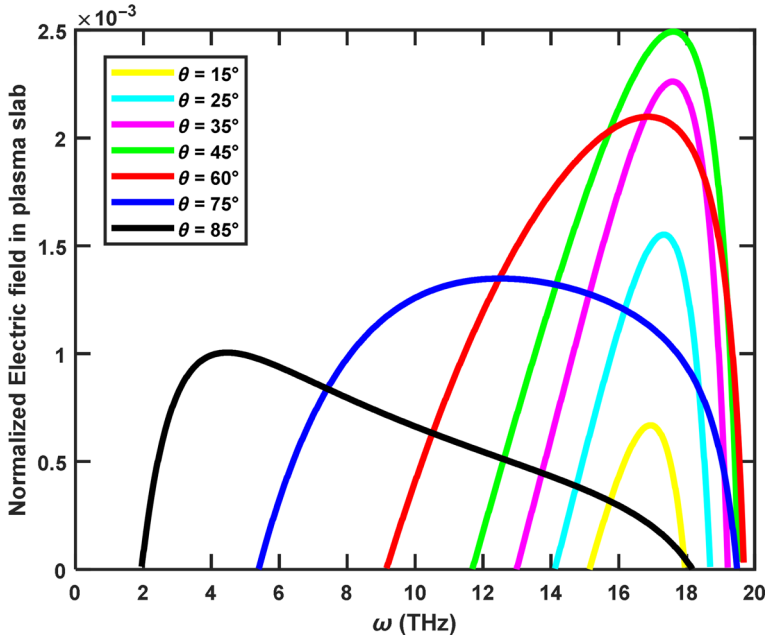

FIGURE 8 Normalized THz field response across various viewing angles as a function of frequency for sinusoidal wave.

Figure 6 that as the plasma slab thickness decreases, the spectrum of radiation also decreases. When the slab thickness is comparable with the laser beam width, the intensity of excited field is the highest as shown in Figure 7. Similar results have been concluded by Frolov et al.[65] for terahertz radiation generation from a low-density plasma slab with the similar plasma parameters as considered here for plotting Figures 6–8.

The relationship between the incident laser amplitude and the generated magnetic field is nonlinear. This means that small changes in laser intensity can lead to disproportionately larger changes in the generated magnetic field. As the intensity of the incident laser pulse increases, the electrons in the plasma are subjected to stronger forces due to the electric field of the laser. The laser pulse's electric field can accelerate free electrons within the plasma, leading to the formation of electron currents. These electron currents are associated with the motion of charged particles and, according to Ampere's law, can generate magnetic fields. Linearly polarized lasers generate magnetic fields perpendicular to the laser's polarization direction, while circularly polarized lasers can produce magnetic fields in different directions. We also report magnetic field in azimuthal direction produced by radially polarized laser pulses. In our study, we create contour plots illustrating the strength of the magnetic field for various laser pulse profiles. Figure 9 depicts the magnetic field pattern in plasma slab for sinusoidal, Gaussian, super-Gaussian, cosh-hyperbolic, triangular, and rectangular-triangular laser pulse envelopes. Through the analysis of these patterns, we observed that the magnetic field reaches highest intensity for super-Gaussian pulse, while it exhibits its lowest strength for triangular pulse waveform. Similar pattern of field strength was obtained from radial electric field contours also for individual laser profiles. The physical mechanism responsible for the generation of azimuthal component of the magnetic field is governed by the ponderomotive forces. The magnetic field azimuthal component is proportional to the square of laser amplitude. The spatial variation of the magnetic field strongly depends on the laser pulse shape and density of plasma.

Figure 10 exhibits the relationship between incident laser amplitude and the self-generated magnetic field. Researchers[66] have identified scaling laws that describe the relationship between laser intensity and the resulting magnetic field. These laws may provide insights into the behavior of the system. Our measured magnetic field values closely align with the values predicted by scaling laws formulated by other researchers. When measuring or observing the generated magnetic field, the angle at which the measurement is taken relative to the laser's propagation direction can affect the observed field strength. The Doppler shift due to the motion of electrons in the plasma can affect the observed frequency and strength of the magnetic field when measured at different angles. The variation of magnetic field with slab thickness is influenced by intensity of the laser, the electron number density of the plasma, and the duration of the laser pulse. Figure 11 depicts the variation of self-generated magnetic field with plasma slab thickness for three different perspective angles. When a laser pulse interacts with a plasma, it ionizes the plasma creating charged particles (ions and free electrons). A thicker plasma slab implies higher concentration of ions and electrons, which can enhance the generation of

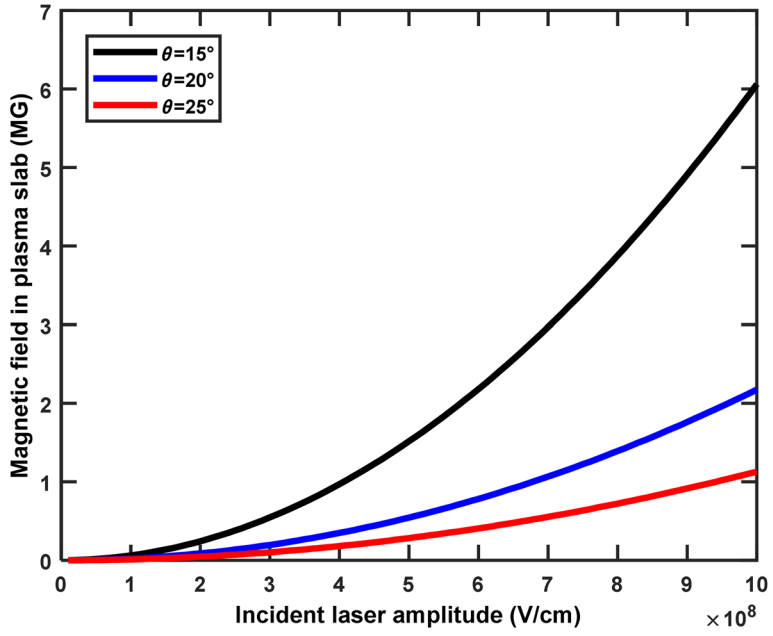

FIGURE 10 Self-generated magnetic field "B_Φ" in plasma slab as a function of incident super-Gaussian laser amplitude E_{ol} (V/cm) for different viewing angles θ.

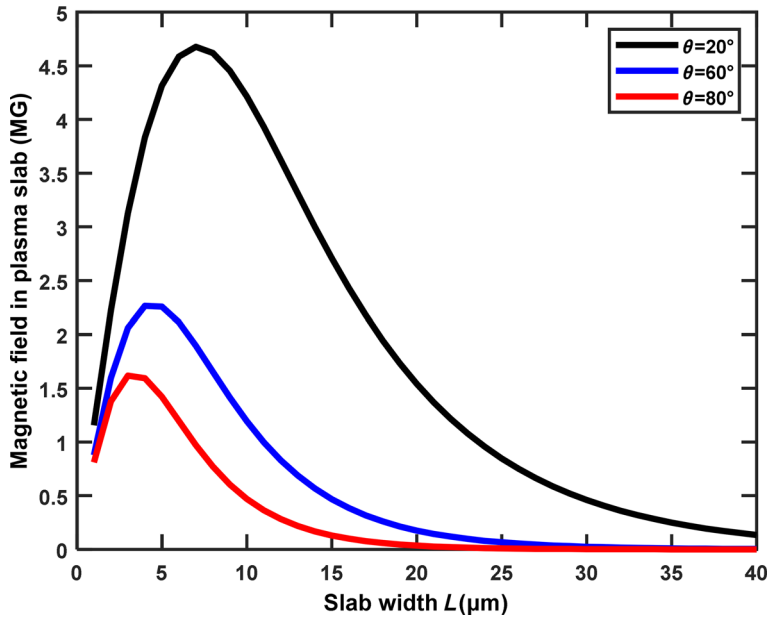

FIGURE 11 Self-generated magnetic field "B_Φ" in plasma slab as a function of plasma slab width "L" on interaction with Gaussian laser pulse for different perspective angles θ.

magnetic fields. However, as the plasma slab becomes very thick, saturation effects are seen. Beyond a certain thickness, the magnetic field strength starts declining. The value of saturation magnetic field and the corresponding slab thickness depends on the detailed properties of the laser pulse profile and the angle at which azimuthal magnetic field is viewed from the center of the slab. Figure 11 shows that as the view angle decreases, the magnetic field strength decreases for thick slabs($L > 15\,\mu m$) while it increases for thin slabs($L < 5\,\mu m$). At a 20° view angle, the maximum observed magnetic field strength is 4.7 MG.

To conduct a comparative analysis of our findings in the context of existing research, we employed the code of Gaussian laser system, utilizing parameters as specified by previous experimental and theoretical studies. At an intensity

15213986, 0, Downloaded from https://onlinelibrary.wiley.com/doi/10.1002/ctpp.202400020 by Delhi Technological University, Wiley Online Library on [13/06/2024]. of 10^{17} W cm^{-2}, Santos et al.[5] were able to generate a magnetic field of 10 MG, when the laser interacted with solid state targets. Lamac et al.[66] reported a generation of azimuthal magnetic field in GG range in their experimental work for high laser amplitudes; a reduction in laser intensity will generate magnetic fields obtained from our mathematical analysis, also justifying the numerical scaling laws. For plasma with electron density $\sim 10^{18}$ cm^{-3}, Gorbunov and Ramazashvili[67] using perturbation theory reported a maximum magnetic field of 350 kG, which is comparable with the field values observed in our analysis. Tatarakis et al.[27] experimentally measured peak magnetic fields in the range 340–460 MG with a laser intensity greater than 10^{19} W cm^{-2}, for higher harmonics. We observed magnetic fields in the range 1–5 MG with laser intensities of 10^{16} W cm^{-2}, which are justifiable as our intensity of laser is comparatively less and we report the results for fundamental harmonic frequency. Park et al.[68] numerically computed a magnetic field of 0.6 GG, but for higher plasma densities and a highly intense laser beam, which is also comparable with our results.

4 | CONCLUSION

We propose an analytical model to investigate the excited radial electric field and self-generated magnetic field in a homogeneous plasma slab during interaction with a radially polarized laser beam with varied pulse profiles such as sinusoidal, Gaussian, cosh-hyperbolic, super-Gaussian, triangular, and rectangular-triangular wave forms. 2D and 3D contour plots are employed to scrutinize the intensity of the electromagnetic fields through simulation. Through a comparison between the observed results and the provided experimental and theoretical framework, the concept is effectively and convincingly exemplified. Super-Gaussian and rectangular triangular beams can generate higher radial electric fields in laser-plasma interactions due to their unique intensity profiles. They have a flatter central region compared with other beam profiles, which means that they can deliver more laser energy to a smaller, well-confined spatial area. The enhanced intensity in the central region of a super-Gaussian beam can trigger stronger nonlinear effects when interacting with the plasma. These nonlinear effects can result in the generation of higher harmonics and more complex plasma responses, including stronger radial electric fields. It is important to note that the specific behavior of varied profile beams in laser-plasma interactions can vary depending on the beam parameters, the plasma conditions, and the desired outcome of the interaction. The choice of beam profile, whether Gaussian, super-Gaussian, sinusoidal, or another profile, depends on the specific experimental or theoretical objectives in laser-plasma physics. The electric vector of a radially polarized laser beam is parallel to radial coordinate and can produce strong longitudinal electric fields if focused.[69] Such electric fields have small laser spot size and useful for optical trapping of particles. Rectangular-triangular, super-Gaussian and sinusoidal lasers exhibit a significantly steeper radial gradient of ponderomotive potential in comparison with other laser profiles, thus exciting intense radial electric fields and generating high order azimuthal magnetic fields in plasma. The cone angle over which the field is emitted expands as the thickness of the slab increases. Decreasing the beam width results in an augmentation of the intensity of emitted THz radiation, while the frequency of the maxima remains nearly constant across various beam width values, remaining comparable with the plasma frequency. The underlying physical mechanism responsible for generating the azimuthal component of the magnetic field is predominantly governed by ponderomotive forces and the symmetric eigenmode in plasma slab. The antisymmetric eigenmode resulted in very low values of excited fields, making the symmetric mode as dominant one. In our analysis of field patterns, we noted that the electromagnetic fields attain peak intensity with the rectangular-triangular and super-Gaussian pulse waveforms, while they demonstrate lowest strength when using the triangular pulse waveform. The saturation magnetic field value, as well as the associated slab thickness, are contingent on the specific characteristics of the laser pulse profile and the angle from which the azimuthal magnetic field is observed relative to the center of the slab. We have employed a nonrelativistic model which is valid as long as the dimensionless laser amplitude $\left(a_o = \frac{eE_{ol}}{m_e c\omega}\right)$ is less than 1. The numerical results presented in this study align closely with the findings obtained in other theoretical and simulation studies, and find numerous applications.

Role of polymers in encapsulation and shape-stabilization of phase change materials (PCMs) for thermal energy storage applications: an overview

Surya Tanwar[1], Raminder Kaur[1,*]

Academic Editor(s): Islam Md Rizwanul Fattah, Raul D.S.G. Campilho

Abstract

Phase change materials (PCMs) are suitable for thermal energy storage (TES) owing to their increased heat storage ability, narrow temperature difference between storage and retrieval of latent heat energy, and readiness in a variety of phase change transition temperatures. Numerous research attempts have been made to develop a broad array of PCMs based on inorganic, organic, and polymeric compounds for a diverse area of applications. To improve the performance efficiency and proper handling of PCMs, they are often encapsulated or confined within a shape-stabilized supporting material of an inorganic or organic origin. This review emphasizes the current research status of the polymer-based PCMs developed using the various PCMs–polymer combinations available, material characteristics, encapsulation, and shape-stabilization methods and provides detailed information on the contribution of polymers toward the enhancement of PCM end-product properties, in an avant-garde technology related to TES.

Keywords: *phase change materials, microencapsulation, shape-stabilized, thermal energy storage*

1. Introduction

The transition in the manufacturing practices, advancements in technology, and the population boom have led to an enormous increase in energy demand in the past few centuries. Over the last half-century, researchers around the world are seeking for new fuel alternatives due to less availability of fossil fuels in the earth's reservoirs and a sudden surge in fuel prices. Moreover, awareness among the people toward the environmental and climatic changes has also inspired researchers and investigators to explore different renewable energy sources. Proposed theories that advocate solar radiation as most appreciably a viable energy source become unrealistic, as solar energy is extremely intermittent in nature leading to discrepancy between the availability and utilization time. The solution to all these energy problems is to stock the energy in the form that can be converted as and when required. The energy storage ensures the performance and steadfastness of energy systems and reduces the discrepancy between the supply and demand.

Thermal energy storage (TES) systems based on phase change materials (PCMs) have gained much attention in the research community over the last few decades. PCMs have latent heat storage properties in which the latent heat energy transfer takes place when a material transforms from the solid to a liquid state or vice versa. Most of the available literature related to PCMs for TES applications reveals the various PCMs contained inside a matrix or supporting material of inorganic or organic nature. Based on a thorough survey made, it has been explored that polymers play a vital role as matrix materials in producing PCM products for TES applications owing to their improved physical and thermal properties, good volume and leakage control, along with a remarkable dimensional stability, especially required for solid–liquid PCMs. This inclusive review presents state-of-the-art PCMs for TES applications, different polymer shells, or polymer supporting matrices, which are used for their preparation. It gives evidence about their enhanced performance and safety, and provides information about the efforts of different researchers in this area.

2. Thermal energy storage (TES)

TES is a temporary storage of high- or low-temperature energy for later use and can be retrieved by heating (melting), cooling (solidifying), or vaporizing a material with energy, which is reflected in the form of heat, when the process is reversed. TES methods (**Figure 1**) can be classified into three broad categories, namely (1) sensible heat storage, i.e., due to temperature change or change in internal energy of the material; (2) latent heat storage, based on the heat capture or release during the phase change of the storage material; and (3) thermo-chemical heat storage, relying on the heat energy derived from the chemical reactions of materials, which are used for storage purposes [2].

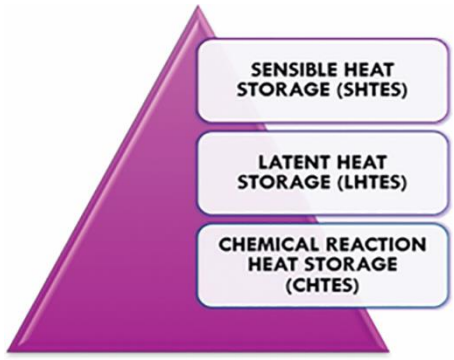

Figure 1• Different types of thermal energy storage (TES) methods. SHTES, sensible heat thermal energy storage; LHTES, latent heat thermal energy storage, and CHTES, chemical reaction heat thermal energy storage.

2.1. Sensible heat thermal energy storage (SHTES) systems

Sensible heat thermal energy storage (SHTES) encompasses the storage of thermal energy by elevating or diminishing the temperature of the storage medium, i.e., solid or liquid. The energy loading potential is corresponding to the amount of the storage material, its specific heat, density, thermal conductivity, and temperature variations during the initial and final stages [3]. The sensible heat stored in any material can be calculated using equation 1:

$$Q = \int_{T_i}^{T_f} mC_p dT = mC_{ap}(T_f - T_i) \quad (1)$$

where Q is the quantity of heat stored (J), T_i is the initial temperature (°C), T_f is the final temperature (°C), m is the mass of the heat storage medium (kg), C_p is the specific heat (J/kg K), and C_{ap} is the average specific heat between T_i and T_f (J/kg K). SHTES has less energy density and entails a huge capacity for the storage that leads to a relatively bigger unit size. These are ideal for small applications, where economics is a leading concern. The conventionally used SHTES materials, since olden times, are sand, rocks, concrete, bricks, water, oils, metals, molten salts, etc. Among these, water is the best SHTES material, as it is cost-free, abundant, and has high specific heat capacity.

2.2. Chemical reaction heat thermal energy storage (CHTES) systems

Chemical reaction heat thermal energy storage (CHTES) works on the principle of the energy absorbed and released in a reversible chemical reaction, by the breaking and re-forming of molecular bonds. These are more beneficial as compared to SHTES due to their high energy densities, ambient temperature storage, and the possibility of heat pumping and long-distance transport. The amount of energy stored is in correspondence with the amount of reacting materials, the extent of conversion, and the endothermic heat of reaction [2]. The amount of energy stored in a thermo-chemical energy storage system can be calculated using equation 2:

$$Q = a_r m \Delta h_r \quad (2)$$

where Q is the quantity of the heat stored (J), m is the mass of the heat storage medium (kg), Δh_r is the heat of reaction, and a_r is the fraction reacted.

2.3. Latent heat thermal energy storage (LHTES) systems

In latent heat thermal energy storage (LHTES) systems, the energy storage process takes place by absorbing and retrieving the thermal energy in the form of latent heat, when the storage material undergoes a change in physical state or phase, i.e., from solid to liquid, liquid to gas, or vice versa. The energy storage of LHTES systems can be described by equation 3:

$$Q = \int_{T_i}^{T_m} mC_p dT = ma_m \Delta H_m + \int_{T_i}^{T_m} mC_p dT \quad (3)$$

where a_m is the fraction of the material melted, ΔH_m is the heat of melting per unit mass (J/kg), and m is the mass of the heat storage medium (kg). The PCMs constitute a significant category of the LHTES system.

3. Phase change materials (PCMs)

Latent heat storage with the aid of PCMs is the highly effective way of thermal energy management owing to their higher energy storage density, with a narrower and almost constant temperature ranges [1]. PCMs work upon the basic principle of phase transformation, when they encounter a temperature swing. The TES occurs in the form of latent heat when the storage material shows phase alteration, typically, among solid–liquid, solid–solid, liquid–gas, or solid–gas, etc. For example, when a solid–liquid PCM is exposed to the heating process, its temperature rises constantly. As soon as the temperature of the storage material approaches the melting point, it begins to melt completely and uniformly. As the melting process is endothermic, it absorbs and stores the thermal energy available in its surroundings in the form of latent heat, in a liquid state. Furthermore, when the cycle is reversed, during the cooling process, with the progressive fall in temperature, the PCM liberates an equal amount of stored energy in the surroundings and transforms back into a solidified state. During the entire heat–cool cycle, the temperature remains constant during the phase change [4]. **Figure 2** represents a schematic outline of the mechanism of the phase change process in a solid–liquid PCM.

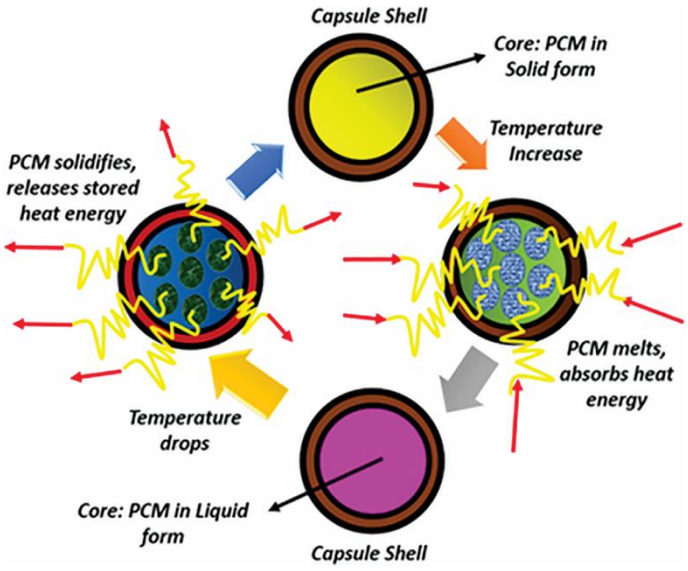

Figure 2 • A schematic outline of the mechanism of the phase change process in a solid–liquid PCM.

The energy storage based on PCMs possesses certain merits such as (1) storing a large quantity of latent heat per unit volume, i.e., high energy storage densities; (2) phase change at a constant temperature, i.e., uniform latent heat transfer; and (3) a broad spectrum of PCMs is available with a wide range of operating temperatures, which enable to develop products with tunable temperatures as per the required application [5]. With the information compiled from different studies, the main characteristic requirements for an ideal PCM for TES applications are as follows:

- ✓ Phase change temperature in the domain of functioning temperature of the heating or cooling of the product to attain optimum performance.
- ✓ High latent heat energy per unit volume to store more thermal energy.
- ✓ High thermal conductivity to support higher heat transfer rates and facilitate rapid charging and discharging.
- ✓ Uniform melting at a constant temperature.
- ✓ Endure repeatable phase transformation cycles for a long period.
- ✓ Negligible or low supercooling.
- ✓ High nucleation rate to promote a faster solidification process and the occurrence of reversible cycles at nearly the same temperature.
- ✓ Experience only a small volume change during the phase transitions to maintain the geometry of the container in-housing them.
- ✓ Low vapor pressure to overcome the risk of rupture of encapsulating the material due to high-pressure build-up situations.
- ✓ High density, which facilitates higher energy storage capacity.
- ✓ Chemical stability to ensure long life and non-reactivity with the encapsulating matrix to avoid the formation of undesirable products and leakage from containers.
- ✓ Non-corrosive to avoid the deterioration of containers.
- ✓ Non-flammable to avoid the risk to building materials and textiles in which it is encapsulated.
- ✓ Non-hazardous and non-poisonous to prevent poisonous emissions during a fire or in case of rupture of the encapsulation.
- ✓ Easy availability and economical.

The different requisite characteristic properties of PCMs for TES applications have been summarized in **Table 1**.

Table 1 • Basic requirements of PCMs for TES applications [6]

Thermal properties	Kinetic properties	Physical properties	Chemical properties	Socio-economical aspect
Suitable phase-transition temperature (melting point) in desired operating temperatures	Low supercooling	Favorable phase equilibrium—no phase segregation	Chemical stability during phase transformations	Abundant
High latent heat of phase change	High nucleation rate	Small volume change	Complete reversible melting/freezing cycles	Economic
Good thermal conductivity in both solid and liquid phases		Low vapor pressure	Compatible with host matrix/encapsulating shell	
Congruent melting pattern		Reproducible phase change cycles	Non-corrosive	
		High density	Non-flammable	
			Non-toxic	

4. Classification of PCMs

PCMs can be classified broadly into three categories based on (1) temperature, (2) phase change, and (3) chemical nature, as shown in **Figure 3**.

4.1. Based on temperature

The temperature range governing the phase transformation of PCMs falls within the three temperature zones: (1) low-temperature PCMs, with phase change temperatures below 15°C, applied in the fields of air conditioning, cold storage, and food industry; (2) mid-temperature PCMs, with phase change temperatures from 15°C to 90°C, applied in the fields of solar power, electronics, smart textiles, biomedical applications, and energy-efficient buildings; (3) high-temperature PCMs, with phase change temperatures beyond 90°C, applied in the fields of aerospace applications, absorptive refrigeration, and various industrial operations [1, 6].

4.2. Based on phase transitions

Phase transition takes place among solid–liquid, solid–solid, liquid–gas, or solid–gas, etc., and the PCMs can be classified accordingly. The characteristics of each transition have been summarized in **Table 2**.

4.3. Based on chemical nature

Based on chemical nature, PCMs can be categorized as inorganic or organic—each category comprising a broad spectrum of commercial and nascent PCMs. The phase change temperatures and the latent heat of fusions of different inorganic (salt hydrates),

organic (paraffins, fatty acid, PEGs, polyalcohols) eutectics, metals, as reported earlier, are given in **Tables 3–10**. In addition to paraffins and fatty acids, a few more hydrocarbons serve as organic PCMs, as included in **Table 6,** along with their phase change temperatures and the latent heat of fusion.

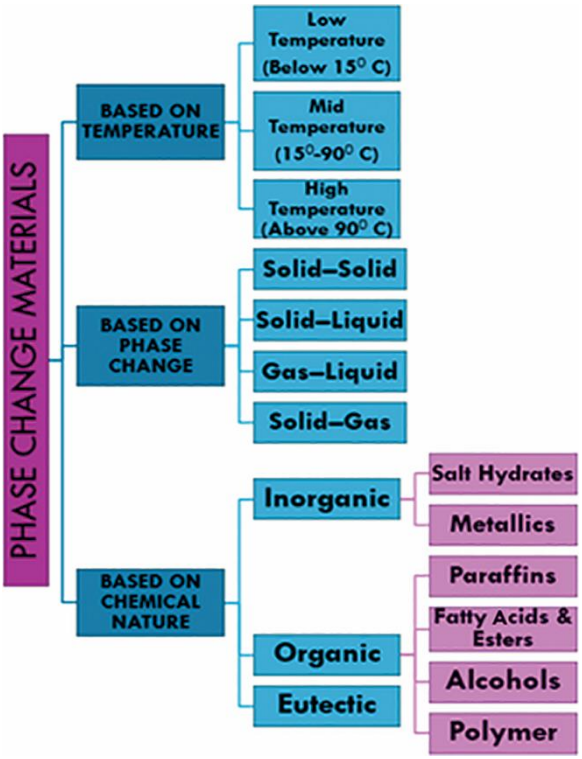

Figure 3 • Classification of PCMs.

Table 2 • Classification of PCMs based on their physical phase transformations

Solid–solid PCMs	Solid–liquid PCMs	Liquid–gas PCMs	Solid–gas PCMs
Involve transformation from crystalline state to amorphous state	Involve transformation from solid state to liquid state	Involve transformation from liquid state to gaseous state	Involve transformation from solid state to gaseous state
Low latent heat energy compared to solid–liquid PCMs	High latent heat energy compared to solid–solid PCMs	Higher latent heat energies	Higher latent heat energies
Small volume change during transitions compared to solid–liquid PCMs	Higher volume change during transitions compared to solid–solid PCMs	Higher volume change during transitions compared to solid–solid PCMs and solid–liquid PCMs	Higher volume change during transitions compared to solid–solid PCMs and solid–liquid PCMs
Need no or lesser encapsulation; leak-proof	Require encapsulation; leak-prone	Require large and bulky containment; leak-prone	Require large and bulky containment; leak-prone
Give better flexibility in design	Practical and economically attractive	Impractical and complex system	Impractical and complex system

4.4. Encapsulation method

Encapsulation refers to the housing of the material in a container/shell of fixed volume to reach certain objectives [5], such as:

- Prevents undesirable exposure of working with PCMs in an outdoor environment.
- Controls PCM leakage during phase change.
- Increases heat transfer.
- Accommodates volume change during the transition.

The encapsulation method is sub-categorized into (1) macroencapsulation, (2) microencapsulation, and (3) nanoencapsulation.

Macroencapsulation deals with the enclosure of PCMs in a container of any geometry such as pockets, pouches, spheres, shells, thin plates, tubes, and so on. This enables easy installation of PCMs in buildings or act as heat exchangers. The size of macroencapsulated PCMs can reach beyond a few centimeter-level ranges. The features of macroencapsulated PCMs include good leakage prevention and volume control, weathering protection, poor heat transfer, the tendency of solidification at the edges, poor thermal conductivity, etc. [79]. Microencapsulation is a process of embedding solid or liquid PCM materials as core inside a thin layer of polymer or inorganic material as a shell [80], to form a capsule, having a diameter range of 1–1,000 μm [78]. Microencapsulation helps in controlling the leakage of PCMs, volume change during heat cycles, improving heat transfer surface area, adding physical support to the product, easy handling, mitigation of odor or taste, prevention against degradation, and evaporation, among others. Nanoencapsulation is a method of encapsulating PCMs inside a nano-sized entity. Nanoencapsulated PCMs have gained much attention as TES materials in the last two decades due to their high surface area to volume ratio and are much better than microencapsulated PCMs [81].

4.5. Shape-stabilized PCMs

These are another class of TES materials, in which the PCM is dispersed in a supporting matrix to produce dimensionally form-stable composites. These materials possess certain attractive features such as large heat densities, good thermal conductivity, providing shape stability, and leak proofing during phase change, thus eliminating the need for any container for encapsulation and improving the durability over long thermal cycling [80].

5. Tools for the characterization of PCMs

The selection of a suitable PCM for a particular TES application is very crucial. The potential PCM should have a suitable melting temperature, desirable heat of fusion, and thermal conductivity specified for that practical application. Numerous techniques are available for the characterization and measurement of thermal and chemical properties of PCMs. Differential scanning calorimetry (DSC) is used for analyzing the thermal properties of PCMs. In DSC test, the sample and the reference (with known thermal properties) are maintained at the same temperature throughout the measurement process, and by measuring the difference of heat added between the sample and the reference material, thermal properties of the sample can be obtained, such as heat of fusion, heat capacity and melting/solidification temperature, and the effect of multiple thermal cycling on thermal properties of PCMs. The thermal stability of the prepared PCMs can be evaluated using the thermogravimetric analysis (TGA) technique. PCMs are heated over a temperature range from ambient temperature to high elevated temperature profiles (800–900°C) at a prescribed heating rate. Some researchers analyzed the limitations of conventional methods, including conventional calorimetry and DSC, and then put forward a new method called T-history method to determine the melting temperature, degree of supercooling, heat of fusion, specific heat, and thermal conductivity of PCMs. The morphology of the prepared PCM samples can be investigated using a scanning electron microscope (SEM) and particle size distribution (PSD). SEM produces images of a sample by focusing an electron beam on it, and PSD lists the values that define the relative amount of a substance into mixture. PSD sometimes is also called as grain size distribution. Chemical compatibility of the mixture is tested using Fourier transform infrared spectroscopy (FT-IR) technique in which infrared (IR) radiation is passed through the sample. Some of the IR radiation is transmitted through the sample and some absorbed into it. Therefore, to ensure accurate measurement and minimize the uncertainties in the measured values, it is necessary to calibrate the equipment in order to obtain the correct data.

6. Polymer-based PCMs

Polymers are being widely used both for the preparation of encapsulated and shape-stabilized PCMs. The advantages of using polymers for PCM storage are listed in **Figure 4**.

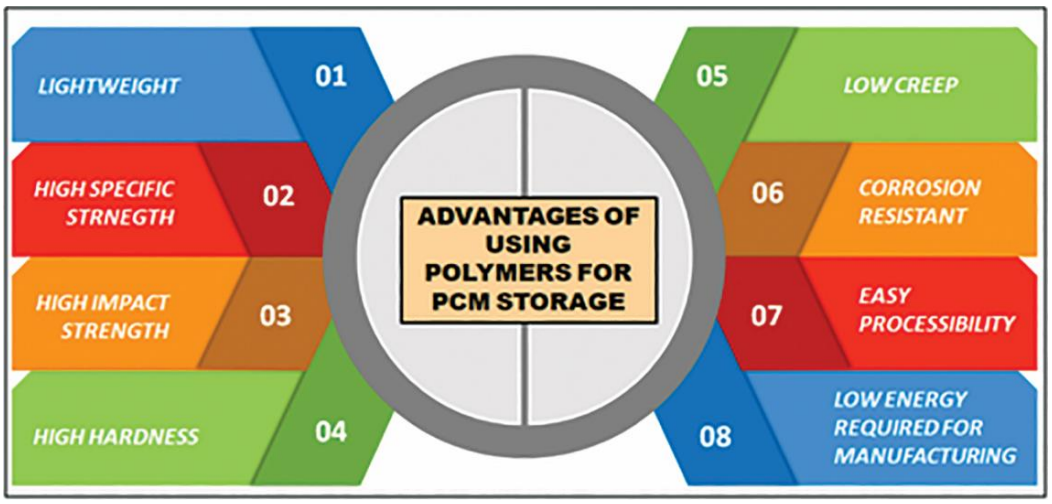

Figure 4 • Benefits of using polymer for PCM storage.

6.1. Polyolefin polymer-based PCMs

Mu et al. [82] produced two different sets of high-density polyethylene (HDPE) shape-stabilized phase change materials (SSPCMs) using twin-screw extruder having low (L-PW, Tm: 18–23°C) and high (H-PW, Tm:56–58°C) melting point paraffin waxes as the TES component. DSC indicated the latent heat enthalpy of SSPCMs with H-PW decreases with increasing H-PW concentration to a higher range due to co-crystallization between H-PW and HDPE. Guo et al. [83] incorporated microencapsulated PCMs (Core: Dodecanol; Shell: MF resin) made by in-situ polymerization into wood–plastic composites (WPCs) based on HDPE matrix to obtain value-added heat storage property. HDPE WPCs containing PCM microcapsules exhibited excellent thermal stability where it undergoes 5% weight loss at 256.9°C. Huang et al. [84] inspected the thermal and structural characteristics of the shape-stabilized composites having organic PCMs such as cetyl alcohol in weight ratio 70–90 wt.% dispersed in HDPE supporting matrix, reinforced by carbon fibers (CF) in varying weight ratio. High dose as much as 5 wt.% CF filled composites showed phase change properties of melting and solidification temperatures at 48.55°C and 41.51°C with accompanied latent heat values of 171.04 and 96.44 kJ/kg, respectively, along with improved leakage control, thermal stability, and thermal conductivity. The addition of expanded graphite (EG) in HDPE containing stearyl alcohol (SAL) as the active PCM, as reported by Tang et al. [85], improved the shape stability of the composites by ensuring good leakage control and an increase in the thermal conductivity from 0.1966 W/(m K) (without EG) to 0.6698 W/(m K) (with 3% EG). The reinforced HDPE composites with SAL mass ratio ~85% had an onset melting temperature of around 57°C with a corresponding latent heat value of 200 kJ/kg.

Halloysite nanotubes (HNTs) were infused with PEG400 and PEG600 to yield form-stable HNT/PCM nano-hybrids mixture, which was melt blended with low-density polyethylene (LDPE) using twin-screw extruder followed by blown film extrusion to finally obtain flexible nanocomposite films with thermal buffering characteristics at low-temperature cold-chain storage and transportation applications. The produced nanocomposite films bestowed reasonable mechanical properties with phase change transition from −17°C to 26°C with associated latent heat of 2.3 J/g. Moreover, nanocomposite films delayed the warming of frozen and chilled samples for 18 and 20 minutes, respectively, relative to neat LDPE films [86]. Premnath et al. [87] used deionized water as the PCM and examined the freezing features of the PCM in LDPE spherical capsule fitted with and without fins. They observed that 50% of the PCM mass has frozen in 21% and 16% of the freezing time with the help of fins when compared to LDPE capsule without fins at −6°C and −9°C bath temperatures.

A shape-stabilized PCM composite composed of HDPE as a packaging material holding paraffin within its macromolecular domain structure containing EG with enhanced thermal conductivity and leakage-proof was prepared. Among all the studied samples in the experiment, the sample made up of HDPE (10 wt.%) and EG (5 wt.%) exhibited the best performance, and its thermal conductivity reached 0.641 W/(mK), which is 2.7 times higher than that of the paraffin. Moreover, the latent heat and thermal cycling test of this sample showed that it can maintain 95% latent heat post 120 thermal cycles, indicating its high thermal storage stability [88].

6.2. Vinyl polymer-based PCMs

Jin et al. [89] fabricated form-stable phase change composite materials (FSPCMs) by compression molding, constituting varying dosage of microencapsulated PCMs (5–25 wt.%) inside polyvinyl chloride (PVC)/wood flour matrix. The mechanical properties were found to be inversely proportional to the PCM microcapsules content, while gradually increasing the weight fraction of microcapsules from 0 to 25 wt.%. The concentration of 10 wt.% of microencapsulated PCMs in PVC/wood flour composites was found to be optimum with good mechanical properties for practical applications. Zhang et al. [90] studied the combined phenomena of the addition of both microencapsulated PCMs as temperature-regulating and TiO_2 nanoparticles as a UV blocking additive to a thin PVC film for solar energy storage applications. The spherical PCM microcapsules of 2–15 µm size range were composed of octadecane as core, well encapsulated inside melamine-formaldehyde resin as a protective shell, synthesized by in-situ polymerization technique. The amount for both PCM microcapsules and TiO_2 nanoparticles in the PVC matrix film was varied according to a weight fraction of 3%, 6%, and 9 wt.%. DSC analysis suggested that PVC films with 6 wt.% octadecane microcapsules showed good heat energy storage density of 8.77 J/g. Further, the incorporation of 6 wt.% TiO_2 nanoparticles to this particular composition of PCM containing films experienced enhanced phase change temperatures and heat storage energy to 9.22 J/g, as compared to other samples. Outcomes of the addition of nano-TiO_2 on the phase change enthalpies and thermal conductivity of the films are shown in **Figure 5**. Temperature-regulating films 6 wt.% micro-PCMs and 6 wt.% TiO_2 nanoparticles displayed excellent thermal reliability where they withstand 100 thermal cycles, with very minute variation phase change temperature and enthalpies as shown in **Figure 6**.

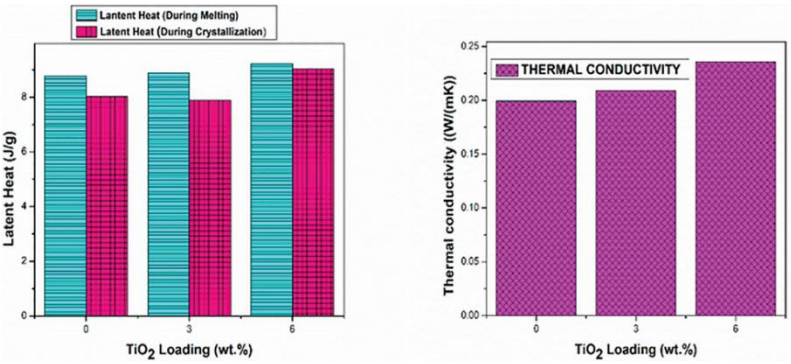

Figure 5 • Influence of nano-TiO_2 addition on enthalpy values and thermal conductivity of the fabricated thermal-regulating films. Data from [90].

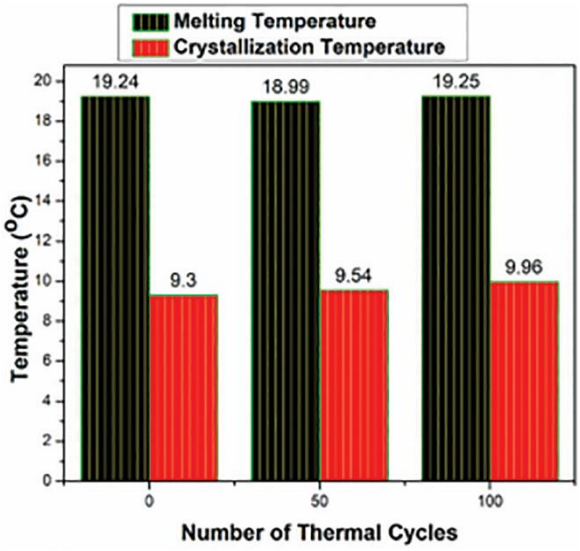

Figure 6 • The thermal cycling stability of the fabricated film incorporated with 6 wt.% micro-PCMs and 6 wt.% nano-TiO_2. Data from [90].

6.3. Styrenic polymer-based PCMs

Giro-Paloma et al. [91] used an emulsion copolymerization technique to obtain a microencapsulated PCM shell made up of poly-(styrene-co-ethyl acrylate) (PScEA) for the encapsulation of paraffins (Capsule A) and palmitic acid (Capsule B) as TES materials. Mean particle sizes of both paraffin and fatty acid encapsulated in copolymer shells were found to be 166 and 265 nm, respectively. AFM data at low and above phase change temperatures represented that Capsule A showed an almost similar force required to collapse the capsules at different temperatures (25°C and 50°C), whereas for fatty acid-loaded Capsule B, the force required to break the capsule at 70°C was ten times than with the amount required at 25°C. Fang et al. [92] worked upon cold TES applications, such as air conditioning, and developed a latent functionally thermal fluid (LFTF) comprising nanoencapsulated PCM capsules with *n*-Tetradecane as core and polystyrene (PS) made by ultrasonic-assisted miniemulsion polymerization with the *n*-Tetradecane core content of 89 wt.%. PS/*n*-Tetradecane nanocapsules with an average diameter of 132 nm were well distributed in the prepared slurry and formed the main energy storage components that possessed the melting and freezing temperatures of 4.04°C and −3.43°C along with their corresponding latent heat enthalpies values of 98.71 J/g and 91.27 J/g, respectively.

Fang et al. [93] synthesized polystyrene (PS)/*n*-dotriacontane (Dot) nanoencapsulated phase change material (NEPCM) by miniemulsion polymerization technique initiated ultrasonically and studied the influence of parameters such as time and temperature, ultrasonic power output, the ratio of co-emulsifiers used (sodium dodecyl sulfate (SDS) and poly-(ethylene glycol) monooctylphenyl ether (OP-10)), Styrene/Dot ratio, etc., on average diameter, rate of polymer conversion, encapsulation efficiency, and latent heat capacities of prepared NEPCM. The results suggested that the applied ultrasonic method produced nanocapsules of a mean diameter of 168.2 nm with high conversion rates (95.02%) and good encapsulation efficiency (61.23%) and high latent heat enthalpy of 174.8 J/g. Fu et al. [94] produced a nanoencapsulated PCM slurry for cold energy storage consisting of *n*-Tetradecane (Tet) core-based nanocapsules with hybrid shell wall (polystyrene-silica, PS-SiO_2), dispersed in a base fluid. Tet/PS-SiO_2 nanocapsules with an average size of 151.3 nm had a melting enthalpy of 83.38 KJ/kg. The incorporation of SiO_2 to nanocapsules by grafting SiO_2 on PS shells led to an increment in the thermal conductivity of Tet/PS-SiO_2 slurry by 8.4%.

Titanium dioxide (TiO_2) nanoparticles decorated (poly-(4-methylstyrene-co-divinylbenzene)) PCM microcapsules containing hexadecane were prepared following a one-pot non-Pickering emulsion templated suspension polymerization. Energy-dispersive X-ray (EDX) and X-ray diffraction (XRD) analysis confirmed the presence of TiO_2 over the polymeric shell. Metal oxide decorated PCM microcapsules with 2.6 wt.% TiO_2 potentially exhibited maximum latent heat enthalpy of 174 J/g with an encapsulation efficiency of 76.6%. Additionally, these microcapsules also showed excellent photo-catalytic activity by synergistic photo-thermal effect and can be utilized as solar energy storage and depollution materials [95]. A flexible composite material based on styrene butadiene styrene (SBS) as a supporting material, paraffin as a PCM, and EG as a thermal conductivity enhancer was fabricated by dissolving in an organic solvent and utilized in battery thermal management system. It was observed that during the 5°C discharge process, the maximum temperature of the battery module can be maintained below 46°C and the temperature difference can be controlled within 4°C. Also, after heating at 55°C for 5 hours, the quality of the composite remained above 99%. As a supporting elastic network material, SBS can effectively improve the flexibility and elastic properties of the PCM. The presence of EG significantly improves the thermal conductivity of the composite PCM, with the thermal conductivity of SBS/paraffin/EG (4%) reaching 0.88 W/(Km); however, the same PCM does not continue to increase when the weight fraction of EG exceeds 4% [96].

6.4. Acrylic polymer-based PCMs

Wang et al. [97] developed microencapsulated PCMs with the value-added function of thermo-chromic property by the introduction of thermo-chromic pigments to the acrylic polymer shells. The thermo-chromic pigments were first treated with a silane coupling agent to improve the affinity toward organic phases and then incorporated on the interface of *n*-octadecane droplets present in oil/water emulsion leading to thermochromic pigment/PMMA shell formation via suspension polymerization technique, as shown in **Figure 7**. Carreira et al. [98] studied the role of thermal initiators such as Benzoyl Peroxide (BPO), Azobisisobutyronitrile (AIBN), and Trigonox 23 (TRIG) and different reaction temperatures on the rate of polymerization and PCM microcapsule properties for the synthesis of octadecane encapsulated acrylic microcapsules, using suspension technique, for thermo-responsive textiles. The obtained microcapsules possessed both energy storage enthalpy, about 175 J/g, and good thermal stability. Huang et al. [99] synthesized and prepared a series of microencapsulated PCMs for thermo-regulated fabrics by selecting poly (allyl methacrylate) (PALMA) as the shell material for encapsulation of organic binary PCM cores including butyl stearate (BS) and tetradecanol (TD). PALMA microencapsulated binary PCMs with an encapsulation content of 76.4 wt.% exhibited phase-transition temperatures and latent energy values of 20.1–32.6°C and 73.3 J/g, respectively. Zhao et al. [100] used a suspension polymerization technique to synthesize microencapsulated PCMs with dual functions of UV-shielding and TES. The developed microcapsules comprised

octadecane as the core PCM confined in polymethylmethacrylate (PMMA) shell embedded with modified TiO_2 nanoparticles, as the UV absorber. DSC analysis showed that the melting and crystallization enthalpy and encapsulation efficiency of doped microcapsules were 48.26 J/g, 153.82 J/g, and 73.2%, respectively. The thermal cycling stability of the synthesized PCM is shown in **Figure 8**.

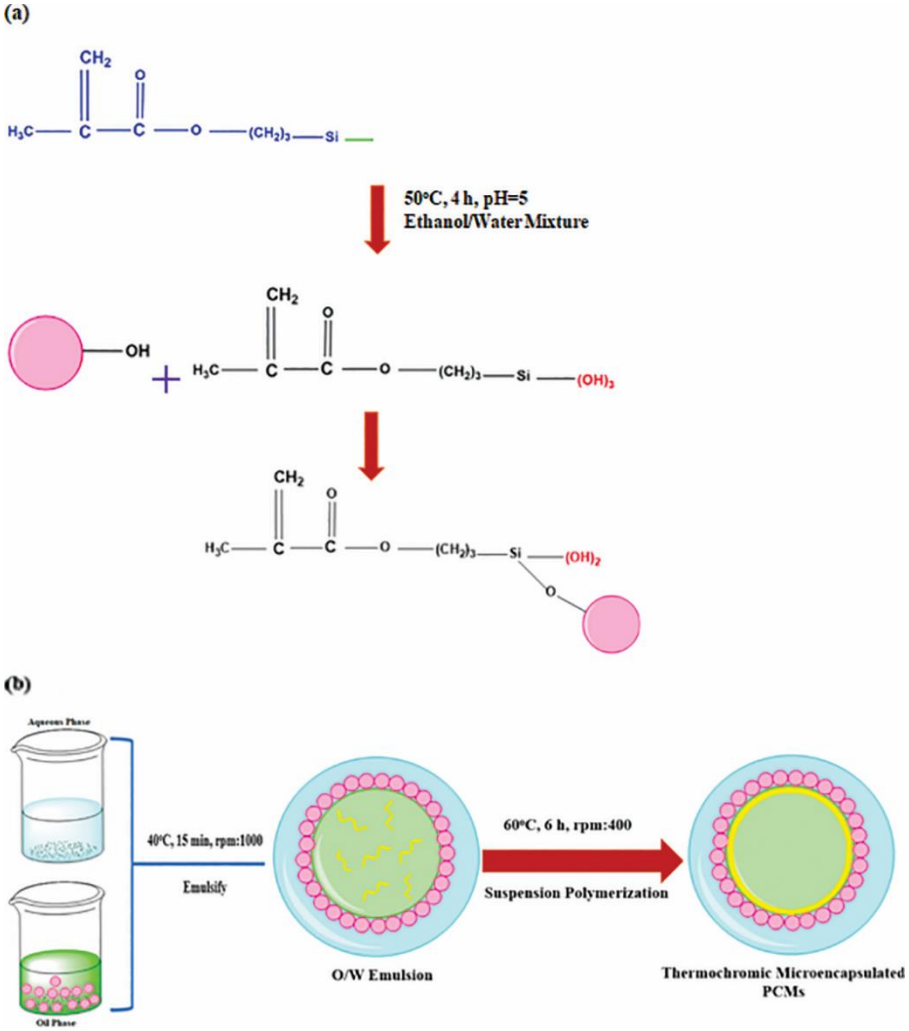

Figure 7 • Schematic fabrication process of thermo-chromatic microencapsulated phase change materials. (a) The modification process of thermo-chromic pigments. (b) The formation process of the TC-micro PCMs based on *n*-octadecane core and thermo-chromic pigments/PMMA shell through suspension-like polymerization. Adapted with permission from [97].

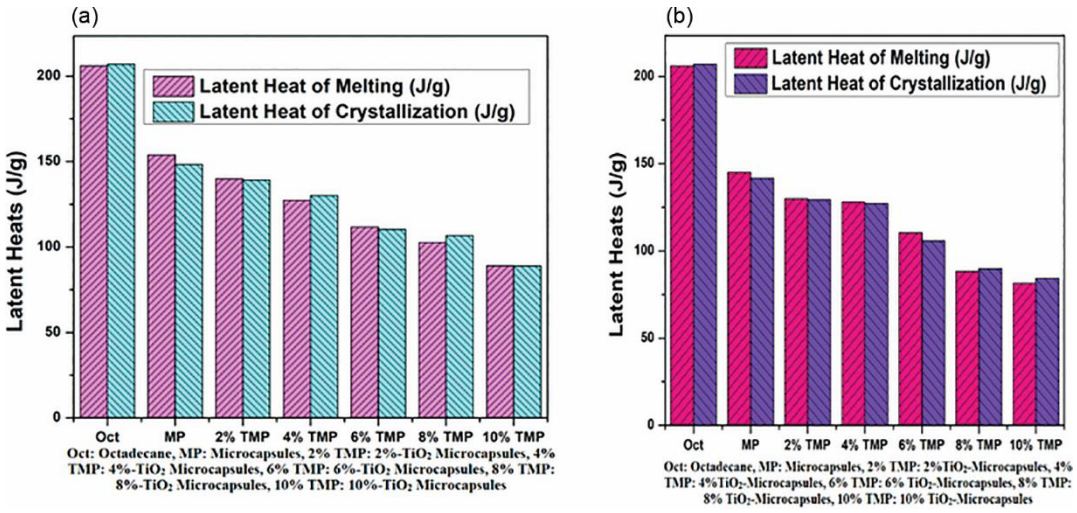

Figure 8 • Thermal cycling stability of synthesized microencapsulated PCMs with varying dosage of titanium nanoparticles (a) 1st cycle and (b) 500th cycle. Data from [100].

Wang et al. [101] obtained nanoencapsulated PCMs by encapsulating stearic acid inside PMMA nanocapsules by using an ultrasonically initiated in-situ polymerization method. DSC data suggested that the thermal storage ability and encapsulation

efficiency of fabricated PMMA/stearic acid nanocapsules were 155.6 J/g and 83.0%, respectively. Su et al. [102] produced microencapsulated PCMs following the free-radical polymerization route where they opted for *n*-octadecane as a core latent heat storage material and PMMA as a shell component, which exhibited a phase change at 22.68°C and energy storage density of 170 kJ/kg with thermal stability behavior above 160°C. Şahan et al. [103] used acrylic copolymer shells to successfully encapsulate behenic acid (BeA) via emulsion polymerization technique to obtain microcapsules with uniform spherical geometry, with particle size ranging below 500 nm. They showed a phase change temperature ranging between 65°C and 85°C with maximum latent heat capacity of 58 J/g. The resulted product was reported suitable for potential applications such as industrial waste heat, electronics, solar residential heating, lithium-ion batteries, automotive applications, and so on.

6.5. Polyamide polymer-based PCMs

Cai et al. [104] determined the structural morphologies and TES properties of electrospun polyamide 6 nanofibers-based phase change composites containing fatty acid eutectics, mainly capric acid (CA). The fabricated composite nanofibers had phase change temperatures and corresponding enthalpies lower than that of pure CA. Cai et al. [105] studied the impact of 10 wt.% of EG on structural and thermal properties of Nylon-6 electrospun nanofibrous mats consisting of fatty acid eutectic mixtures of CA. These polyamide nanofibers composites were made as PCMs by soaking them for ten hours until saturated absorption into an ultrasonically melt-blended solutions of capric acid (CA)-lauric acid (LA), capric acid (CA)-palmitic acid (PA), and capric acid (CA)-stearic acid (SA) to allow their absorption by the fabricated nanofibrous mats. SEM images indicated that Nylon-6/EG nanofibers become more uniform and straight upon EG addition; also, the average diameter of Nylon-6/EG was lower than pure Nylon-6. Casado et al. [106] worked on the design optimization and improvement of fatigue resistance of injection-molded short-fiber glass-reinforced polyamide structural parts used in high-speed rail fastenings. The addition of an inorganic hydrated salt PCM ($Na_2S_2O_3.5H_2O$) provided a cooling effect to the reinforced polyamide component and controlled the increase in polymer temperature, as a viscoelastic response under the dynamic cyclic fatigue loads. Fatigue resistance of these structural components filled with PCMs increased by 400% against the polyamide parts without PCMs.

6.6. Polyester polymer-based PCMs

Cai et al. [107] investigated the outcome of the silica nanoparticles (nano-SiO_2) addition on morphological, thermal stability, heat storage, and combustion characteristics of electrospun LA containing polyethylene terephthalate (PET) composite fibers. DSC analysis indicated that the heat storage enthalpy values initially increase with increasing nano-SiO_2 and then decrease with further nanoparticles loading. Golestaneh et al. [108] fabricated phase change composite fibers by an innovative co-electrospinning method utilizing eutectics mixtures of binary fatty acids: capric-lauric acid (CA-LA) and capric-palmitic acid (CA-PA) as the energy storage component and PET as the supporting matrix fibers (**Figure 9**). Morphological results indicated that the fatty acids were fairly dispersed in the PET filaments and the mean diameter of composite fibers improved by raising the PCM concentration in the PET matrix. The fabricated fibers possessed a wider range of phase change temperatures (−9 to 34°C).

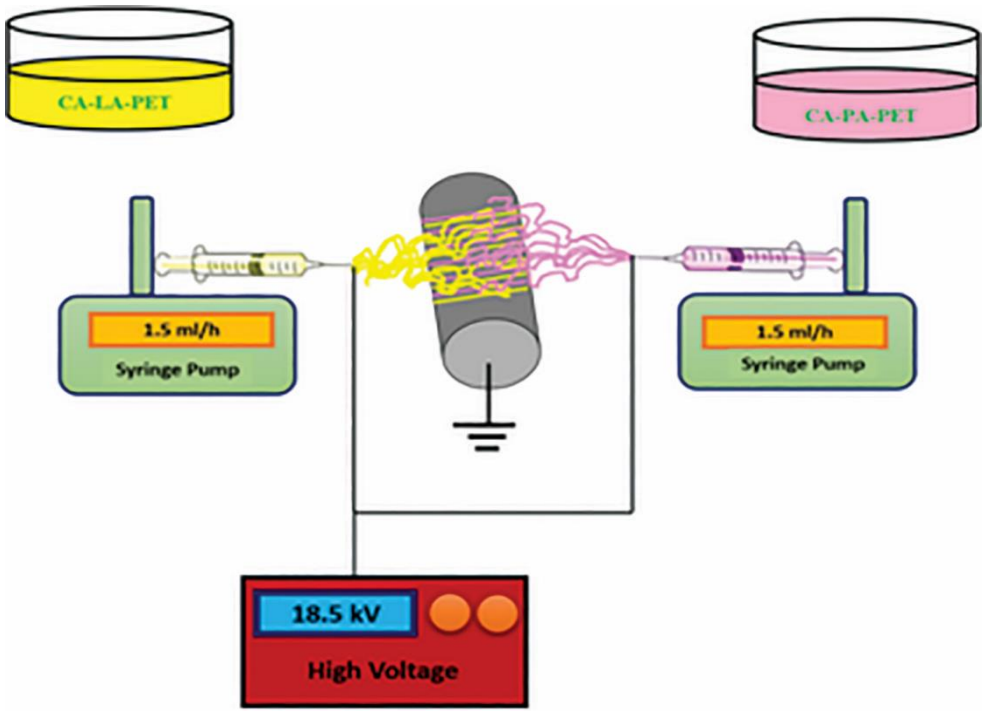

Figure 9 • The schematic view of the co-electrospinning setup. Adapted with permission from [108].

Nejman et al. [109] studied the effects of heating/cooling cycle rates (1, 5, 10, 15°C/min) on TES and retrieval properties of polyester-based knitted and woven fabrics impregnated with polymer pastes, containing 40 wt.% of two microencapsulated PCMs. It was evident that an increase in heating/cooling rates led to an increase in endothermic phase transitions and a decrease in crystallization temperatures. The variations of latent heat energies of fabrics with different heating rates are illustrated in **Figure 10**.

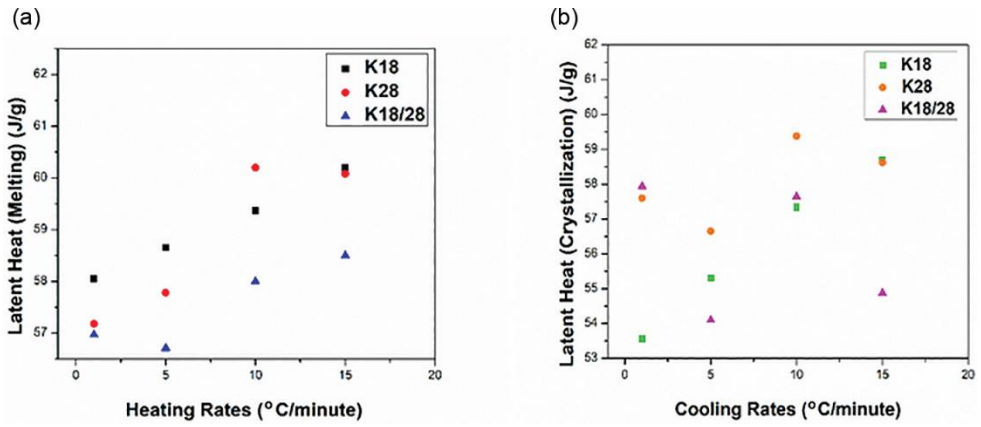

Figure 10 • Phase change temperatures and variation of latent heat energies of fabrics with different heating rates. (a) Latent heat of melting and (b) latent heat of crystallization. Data from [109].

6.7. Aminoplastic-based PCMs

Yoo et al. [110] investigated the effect of incorporation of eicosane-filled melamine-formaldehyde microcapsules into glass fibers (GF) reinforced epoxy resin on thermo-physical properties of fiber-reinforced plastics composites. Thermal conductivities of produced composites showed decreasing trends with increasing microencapsulated PCMs, owing to the low thermal conductivity of capsule shell layer. Thermal stabilities of the prepared composite were decreased due to lack of interfacial adhesion between fibrous filler and the matrix. Hu et al. [111] used an in-situ polymerization technique to achieve carboxymethylcellulose (CMC)-modified melamine-formaldehyde (MF) spherical nanocapsules of an average diameter of around 50 nm. The DSC test reported that the heat energy enthalpies were improved by CMC addition to a certain concentration and reached an optimum latent heat enthalpy value of 83.46 J/g, with an encapsulation ratio of confined paraffin of 63.1%. Zhang et al. [112] incorporated graphene oxide (GO) nanosheets as an extra protective layer at the junction between core and shell materials made by in-situ polymerization composed of paraffin and melamine-formaldehyde resin (MF) to develop a new type of microencapsulated PCMs as represented in **Figure 11**. The average diameters of the capsules gradually enlarged with an upsurge in GO content from 6.32 to 15.89 µm against a diameter of 5.63 µm in the absence of GO nanosheets. An additional GO layer enabled the prepared microcapsules to efficiently control and minimized the paraffin leakage rate from the MF shell by 93.1% during 50 hours of thermal exposure.

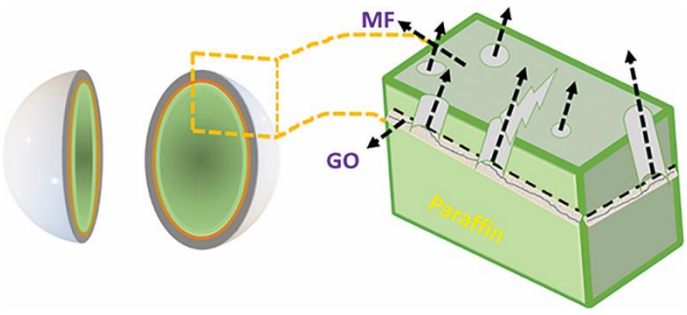

Figure 11 • Schematic view for possible permeation through the shells with GO. Adapted with permission from [112].

Konuklu et al. [113] used various aminoplastic-based shell materials including urea-formaldehyde (UF) resin, melamine-formaldehyde (MF) resin, and urea-melamine-formaldehyde resin for encapsulation of CA, by coacervation method for TES purposes. It was clear that UF resin was a more suitable capsule material among all other used shell materials which offered latent heat enthalpies of 93.9 and 106.1 J/g during the heating and cooling process, respectively. Liu et al. [114] developed a LFTF to be employed as direct absorption solar collectors (DASCs) by dispersing the paraffin encapsulated graphite nanoparticles modified MF microcapsules in an ionic liquid, 1-butyl-3-methylimidazolium tetrafluoroborate ([BMIM]BF4). The microencapsulated slurries with encapsulated paraffin content of 51.1 wt.% exhibited phase change temperature and latent heat enthalpy of 50.5°C and 90.8 J/g, respectively, while the incorporation of graphite nanoparticles to the MF shell enhanced the thermal conductivity of produced LFTF as illustrated in **Figure 12**. Upon irradiation, the temperature of LFTF increased from 30°C to 113°C proving the high photo-thermal performance and thermal storage potential of these developed slurries, which was about twice that of the pure ionic liquid.

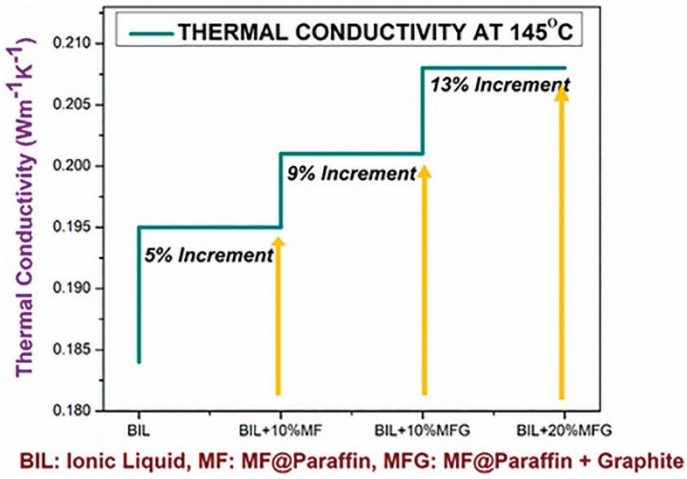

Figure 12 • Thermal conductivity of [BMIM]BF4 and the slurries containing different microencapsulated PCMs. Data from [114].

Microencapsulated PCMs composed of graphene oxide supported urea-formaldehyde (UF) resin capsules, filled with paraffin wax with a phase change temperature of 30.83°C and an associated heat of fusion equal to 90.23 J/g were developed via in-situ polymerization technique. This solution was further mixed with cement to form a cement slurry to control the heat evolution and prevent or delay the undesirable speed of the

hydration reaction in the cement, in addition to reducing the contents of C–S–H and $Ca(OH)_2$. The thermal conductivity values were found to be varied linearly with increasing order of graphene oxide concentrations where at 0.30% graphene oxide content, a hike of 53.84% in the thermal conductivity value was observed. This evaluated cement slurry can be resourceful in meeting the requirements of marine sector [115]. Gao et al. [116] focused on the synthesis of PCM slurry for direct absorption solar collector with optimal heat storage properties and photo-thermal conversion, by dispersing the spherical PCM microcapsules of 4 μm in diameter made up of melamine-formaldehyde (MF) resin and octadecane containing oleic acid-coated magnetic nanoparticles (OA-MNs) as the shell and core, respectively, into MWCNTs-H_2O nano-fluids. The prepared super-paramagnetic micro-encapsulated PCM particles had encapsulation efficiency of 63.51% corresponding to phase change enthalpy of 145 J/g. The oleic acid-modified magnetic nanoparticles were found to have boosted the thermal conductivity of the PCM microcapsules. Therefore, the resultant slurry consisting of 0.01 wt.% MWCNTs and 15 wt.% PCMs had the optimal photo-thermal conversion properties and thermal storage capacity.

Srinivasaraonaik et al. [117] used an in-situ polymerization technique to obtain the microencapsulated PCM consisting of fatty acid eutectic mixture—75% stearic acid (SA) + 25% CA as the core and MF resin as the shell material. They found out that a balanced pH (3.2) and stirring rates (1,500 rpm) controlled the microstructures of the obtained microencapsulated PCM, having spherical configurations with the smooth surface morphology and a particle size of 10.41 μm. The melting point and latent heat of fusion of the produced microcapsules were found to be 34.5°C and 103.9 kJ/kg, respectively. The obtained microencapsulated PCM also showed improved thermal stability, because of the outer MF resin protective layer as compared to the raw PCM with high encapsulation efficiency of 85.3%. Zhang et al. [118] prepared zirconium carbide (ZrC) nanoparticles decorated with the microencapsulated PCM containing melamine-urea-formaldehyde (MUF) shells filled with paraffin and studied the effect of ZrC nanoparticles on microstructure, thermal storage, thermal stability, thermal conductivity, and photo-thermal conversion behavior. They observed that the thermal properties of microcapsules consisting of 4% ZrC nanoparticles were better than the unfilled microencapsulated PCM and concluded that the enthalpy was slightly increased by 14.92% and the thermal conductivity was increased by 225.16%, owing to the presence of metal nanoparticles. In addition, they showed remarkable optical absorption capability of 70.23%. Nanoencapsulated PCMs comprising of paraffin wax as latent heat storage core component and melamine-formaldehyde (MF) as shell were synthesized by the in-situ polymerization technique. The spherical nanocapsules were present in average diameter of 260–450 nm. They undergo phase transitions at 49°C and 54°C, respectively, with corresponding latent of fusion and crystallization recorded as 107.4–135.3 and 109.8–133.1 J/g, respectively. They possessed good thermal stability and also exhibited decent thermal reliability after withstanding 2,000 thermal cycles [119]. A series of microencapsulated PCMs with boron nitride (BN) reinforced melamine-formaldehyde resin shell for improving the thermal conductivity was successfully synthesized via in-situ polymerization technique. The obtained metal particles decorated with PCM microcapsules exhibited spherical profiles with a diameter ranging between 5 and 10 μm and possessed high latent heat storage density of 145.5 J/g. Moreover, highly thermally conductive BN effectively enhances the thermal conductivity of the microcapsules and supplies them with a fast thermal-responsive rate [120]. Naikwadi et al. [121] put efforts to develop solar TES coating using melamine-formaldehyde (MF) shell microcapsules with an *n*-Tetracosane as core PCM, which were subjected to an epoxy primer-polyurethane (EP-PU) topcoat system in different loading concentrations (0–25 wt.%). The microcapsules tend to melt at 53.07°C with latent heat of melting of 134.74 J/g and crystallize at 48.81 with latent heat crystallization of 133.32 J/g. The phase change properties of the coated material were found to increase with the increase in the microcapsule loading. Coating properties (pencil hardness, flexibility, and scratch resistance) deteriorate with increased microcapsule loading.

6.8. Polyurea and polyurethane polymers-based PCMs

Lu et al. [122] carried out the microencapsulation of BS inside a three-dimensional polyurethane (PU) shell network using pentaerythritol as a cross-linking agent, via interfacial polymerization. The resultant cross-linked microcapsules possessed smooth and compact surface morphology with good thermal stability and heat storage characteristics. Zhan et al. [123] synthesized polyurea microcapsules encompassing paraffin as a core for TES applications by interfacial polycondensation technique. The resultant polyurea microcapsules showed heat of phase change about 92.5 J/g with successful encapsulation of 44.5 wt.% of paraffin PCM. Sundararajan et al. [124] synthesized hyperbranched polyurethanes by reacting an adduct of PEG-IPDI capped isocyanate with a trifunctional monomer, trimethylolpropane (TMP) in varying molar concentrations, as a polymeric solid–solid PCM. The prepared polymeric solid–solid PCM possessed maximum fusion enthalpy of 145 J/g, which was found to increase with increasing PEG mass ratio and undergoes a phase transition at 55°C. Zhou et al. [125] incorporated HNTs as a reinforcing agent to the prepared solid–solid PCM made by reacting polyethylene glycol (PEG, M.W. 4000) and hexamethylene diisocyanate biuret (HDIB), leading to cross-linked polyurethane (PU) structures. HNTs offered excellent thermal stability. However, with an increase in HDIB concentrations, the phase change temperature decreased from 32.9°C to 24.2°C and the latent enthalpies reduced from 123.7 to 85.8 J/g owing to excessive cross-linking.

Wang et al. [126] utilized Pickering emulsion polymerization to synthesize polyurethane shells filled with methyl laurate-based PCMs. The obtained microcapsules exhibited core–shell arrangement and a smooth surface with shell thickness of 8~10 μm and the particle size ranging between 150 and 350 μm. The melting and crystallization enthalpies of microcapsules were as high as 147.71 and 143.36 J/g, respectively, accompanied with 83.34% of encapsulation efficiency. They also showed excellent thermal reliability and thermal cycling stability. Zhu et al. [127] developed temperature controlling coating materials containing microencapsulated PCMs composed of *n*-octadecane as core and polyurea as shell walls, which were synthesized via interfacial polymerization technique. Morphological studies reveal the PCM microcapsules can maintain its original shape and be dispersed uniformly in the coatings with 30 wt.% microencapsulated PCM loads and ensured the latent heat capacity of microencapsulated PCMs and the heat storage coatings are 151.89 and 45.5 J/g,

respectively. Test chambers having wall boards painted with and without microencapsulated PCM coatings were tested under the same conditions and compared. Overall, the chamber with microencapsulated PCM coatings can maintain a stable temperature of 26–28°C for approximately 77 minutes when the heating load is 80 W/m². However, the chamber without PCM coating can only maintain such temperature for 13 minutes.

7. Other non-polymeric-based PCMs

In a recent study, PCM composites were developed by using the eutectic PCMs mixture of CA and LA as the active PCM and waste fly ash as a supporting material. The performance of these PCM composites was evaluated through simulation, by taking Guangdong as a reference city, with desirable temperature around 25°C. The required temperature properties were achieved by using a mass ratio of CA/LA of 4:6. The optimum FA/PCMs composite has a latent heat of 45.38 J/g and has good thermal reliabilities. The results proved that the preparation of such PCMs is an efficient way for the reuse of solid waste FA by subjecting the inorganic material for good contribution to the development of energy-saving buildings [128]. Li et al. [129] fabricated PCM composites by introducing PEG into mesoporous pores of ZSM-5 assisted with vacuum impregnation. The latent heat of the as-prepared PCMs reaches 76.37 J/g without any leakage. Shape-stabilized PCMs based on polyethylene glycol (PEG) loaded in varying loadings of 60–90 wt.% confined in porous fumed silica (FS) as the porous support were successfully investigated. The optimum 80 wt.% PEG/FS PCM possessed a high crystallinity of 93.1%, corresponding to a remarkable TES capacity of 130.6 J/g, and excellent thermal reliability post experiencing 500 thermal cycles. It was observed that porous silica provided sufficient cavities to confine a large amount of PEG with interactions such as surface tension, capillary, and interfacial hydrogen bonds (H-bond). The interfacial H-bonds negatively affected the crystallinity of PEG and decreased the TES capacity, which could be relieved by a large content of confined PEG [130]. He et al. [131] successfully developed temperature-regulating cement-based PCMs by incorporating PCM microcapsules composed of CA as latent heat storage component and hydroxyapatite as the shell wall material. Fatty acid-filled hydroxyapatite microcapsules exhibited high CA absorption ratio and good physicochemical stability. The incorporation of CA/HAP in cement-based materials leads to a decrease in workability, acceleration of hydration process, and significant improvement of thermal regulation property. The compressive strength of mixtures containing PCM capsules is noted to be increased when incorporating 10% of PCM microcapsule by volume.

8. Conclusions

This comprehensive review presents the necessity of energy storage and known TES technology, including PCMs available to mankind. Fatty acid-based PCMs can be effectively useful in reducing the reliance on the latent heat storage materials generated through fossil fuels while potently acting as an environmentally friendly energy solution in making a “cleaner” and “greener” ecosystem as well as boosting the concept of sustainable development. This study will help readers in understanding the working, selection criteria, nature of a broad range of PCMs, and also storage methodologies for their effective usage in practical applications. This detailed literature study is focused on highlighting the significance of polymers in vast research and development activities carried out by various research groups in the pathway of search of future PCMs for latent heat storage technology based on polymers. The scattered research available on this significant topic has been clubbed up to shape up as a detailed review on the utility of polymers, whether natural or synthetic, in the development or production of new and advanced PCMs in the form of encapsulated or shape-stabilized PCMs composed of different types of PCMs, different shell wall materials, or supporting matrices.

ORIGINAL PAPER

Shallowfake and deepfake image manipulation localization using noise and RGB-based dual branch method

Abstract
The reliability of multimedia is being progressively tested by sophisticated Image Manipulation localization (IML) methods, which has led to the creation of the IML domain. A good manipulation model requires extracting non-semantic differences features between manipulated and authentic regions to exploit artifacts, which calls for explicit comparisons between the two areas. Existing models either use handcrafted-based feature methods, convolutional neural networks (CNNs), or a combination of both. Handcrafted feature methods assume the tampering beforehand, limiting their capabilities for diverse tampering operations, while CNNs model semantic information, which is not enough for the manipulation artifact. To improve these limitations, we have designed a dual-branch model that combines handcrafted feature noise and CNNs as an Encoder-decoder(ED) powered by the attention mechanism. This dual-branch model uses noise features on one branch and RGB on the other before feeding to an ED architecture for semantic learning and skip connection deployed to retain spatial information. Furthermore, this architecture uses channel spatial attention to strengthen further and refine the features' representation. Extensive experimentation on the shallowfakes dataset (CASIA, COVERAGE, COLUMBIA, NIST16) and deepfake datasets Faceforensics + + (FF + +) to demonstrate the superior feature extraction capabilities and performance to various baseline models with AUC score even reaching 99%. Also, it is one of the first methods to perform localization on the deepfake dataset. The model is relatively lighter, has 38 million parameters, and easily outperforms other State-of-the-Art(SoTA) models.

1 Introduction

In recent years, computer graphics and deep learning development have given people access to more sophisticated tools for creating false images. With the advancement of such sophisticated editing AI tools, it is possible to alter the content of multimedia data with great ease to produce highly realistic content. Therefore, images altered to transmit false information and propagate rumors will harm our lives, mainly if they do so quickly and widely throughout the Internet [1]. Traditional image-editing tools or graphics-based methods are called "shallow fakes" [2]. Deep learning-based methods, also called "Deepfakes", have replaced more conventional graphics-based methodologies in this methodology. Deepfake has gained attention as it allows the creation of highly realistic and believable content easily. As such sophisticated technologies advance, we require more advanced IML techniques to deal with manipulated images that are already out there and prevent security threats.

The localization task aims to identify altered regions in an image and to segment the manipulated regions at the pixel level. In shallow fakes, there are three types of image manipulation [2] (Fig. 1):

1) *Splicing* It is copying and pasting a section of one image into another.
2) *Copy-move* duplicating a section of an image.
3) *In-painting* removing portions of images and filling in the gaps with visually appealing information.

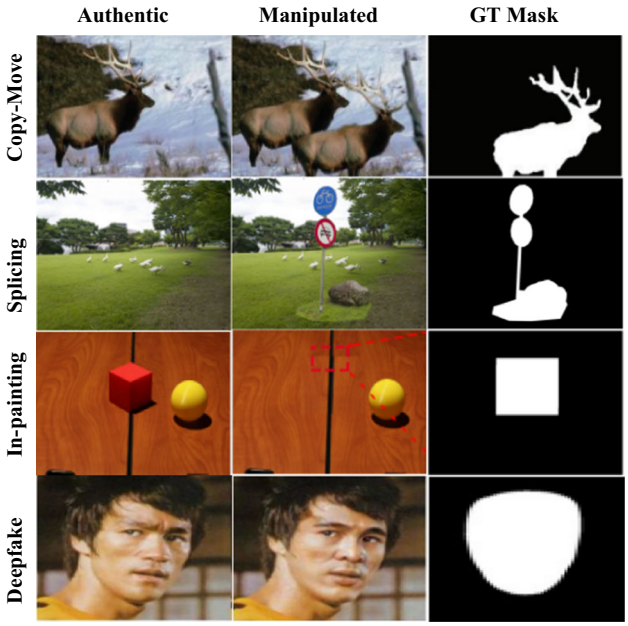

Fig. 1 Example of different kinds of image manipulation

Also, in Deepfake, three types of categorization can be made [1]:

1) *Face Swap* A face is transferred from the source image/frame to the target.
2) *Face Reenactment* Expression or movement is derived from the source image/frame to the target.
3) *Entire Image Synthesis* The powerful AI tools synthesize the entire image.

Handcrafted feature-based methods typically work assuming that a particular manipulation artifact exists. They seek to reveal the forgeries by investigating local discrepancies in color filter array [3], photo response non-uniformity noise (PRNU) [4], JPEG blocking artifacts [5], texture modules [6], and illumination [7]. However, these methods assume the tampering is known beforehand, limiting their capability in diverse scenarios. Deep learning methods, especially CNNs, generally tend to learn contextual(semantic) information and various SoTA methods of image forgery forensic techniques [8–10] resort to them [11]. However, CNNs have a locality basis, expound the relationship between neighboring regions, and may overlook the global manipulation between the artifacts. Inconsistencies in low-level features (like noise or high-frequency) that are not visible to the naked eye and distinctly visible traces are referred to as "artifacts" [12]. Accordingly, based on earlier research, the key to the IML task is to discover low-level inconsistencies and observable traces that are not semantic to capture the artifacts.

Handcrafted features have the limitation that they assume the tampering types beforehand and may overlook other kinds of tampering, and CNNs learn the semantic features and expound neighboring relationships for artifacts, which is not enough to learn the manipulation artifacts. To improve these limitations, we have designed a dual-branch model that uses handcrafted features such as noise inconsistencies on one branch and RGB information on another. This is one of the first few architectures to perform localization of the deepfake dataset. The following are the paper's primary contributions:

- Designed a novel dual-branch architecture that uses RGB information on one branch and noise features on another. Both branches employed channel and spatial attention, followed by ED architecture to represent artifacts better. A dual attention module for down-sampled features is used to learn semantic interdependencies along spatial and channel domains.
- Experimentation is done on the shallowfakes dataset, which is CASIA, Columbia, Coverage and NIST16, and the deepfake dataset FF + + outperforms other models to demonstrate the discriminative abilities of the model.
- Ablation studies are conducted to study the relevance of different components in the overall model.
- Complexity computation analysis was done to show that the model with 38 million parameters is relatively less complex than the various SoTA models.

2 Related work

Based on the feature representation, IML methods can be broadly classified into two groups: Handcrafted features and deep learning-based methods, which are discussed in this section.

2.1 Handcrafted features

Traditionally, by modelling authentic images, handcrafted feature-based techniques expose the statistical connection among pixels and capture the statistical deviation resulting from image tampering operations. For instance, the spatial rich model (SRM) [13], which is frequently used in image steganalysis, was generalized in [14] to extract residual-based features for the multidimensional Gaussian model and support vector machine (SVM) classifier for image manipulation detection and localization. However, altering an image will always result in changes to its visual components, which local image describers can use to detect forgeries. To detect the distortions by image splicing, [7] aggregated the statistical information retrieved by different local descriptors

that examine texture, lighting, shape, and color variables. Image manipulation affects the non-semantic features and results in low-level features like noise inconsistencies, and researchers expounded on such features to get better discriminative features. Zhang et al. [15] use an improved model of constrained convolution to extract noise features that serve as more subtle traces of manipulation fed to a dual-branch architecture for further feature learning. However, such noise features are inconsistent and robust regarding JPEG compression and Gaussian blur. Zhang et al. [16] also use an improved noise extraction method that uses two high-resolution and contextual branches to extract subtle manipulation traces. Handcrafted features assume that latent manipulation features are observable in specific manipulation artifacts, and a method designed to capture such artifacts would provide better results. However, this limits their generalization, and such methods are not robust enough for various manipulation operations.

2.2 Deep learning-based methods

Deep learning-based systems can automatically train and improve feature representations for forgery forensics, in contrast to conventional approaches that require the laborious feature engineering process to create the handcrafted features. Wu et al. [10] proposed that ManTra-Net detects and localizes generalized image manipulations. It recognizes the local anomalous features that can identify fabricated pixels and universal solutions to various forgeries. They are obviating the requirement for pre-and post-processing. However, the model has a few limitations: it cannot work for multi-forgeries and images with highly correlated noises. In Noiseprint [17], siamese networks were used to capture artifacts in the camera model based on noise residual features for manipulation localization. One of the main challenges in image manipulation detection is identifying specific generalizable features to avoid false alarms on authentic images yet sensitive to manipulations in novel data. Chen et al. [18] address both aspects through multi-scale supervision and multi-view feature learning in his paper. The former tries to acquire semantic independent features and more generalizable characteristics by using boundary artifacts and noise distribution surrounding tampered regions. The latter enables us to learn from authentic images that are too complicated for the existing semantic segmentation network-based techniques to handle. The model performs relatively better in cross-dataset scenarios and is robust to various post-processing procedures. Using ground truths of forged boundaries and regions, a multi-task fully convolutional network (MFCN) was trained for forgery localization [8]. A hybrid LSTM and ED network model was recently developed in [9] for pixel-wise forgery localization. This method uses spatial characteristics and resampling to capture irregular transitions between fake and real patches. The CNN methods are better at understanding the visual context or learning the semantic features to perform better at image classification tasks. Image manipulation is semantic-agnostic, so such methods tend to be less effective against image manipulation. Also, CNNs have inductive and locality biases and do not capture the global correlation of features. Objectformer [19] and Transforensics [20] are transformer-based methods proposed over the years. These two models' general architecture and design philosophies hardly align with ViT. Specifically, in contrast to ViT, which embeds the patched images immediately before encoding, both approaches extract feature maps using many CNN layers and then use transformers for additional encoding, neglecting important first-hand low-level information.

To improve the existing models' limitations, we designed a dual-branch model that uses handcrafted features, noise and CNN-based features. The dual-branch has RGB info at one branch and noise information fetched by the Bayar convolution on the other, and these features are strengthened and refined by the channel, and spatial attention and ED architecture are further employed to localize manipulated features.

3 Proposed model

The proposed model consists of two parallel branches; one uses an RGB image as an input, while the other uses noise/residual features as an input feature determined by the Bayar convolution and SRM convolution filters. These kernel filters suppress semantic content and enhance low-level manipulation traces (Fig. 2). The channel refines RGB and noise feature representation of manipulation and spatial attention maps generated by their respective modules. The input features are multiplied with the attention maps to strengthen discriminative features. ED architecture is employed where the encoder translates the intermediate features into discriminative feature maps, which are then further processed and recovered by the decoder to generate classification predictions down to the pixel level. Skip connections improve the propagation capabilities of encoder-decoder network features. A dual attention network further improves feature representation by adapting global dependencies along the spatial and channel axes and local semantic characteristics, resulting in a more precise manipulation of localized features. The resulting features from both branches are concatenated for a more accurate final manipulation prediction.

Three components are used in the above model: Residual/Noise filters, ED with skip connection, and visual Attention modules.

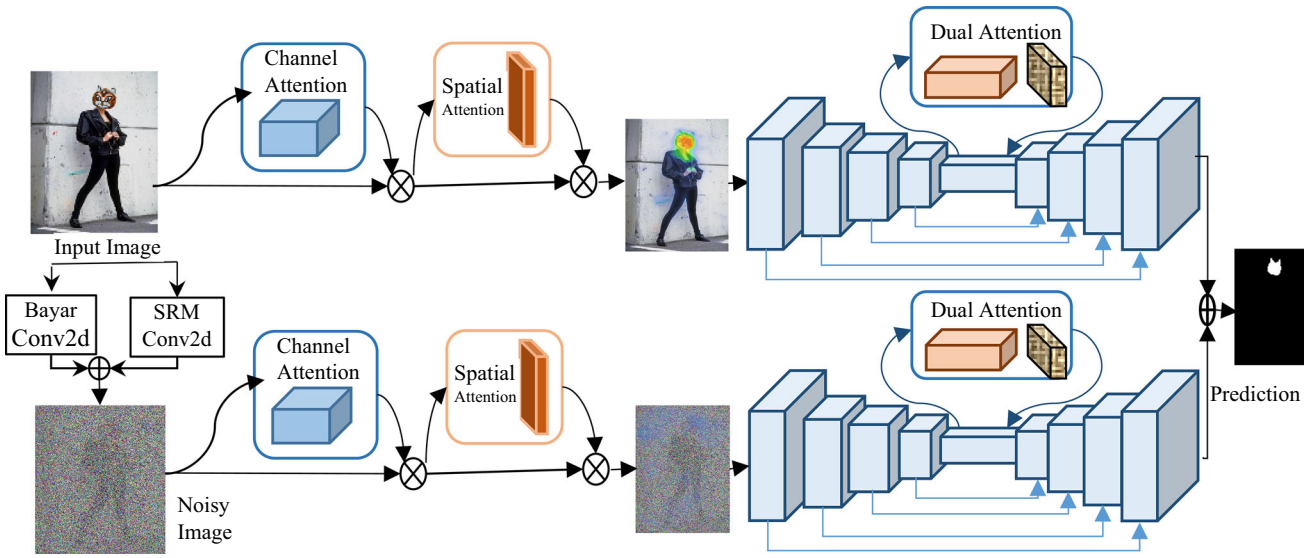

Fig. 2 Overview of the proposed model consisting of a dual branch consisting of RGB and noise branch followed by ED architecture

3.1 Noise inconsistencies

An actual image has uniform noise distribution throughout the image. The intuition behind noise residual as a feature is that when an object is removed from one image/section (of an image) and copied/pasted onto another/section of an image, the noise features of the two are less likely to match. In this configuration, the noise residual is the disparity between a pixel's actual value and its estimated value, which is derived via interpolating the values of nearby pixels, which serves as the model for noise. Bayer and SRM filters are the most standard filters that successfully capture the low-level noise residual features.

3.1.1 Bayar convolution or constrained CNN

Using data, constrained CNN can learn the modifications brought up by image manipulation methods into local pixel relationships. Hence, this approach can suppress image-level content and subsequently learn the latent traces of image manipulation [21]. Constrained CNN's primary purpose is to learn prediction error filters, producing feature maps utilized as low-level forensic traces since they offer superior robustness and universality. To force the CNN to learn the low-level traces, the following constraints are enforced on the weights of the kernel of CNN:

$$\begin{cases} \omega_k^{(l)}(0,0) = -1, \\ \sum\limits_{m,n\neq 0} \omega_k^{(l)}(m,n) = 1, \end{cases} \tag{1}$$

Equation (1) represents the constraints enforced on the filter of the kernel. The superscript indicates the CNN layer. l^{th}, the k^{th} convolutional filter within a layer is indicated by the subscript k, and for a CNN filter, the central value is represented by the spatial index (0,0).

3.1.2 Steganalysis features

Another method used to extract features from an image's noise residuals is SRM (Spatial Rich Models) filters. Fridrich et al. [13] first introduced the concept of SRM. It was primarily created for steganalysis, extracting latent or hidden features from an image's noisy residuals by applying a set number of high-pass filters. Subsequently, those features are combined and sent to ensemble classifiers. It is a specially designed method that essentially calculates the statistics required to extract specific characteristics from the noise residuals surrounding the neighborhood of pixels in an image. This approach yields a feature that can be considered a local noise descriptor.

3.2 Encoder-decoder with skip connection

The architecture used by most semantic segmentation algorithms today is the ED structure. Our encoder network consists of a Vgg-16 network with 13 convolutional layers (w/o fully connected layers), followed by max-pooling layers and is divided into five stages wherein, at each stage, the spatial resolution is halved at every stage, and the channel dimension keeps doubling. This approach allows the model to acquire complex hierarchical representations of visual characteristics, resulting in more reliable and precise predictions. The rationale behind using VGG16(w/o FC layers) as an encoder network is that it has fewer parameters that enable the powerful representation of discriminative visual

features. Hence, an encoder module gathers more semantic information while decreasing the feature mappings and increasing channel dimensions. The decoder network enables up-sampling by mapping low-resolution encoded feature maps to full-scale input-resolution feature maps. The proposed architecture uses the transpose convolution layers for the decoder module to enhance the coarse feature mapping of the full-resolution segmentation map. ED employs skip connection to enhance the neural network feature propagation abilities and to prevent gradient vanishing and exploding gradients [22].

3.3 Attention mechanism

The attention mechanism uses input-dependent weights to replace the traditional learnable fixed weights, allowing the CNN to learn input-aware relationships that help it emphasize the critical features. Two attention modules are used in the model to encode discriminative features more effectively, which are as follows:

3.3.1 Channel attention

A channel attention map is created by utilizing the inter-channel relationship of features. For manipulated localized features, channel attention emphasizes "what" is meaningful for the end task [23]. The module first models the spatial features of various feature maps to generate context descriptors using average and max pooling operations. Subsequently, both descriptors are transmitted to a Multi-layer perceptron (MLP) [23]. Next, the output feature vectors are combined using element-wise summation, and the resulting vector is then normalized using the sigmoid function.

$$\boldsymbol{M_c}(\boldsymbol{F}) = Sigmoid(MLP(AvgPool(\boldsymbol{F})) + MLP(MaxPool(\boldsymbol{F}))) \tag{2}$$

where $\boldsymbol{M_c}(\boldsymbol{F})$ Denotes the feature map that captures channel attention.

3.3.2 Spatial attention

The inter-spatial interaction among features generates the spatial attention map. It is complementary to channel attention and differs in that it concentrates on "where" manipulation localization is presented. Initially, the average-pooling and max-pooling operations are performed on the channel axis to calculate the spatial attention. Subsequently, these results are combined to provide a suitable feature descriptor [23]. The concatenated feature descriptor is subjected to a convolution layer to generate a spatial attention map delineating regions where desired features are prioritized over undesirable ones.

Below are the equations of the spatial attention map.

$$\boldsymbol{M_c}(\boldsymbol{F}) = Sig\big(f^{7\times7}([AvgPool(\boldsymbol{F})); MLP(MaxPool(\boldsymbol{F})])\big) \tag{3}$$

3.3.3 Dual attention mechanism

The Dual Attention network incorporates a self-attention mechanism identifying spatial and channel feature dependencies.

3.3.3.1 Position attention module The purpose of the self-attention mechanism in the position attention module is to capture the spatial relationships between any two positions in the feature map [24]. A local feature $\alpha \in \mathcal{R}^{C\times H\times W}$ applied into the layer of convolution, resulting in the generation of two additional feature maps., $\beta \in \mathcal{R}^{C\times H\times W}$ and $\gamma \in \mathcal{R}^{C\times H\times W}$, respectively. Next, reshape them $\mathcal{R}^{C\times N}$ where $N = H \times W$ denotes the number of pixels of a layer. The spatial attention map $\check{S} \in \mathcal{R}^{N\times N}$ which is then computed by performing a matrix multiplication between the transpose of β and γ and applying a softmax layer:

$$s_{ji} = Sigmoid(\beta_i, \gamma_i)\, where\, i = 1,2, \ldots, N \tag{4}$$

where s_{ji} quantifies the impact of i^{th} position is on j^{th} position. Subsequently, passes the feature α through convolution layers to generate feature $\delta \in \mathcal{R}^{C\times H\times W}$ e and reshape it to a size of $\mathcal{R}^{C\times N}$. Next, calculate the matrix multiplication of δ and the transpose of $\mathbb{S}$ and reshape the resulting matrix to have dimensions$\mathcal{R}^{C\times H\times W}$. Eventually, we determine the product of the input by a scaling factor ρ and aggregate it with the characteristics α using an element-wise summation to obtain the final result. $\theta \in \mathcal{R}^{C\times H\times W}$ Moreover, it is described below:

$$\theta_j = \rho \sum_{i=1}^{N} \big(s_{ji}\delta_i\big) + \alpha_i, \tag{5}$$

The outcome characteristic θ is obtained by taking a weighted sum of the initial characteristics and all the features at each point. Consequently, it selectively combines different contexts based on the spatial attention map and provides a global contextual view.

3.3.3.2 Channel attention module By considering the connections between channel maps, it is feasible to emphasize the interdependence of feature maps and improve the representation of features in a specific semantic domain. Consequently, the channel attention module directly represents channel interdependencies [24]. As opposed to the position attention module, the channel attention map $\acute{Z} \in \mathcal{R}^{C\times H\times W}$

directly from the original features $\mu \in \mathcal{R}^{C\times H\times W}$. To be more precise, we reshape μ to $\mathcal{R}^{C\times N}$ and then multiply μ by its transposition in a matrix. Eventually, a softmax layer is employed to produce the channel attention map $\acute{Z} \in \mathcal{R}^{C\times c}$:

$$z_{ji} = Sigmoid\left(\mu_i, \mu_j\right) where\, i = 1,2, \ldots, C \tag{6}$$

where z_{ji} measures the influence of the i^{th} position's influence on j^{th} position. Furthermore, we apply a matrix multiplication using the transpose of $\acute{Z}$ and μ, transforming the outcome into $\mu \in \mathcal{R}^{C\times H\times W}$. The final output, $F \in \mathcal{R}^{C\times H\times W}$, is then obtained by multiplying the result by a scaling parameter ϑ and using an element-wise sum operation with μ.

$$F_j = \vartheta \sum_{i=1}^{C}\left(x_{ji}\mu_i\right) + \mu_i \tag{7}$$

Equation (7) demonstrates the final feature of each channel, which represents the long-range semantic linkages between feature maps and is computed as a weighted sum of the features from all channels and the original features. It improves the ability to discriminate between different features [24].

3.4 Loss function

Two famous classification and segmentation loss functions have been used: Binary Cross Entropy(BCE) Loss and Focal Loss(FL).

*BCE loss a*ttempts to measure the difference in probability distributions of the estimated and ground-truth masks [25]. It is defined as:

$$\mathcal{L}_{BCE}\left(G_m, \hat{P}_m\right) = -\left(G_m \log\left(\hat{P}_m\right) + (1 - G_m)\log\left(1 - \hat{P}_m\right)\right) \tag{8}$$

where G_m Is the ground truth pixel value of the mask and $\widehat{P}_m$ is the estimated pixel value of the mask. It computes the Loss for every pixel separately and treats every pixel equally.

Focal Loss is another prevalent loss in segmentation tasks and is utilized as an extension of BCE in severely class-imbalanced detection tasks [26]. This allows the model to learn more complicated cases by down-weighting the contribution of less complex ones. Focal Loss uses a modulating factor, p, to down-weight simple examples and concentrate training on hard negatives.

$$\mathcal{FL}_{\gamma,\alpha} = -\left(\alpha(1 - p_i)^{\gamma} y_i log p_i + (1 - \alpha) p_i^{\gamma}(1 - y_i)\log(1 - p_i)\right) \tag{9}$$

where p_i is the predicted probability distribution for the class label, which is unity. An equilibrium factor is α, and parameter γ specifies the rate at which lesser complex data samples are given lesser significance.

The combined loss function is a powerful combination of BCE and focal Loss. BCE loss penalizes the normal distribution of data samples, while focal Loss addresses the problem of class imbalance and focuses on the highly complex task by down-weighting the contribution of easier ones using their hyper-parameter settings.

$$\mathcal{L}_{combined} = \mathcal{L}_{BCE} + \mathcal{FL}_{\gamma,\alpha} \tag{10}$$

Equation (10) represents the combined loss function used for this model. The model uses this integrated loss function during the entire training process.

4 Experiments

This section aims to evaluate the performance of the proposed methodology by validating it on various benchmark datasets and comparing it with various SoTA manipulation localization methods.

4.1 Datasets

4.1.1 Shallowfake dataset

A massive data hunger characterizes deep learning network training. There are insufficient images in the usual datasets used for image manipulation detection today to support deep neural network training. Furthermore, a standard dataset's altered images may not be sufficient for training because they have fewer artifacts. The model undergoes pre-training using CASIAv2, subsequently fine-tuning with additional datasets, and testing is done on them. Table 1 contains the details of the split of the training–testing dataset with their kind of manipulation.

4.1.2 Deepfake dataset

No deepfake image dataset currently contains a ground truth mask for the manipulated regions. Zhang et al. [31] have built their dataset of Faceforensics + + [32], the only deepfake dataset containing masks for most of its videos. Famous FF + + (c23 compressed version used for our work) contains 1000 videos and 5000 fake videos manipulated methods (Deepfakes, Face2Face, Faceshifter, Face-Swap and NeuralTextures). Four manipulations are considered for the frames extracted as 1000 face shifter videos contain no ground truth mask from the videos. Two frames are extracted for each video, and due to some accessibility concerns prevented us

Table 1 Training and testing split of the various benchmark datasets. S means splicing, C means copy-move, and R means removal

Datasets	Training Set	Testing Set	Total Samples	Types of manipulation
CASIA V2.0 [27]	5063	–	5063	S, C
CASIA V1.0 [27]	–	920	920	S, C
COLUMBIA [28]	130	50	180	S
COVERAGE [29]	75	25	100	C
NIST16 [30]	414	150	564	S, C, R

from downloading some legitimate and bogus videos. We have obtained a total of 8449 genuine frames and 7330 counterfeit frames.

4.2 Experimental setup

We use the Vgg-Net16 [32] as a backbone for encoder-decoder architecture, pre-trained on ImageNet [33], to develop our model using the PyTorch framework. The model is executed using two NVIDIA RTX A5000 GPUs, and the image is scaled to 256 × 256. The model is optimized using the Adam optimizer with a batch size 32 during the training and testing phase. The starting learning rate is 1e-4, which decays every 10th step with a decay rate of 0.8.

4.2.1 Quantitative analysis

We have quantitatively assessed the performance of the shallowfake and deepfake datasets.

4.2.1.1 Shallowfake dataset Following the approach [34], the model was trained using the CASIA2 dataset and fine-tuned with standard shallowfakes datasets like Nist16, Coverage, Columbia, and CASIA1. The AUC and F_1 scores of these datasets are recorded in Table 2. For comparison, two categories of models are considered, i.e. unsupervised and DNN models. The table shows that the model outperforms the unsupervised models by a significant margin. The performance of handcrafted features intended for the specific type of manipulation is severely constrained, and all of these traditional methods capture certain tampering artifacts with limited information for detection. Our method's scores are comparable and outperform the other DNN-based methods at various datasets. For the CASIA and Columbia, our model performs significantly well with an AUC score even reaching 96.72%, and on the Nist16 dataset, it has a comparable score to other models (AUC ~ 99.9%).

In comparison, the model performs poorly on the COVERAGE dataset, with an AUC score reaching 77.38% owing to fewer images and the dataset containing copied/moved objects of similar appearance. Our technique captures the broader range of features like RGB features, noise inconsistencies, and global context rather than the neighboring pixels, which helps gather more information for manipulation classification. Various complex CNN models cannot perform well; this could be attributed to most DNN-based methods that model the network by superimposing multiple CNN networks or adding complex branches. For instance, TDA-Net combines three CNN streams, such as end-to-end training for a complex network, which makes it harder for the network to train and requires more computing power. Also, few models are so much simpler that they focus only on the semantic features and hence fail to locate the tampered segments accurately. On the other hand, our model is relatively less complex, easily captures non-semantic features and does not require significant training data to achieve comparable performance.

4.2.2 Deepfake dataset

Ten models are considered for evaluation on the deepfake dataset. Six are the SoTA image manipulation models; the others are the standard image-segmentation models. Codes of the models that are available on GitHub are considered for comparison. Pre-trained Pytorch models are used for image segmentation models, which are further fine-tuned. Three evaluation metrics are used for a more comprehensive evaluation. Table 3 shows the experimental results of the deepfake on the various models. All the models performed decently except MantraNet [10] on the various categories of the Face-forensics + + dataset. It could be attributed to the fact that most of the manipulations are of the face, and there is a single entity that occupies the entire frame, and all the models are powerful enough to capture such apparent artifacts. MantraNet performs poorly on all categories of the deepfake, possibly because images/frames are not high-resolution and contain blurriness and noise, which the model cannot process and learn the latent discriminative features. NedB-Net [16] is another model that has performed well but has a relatively lower score than other SoTA models, which may be due to the low-quality images and the more significant manipulated regions; the paper's authors also highlight this problem. DL-Net [44] performs reasonably well in the FF + + dataset, with the F1 score reaching 96%, owing to its capability to capture high and low-level cues using noise level segmentation map prediction, which constraints the model to focus on

Table 2 Evaluation experiments results of various models on the shallowfake dataset

"–" means unknown score
Bold values represent the highest score among the compared models

the manipulated regions. However, the model has a low score for Face-swap manipulation among the four categories of FF + + manipulation. Another method [45] used for deepfake localization uses a weak supervision framework and uses three methods, i.e. GradCAM, Patches and Attention, for results illustrations. We have used GradCAM methods for score comparison. The method performs outstanding well in the weak supervision setting, showing the powerful discriminative capabilities of the model. However, like the earlier model, the model has a drop in performance for the FS category of manipulation, which could be the network's inability to make accurate predictions at the edges. DADF method [46] performs better than most models, which use multi-scale adapters to capture short and long-range forgeries and guided attention mechanisms, enhancing rich forgery clues. Their scores are at par with other methods and a proper State-of-the-art method for comparison. Another method [31] used also performed well, with the F1 score reaching 98%. Their method is built on top of existing UperNet and uses Bayar convolution methods to trace noise clues. Despite being these State-of-the-art models, all models score more than 90%, which could be attributed to the fact that most of the manipulation has been done on the face, which is easy for the models to recognize. Our model has performed considerably well in the various categories of the FF + + dataset and outperformed the scores of other standard models. These evaluations showed that different modules designed well to work in tandem resulted in the robust learning of the discriminative for varied manipulation.

4.3 Qualitative analysis

This section compares our method with the two most competitive methods, i.e. MantraNet and MVSSS, to give some specific qualitative outcomes on both shallowfakes and deepfake datasets. Figure 3 shows the visualization results of image manipulation detection. Our method achieves better localization results than other methods, as the other methods generate many false positives. In the case of the shallowfake dataset, the method has superior localization performance for CASIA, Columbia and Nist16 datasets. For the deepfake dataset, localization seems much easier, as most image manipulation is done on the face, making it easy for localization. MantraNet exhibits a significant departure from the ground truth, whereas MVSSNET exhibits a significant rate of false positives in regions that have not been altered. The primary cause of this outcome is that during the training phase, MVSSNET used a lot of natural images, which could have a clear negative impact on network training. Additionally, MVSSNET dramatically increases false positives due to

Bold values represent the highest score among the compared models

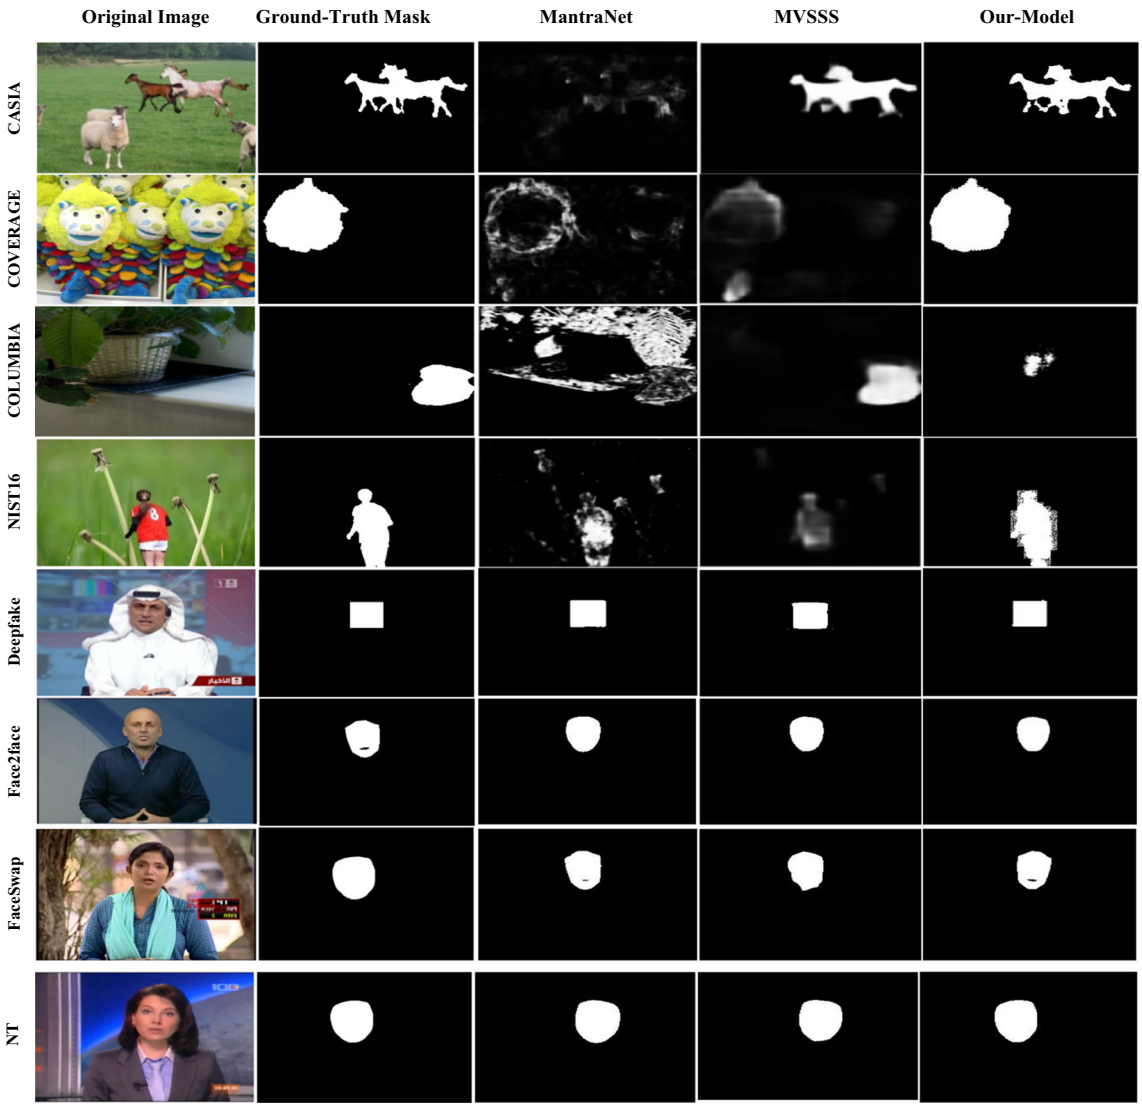

Fig. 3 Qualitative visualization results of the manipulation localization for shallow fakes and deepfake dataset images for different methods

frequently responding to altered and non-manipulated portions of the image. On the contrary, our method focuses on low-level features like noise and high-level contextual features, leading to better localization of manipulated artifacts.

4.4 Ablation studies

We assess the proposed network in various settings with the components introduced one at a time to study the impact of each component. All the components were trained on the CASIA2 dataset and then evaluated on the different shallowfakes datasets, i.e. NIST16, Columbia, Coverage and CASIA1. Table 4 shows the results of the ablations experiment. The different experimental settings are discussed below:

Case A: Model without Channel Attention Channel attention modules have been removed from both branches to study their impact. AUC and F_1 scores decrease slightly, showing inter-relation along the channel axis containing potential features that assisted in the detection task. Two things worth noting: for the Columbia and Nist16 dataset, scores decreased very slightly, nearly ~ 2%(AUC score), while for the Coverage dataset, it decreased significantly by nearly ~ 9%, showing that where data samples are less, attention mechanism plays a pivotal role.

Case B: Model without Spatial Attention From scores, it perceives that spatial attention contributes less in comparison to channel attention to the detection features. It could be attributed to spatial attention focusing on high-level or semantic features, which is less critical for manipulation.

Table 4 Ablation experiment of different components where the model trained on CASIA2 and tested on other datasets

Cases	NIST16		COLUMBIA		COVERAGE		CASIA	
	AUC	F1	AUC	F1	AUC	F1	AUC	F1
Case A	0.9246	0.9688	0.9516	0.8758	0.6891	0.3623	0.8868	0.8078
Case B	0.9327	0.9896	0.9626	0.9285	0.7208	0.3953	0.9123	0.852
Case C	0.8055	0.8302	0.8328	0.7497	0.7373	0.3946	0.8033	0.4254
Case D	0.9087	0.9291	0.93	0.8398	0.7307	0.4049	0.9210	0.8560
Case E	0.8688	0.8015	0.8873	0.7333	0.7261	0.3871	0.7543	0.4852
Case F	0.9239	0.9488	0.9435	0.8569	0.6052	0.2879	0.8863	0.8562
Overall model	0.9441	0.9952	0.9641	0.8988	0.7542	0.4272	0.9313	0.8650

Table 5 Computation complexity analysis of different models

Methods	Parameters (millions)	CPU time (sec)	GPU time (sec)
MantraNet	3.80	8.06	0.14
MVSS-Net	142.782	9.66	1.13
SPAN	4.06	8.08	0.278
Nedb-Net	45.085	10.11	1.171
DeepLabv3_ResNet50	39.63	9.97	1.17
FCN_ResNet50	32.946	10.20	1.14
LRASPP_MobileNet	3.21	9.01	1.01
Our_model	38.86	9.09	0.94

GPU and CPU time are measured for an epoch of batch size of 32

Also, one of the trivial observations is that scores declined slightly and uniformly across all the datasets.

Case C: Model without Channel and Spatial Attention In this case, channel and spatial have been removed from both branches to study their relevance. Scores have decreased significantly, nearly ~ 14%, across all the datasets except the Coverage dataset. It shows that these modules work better together to capture informative features and global correlations along every axis and emphasize such critical features.

Case D: Model without Dual Attention Dual attention modules are axed from the Encoder-decoder architecture to investigate their importance. This dual attention contributes less to the overall detection task of either the spatial or channel attention module. Also, the dual attention works almost uniformly for every dataset, showing its ability to capture long-range contextual information for varied manipulations.

Case E: Model without Noise branch Here, the noise branch, consisting of the RGB branch, is completely removed from the model. This means that RGB high-level or semantic features are primarily used for detection. Here, the performance decreased drastically by nearly ~ 8%, confirming that low-level features like noise consistencies are crucial indicators in the overall detection task. For the CASIA model, scores have decreased to a greater extent, around ~ 19%, as it varied manipulation like splicing and copy-move, showing the relevance of residual noise feature to varied manipulation.

Case F: Model without RGB branch The RGB branch is completely removed from the overall model, and the noise branch is used for manipulation detection. In this scenario, the AUC score is decreased to a smaller extent, around 4%, again confirming that the low-level noise features have more relevance than high-level semantic features for the detection task. For the Coverage dataset, the performance has decreased drastically, meaning that noise branches need ample datasets to learn noise inconsistencies for detection tasks.

5 Computational complexity analysis

In this section, we assessed the complexity of three distinct deep networks: MantraNet, SPAN, MVSSNET, Nedb_Net [16], DeepLabv3_ResNet50 [48], FCN_ResNet50 [51] and LRASPP_MobileNet [50]. All experimental analysis is done on two NVIDIA RTX A5000 GPUs. Table 5 shows the computational analysis of different models compared to ours. Regarding the number of parameters, the model is relatively lighter, with 38.86 million parameters compared to MVSS-Net and Deeplab. MantraNet and LRASPP are many relatively lighter models than other models. Another metric was calculated in CPU and GPU time for one epoch for a batch size of 32 images of the CASIA dataset. The model

runs on the GPU and CPU to measure their time in seconds. GPU time is always less time for different models. Our model takes less time both on GPU and CPU.

6 Conclusion

This paper proposes a novel dual-branch architecture consisting of Noise Residual extraction modules at one branch and RGB information at the other branch powered by the attention mechanism before feeding to the ED architecture for precise IML prediction. The model effectively captures the low-level inconsistencies critical for IML tasks and additional semantic features. Extensive experiments on the shallowfakes and deepfake datasets have shown that the model is able to capture subtle traces of manipulation and achieves SoTA results. Future work may involve checking the model's generalizability on the unseen dataset and robust evaluation of various compression scenarios.

Abstract
The proliferation of electric vehicles (EVs) necessitates accurate EV charging load forecasting for demand-side management and electric-grid planning. Conventional machine learning-based load forecasting methods like long short-term memory (LSTM) neural networks rely on large amounts of historical data, which can be resource-intensive and time-consuming to collect. In this study, we employ Transfer Learning (TL) and Model-Agnostic Meta-Learning (MAML) for short term EV charging load forecasting. These methods involve pre-training a base model on a larger comprehensive EV charging dataset followed by fine-tuning using a few days' worth of EV charging data in our target location. We find that the performance of both the TL and MAML models outperform traditional LSTM models and other classic machine learning models in the context of forecast accuracy when working in three different settings with limited data , load variance, and diverse geographical locations. The error metrics from TL and MAML are up to 24% and 61% lower than deep learning and classic machine learning models respectively.

1 Introduction

The increasing incorporation of renewable energy sources (RES) and electric vehicles (EVs) introduces complexities in achieving coordination between electricity supply and demand due to their inherent uncertainties. Consequently, accurate forecasting of electricity generation and loads assumes pivotal importance in sustaining a stable smart grid, enabling the precise matching of supply and demand across various time scales [1]. On the supply side, wind and solar energy sources exhibit intermittency, relying on external weather variables outside human control.

Published online: 14 June 2024

Simultaneously, the forecasting of EV charging loads becomes a necessity for long-term infrastructure planning and medium-to-short-term demand-side management. These efforts mitigate peak loads, reduce costs, and minimize the curtailment of RES [2]. Furthermore, harnessing demand-side flexibility has the potential to yield cost savings in both planning and operational aspects [3].

Traditionally, EV charging load forecasting is treated as a time series problem and involves the application of statistical and machine learning approaches [2]. Among statistical methods, autoregressive integrated moving average (ARIMA) and exponential smoothing (ETS) are popular due to their simplicity, robustness, efficiency, and accuracy [4]. Machine learning techniques, such as Long Short-Term Memory (LSTM) networks, a type of recurrent neural network (RNN) that leverages both current and stored information in memory, are widely used for time series forecasting, at times surpassing the performance of statistical methods [4]. To enhance the predictive accuracy further, the authors in [2] adopted ensemble learning techniques that combine the strengths of multiple machine learning models, effectively synergizing their capabilities to enhance the precision of EV charging load forecasting.

However, neural network (NN)-based forecasting methods exhibit suboptimal performance in scenarios characterized by limited training data. This limitation often arises when data collection proves challenging, expensive, subject to strict regulations, or when dealing with newly established setups [5]. One approach to address this challenge is transfer learning (TL), which leverages pre-trained forecasting models developed using extensive and diverse datasets as initial models. These pre-trained models can then undergo fine-tuning using a limited dataset specific to the problem at hand [6]. [7] proposed the use of transfer learning using deep generative models for cold-start forecasting of residential EV charging behavior. Generative models were used to augment the small samples in the target dataset before fine-tuning. A hybrid LSTM transfer learning model was used in [8] to predict EV charging demand and network voltage profiles with limited data within a single city.

Another promising algorithm for mitigating the data scarcity issue is model-agnostic meta-learning (MAML). MAML is capable of training on a variety of learning tasks, enabling it to adeptly tackle new learning tasks with a limited number of available training samples [9]. [10] introduced a transferable MAML model tailored for short-term load forecasting in individual Australian households. [5] harnessed transfer and meta-learning techniques to predict personalized residential loads in Korea and substation loads in Portugal but ignored load patterns during weekends and holidays. Both [10] and [5] performed univariate load forecasting where the only feature used to predict load was historical load. [11] employed a meta-learning model to forecast load profiles at the transmission level, utilizing open-access data from Elia, a Belgian transmission system operator. In [11], the forecast was performed to find the future values in the same source dataset, meanwhile [10] and [5] forecasted loads of similar scale in the same country.

In this study, we employ TL and MAML techniques for short-term aggergate EV charging load forecasting. Our investigation spans two distinct geographical areas: the Calfifornia Institute of Technology (CalTech) campus [12] and the Trondheim region in Norway [13]. We accomplish this by leveraging a comprehensive EV charging load dataset sourced from Boulder, Colorado for pre-training [2]. These

datasets encompass varying scales, including campus-level, housing initiative-level, and city-level data. Moreover, they originate from different locations, namely Pasadena, CA, USA; Trondheim, Norway; and Boulder, CO, USA. Additionally, we work with aggregated EV charging data in both shared charger and private charger settings. To assess the effectiveness of our approach, we evaluate the performance of different TL, MAML, and traditional LSTM network variants on these diverse datasets at the time scales of 10–20 days. The models only get to be fine-tuned on 10 or 20 days' worth of data to predict the next 5–10 days on each of the investigated datasets. It is worth noting that, to the best of our knowledge, our study represents the first of its kind in this context. We compare our results to traditional LSTM deep learning networks and to other classic machine learning models.

The key contributions of our paper can be summarized as follows:

- We use TL and MAML training to create short-term load forecasting models;
- Additional temporal features such as seasons, weekends and holidays are incorporated to create richer data;
- Utilize adjacent time windows as query and support sets for MAML;
- Models utilize small amounts (10 or 20 days) of fine-tuning data;
- We ensure the robustness of models in making predictions across varying scales, geographies and demographics by utilizing multiple datasets;

The subsequent sections of this paper are structured as follows:

Methods: This section provides a comprehensive overview of the diverse models employed for short-term EV charging load forecasting. Additionally, it outlines the particulars of the datasets, and delves into the data pre-processing procedures, model architectures, hyperparameters, and details concerning the experimental configuration.

Results: In this section, we present the outcomes of our study and highlight the noteworthy observations derived from the experiments.

Discussion: The concluding section summarizes our findings and provides prospective directions for future research endeavors.

2 Methods

2.1 Datasets

We utilized three distinct publicly available datasets:

2.1.1 Colorado dataset

The dataset from Colorado [14] used in the work of [2], encompasses records of individual EV charging transactions recorded at city-owned shared charging stations located in Boulder, Colorado, USA, covering a time frame extending from January

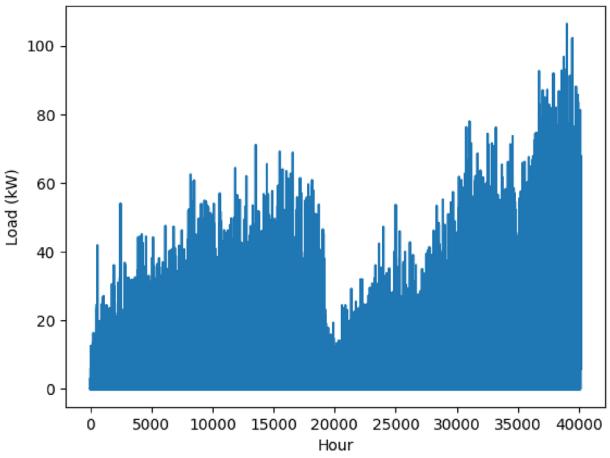

Fig. 1 Aggregate EV charging load distribution in the Colorado dataset

1, 2018, to July 31, 2022. The aggregated EV charging load data is visually represented in Fig. 1.

2.1.2 ACN dataset

The dataset from the Adaptive Charging Network (ACN), as detailed in [12], comprises records of EV charging transactions logged at the CalTech and JPL campuses. Our particular focus centers on the CalTech data, primarily because it exhibits lower EV penetration and a more sparse nature, as visually depicted in Fig. 2. This dataset encompasses a timeframe ranging from April 4, 2019, to September 16, 2021.

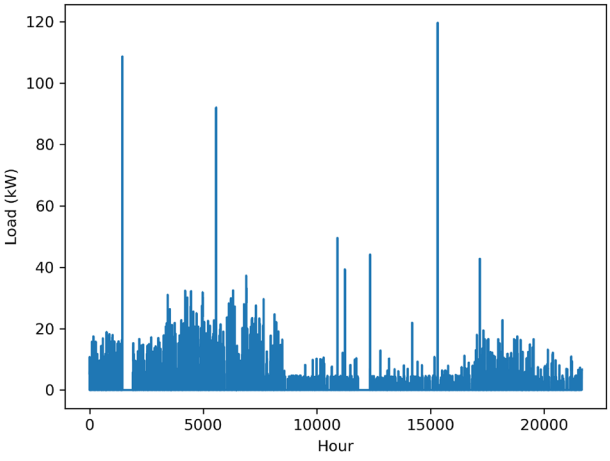

Fig. 2 Aggregate EV charging load distribution in the ACN dataset

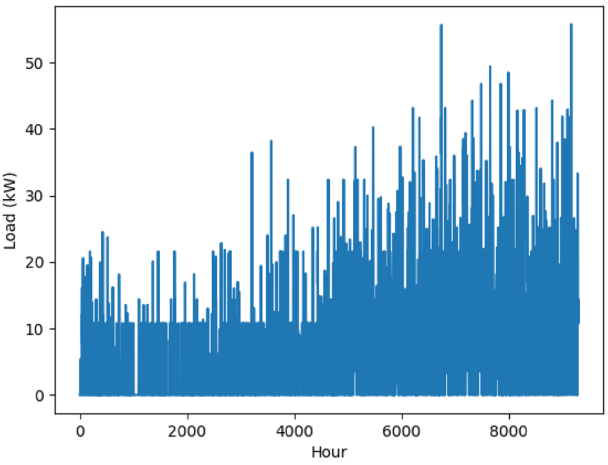

Fig. 3 Aggregate EV charging load distribution from shared chargers in the Norway dataset

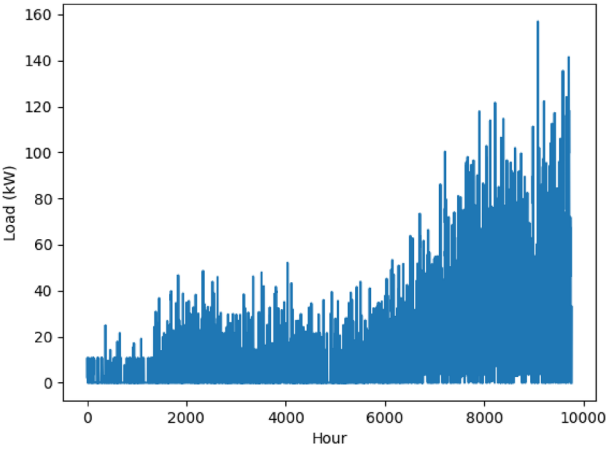

Fig. 4 Aggregate EV charging load distribution from private chargers in the Norway dataset

2.1.3 Norway dataset

The Norway dataset [15] used in [13] contains hourly charging load data from charging stations within a residential block in the Trondheim region of Norway. It consists of two parts—aggregate shared charger data and aggregate private charger data visualized in Figs. 3 and 4 respectively. Both these datasets exhibit an irregular and challenging data distribution because chargers were added in each of these settings over time. Additionally, we can see that the magnitude of the aggregated private charger data is about three times the aggregated shared charger data. The aggregate shared charger data was collected from January 10, 2019 until January

31, 2020 while the aggregate private charger was collected from December 21, 2018 until January 31, 2020.

2.2 Data pre-processing

We transformed both the Colorado and ACN datasets, originally containing charging transactions, into an hourly load format. Following this, all four datasets (Colorado, ACN, Norway-shared, and Norway-private) underwent an extensive pre-processing procedure, incorporating a comprehensive set of 10 features encompassing hour, quarter-of-day, day, day-of-week, week-of-year, month, quarter-of-year, season, and load (kW).

The data was then structured into input–output pairs, with the input comprising a sequence of 24 consecutive hours as features, with the load of the 25th hour serving as the target variable. $D = (x_t, y_t), t \in T$ with $x_t \in \mathbb{R}^{10X24}$ and $y_t \in \mathbb{R}$. Given the substantial size and density of the Colorado dataset, we opted to employ it for the pre-training phase of both the MAML and TL models. Subsequently, these pre-trained models underwent a fine-tuning process utilizing subsets of the ACN and both the Norway datasets. The fine-tuning was conducted using 10-day and 20-day subsets, requiring the models to make hourly load forecasts for the subsequent 10 and 20 days, respectively. This approach compelled the models to adapt to very limited historical data when making predictions about future trends.

2.3 Models

2.3.1 Neural networks

In the context of forecasting, which falls under supervised learning, a neural network (NN) can be represented as $z = f_\theta(x)$, where x represents the input, z denotes the output, and $\theta \in \mathbb{R}^n$ encompasses parameters distributed across multiple layers in the network. Typically, θ comprises weights W that signify the strength between neuronal connections in adjacent layers, as well as biases b within each layer.

These parameters are subject to optimization for a specific task $\mathcal{T} = (D, L)$, minimizing a loss function L over a designated subset of data $D = (x_t, y_t) \mid t \in T$, employed for training $D_{train} = (x_t, y_t) \mid t \in T_{train}$. x_t represents the input data and y_t stands for the corresponding labels. T encompasses the total number of samples within the dataset, and T_{train} denotes the portion of samples reserved for training. The loss function L leverages a distance metric $d()$ to capture the dissimilarity between the model outputs z and the ground truth labels y.

$$L(\theta) = \sum_{t \in T} d(z_t, y_t) = \sum_{t \in T} d(f_\theta(x_t), y_t) \tag{1}$$

For regression problems, L1 loss and mean squared error (MSE) loss are the prevalent loss functions as shown in Eqs. (2) and (3). The MSE loss is used when we want to penalize larger errors more heavily, while the L1 loss is used in the presence of outliers in the data and when the distribution of errors is not necessarily normal.

$$L_{L1}(\theta) = \frac{1}{T} \sum_{t \in T} |f_\theta(x_t) - y_t| \tag{2}$$

$$L_{MSE}(\theta) = \frac{1}{T} \sum_{t \in T} (f_\theta(x_t) - y_t)^2 \tag{3}$$

The optimal parameters θ^* are achieved through the iterative application of the back-propagation algorithm, as depicted in Eq. (4), that minimizes the loss function across the training data. Here, α represents the learning rate, and $\nabla_\theta L()$ denotes the gradient of the loss function.

$$\theta \leftarrow \theta - \alpha \nabla_\theta L(\theta) \tag{4}$$

2.3.2 LSTM

Long Short-Term Memory (LSTM) networks, an extension of NNs are designed to handle long-term dependencies [4]. The fundamental components of LSTM units encompass a cell, an input gate, an output gate, and a forget gate, each playing a distinct role in information processing [16]. In the description below, the symbols W denote weights, while b represents biases. x_t represents the current input and h_{t-1} is the historical output. A visual representation of the various LSTM network components is provided in Fig. 5.

The functioning of an LSTM network can be explained through its individual components:

Forget Gate (f_t): The forget gate determines the information discarded. It operates on x_t and h_{t-1} using weights $W_{f,x}$ and $W_{f,h}$, followed by the application of the sigmoid function $\sigma()$ which yields an output in the range (0,1).

$$f_t = \sigma(W_{f,x}x_t + W_{f,h}h_{t-1} + b_f) \tag{5}$$

Input Gate (i_t): The input gate determines what information should be retained in memory. Weights $W_{i,x}$ and $W_{i,h}$ associated with the x_t and h_{t-1}, facilitate this decision.

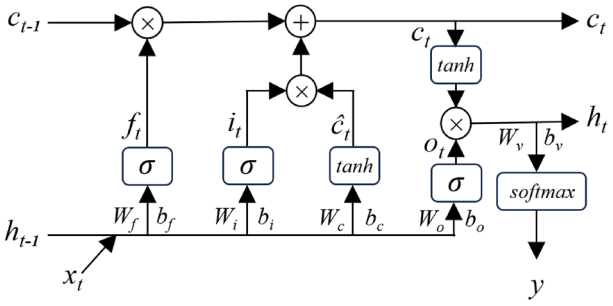

Fig. 5 Structure of an LSTM network highlighting the various gates, weights, biases and operations

$$i_t = \sigma(W_{i,x}x_t + W_{i,h}h_{t-1} + b_i) \tag{6}$$

Current Cell State Estimate ($\hat{C}_t$): A hyperbolic tangent function *tanh*(), which generates outputs within the range (-1,1), is employed to compute the estimate of the current cell state. This estimation relies on parameters $W_{c,x}$, $W_{c,h}$, and b_c.

$$\hat{C}_t = tanh(W_{c,x}x_t + W_{c,h}h_{t-1} + b_c) \tag{7}$$

Current Cell State (C_t): C_t is updated using the previous cell state C_{t-1}, $\hat{C}_t$, and the outputs of f_t and i_t.

$$C_t = f_t \times C_{t-1} + i_t \times \hat{C}_t \tag{8}$$

Output Gate (o_t): The output gate interacts with x_t and h_{t-1} through weights $W_{o,x}$ and $W_{o,h}$.

$$o_t = \sigma(W_{o,x}x_t + W_{o,h}h_{t-1} + b_o) \tag{9}$$

Current Output (h_t): h_t is generated by combining the results of the o_t and C_t.

$$h_t = o_t \times tanh(C_t) \tag{10}$$

Final Output (y): The final output y is obtained by applying a softmax function to the product of weights W_y and h_t.

$$y = softmax(W_y h_t + b_y) \tag{11}$$

LSTM models require access to substantial amounts of historical data to generate meaningful results. This can pose a challenge when dealing with newer or smaller hubs with limited data availability.

2.3.3 Transfer learning

Transfer Learning (TL) is designed to address challenges arising from limited training data. The TL process begins by initially pre-training models on a larger, separate dataset. These models are then fine-tuned through training on the target dataset, allowing them to extract general patterns from the larger dataset and adapt this knowledge to the smaller, intended dataset, as outlined in [6]. TL is employed to enhance learning in a target task, denoted as $\mathcal{T}_T = (D_T, L_T)$, by leveraging knowledge from a different yet related task, $\mathcal{T}_S = (D_S, L_S)$.

The optimal parameters θ_S, obtained from a NN trained on $D_{S,train}$ and validated on $D_{S,test}$, serve as the initial weights and biases for the NN model intended for the target task $\mathcal{T}_T$ as shown in Algorithm 1. Subsequently, the TL model undergoes fine-tuning by training on $D_{T,train}$ and is evaluated on $D_{T,test}$ to obtain optimal parameters θ_T specific to the target task $\mathcal{T}_T$.

It is essential to acknowledge a primary limitation of TL models. Fine-tuning may not fully mitigate the disparities in datasets and trends, potentially resulting in sub-optimal performance when transitioning from the source to the target task.

Algorithm 1 Transfer Learning (TL)

Require: $\mathcal{T}_S = (D_S, L_S)$: Source task
Require: α: Step size hyperparameter
1: Randomly initialize θ
2: **while** not done **do**
3: Batch load data (x_i, y_i) from $D_{S,train}$
4: Evaluate $\nabla_\theta L_{\mathcal{T}i}(f_\theta)$ using 2 or 3
5: Update $\theta \leftarrow \theta - \alpha \nabla_\theta L_{\mathcal{T}i}(f_\theta)$
6: **end while**
7: Use optimal θ_S as initial parameters for fine-tuning

2.3.4 Model-agnostic meta-learning

Model-Agnostic Meta-Learning (MAML) represents a recent advancement within the realm of Deep Learning (DL) that offers a solution to the limitations of conventional DL and TL, as introduced in [9]. In the context of meta-learning, specifically MAML, a large dataset is initially divided into numerous meta-tasks, each comprising only a limited number of data points. The model is subsequently exposed to these tasks, essentially becoming proficient in "learning to learn". This means that instead of directly updating its parameters based on an extensive external dataset, the model focuses on acquiring the ability to efficiently adjust its parameters in order to maximize its performance when faced with new tasks.

In the case of time series data, following the generation of features and time windows as outlined in Sect. 2.2, the dataset $D = (x_n, y_n)$ is partitioned into N tasks denoted as $\mathcal{T}_i, i \in (1, N)$ that each contain the same number of time windows $2l$. $2l$ consecutive time windows with a random starting point are selected for each task. Alternate time windows in each task $\mathcal{T}_i$ are segregated into exactly l support sets trained in an inner loop and l query sets trained in the outer loop. This is because alternate time windows are temporally correlated [17].

The NN model utilized for MAML is initialized with random parameters θ. The time windows $(x_{i,k}, y_{i,k}), k \in (1, l)$ in the support set of each task $\mathcal{T}_i^{sup}$ are used to iteratively update temporary parameters θ_i' by using θ and the gradient of the loss function as expressed in Eq. (12) for a number of adaptation steps set by the user. α is the inner loop learning rate.

$$\theta_i' = \theta - \alpha \nabla_\theta L_{\mathcal{T}_i^{sup}}(f_\theta) \tag{12}$$

Following this parameter update, the meta-learning rate β, parameters θ_i' and their gradients as well as time windows $(x_{i,j}, y_{i,j}), j \in (1, l)$ from the query set of each task $\mathcal{T}_i^{que}$ are employed to adjust θ, as demonstrated in Eq. (13).

$$\theta \leftarrow \theta - \beta \sum_{i=1}^{N} \nabla_\theta L_{\mathcal{T}_i^{que}}\left(f_{\theta_i'}\right) \tag{13}$$

The model, now meta-trained, can be fine-tuned on smaller datasets, allowing it to adapt quickly and learn effectively without being hampered by data scarcity or external dataset influences. The entire process is shown in Algorithm 2.

Algorithm 2 Model-Agnostic Meta-Learning (MAML)

Require: Tasks $\mathcal{T}_i, i \in (1, N)$: Derived from dataset D
Require: α, β: Step size hyperparameters
Randomly initialize θ
while not done **do**
  Sample batch of tasks $\mathcal{T}_i$
  for all $\mathcal{T}_i$ **do**
    Sample data $(x_{i,k}, y_{i,k}), k \in (1, l)$ from support set $\mathcal{T}_i^{sup}$
    Evaluate $\nabla_\theta L_{\mathcal{T}i}(f_\theta)$ using equation 2 or 3
    Compute temporary parameters with gradient descent using equation 12
    Sample data $(x_{i,j}, y_{i,j}), j \in (1, l)$ from query set $\mathcal{T}_i^{que}$ for meta-update
  end for
  Update θ using equation 13
end while
Use θ as initial parameters for fine-tuning

2.3.5 Classic machine learning

In order to justify the use of complex deep learning experiments, it is essential to compare performances with classical machine learning (CML) models. We utilize two algorithms, namely Random Forests (RF) and K-Nearest-Neighbors (KNN) due to their popularity, simplicity, and known efficacy at regression problems [18]. Other popular models such as Support Vector Machines were also included in experimentation, but their performances were consistently poor and are thus not included in the results.

The basic unit of a RF is a decision tree. A Decision Tree (DT) is a machine learning model that splits features into branches of a tree. The tree starts with a root node, representing a decision or a test on a specific feature. From there, it branches into child nodes, each corresponding to different outcomes of that decision. This branching continues until the final decisions are reached, expressed as leaf nodes. The splitting criterion, in our case, was MSE as described in Eq. 3.

RF models are a collection of DTs, each trained on a different randomly divided subset of the data. Each DT then predicts the outcome, and the final prediction is based on the average prediction of the ensemble of DTs. This ensemble approach helps to reduce overfitting.

In KNN regression, each data point is positioned in a multidimensional space according to its features. KNN locates the k-nearest instances in this space to the input data point in question via euclidean distance. The predicted value is calculated as the average of the target values of these neighbors as shown in Eq. 14. We selected *k* as 5.

$$\hat{y}(x) = \frac{1}{k} \sum_{i=1}^{k} y_i \tag{14}$$

Here, $\hat{y}(x)$ is the predicted value for the input x, k is the number of nearest neighbors considered and y_i are the target values of the k nearest neighbors to the input x.

2.3.6 Experimental setup

In our experimental setup, we employ LSTM networks as the foundational architecture. We configure an LSTM network comprising of two LSTM layers, each housing 48 neurons. This is followed by a Dense layer with 48 neurons and culminating in a single-neuron output layer. To optimize the network, we employ an RMSprop optimizer with a learning rate (α) of 0.001. Our experiments are conducted using Pytorch and the learn2learn library [19] in Python, hosted on Google Colab, which provides ample resources including 12.7 GB of RAM and an NVIDIA Tesla T4 GPU. Multiple variations of the above network were trained and tested, including number of layers, number of neurons in each layer, number of LSTM layers, bidirectionality, and learning rate. The settings mentioned were selected because they provided the best results.

For our meta-learning approach, we commence by partitioning the Colorado dataset into 500 tasks (N), with each task encompassing 200 consecutive data points (2 l). The number of tasks and data points per task were selected on the basis of performance by testing each of them in steps of 50 starting from 50 until 500. The LSTM network is encapsulated within a MAML module with a learning rate (β) of 0.05. We create two distinct models, one trained with L1 loss and the other with MSE loss. Our training process consists of 50 iterations. Within each iteration, the model encounters 32 tasks, where each task is further divided into query and support sets. Specifically, every alternate 24-hour input time window serves as a support set, while its subsequent time window serves as the query set. The model adapts to the support sets in the inner loop and evaluates its performance on the query sets, iteratively updating its parameters to enhance its performance across tasks. In each iteration, a new copy of the MAML model is employed. This practice involves cloning the original model before adaptation, effectively isolating changes made during adaptation to a specific task ensuring proper generalization.

Upon completing the meta-learning phase, we create fresh LSTM models, initializing them with the same parameters θ as the meta-trained LSTM. These models are then subjected to fine-tuning on the remaining datasets (ACN, Norway-shared, and Norway-private). We select 20-day and 40-day subsets from these datasets, splitting them evenly into training and testing sets. Fine-tuning is carried out over 50 iterations, employing L1 loss as the objective function.

In contrast, our TL approach involves training LSTM models with the previously described architecture directly on the entire Colorado dataset. Two separate models are trained-one with L1 loss and the other with MSE loss-for 50 iterations. Subsequently, these models are fine-tuned on the ACN and Norway datasets in a manner consistent with the process outlined above.

For traditional DL, where no pretraining is involved, models are directly trained on the first halves of the selected subsets for 50 iterations using L1 loss and then evaluated on the remaining halves. The CML models are also directly trained on the same portions of the data after flattening the input vector. The evaluation metrics include mean absolute error (MAE), root mean squared error (RMSE), and coefficient of determination (R2) scores. To ensure robustness, each experiment is conducted five times, and the average values of all metrics are reported.

3 Results

This section is divided into 3 subsections pertaining to each of the datasets under investigation. Tables 1, 2 and 3 provide the metrics for the seven EV charging load forecasting models : TL with MSE and L1 loss, MAML with MSE and L1 loss, DL with L1 loss, RF and KNN.

3.1 ACN dataset

Analyzing the ACN dataset results presented in Table 1, it becomes evident that TL L1 exhibits the most favorable performance, particularly in terms of MAE and RMSE. Notably, TL L1's RMSE score is surpassed only by TL MSE in two subsets of the ACN dataset considered. In contrast, DL consistently lags behind the performance of competing models across all metrics. With the exception of the first and third subsets wherein RF performs competitively, CML models are well-beaten by the deep learning models.

Furthermore, when comparing L1 variants to their MSE counterparts within the MAML and TL models, it becomes apparent that L1 variants outshine their MSE counterparts. Additionally, examining the R-squared (R2) scores reveals that TL models excel in capturing and adhering to the underlying trends in the data.

Analyzing the trends depicted in Figs. 6 and 7, we can evaluate how well each model aligns with the actual hourly load patterns. It is evident that, in general, models tend to exhibit suboptimal performance during peak load periods, occasionally either overestimating or underestimating the peak values. Interestingly, models display a higher level of accuracy in predicting periods of zero load, with some exceptions noted in the case of DL and MAML L1, as illustrated in Fig. 6. From both figures, we see that the CML models perform very poorly during zero-load hours. While they are able to understand the general trend, they predict the trend to continue even when there is no actual load.

3.1.1 Norway shared charger dataset

Examining the Norway shared charger data presented in Table 2, it is clear that MAML demonstrates the most robust performance, specifically excelling in terms of MAE and RMSE. Interestingly, in this dataset, DL manages to outperform TL models, yet it still falls short when compared to the performance achieved by MAML

Table 1 Mean MAE, RMSE and R2 scores of the forecasting models on the ACN dataset

Specification		Mean scores		
Subset	Model	MAE	RMSE	R2
18th September 2019, 10 Days	TL MSE	1.48	***2.97***	***0.83***

models. CML models expectedly underperform, with KNN showing negative R2 scores. In the second subset of the dataset, the MAE exhibited by DL is 10% higher than that of MAML MSE but 5% lower than that of TL MSE. Additionally, the R2 scores affirm that MAML models tend to make predictions that closely align with the actual data trends, demonstrating their superior predictive capability.

From Figs. 8 and 9, we can assess how each model fits the real hourly load trend. We can see that the models under-perform at the two peaks greater than 15 kW in Fig. 8, and the CML models continue to predict loads even when there are none, as discussed previously. Additionally, Fig. 8 displays an interesting phenomenon—models appear to arrive with a delay of one timestep with respect to the peaks, suggesting that they are under-confident in predicting the starting edges of the peak periods.

3.1.2 Norway private charger dataset

From the data outlined in Table 3, it becomes evident that TL L1 demonstrates the most robust performance across all subsets examined within the Norway private charger dataset. Conversely, DL exhibits relatively poorer performance in most instances.

Table 3 Mean MAE, RMSE, and R2 scores of the forecasting models on the Norway private charger dataset

Specification		Mean scores

	RF	5.50	8.57	0.46
	KNN	7.36	10.21	−0.31

The values in bold and italics represent the best metrics achieved by the models for the subset of data in consideration

For example, consider the MAE scores: TL L1 achieves scores that are 20% and 31% lower than those attained by DL for the first and second subsets within the dataset. Moreover, TL L1 outperforms MAML L1 (the better-performing MAML) by approximately 15% and 21% for the same subsets. CML models expectedly underperform again. Additionally, it's worth noting that both MAE and RMSE values for all models within the Norway private charger dataset are higher when compared to those of the Norway shared charger dataset and the ACN dataset. This discrepancy might be attributed to the Colorado dataset containing charging transactions acquired from shared chargers that might exhibit similar patterns to Norway shared

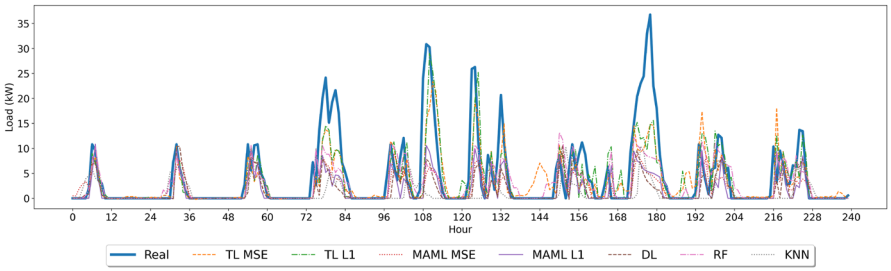

Fig. 10 Results from the forecasting models compared to the true load value on a subset of the Norway private charger dataset starting from February 21, 2019 for 10 days

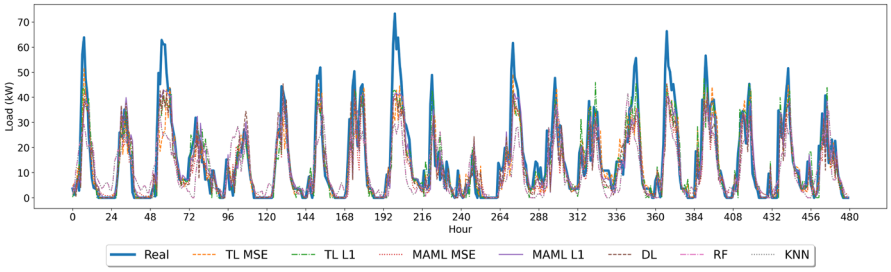

Fig. 11 Results from the forecasting models compared to the true load value on a subset of the Norway private charger dataset starting from September 17, 2019 for 20 days

charger dataset and the ACN dataset (shared chargers on campus). Achieving an optimal balance between private and shared charging data during pre-training may be necessary to enhance the final results.

Analyzing Figs. 10 and 11, we can evaluate how well each model aligns with the actual hourly load trends. Notably, all models, with the exception of TL L1 and TL MSE, exhibit significant underperformance. TL models struggle to accurately predict peaks exceeding 15 kW as seen in Fig. 10. However, Fig. 11 shows a relatively improved performance, though the models still face challenges in accurately predicting peaks exceeding 50 kW.

4 Discussion

Our research demonstrates the effectiveness of MAML and TL models in short-term load forecasting, particularly in scenarios with limited data availability. These models exhibit the capability to forecast accurately across diverse geographical regions, scales, and data distributions by employing a pre-training strategy on a more extensive dataset followed by fine-tuning on the smaller target dataset. Notably, both MAML and TL models exhibit competitive performance, with MAML excelling for the Norway shared charger dataset and TL performing exceptionally well for the ACN dataset as well as the Norway private charger dataset. MAML seems to perform

best when the target dataset closely matches the setting of the source dataset but this does not seem to matter too much for TL. In this work, the Colorado dataset was the only dataset used for pre-training and the data is obtained from shared chargers dispersed in Colorado which is similar to the Norway shared charger dataset with data from shared chargers in Trondheim. Achieving an optimal balance between private and shared charging data during pre-training may be necessary to enhance forecasting metrics. Across all three evaluation metrics, both MAML and TL models consistently outperform traditional Deep Learning (DL) models. Classical Machine Learning (CML) models are clearly not adequate for the complexity of the task. It's worth noting that while the differences in scores are generally significant, there may be instances where DL models outperform specific MAML and TL configurations.

We also see that models tend to exhibit suboptimal performance during peak load periods, occasionally either overestimating or underestimating the peak values. However, most models display a higher level of accuracy in predicting periods of zero load except CML models. While CML models are able to understand the general trend, they predict the trend to continue even when there is no actual load. It is also worth noting that sometimes the models appear to perform well after a delay of one timestep when the load jumps from zero to a higher value. This suggests that the models are under-confident in predicting the starting edges of the peak periods.

A few variations of the models were tested before arriving at the final models. We tried pre-training the models for MAML and TL on the same timespan as the test data i.e. if the test data was October to November 2019 then we pre-trained the models of data only from August to September 2019. The results were poor compared to the results discussed above. Additionally, multiple variations of the models were tested by tuning various hyperparameters before settling on the model architectures utilized for forecasting.

4.1 Future research

The addition of more diverse data in the source dataset for pre-training can potentially improve forecasting accuracy. Another avenue worth exploring is the possibility of predicting individual user-specific charging loads rather than aggregate loads with aggregate load pre-training, potentially protecting privacy and enhancing forecasting precision. Additionally, the adoption of ensemble models (combination of TL and MAML) could be investigated as a means to further improve forecasting metrics.

In the realm of medium and heavy-duty electric vehicles EVs, MAML and TL find valuable applications beyond forecasting aggregate loads. They prove beneficial for predictive maintenance, onboard diagnostics, and adapting to various routes, drivers, and weather conditions. Predictive maintenance models have the capacity to adjust to the unique usage patterns and wear and tear experienced by each individual truck. MAML aids in the generation of optimal driving decisions, facilitating rapid adaptation to diverse driving conditions, routes, and cargo loads.

Mandates in specific regions, such as California, may offer access to extensive early-stage data, which can be harnessed for pre-training. Subsequently, these

models can undergo fine-tuning for future adopters. This process contributes to the planning of advanced high-power charging infrastructure and enhances driving and energy efficiency.

Abstract

This work reports the synthesis of blue-emitting graphene quantum dots (GQDs) with an average diameter of 3.8 ± 0.5 nm from paddy straw, a sustainable biomass resource, via hydrothermal synthesis. These GQDs demonstrate excellent performance in bilirubin (BR) detection. The GQD photoluminescence (PL) intensity exhibits a proportional decrease with increasing BR concentration, indicating efficient quenching. The limit of detection for BR reaches a low value of 87.9 nM, highlighting the high sensitivity and selectivity of the GQD-based sensor. The observed quenching likely arises from a combined mechanism involving static quenching due to GQD-BR complex formation, inner filter effect (IFE), and Förster resonance energy transfer facilitated by spectral overlap.

Keywords Biomass waste · Paddy straw · Graphene quantum dots · Bilirubin · Forster resonance energy transfer

Introduction

Carbon nanostructures have collected all important attention repaid to their striking mechanical vigorous, electrically conductive abilities, and noteworthy chemical and thermal qualities [1]. In particular, graphene, known as the principal form of carbon graphite, contains only one layer of carbon atoms joined together by coinciding sp^2 hybrid bonds [2]. Unlikely graphene, GQDs are non-zero band gap materials [3] that exhibit their strong quantum confinement [4] and edge effects [5]; for this reason, GQDs possess remarkable optical and electrical properties. They serve important properties such as strong water solubility, low cost, stable photoluminescence (PL), tunable bandgap, good compatibility, and low toxicity [6–8]. GQDs possess their unique inner structure and surface chemical groups [9]. GQDs normally have features that drop below a diameter of 20 nm [10]. Because of its small size, GQDs carry a declaration for biomedical applications in comparison with graphene or graphene oxide (GO) [11, 12].

Biomass waste, described from its green, affordable, abundant, easily accessible, and carbon-rich nature, introduces a promising option as a precursor for creating GQDs. The management and renewal of biomass waste presents an important confrontation in today's world. The effective use of biomass waste not only helps in reusable obstacles but also gives a low-budget source for GQDs synthesis. This plan considered using biomass waste as a low-budget and sustainable precursor [13]. Rice is one of the highest-expanded crops globally [14]; however, agricultural waste for example paddy straw is a usual agricultural residue that consists of generous carbon content because of the existence of cellulose and lignin [15]. The maximum paddy straw manufactured is currently inclined through open field burning. This procedure leads to air pollution, energy wastage, and the occupation of landfill areas [16]. Constructively modifying paddy straw biomass waste into valuable products can capitulate essential economic and environmental benefits [17].

GQDs synthesis techniques are often divided into two distinct categories: top-down and bottom-up methods. Bottom-up techniques utilize detailed effective steps and particulate organic elements, imposing obstacles for optimizing circumstances [11]. On the other hand, top-down techniques include breaking down and separating easily available bulk graphene-based materials, like graphite, under the worst circumstances. These procedures typically consist of different steps involving strong oxidizing agents, concentrated

Published online: 28 June 2024

acids, and elevated temperatures [10]. Top-down techniques include sol–gel method [18], hydrothermal method [19], electrochemical exfoliation [20], chemical oxidation [21], nanolithography [22], microwave-assisted [23], and ultrasonic shearing [24]. The PL can be readily monitored by simply altering the dimension and surface chemistry of GQDs. GQDs originated from paddy straw that can be dispersed in water with strong PL and excellent biocompatibility, presenting better capability for use in biological and medical fields [24]. GQDs have been employed to detect BR, which is a yellow pigment with a structural formula, as shown in Fig. 1, produced during the instinctive breakdown of red blood cells (RBCs) as part of the body's cleansing process [25]. It is an important component of bile, an essential digestive liquid the liver produces. Uplifted steps of unconjugated BR in the blood are important signs of many strict situations such as jaundice and hyperbilirubinemia [26, 27]. The ongoing analysis proves a hydrothermal method for synthesizing GQDs, engaging paddy straw as an economical raw material. The GQDs produced exhibit high and particular sensitivity to BR, making them potentially useful for BR detection purposes.

Experimental Sections

Materials

The agricultural waste of paddy straw was gathered from Pundri village in the Kaithal district of Haryana, India, and kept in dry conditions at room temperature to serve as a precursor for synthesizing GQDs. The analytes bilirubin, urea, uric acid, fructose, glucose, 7-azaindole (AI), ethylenediamine-tetra acetic acid (EDTA), and bis-(trimethylsilyl) acetamide (BSA) were all acquired from CDH chemicals.

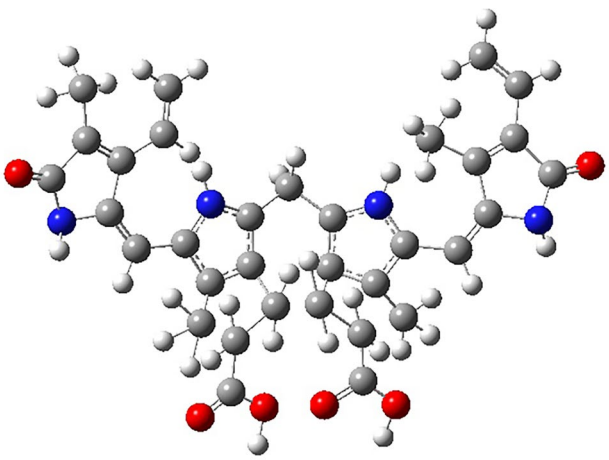

Fig. 1 Structure of bilirubin

Deionized water (DI) and hydrochloric acid (HCL) were utilized to prepare solutions for the analysis.

Preparation of Graphene Quantum Dots from Paddy Straw

A specimen of paddy straw weighing 2.0 g was taken, washed thoroughly with DI water, dried, and then ground into fine powder using mechanical crushing. Subsequently, the powder was heated at 50 °C for 3 h after being washed with 0.15 M HCl. Further, in 25 mL of water, 150 mg of crushed paddy straw was mixed and then placed in an oven for 7 h in a Teflon-lined autoclave at 160 °C. After cooling, the solution was filtered with a pore size of filter to be 11 µM, and additionally, the GQDs were further purified by centrifugation at 8000 rpm for 15 min, which separates them from any bigger precursor materials, byproducts, or contaminants that might be penetrated through the filter paper. This byproduct was gathered at the tube's bottom as precipitation in the form of silica. We collected the supernatant and used it for the experiment. Precipitates were thrown away. Figure 2 depicts a schematic illustration of the GQD preparation procedure.

Characterization

UV–vis spectroscopy experiments were used to analyze and study absorption spectra using a dual–beam UV/VIS/NIR spectrometer (Lambda 750, Perkin Elmer, USA) [28]. For the samples, a quartz cuvette with optical path of 10 mm was used. The Fluorolog-3 spectrofluorometer (Horiba Jobin Yvon) was utilized to record PL and PL-excitation measurements, which was configured with a photomultiplier tube (PMT), 450W Xenon, and flash lamps. Using Bruker D8 advance which is equipped with a Cu (K_α) radiation source with an accelerating voltage of 40 kV and 20 mA current, X-ray diffraction (XRD) patterns were obtained [1]. Fourier-transform infrared spectroscopy (FT-IR) was used to obtain the spectra under the frequency range 500–4000 cm^{-1} using Perkin Elmer, FTIR spectrometers. High-resolution images of the GQDs were taken by transmission electron microscopy (TEM) with an accelerating voltage of 200 kV using TALOS thermos-scientific instruments.

Results and Discussion

Structural, Morphological, and Optical Characteristics of GQDs

The XRD was utilized to study the structural property. Figure 3 displays the peak at 25.4°, which corresponds to the (002) diffraction plane in the XRD of GQDs [1, 29]. The

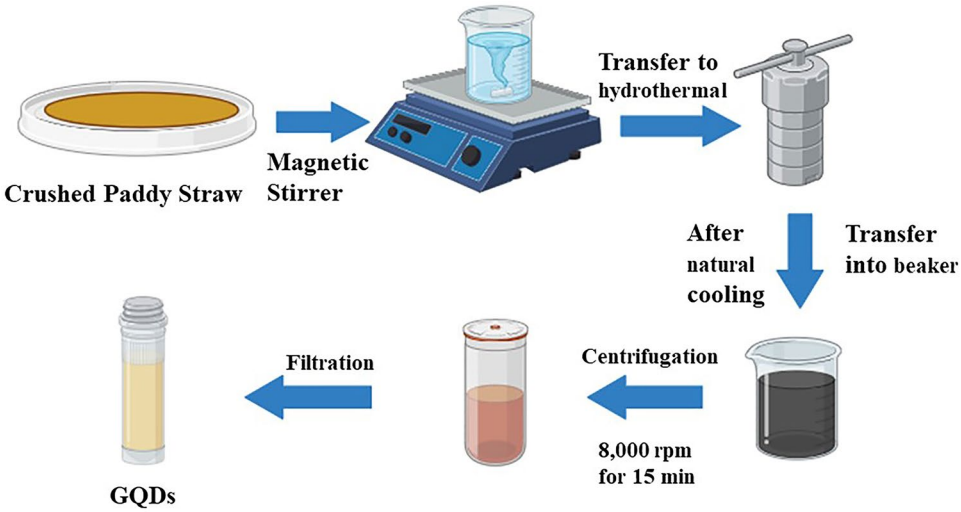

Fig. 2 Schematic representation preparation of GQDs

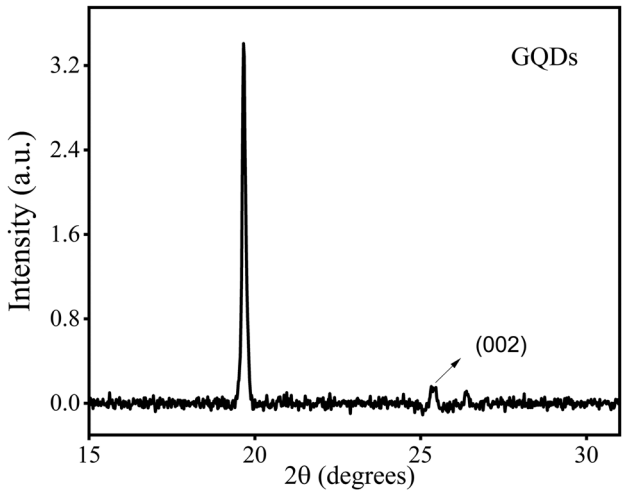

Fig. 3 XRD pattern of GQDs

highest peak in the figure may indicate the existence of residual silica ions [30, 31]. This silica may come from the sediment remaining at the bottom of the centrifuge [32].

The fabricated GQDs were also analyzed through TEM, as illustrated in Fig. 4a. To prepare the sample, drop the sample solution onto a grid of copper and then allow it to dry at room temperature. The size distribution of the GQDs, which is 3.8 ± 0.5 nm is illustrated in Fig. 4b. The observed spherical particles are fairly polydispersed.

Figure 5 depicts the FTIR spectrum of GQDs, where a wide band at 3318 cm^{-1} is assigned to the stretching vibrations of amine (N–H) and hydroxyl (–OH) groups [33]. The presence of OH and C–H linkages is revealed by the peak observed at 2112 cm^{-1}. The stretching vibrations of C–O and aromatic rings C = C, which correspond to epoxy and ether groups, respectively, are responsible for the observed peaks at 1639 and 1103 cm^{-1} [13]. Because of the abundance of oxygen-bearing functional groups, GQDs are allowed to remain stably suspended and effortlessly disperse in water.

The optical parameters of GQDs were examined using a steady-state spectroscopic technique. The UV–vis absorption

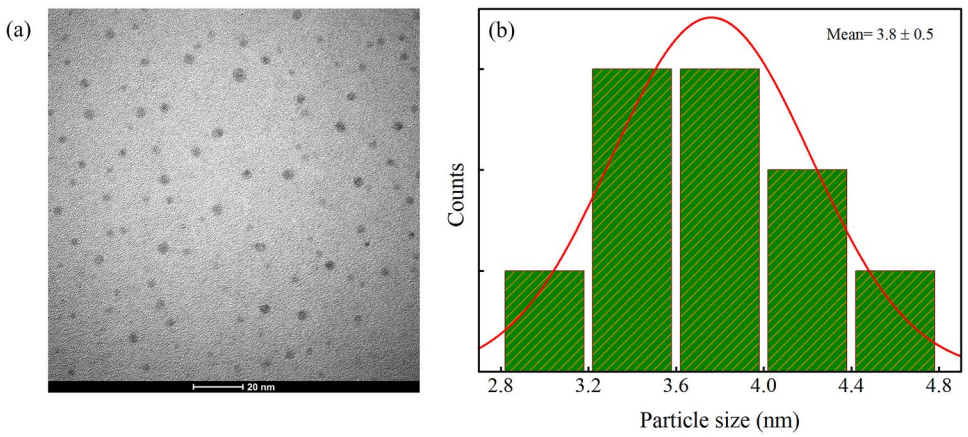

Fig. 4 TEM images (**a**) and size distribution (**b**) of GQDs

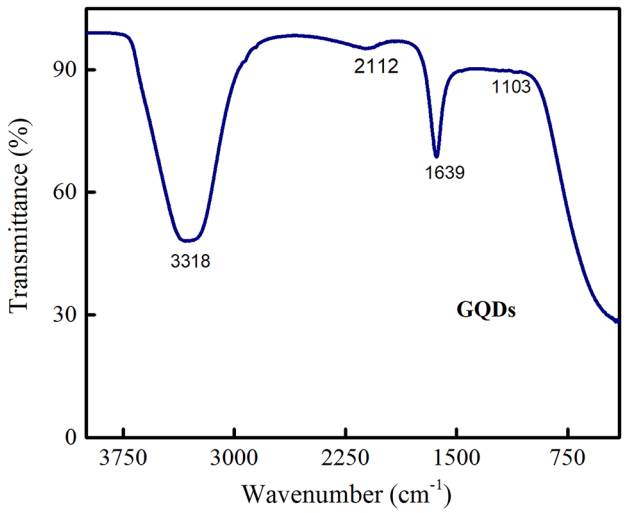

Fig. 5 FT-IR spectrum of GQDs

spectrum of GQDs is illustrated in Fig. 6a, showing a prominent absorption peak in the UV region at around 278 nm. The intense and sharp peak of absorption below 300 nm exhibits the π-π* transitions of the C = C aromatic bonds, indicating the involvement of sp^2 hybridization domains. Also, the functionalized oxygen group on the surface of GQDs generates an absorption associated with the n-π* transition of the C = O bonds, which is observable in the region of 290–320 nm [28]. From the absorption spectrum, the optical bandgap of the GQDs was determined by using a Tauc plot [34], which illustrates the relationship between $(\alpha h\nu)^{1/\gamma}$ vs. photon energy $h\nu$. The γ factor, which is reliant upon the nature of the material is ½ for direct and 2 for indirect bandgap materials, respectively [35]. Therefore, a direct bandgap of GQDs was estimated to be ~ 4.07 eV as illustrated in Fig. 6b. Upon stimulation at the excitation wavelength, the GQDs demonstrate intense PL.

The optical properties were further investigated, and photoluminescence (PL) spectra were studied across a wide range of excitation wavelengths. As illustrated in Fig. 7a, when excited at a wavelength of 370 nm, the PL spectrum exhibits a broad peak with maximum intensity at 450 nm and the position of the peak changes gradually with variations in excitation wavelengths (Fig. 7a, b). A large stokes shift is observed with excitation wavelengths [36]. The intensity of PL from the GQDs decreases as the excitation wavelength increases, resulting in a redshift. PL maximum shifted in response to variations in the excitation wavelength (Fig. 7b). The Stokes shift in wavelength offers a beneficial feature for utilizing GQDs in sensing applications [37–39]. Using quinine sulfate, which has a quantum yield (QY) of 54% as a reference, it was determined that the QY of GQDs was 3.5% using following equation.

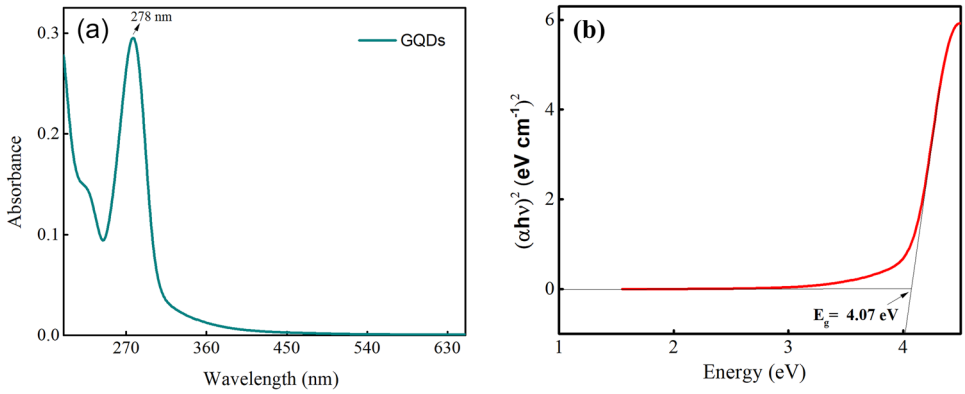

Fig. 6 UV–vis spectrum of GQDs (**a**) and Tauc plot for direct band gap GQDs (**b**)

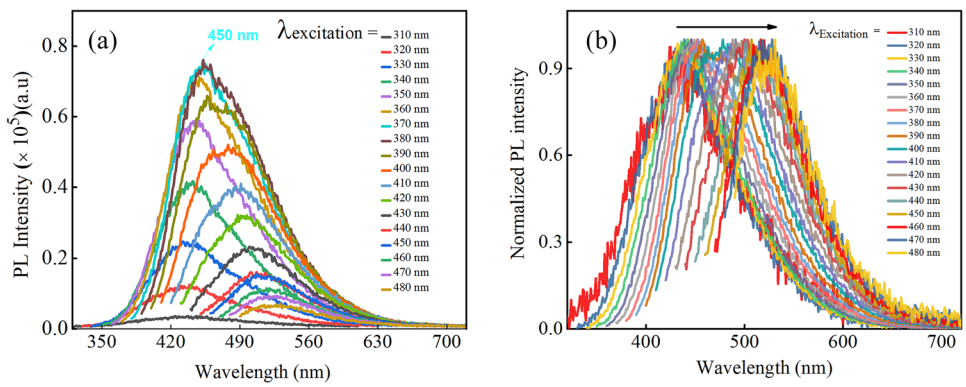

Fig. 7 Photoluminescence spectra at a range of excitation from 310 to 480 nm (**a**) and normalized PL spectra (**b**) of GQDs

$$QY_{sam} = QY_{ref}\left(\frac{PL_{sam}}{PL_{ref}}\right)\left(\frac{Abs_{ref}}{Abs_{sam}}\right)\left(\frac{\eta_{sam}}{\eta_{ref}}\right)^2$$

where QY_{ref} indicates the quantum yield of quinine sulfate (reference) and QY_{sam} indicates the quantum yield of GQDs. Abs indicates the absorbance of reference and GQDs, and the integrated areas of PL spectra are represented by PL_{sam} and PL_{ref} and η represent the refractive index of distilled water and sulfuric acid, which are used as the solvents in QDs and reference, respectively.

Sensing of Bilirubin

Preparation of Bilirubin Solution

A stock solution of bilirubin (1 mM) was prepared by dissolving the required quantity of bilirubin in water by adjusting the pH to 8 using a 1 M NaOH solution, as bilirubin does not dissolve in water, but it becomes soluble in an alkaline environment. A small portion was then taken from this stock solution, and the pH was adjusted accordingly for the experimental requirements using a 1 M HCl solution when needed. All experiments were conducted in low-light conditions.

Sensitivity and Selectivity of BR

Various concentrations of bilirubin were prepared in an ideal environment to analyze the sensing capabilities of GQDs. As illustrated in Fig. 8a, the absorption spectra of GQDs at different concentrations ranging from 0.0 to 115 µM were observed, with and without the presence of BR. Along with the absorption intensity at 278 nm, the band-edge absorption intensity at ~ 327 nm also increased. The intensity of the band-edge increased due to the n-π^* transition in GQDs. When the concentration of BR increases, the intensity of the absorption also increases and is nearly constant at the concentration of 115 µM and higher [40]. The increase in the absorption intensity indicates the interaction between GQDs and BR. This interaction might involve the formation of a stable complex due to bonding between the hydroxyl group of BR and functional groups of the GQDs in the ground state. Such complex formation between GQDs and BR potentially leads to enhanced absorption intensity at 278 nm without showing any extra peak of BR. To further strengthen the evidence for this interaction, the Benesi-Hildebrand (BH) method was employed [8]. The plot of $1/(A_0\text{-}A)$ vs. 1/conc. of BR, where A_0 represents the absorbance without BR and A represents the absorbance with BR in the range of 0–115 µM is quite linear with $R^2 = 0.99$, as depicted in the inset of Fig. 8a. The plot indicates the formation of a 1:1 complex between BR and GQDs. The calculated binding constant (K_b) is $5.15 \times 10^3\ M^{-1}$ [41]. The linear relation observed between the absorbance of GQDs and the concentration of BR signifies that GQDs can be utilized as a probe for the detection of BR.

Before bilirubin addition, the PL spectra exhibited a peak at 450 nm when excited with a wavelength of 370 nm. To analyze the PL, different concentrations of bilirubin were mixed with the GQDs solution and it has been acclaimed that if there is an increase in the concentration of bilirubin, the PL intensity of the GQDs is significantly reduced as shown in Fig. 8b. Gradually adding bilirubin aliquots led to a consistent decrease in peak intensity. At a bilirubin concentration of 115 µM, almost 90% of the intensity was quenched. While the findings suggest the formation of a ground-state complex between BR and GQDs (Fig. 9), it also leads to the quenching of GQDs PL intensity along with several possible mechanisms, such as non-fluorescent ground-state complex, inner filter effect (IFE), and Förster resonance energy transfer (FRET) [42]. The reduction in peak intensity corresponding to a specific bilirubin concentration was quantified using a Stern–Volmer (SV) plot that shows a relationship between the PL intensity ratio (I_0/I)-1 vs. bilirubin concentration, where I and I_0 represent the PL peak intensity in the presence and absence of bilirubin, respectively. Based on the plot analysis, a linear regression ($R^2 = 0.99$) was obtained within the range of 9.9–115 µM, as depicted in the inset of Fig. 8b.

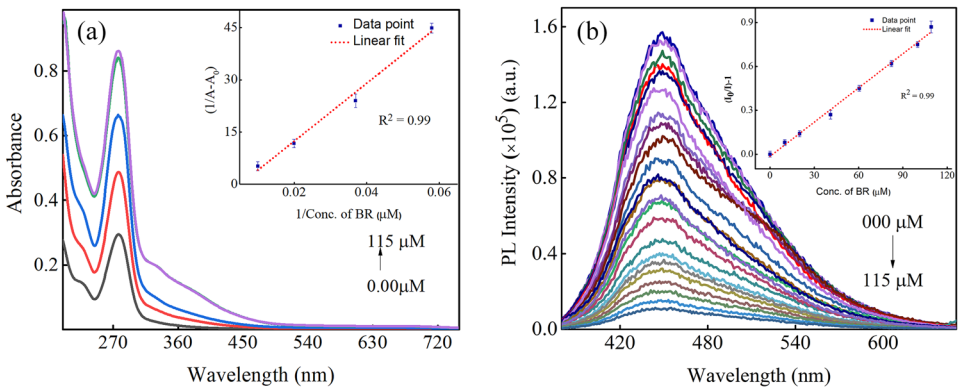

Fig. 8 Absorption spectra (**a**) and photoluminescence spectra (**b**) of GQDs in the absence and presence of multiple BR concentrations and inset of **a** represent BH plot and **b** the corresponding linear S-V plot

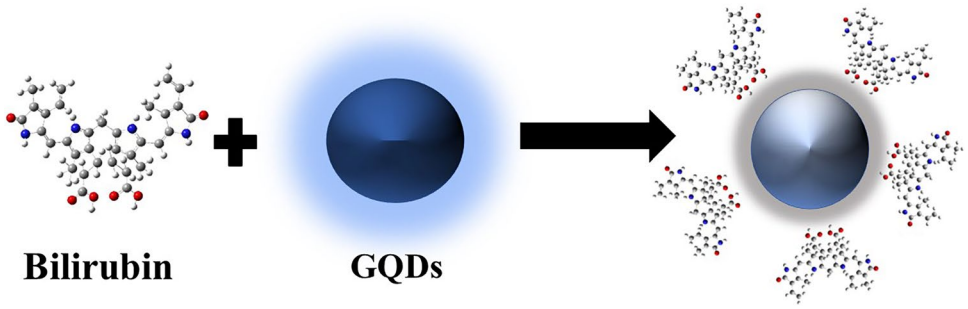

Fig. 9 Complex formation by the interaction of GQDs with BR

A linear relation indicates possibly a static quenching process involving a single kind of binding site or a possible collisional quenching mechanism. Thus, the linear SV and BH plots support predominantly the static quenching. The calculated value of K_{sv} from the S-V plot was determined to be 7.79×10^3 M^{-1}, suggesting that GQDs have significant potential for detecting bilirubin with high sensitivity. The estimated value of the limit of detection (LOD) was determined to be 87.9 nM.

As shown in Fig. 10a, the spectral overlap between the PL spectrum of GQDs as donor and the absorption spectrum of BR as acceptor indicates the chances of FRET mechanism [43]. As the PL spectrum of GQDs significantly overlaps with the absorption spectrum of BR, there is a possibility of energy transfer from excited GQDs to bilirubin molecules through FRET. The energy transfer would decrease the PL intensity of GQDs. By using an equation $J(\lambda) = \int_{\infty}^{0} F_D(\lambda)\varepsilon_A(\lambda)\lambda^4 d\lambda$, the spectral overlap integral, denoted by $J(\lambda)$, is determined. The value of $J(\lambda)$ is calculated to be $9.015 \times 10^{17} nm^4 M^{-1} cm^{-1}$ where $F_D(\lambda)$ and $\varepsilon_A(\lambda)$ represent the donor fluorescence intensity and acceptor's extinction coefficient at λ, respectively, as discussed in SI1 of supporting information (SI). Blue-emitting GQDs could detect bilirubin with the result of some parameters such as strong PL, high sensitivity, and selectivity of GQDs towards bilirubin. GQDs feature hydroxyl (–OH), epoxy, and carboxyl groups among other functional groups on their surface. These functional group interacts with the hydroxyl group of bilirubin, potentially leading to the observed quenching of GQDs PL intensity with increasing concentration of BR [43]. The PL-based sensor's ability to selectivity detect bilirubin was assessed by testing it with various biomolecules commonly encountered in biochemical engineering, including urea, uric acid, ascorbic acid, 7AI, glucose, fructose, EDTA, and BSA. Figure S1 of SI shows the absorption spectra of GQDs in the presence of BR and other biomolecules. Then, it was cleared that BR selectively quenched the PL of GQDs, whereas other biomolecules used for testing were not able to quench, as shown in Fig. 10b. These biomolecules have the potential to interfere with the specific detection of bilirubin in the biomedical field. Figure 11 shows the stability of GQDs by comparing the PL intensity as a function of months.

Conclusion

Water-dispersible GQDs with an average diameter of 3.8 ± 0.5 nm were developed from paddy straw using a hydrothermal synthesis technique. The GQDs are showing bright blue photoluminescence under 365 nm irradiation and achieve the strongest PL intensity at the 450 nm band with 370 nm excitation. The PL of GQDs was strongly quenched by the presence of bilirubin following the formation of a non-fluorescent ground-state complex (static quenching), inner filter effect (IFE), and Förster resonance energy transfer (FRET) as a quenching mechanism. The GQDs demonstrated high selectivity and sensitivity in detecting bilirubin.

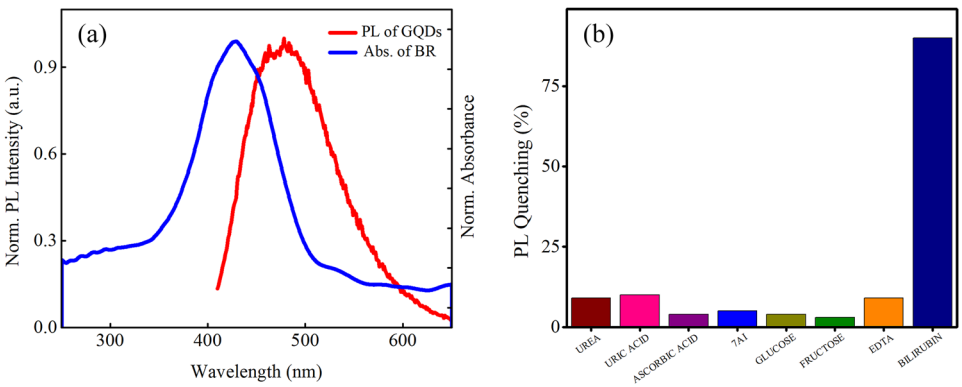

Fig. 10 Overlapped normalized absorption spectrum of BR and PL spectrum of GQDs (**a**) and a bar diagram of PL intensity of GQDs with BR and various other analogous analytes (**b**)

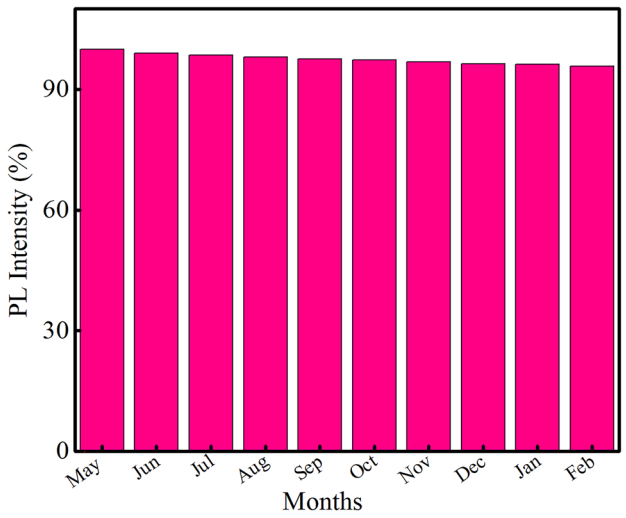

Fig. 11 PL intensity (%) of GQDs over a period of months, showing stability/photostability of GQDs

The large value of K_{sv}. i.e., 7.79×10^3 M^{-1} indicates their potential for sensitive bilirubin detection with a limit of detection (LOD) of 87.9 nM. A calibration plot for GQDs PL quenching by bilirubin showed a linear range between 9.9 and 115 µM.

Abstract Software vulnerabilities reported every year increase exponentially, leading to the exploitation of software systems. Hence, when a vulnerability is reported, a requirement arises to patch it as early as possible. Generally, this process requires some time and effort. For proper channelizing of the efforts, a requirement comes to predict the severity of the vulnerability so that the more critical ones can be given a higher priority. Therefore, a need arises to build a model that can analyze the data available on vulnerabilities and predict their severity. The experiment of this study is conducted on vulnerability reports of five software of Mozilla. As the data is textual, text mining techniques are applied to preprocess the data and form feature vectors. This input as text creates very high dimensional feature vectors leading to the requirement of dimensionality reduction. Hence, feature selection is done using chi-square and information gain. To develop the classifier, seven machine learning algorithms are chosen. Hence, fourteen software vulnerability severity prediction models (SVSPM) are developed. The result analysis allowed us to find the best-performing SVSPM. It is concluded that the model performed better for the medium and the critical severity level of the vulnerability. Out of the two feature selection techniques, information gain gave better results. An optimum number of features is also determined at which SVSPM gave good results. The best SVSPM using a machine learning algorithm corresponding to each dataset is found as well. A comparison is also made to identify significant differences among various SVSPMs developed using Friedman and Wilcoxon Signed Rank test.

Keywords Text mining · Vulnerability severity level · Feature selection · Prediction model · Machine learning

1 Introduction

A software vulnerability is defined as a weakness that attackers can exploit to intrude into a software system (Alves et al. 2016). The presence or absence of vulnerability in a software system greatly determines the quality of the software system (Erturk and Akcapinar 2015). With an increase in complexity and diversity in a software system, it is impossible to develop error-free software. Thus, taking care of the security aspect of a software system has become the utmost priority for any software developer (McGraw 2006; Furnell 2009; Violettas et al. 2013). The number of software vulnerabilities reported increases exponentially (Younan 2013; Coulter et al. 2020), and once a vulnerability is reported, its chances of getting exploited increase catastrophically (Bilge and Dumitra 2012). Therefore, developing a software vulnerability severity prediction model (SVSPM) is essential. It will automate the process of predicting the severity of software vulnerability. This helps speed up the process of prioritizing the vulnerabilities so that more severe ones can be fixed first. For the assessment of a software vulnerability, various types of vulnerability scoring frameworks (Microsoft 2022; US-CERT 2006; Sans 2022) are proposed. Among these frameworks, the common vulnerability scoring system (CVSS) (FIRST 2007) by the Forum of Incident Response and Security Teams (FIRST) is considered to be a standard framework to measure the severity of software vulnerabilities. Once a vulnerability is discovered, it is

Published online: 31 May 2024

documented in the common vulnerabilities and exposures (CVE) database (Mitre 2022) which is an example of a vulnerability database. This database has vulnerability reports containing vulnerability descriptions, which are textual data.

When textual data is used as input, high-dimensional features are likely to be developed. High-dimensional data suffer from data quality problems that degrade the model's performance and increase computational cost. It is also estimated that 80–85% of the data is unstructured (Blumberg and Atre 2003; Grimes 2008). Mining such types of data is a challenge as it has various problems such as the data being unlabeled, vague, and noisy. To mitigate these problems, feature selection (FS) techniques can be applied, which help eliminate irrelevant and duplicate features and find the optimal subset that holds the maximum information, improving the performance of the model (Liu et al. 2010). Previous research in this field indicates that if FS techniques are not applied, the prediction model's performance will be degraded (Wang et al. 2019a, b; Russell et al. 2018; Gupta et al. 2015; Khazaei et al. 2016). Hence, the FS process is considered a vital aspect of the prediction process. FS techniques are broadly categorized into two techniques (1) Filter, and (2) Wrapper techniques. Researchers widely use filter techniques because of their simplicity and speed. Moreover, the result of the classifier technique does not get biased because of filter techniques. Therefore, in this study, we decided to opt for information gain (IG) and chi-square (CHI-2) FS techniques which come under filter FS techniques. Classifier is developed using machine learning (ML) algorithms. Although this idea is not new, most of the existing works are focused on security vulnerability prediction based on various derived features of the source code (Theisen and Williams 2020). As opposed to these, we propose an approach that relies on textual analysis.

The framework proposed in this study takes vulnerability reports of various software of Mozilla. These are Mozilla Firefox, Mozilla Thunderbird, Mozilla Seamonkey, Mozilla Firefox ESR, and Mozilla Thunderbird ESR. Among text mining techniques, tokenization, stop word removal, and stemming are applied to the vulnerability reports for data preprocessing. Further used bag-of-words, term frequency-inverse document frequency (TF/IDF) for the formation of feature vector and weighing terms in that feature vector, respectively. TF/IDF is a statistical technique applied most commonly in text mining (Huang et al. 2019). All these techniques convert text into numeric data. As high-dimensional feature vectors are generated, removing the curse of dimensionality becomes important. Therefore, after the formation of the feature vector, two FS filter techniques are used (IG and CHI-2) which act as fast feature selector (FFS). For the development of classifier, among ML algorithm, Bagging algorithm, Boosting algorithm, decision tree (DT), multinomial Naïve Bayes (MNB), Naïve Bayes (NB), random forest (RF), and support vector machine (SVM) are used. The selection of ML algorithms is done in such a way that we can include basic as well as more powerful ML algorithms (Sagi and Rokach 2018). Hence, fourteen models are developed using one FS technique out of two and one ML algorithm out of seven. Here, we would like to mention that the purpose of our study is not to do any comparative analysis of various text mining methodologies. We selected to work with those algorithms that are widely accepted, popularly used in the literature, and suited for our research problem.

To evaluate the performance of the SVSPM developed, AUC values are used as a performance parameter across five Mozilla datasets. The values of AUC are recorded for all four levels of severity. It is considered a good choice among various other parameters as it finds a balance between specificity and sensitivity values. Moreover, it is considered to be a nice option when dealing with imbalanced data problems (He and Garcia 2009). Statistical testing is also applied to the result values obtained to find a significant difference among various experimental scenarios, judging the effectiveness of the proposed modules for FS which is explained in detail below in this paper.

The main contribution of this study is listed as follows:

1. This paper demonstrates the significance of FS techniques, by gauging the performance of the models at different numbers of features (5, 25, 50, 100) and thus finding an optimum number of features at which the performance is maximum. Also, the effect of different levels of severity on the performance of the model is evaluated and their inference is discussed further.
2. To evaluate the effectiveness of the model developed, various experiments are conducted which help in indicating which FS technique and ML algorithm gave the best performing model.
3. Comparison is done using statistical analyses to determine if the performance of the different models differs significantly or not.

The experiments conducted in this study aimed to find the answers to the following Research Questions (RQs):

RQ1: What is the predictive capability of the SVSPM developed in this study?
AUC is used to measure the effectiveness of SVSPM. According to the values of AUC, the performance of SVSPM is analyzed.
RQ2: Does the performance of SVSPM change with a change in FS technique?
This question tries to compare the results obtained by all the SVSPM and find a conclusion about the performance of the FS technique, stating among the two which performed better.

RQ3: At which level of severity of the vulnerability, the best results are produced?
To answer this question, the results obtained are analyzed severity level-wise. The answer helps in interpreting results to conclude which level gave the highest values of the performance measures.
RQ4: Which ML algorithm works best at a particular severity level among all the ML algorithms used?
In this question, a detailed analysis of the results is done so that the name of the best ML algorithms for a particular severity level can be deduced.
RQ5: What should be the appropriate number of terms selected by the FS technique to obtain the best results?
The answer to this RQ helps in investigating the two FS techniques separately and analyzes their performance based on the selection of Top-N terms. In this study value of N is taken to be 5, 25, 50, and 100.
RQ6: Whether the performance of different SVSPMs differs significantly or not?
This RQ helps us determine the significant difference among various SVSPMs with the help of the Friedman Test and Wilcoxon Signed Rank Test.

The rest of this article is organized as follows: The related work is summarized in the next section. Section 3 lists all the preliminaries used to carry out the experiment of the paper. In Sect. 4, the proposed framework is illustrated. In Sect. 5, RQs are answered, and the results are interpreted. Threats to vulnerability are disseminated in Sect. 6. Finally, a conclusion is drawn and future work is identified in Sect. 7.

2 Related work

The key focus of this paper is on vulnerability severity prediction (i.e., predicting severity levels of vulnerabilities), rather than vulnerability prediction (i.e., classifying whether the current artifact is vulnerable or not). Therefore, in this section, previous work done in the literature matching the scope of the paper is discussed.

Han et al. (2017) implemented four baseline models and compared their performances with their proposed models. Term frequency/inverse document frequency+support vector machine (TF/IDF+SVM), word embeddings+SVM, word embedding+2-layer convolution neural network (CNN), and word embedding+CNN with long short term memory (LSTM), these four combinations are used for implementing four baseline models. The proposed approach uses word embedding+1-layer CNN combination. This combination of word embedding+1-layer CNN gave the best results with mean precision, recall, and f1-measure as 0.818, 0.815, and 0.816, respectively.

Spanos and Angelis (2018) worked on the multi-target classification of vulnerabilities. Among RF, Boosting, and DT, RF gave good results. The author specifically cited that for some vulnerability characteristics like access vector and access complexity, the results are not so good, requiring more research.

Liu et al. (2019) used CNN, LSTM, TextRCNN, and extreme gradient boosting (XGB) to develop the models. The first three technologies are the deep neural network, and the last is an ML algorithm. Results reported by the author showed that TextRCNN gave the best performance with a classification accuracy of 93.95%.

Sahin and Tosun (2019) used word embedding for feature extraction and CNN, LSTM, and XGBoost for prediction model development. Results are documented for all four levels of vulnerability, and their mean is calculated. According to the mean values, LSTM gave the best performance with a value of 0.759, 0.761, and 0.756 for precision, recall, and f1-score, respectively.

Le et al. (2019) also aimed at predicting seven vulnerability characteristics using just vulnerability descriptions. Out of seven characteristics, four are predicted well by the model developed using the light gradient boosting machine (LGBM). The model developed using XGB performed best for the other two characteristics and the logistic regression (LR) Model for the remaining one.

Wang et al. (2019a, b) used principal component analysis (PCA) on the textual description of vulnerabilities for feature extraction. SVM, LR, RF, and XGB are used for model development. Among these, the model developed using XGBoost gave the best accuracy results, which is above 90%.

The research done by Chen et al. (2020) on ten datasets having textual data on vulnerabilities. ML algorithms, namely RF, K-nearest neighbours (KNN), DT, NB, and SVM are used to build the proposed classification vulnerability model. Before applying ML algorithms, term weighing, and feature selection is done. Two techniques, TF/IDF and term frequency/inverse gravity model (TF/IGM), are used for term weighing. TF/IDF is one of the most popular and conventional methods of term weighing. On the other hand, TF/IGM is the technique proposed in this study. IG is used for FS. The result stated in the paper proves that TF/IGM is a better technique for term weighting than TF/IDF. Also, FS helps in improving the efficiency of the vulnerability classification model.

Kudjo et al. (2020) did a Bellwether analysis, which means selecting a subset of data to be treated as training data giving better performance. Deep neural networks, LR, KNN, and RF are used for model development. The results show that the Bellwether approach achieves an F-measure ranging from 14.3 to 97.8%, improving the benchmark techniques.

Babalau et al. (2021), Sharma et al. (2020), and Ni et al. (2022) also used word embedding and CNN to develop the prediction model. The experiment is conducted on different datasets, and accuracy is recorded. Ni et al. (2022) did a comparison with Sharma et al. (2020) and Han et al. (2017) and proved that his approach using bidirectional encoder representations from transformers (BERT) with CNN gave the best results.

Okutan and Mirakhorli (2022) also used CNN to build the prediction model. In this paper, the results are recorded for high and medium level of severity only.

Kekul et al. (2022) demonstrated the use of various techniques for converting text to vectors. Bag of Words (BoW), TF-IDF, 2Ngram under statistical techniques and Word2Vec, Doc2Vec, FastText under word embedding techniques. NB, DT, KNN, MLP, and RFC are used for classification.

Kudjo et al. (2023) introduced the use of the Normalized Difference Measure in this domain which was originally introduced by Rehman et al. (2017) for text classification. Five ML algorithms, namely, NB, MNB, SVM, K-NN, and DT are used for developing prediction models.

Li et al. (2023) used pre-trained language models (PLMs) such as BERT and RoBERTa as word embedding technique which is also capable of better extracting the semantic information of the text.

Mehta et al. (2023) used latent semantic indexing (LSI), latent Dirichlet allocation (LDiA), and (non-negative matrix factorization) NMF for topic modeling and LR, LDA, KNN, DT, (artificial neural network) ANN, NB, LSVM, SVM, RF, and Gaussian Naïve Bayes (GNB) for developing the classifier.

Analyzing the literature, it can be concluded that apart from ML algorithms, the use of deep learning algorithms not just for developing classifiers but also for word embeddings has given better-performing prediction models (Han et al. 2017; Sharma et al. 2020; Babalau et al. 2021; Ni et al. 2022; Kekul et al. 2022; Li et al. 2023; Mehta et al. 2023). The use of word embedding advances over traditional methods because word embedding methods also consider the semantic information of the text. Spanos and Angelis (2018) and Le et al. (2019) worked on a different objective. The prediction model developed not only predicted the severity but also predicted other features of the vulnerability report such as access vector, integrity impact, confidentiality impact, etc. Chen et al. focused on developing a new methodology for data normalization and named it TF/IGM. Unlike other studies, Şahin and Tosun (2019) and Ni et al. (2022) recorded the results for all four levels of severity of vulnerability. Wang et al. (2019a, b) recorded the performance for a different number of features to observe their influence on the performance of the prediction model.

In our study, various RQs are framed such that a comprehensive analysis can be performed on the results of the experiments conducted. The results are recorded and tabulated for different numbers of features distinctively so that the significance of FS techniques can be gauged clearly. Graphs are also framed for a better interpretation of these results. Apart from this, as results are recorded for all four levels of severity, it gave us an opportunity to do result interpretation level-wise that which level gave the best/poor performance and why. In a nutshell, it can be said that our result analysis analyzed the effect of every experimental setting on the performance of the prediction model, regarding the choice of FS technique, ML algorithm, number of features, and effect of level of severity allowing researchers to design their model carefully taking care of every experimental setting.

3 Preliminaries

This section of the paper has described the dataset, techniques, and tests used to develop the model.

3.1 Data collection

To carry out this study, we collected security vulnerabilities of six different software of Mozilla. Mozilla Firefox, Mozilla Thunderbird, Mozilla Seamonkey, Mozilla Firefox ESR, Mozilla Thunderbird ESR, and Mozilla Firefox OS from 'CVE Details,' which is a publicly available data source. After data collection, it is found that only fourteen vulnerabilities are present in Mozilla Firefox OS. As it is a very small number, therefore we have worked on the vulnerability of the remaining five datasets. The vulnerability report contained information such as ID, publish date, update date, vulnerability type, access, complexity, etc. However, we concentrated only on vulnerability description and CVSS score to conduct our experiment. Further details of the dataset are elaborated in Table 1.

CVSS is a scoring system formulated to rate vulnerabilities in the range of 0–10 (Zerkane et al. 2017). According to the most recent version of CVSS, v3.0, 'None' rating is for vulnerabilities with a 0.0 score, 'Low' severity rating is for vulnerabilities with a score of 0.1–3.9, 'Medium' rating is for vulnerabilities with a score of 4–6.9, 'High' rating is for

Table 1 Details of dataset used severity level wise

Data source	Low	Medium	High	Critical
Mozilla Firefox	164	897	296	516
Mozilla Thunderbird	22	372	164	363
Mozilla Seamonkey	13	291	61	333
Mozilla Firefox ESR	10	284	175	203
Mozilla Thunderbird ESR	1	69	15	131

vulnerabilities with a score of 7–8.9, 'Critical' rating is for vulnerabilities with a score 9–10.

3.2 Feature selection and machine learning algorithm

FS techniques are used to do dimensionality reduction. It helps reduce what is generally referred to as the 'curse' of dimensionality. This is done by selecting a subset of features and removing the features that are found to be irrelevant from the entire set. Those features which do not contribute in finding the prediction variable or the output are known as irrelevant features.

To check whether there is a dependency between feature t and category c, the researchers uses the CHI-2 (Yiming and Pederson 1997) statistical test. Ideally, it is assumed that there is no relation between feature t and category c, and both are independent of each other. If this ideal case is true, we cannot use feature t to find if the text belongs to category c. The CHI-2 test is used to describe its relevance. The value of CHI-2 is calculated according to the Eq. (1) listed below.

$$CHI\left(t_i, c_j\right) = \frac{N * (ps - qr)^2}{(p+q) * (q+r) * (r+s) * (s+p)} \tag{1}$$

In Eq. (1), N represents the total number of vulnerabilities, p represents vulnerabilities having t_i term of c_j category, q represents vulnerabilities having t_i term but not of c_j category, r represents vulnerabilities not having t_i term but of c_j category and s represents vulnerabilities neither having t_i term nor of c_j category. Hence, finally, Eq. (1) gives the CHI-2 score of term t_i and category c_j.

The term t_i is concluded to have higher significance if the chi-square value is also considerable.

According to the above stated formula, the CHI-2 score is calculated for all the terms and the top n terms having the highest score are selected after dimension reduction.

IG is the second technique used for dimensionality reduction. Menzies and Marcus (2008) in their paper found out those words that best simplify the target concept. Its concept is based on entropy. The amount of information gained from feature A given the class label as C is calculated by the following formula:

$$Infogain\left(\frac{C}{A}\right) = \mathrm{H(C)} - \mathrm{H(C/A)} \tag{2}$$

In the formula stated above, H(C) is the entropy of the class label; C and H(C/A) are the conditional entropy of C given A.

Like CHI-2, top n terms with the highest IG scores are selected after dimensionality reduction.

Among ML algorithms, the Bagging algorithm, Boosting algorithm, DT, MNB, NB, RF, and SVM are used in this study. A brief description of these algorithms can be found in Kumar and Srinivas (2021).

3.3 Statistical test selection

Hypothesis testing is done and verified using various statistical tests (Malhotra 2016). These statistical tests can be categorized as parametric and non-parametric tests. When the data samples follow specific properties, like following normal distribution, then parametric tests can be applied; else non-parametric tests will be applied. This is one way of categorizing the techniques. The other is if it is required to apply the test on two or more than two samples that are dependent or independent of each other. According to all these selection criteria, a statistical test is selected suitable for any research.

One-way ANOVA, Kruskal–Wallis, T-test, Mann Whitney U, Fridman, Paired t-test, and Wilcoxon signed-rank are some of the statistical tests. As we are dealing with more than two samples which not necessarily follow the normal distribution, the Friedman Test and Wilcoxon Signed Rank Test are found to be appropriate statistical tests for our data set.

3.4 Performance evaluation

Performance evaluation is necessary to judge the prediction power of the model developed. A confusion matrix and other parameters derived from its elements are used to do so. It is made up of four essential components, namely true positives (tp), true negatives (tn), false positives (fp), and false negatives (fn).

Other measures for performance evaluation, such as AUC, sensitivity, specificity, accuracy, etc., can be derived using this confusion matrix and its components. One thing to underline here is that the research problem we are dealing with is a multiclass classification problem. Therefore, instead of a simple confusion matrix, the confusion matrix for multiclass looks something like depicted in Fig. 1. It shows the structure of the confusion matrix if we have three classes, C1, C2, and C3, to predict.

In this study, we used AUC as the performance measure to evaluate the effectiveness of our experiment conducted. AUC plots sensitivity values on the x-axis and specificity values on the y-axis. It is used to measure the accuracy of a model, and the value lies between 0 and 1. If the AUC value is considerable and reaches near to 1, then the prediction model is considered to have good performance. AUC as a performance measure is a popular choice among researchers as it finds a balance between both specificity and sensitivity values. Moreover, it is considered to be a good choice when dealing with imbalanced data problem (He and Garcia 2009).

4 Research methodology

The methodology followed in this study is discussed in this section. The proposed approach is depicted in Fig. 2. It involves various steps, which are elaborated below:

1. In Step 1, data is extracted, and a CSV file is formed targeting the required fields from the vulnerability reports. As five different software of Mozilla are taken into account, five different CSV files are formed. The required fields include a description of the vulnerability and the CVSS score.
2. Step 2 aims at converting the unstructured data regarding vulnerability into a structured form using various text mining techniques so that the prediction can be made further with the application of a ML algorithm.

To achieve this, data preprocessing steps are applied to the textual description of the vulnerabilities (Vijayarani et al. 2015). Tokenization, stop-word removal, and stemming are the steps involved in doing data preprocessing. Tokenization is a process of finding tokens from the text by doing its separation into words where every word is considered to be a token. After tokenization, stop word removal is done to remove all the little words from the text, allowing us to focus on essential and valuable words which contain the actual information. 'Is,' 'the,' and 'for' are some examples of stop words in the English language. In this study, we have used a default list of stop words present in python's NLTK package. Finally, stemming is performed, which is the last step of data preprocessing. Applying stemming reduces the words to their root form. For example, 'fishes', 'fishing' all are

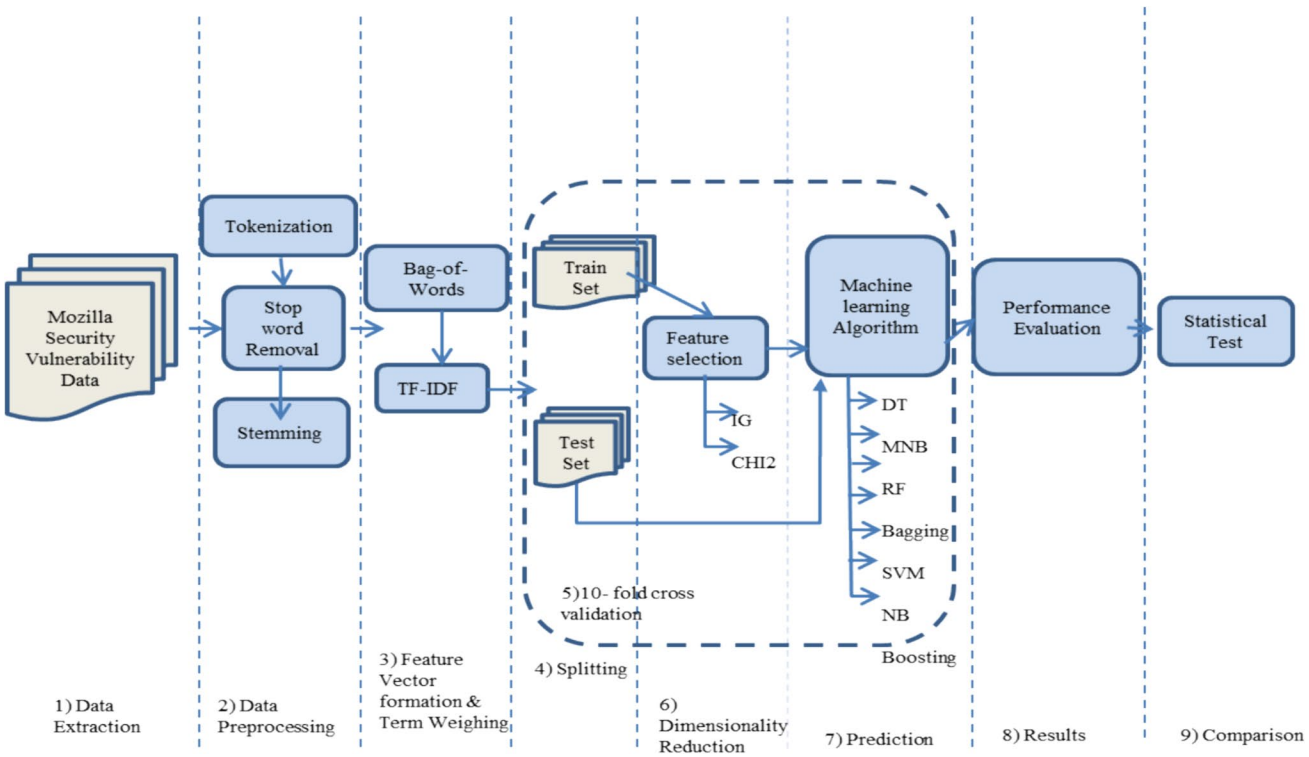

Fig. 2 Framework of our proposed approach

reduced to their root word, i.e., 'fish'. This is achieved by many researchers, and many algorithms are developed, but the most widely used and accepted algorithm is the Porter stemmer algorithm (Porter 1980). Hence, we have used it too in this study. After the application of all these three steps and completing the process of preprocessing, we are left with unique and meaningful tokens. These tokens are nothing but features that will be used by SVSPM to make predictions.

3. In Step 3, the features formed after Step 2, representing vulnerabilities, are converted into feature vectors. Bag-of-words that are formed after data preprocessing are used for the construction of these feature vectors. The length of the feature vector is the same as the number of tokens in bag-of-words. For every token in the feature vector, it contains its frequency, as seen in the textual description of the respective vulnerability. Features are reduced further by using the TF/IDF approach (Keefe and Koprinska 2009). It is a weight that is calculated for every token using TF/IDF. The calculation of the weight is done according to Eq. (3)

$$\text{For a term i in document j}: w_{i,j} = tf_{i,j} X \log\left(\frac{N}{df_i}\right) \quad (3)$$

$tf_{i,j}$ = frequency if i in j, df_i = number of descriptions containing I, N = total number of descriptions.

4. After finalizing the feature vector, the entire data is divided into training and testing data in the ratio of 80:20 as depicted in Step 4. This splitting of data is undergone under tenfold cross-validation so that much more reliable results can be obtained. In tenfold cross-validation, the entire dataset is split into 10-folds. For each ninefold of the dataset, SVSPM is developed, and performance is evaluated based on the 10th fold. This process is repeated until all the 10-folds have individually served as test data. Hence the final result is obtained by averaging the results of the ten runs of SVSPM. The training and the testing data produced using tenfold cross-validation are then fed into SVSPM. This is depicted in Step 5 of Fig. 2. Dimensionality reduction techniques are applied, which will help reduce features by selecting the most significant top-N features and removing irrelevant features. When dealing with unstructured data, the data dimension is very high, having irrelevant features. Table 2 gives the total number of textual features for individual datasets. The features that do not have any significance in finding the prediction variable or the output are considered irrelevant features. This type of dimensionality reduction is known as FS. As represented in Step 6 of Fig. 2, CHI-2 and IG are used for FS. The ML algorithms used are DT, SVM, NB, MNB, RF, Bagging, and Boosting for prediction. Hence, fourteen SVSPMs are developed, using two FS techniques and seven ML algorithms. The results are calculated using AUC values over the testing data for the performance evaluation of these prediction models.
5. While doing FS, top-5, 25, 50, and 100 terms are selected and these terms are used as attributes in the SVSPM. Therefore, when the values of AUC are recorded, the top-N terms are considered, and the results' values are recorded for this multiclass classification problem. Lastly, as can be seen in Step 9, in addition to performance measurement, hypothesis testing is done using the Friedman test and Wilcoxon Signed Rank test. Null and alternative hypotheses are formed (Ho and Ha) and are accessed at a 0.05 level of significance. This test helps check whether the difference in the effectiveness measure of the ML algorithms is statistically significant or not. Therefore, the hypothesis is stated as below:

   Ho = The performance of all SVSPM developed using different ML algorithms is the same.
   Ha = There is a significant difference between the performance of all SVSPM developed using various ML algorithms.

Based on the rejection and acceptance of these hypotheses, the Friedman test will help rank all the SVSPMs, whereas the Wilcoxon Signed Rank test will help do a pairwise comparison of SVSPMs.

5 Result analysis

In this section, we will answer the RQs which are discussed above. After analyzing the result concerning a particular RQ, it is concluded with a meaningful finding.

Table 2 Size of Dataset in terms of number of vulnerabilities and word count

	Mozilla Firefox	Mozilla Thunderbird	Mozilla Seamonkey	Mozilla Firefox ESR	Mozilla Thunderbird ESR
Vulnerabilities	1873	921	698	672	216
Text features	23,887	11,903	8862	9094	2841

RQ1: What is the predictive capability of the SVSPM developed in this study?

Tables 3, 4, 5, 6 and 7 present the performance of the models using AUC over the FS techniques with respect to the top 5, 25, 50, and 100 terms. For Mozilla Thunderbird ESR, the value of AUC for low severity level of vulnerability is 'nan' as only one vulnerability is present, which is depicted in Table 1. For a detailed analysis of the effect of the FS technique, the values of AUC are recorded at four different values of N, i.e., 5, 25, 50, and 100. After analyzing the results, the following conclusion is obtained:

1. For all five datasets, irrespective of the FS technique and ML algorithm used, we can conclude that better results are obtained for the top-100 terms.
2. Secondly, result values are also varying as the level of severity of the vulnerability changes. A typical pattern is observed for all the datasets. Irrespective of the FS technique and ML algorithm, better results are obtained for the medium and the critical level of severity of vulnerabilities.

Table 8 is constructed in which the fourteen models which are developed in this study are given names according to the FS technique and ML algorithm used. These model names are used below in the text while addressing RQs.

RQ2: Does the performance of SVSPM change with the change in FS technique?

As analyzed by RQ1, the best results are obtained for the top 100 terms. Therefore, to answer this RQ, values recorded for top-100 terms in Tables 3, 4, 5, 6 and 7 are analyzed. Analyzing these values, Table 9 is framed which contains the best and the second-best AUC values for all five databases. Apart from AUC values, the name of the model, the technology used by the model, and the corresponding severity level are also recorded. Looking at these observations of Table 9, it is observed that out of the top fifteen AUC values, nine AUC values are recorded when IG is used as the FS technique. Also, for all five datasets, if not the best, the second-best result is obtained when the IG FS technique is used. Graph of Fig. 3 is also constructed which plots the mean AUC values over five datasets with respect to top-100 terms for CHI-2 and IG FS techniques. Looking at this graph, we can say that IG produces better results if compared with CHI-2. Hence, we can conclude that when the AUC values are observed for an individual model or when the mean AUC values are observed, in both cases, IG came out to be a better-performing FS technique as compared to CHI-2.

RQ3: At which level of severity of the vulnerability, the best results are produced?

In this RQ, the AUC values recorded in Tables 3, 4, 5, 6 and 7 are analyzed in such a way that it can be figured out whether the performance of the model is dependent on the level of severity of the vulnerability. For this purpose, graphs of Fig. 4 are constructed which plots the performance of the models developed for all five databases FS technique-wise. A common pattern is observed in these graphs that the AUC values obtained for the medium and the critical level of severity of vulnerability are much higher as compared with the AUC values of the low and the high level of severity of the vulnerability.

Hence, it can be concluded that irrespective of FS technique and ML algorithms, SVSPM gave better performance better for the critical and the medium level of severity as compared to the low and the high level of severity.

RQ4: Which ML algorithm works best at a particular severity level among all the ML algorithms used?

This RQ tries to find the best among all the ML algorithms which are used to conduct the experiment of the study, level-wise. Keeping in mind the conclusion drawn from the above RQs, we concentrated on the values produced by selecting top-100 terms. To obtain the best algorithm for all five datasets at a particular severity level, the algorithm giving the best and second-best value of AUC is recorded in Table 10. The second-best AUC value is recorded only if the

difference between the two is not more than 0.05. Grey cells in Table 10 represent that the documentation of the second-best value is not needed and ML algorithm name which is in bold is the one giving good performance for all datasets. Looking at the values recorded in Table 10, for the low level of severity, no ML algorithm is able to produce good results. For the medium level of severity, if not the best, the second-best value is achieved by Boosting algorithm. Similarly, for the high level of severity, the common ML algorithm which gave good results is the NB ML algorithm. For the critical level of severity, the common ML algorithm which gave good results is the Boosting ML algorithm.

From the above analysis, we come to the conclusion that, out of four, boosting gave good results for two levels of severity. Hence, we can say that, apart from traditional ML algorithms, more powerful ensemble boosting technique gave promising results.

RQ5. What should be the appropriate number of terms selected by the FS techniques to obtain the best results?

The number of terms is the value of N in top-N terms. These are the most significant terms having the most importance out of all text features. A very small value of N will lead to a loss of information, and subsequently, the efficiency of the model will be low. In contrast, a very big value of N will lead to an increase in dimensionality, leading to an increase in the complexity of the model. Therefore, a search for the optimum value of N is required. Keeping this in mind, we executed our experiment for four different values

of N, which are 5, 25, 50, and 100. The results are recorded in Tables 3, 4, 5, 6 and 7 which contain the AUC values of all these four instances. Using these results as the base, we did its analysis and tried to obtain if any relation between the AUC measure and the value of N exists.

We plotted a graph between the number of terms, i.e., N, and corresponding AUC values to do the analysis. There are many different combinations available for graph plotting because we had four levels of severity, two FS techniques, seven ML algorithms, and five datasets. For our simplicity, we considered the level of severity that gave the best results, which is the critical level, as discussed in RQ3. Among all ML algorithms, we considered the algorithm that gave the best results at the critical level, which is boosting, as discussed in RQ4. The graphs are depicted in Fig. 5 in which the x-axis represents the number of features, and the y-axis represents the value of AUC.

Looking at the lines in the graph, we can conclude that as the value of N or the number of features increases, the performance of SVSPM gets better and later on becomes stable or slightly reduced due to the addition of some redundant or irrelevant features.

RQ6. Whether the performance of all the SVSPM developed differ significantly or not?

To check whether the performance of all the ML algorithms differs significantly or not, the Friedman test is used. The hypothesis is framed and is stated as given below:

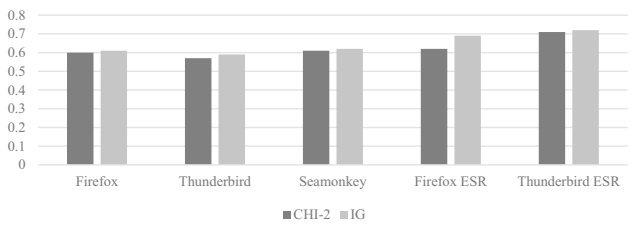

Fig. 3 Plot of Mean AUC values database-wise for CHI-2 and IG FS Techniques

Ho = The performance of all SVSPM developed using different ML algorithms is the same.
Ha = There is a significant difference between the performance of all SVSPM developed using various ML algorithms.

The input to the Friedman test is taken from Tables 3, 4, 5, 6 and 7. From the available set of AUC values, we have taken values as input to the Friedman test that is recorded for the top 100 terms. For low level, 0.692 and 0.066 are the p-values that came when CHI-2 and IG are used for FS respectively. For the medium level, 0.004 and 0.286 are the *p* values that came when CHI-2 and IG are used for FS respectively. For the high level, 0.053 and 0.054 are the *p* values that came when CHI-2 and IG are used for FS respectively. For the critical level, 0.014 and 0.166 are the *p* values that came when CHI-2 and IG are used for FS respectively. The results of the Friedman test showing the mean rank for all SVSPM are documented in Table 11.

According to the *p* values recorded, Ho is retained for all four levels of severity, when IG is used as FS technique. This depicts that there is no significant difference in the models' performance. Hence, Friedman's test results also validate the finding of RQ2 that is the IG FS technique gives better results. Therefore, when the IG FS technique is used, all SVSPM gave a good performance with no significant difference in result values. Ho is retained for low and medium level of severity as well. This friedman's test result validates the finding of RQ3. Analysis of RQ3 tells that SVSPM performance was not good for low and high level of severity. Hence as bad results came for both the levels for all ML algorithms, therefore no significant difference exists in the performance of SVSPM.

Looking at the *p* values for the medium and critical level of severity, Ho is rejected when CHI-2 is used as a FS technique.

Wilcoxon signed-rank test is used to extend our investigations pairwise for the above-stated cases in which Ho is rejected. The pairwise analysis will help us determine which

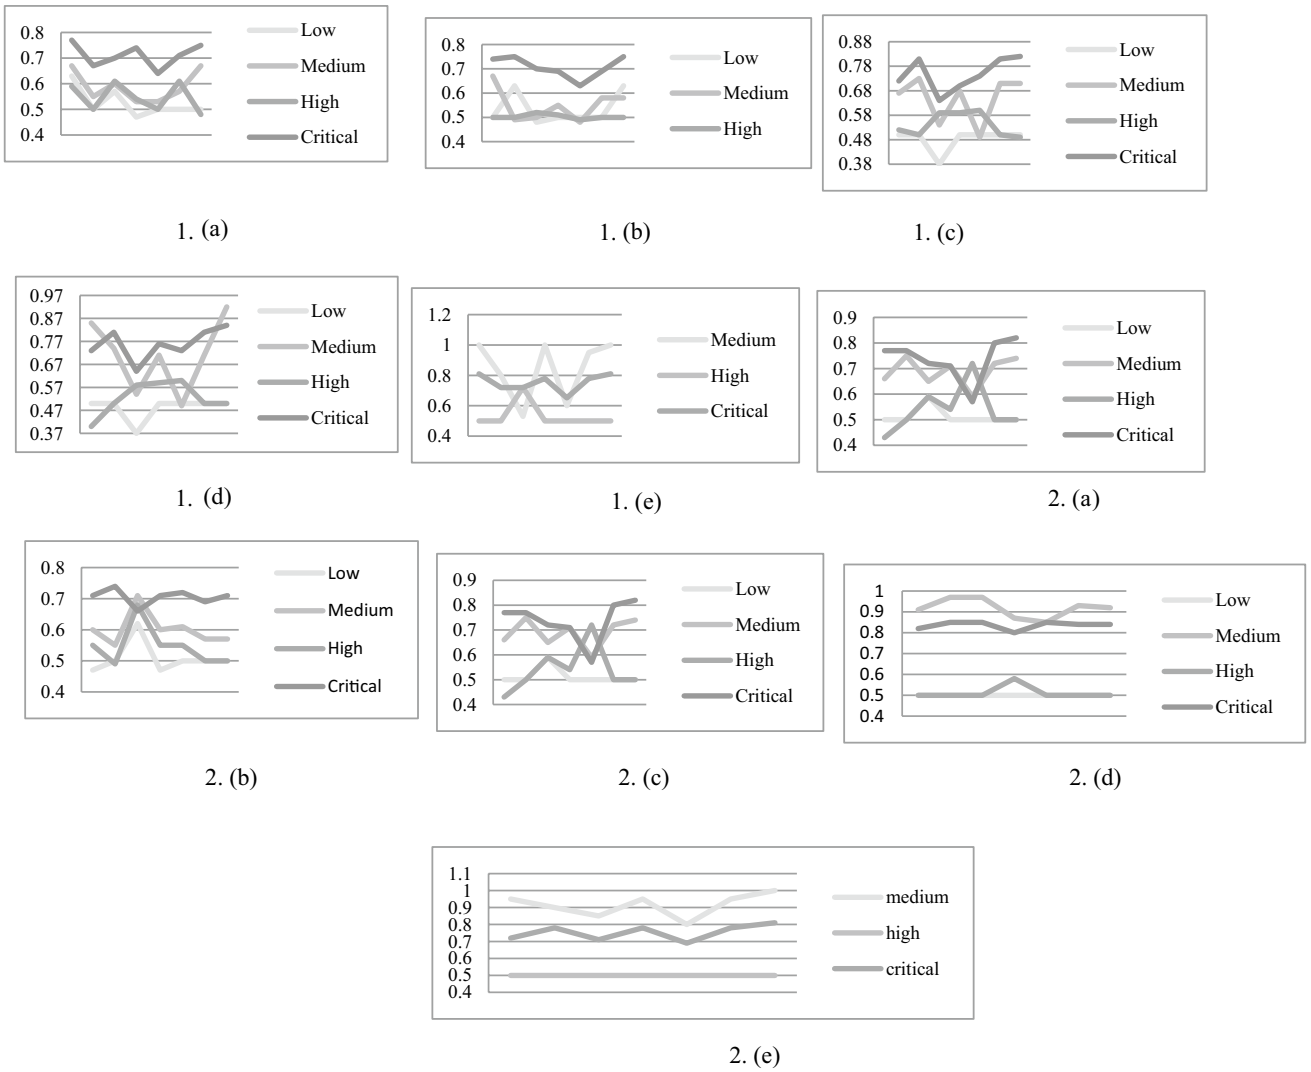

Fig. 4 The AUC values obtained severity level wise for all datasets with 1. **a** CHI-2 for Mozilla Firefox, **b** CHI-2 for Mozilla Thunderbird, **c** CHI-2 for Mozilla Seamonkey, **d** CHI-2 for Mozilla Firefox ESR, **e** CHI-2 for Mozilla Thunderbird ESR and 2. **a** IG for Mozilla Firefox, **b** IG for Mozilla Thunderbird, **c** IG for Mozilla Seamonkey, **d** IG for Mozilla Firefox ESR, **e** IG for Mozilla Thunderbird ESR

pair of ML algorithms significantly differ from each other. Hence, for Wilcoxon Signed rank test, the hypothesis framed are stated as follows:

- Ho: No significant difference is there between the performance of two SVSPM
- Ha: Significant difference occurs between the performance of two SVSPM

The results are tabulated in Table 12. The values in bold in Table 12 depicts that, for that particular pair of ML algorithm, a significant difference exists in the result values of the model. If we focus on Boosting algorithm, a total of six pairs are made with it. Out of six pairs, the following four Boosting-NB, Boosting-Bagging, Boosting-MNB, and Boosting-RF showed significant differences in performance. Hence a conclusion can be drawn that SVSPM developed using boosting algorithm are having good performance and gave good results for the medium and critical level of severity. This validated our findings of an analysis of RQ4 as well. Apart from these, the other pairs which showed significant differences are NB-DT, MNB-DT, and MNB- SVM for medium level and NB-DT, MNB-SVM for critical level.

6 Threats to validity

The possible validity threats to our study are as follows:

The particular pair of ML algorithm where a significant difference in the result values is found according to Wilcoxon signed-rank test are shown in bold

1. There is a possibility that new vulnerabilities are being reported and added to the vulnerability database now but not included in the data collected, which we did initially to carry out the study.
2. For this study, five data sets are used, over which fourteen classification models are being developed. A selection of these can cause biased results obtained in the study.
3. In the literature, there is a diversity of classification models that could have been considered. Still, our selection represents the most widely used classification model, and hence we can claim them to be representing all other models.
4. The results obtained in this study cannot be generalized to the other available datasets.
5. Use of tenfold cross-validation reduced the risk of threat to internal validity.
6. Statistical test reduces the threat to the validity of conclusions by justifying the comparison of all the SVSPM developed properly.
7. For performance evaluation, out of so many parameters, only AUC values are considered, which again may threaten the validity of results.
8. A vulnerability report contains many fields, but our research used only the description portion. The use of limited fields from the available ones can also threaten the validity of the study.

After answering all the RQs, the findings of the result analysis can be summed up as depicted in Table 13.

7 Conclusion and future work

Nowadays, when most human activities depend on different software systems, it becomes crucial to keep in mind their reliability. As most of the activities are carried out online, it poses a threat to exploit various vulnerabilities. Therefore a need arises to automate the task of severity prediction of vulnerabilities and build an SVSPM. SVSPM aims at severity prediction so that appropriate actions can be performed to protect software from exploiting the vulnerability. To achieve this aim, in this study, we focused on vulnerability reports. From these reports, the description is targeted and acted as input to SVSPM. As it contains textual information regarding the vulnerability, text mining concepts are applied to handle this unstructured data. FS is also applied to handle the "curse-of-dimensionality" so that the prediction can be made ahead using various ML algorithms. With the use of two FS techniques and seven ML algorithms, we ended up with the development of fourteen SVSPM. After doing the result analysis, we concluded the following conclusion points:

1. The model performed better for the medium and the critical severity level of the vulnerability. Out of two FS techniques, IG gave better results.
2. Best SVSPM using ML algorithm corresponding to each dataset is found as well. For medium and critical level of severity, SVSPM developed using Boosting algorithm performs the best. Although results were not good for the low and the high level of severity, NB gave comparatively better results.
3. A comparison is also made to identify significant differences among various ML algorithms using Friedman and Wilcoxon Signed Rank test. The results for medium and critical level of severity, when CHI-2 was used for FS technique came out to be significant. Proceeding with pair-wise Wilcoxon signed-rank test, boosting algorithm proved to be the best performing algorithm.
4. It is found that, with the increase of number of features, i.e., N, the performance of SVSPM improves and later on becomes stable or slightly reduced due to the addition of some redundant or irrelevant features.

In the future, there are three possible pathways for further development. Firstly, looking at point 2 of the conclusion, the data which was taken as input is analyzed. Looking at the data, it is found that the data on which we are working is imbalanced data having an unequal number of instances for different levels of severity of vulnerability. Therefore, we aim to solve the issue of imbalanced data, so that better results can be obtained for all levels of severity, including the low and the high level of severity (e.g., Zhou et al. 2018). Different data balancing strategies are used to overcome imbalanced data issues, categorized as data level,

Table 13 Results in a Nutshell

Which FS technique gave better results?	IG
Which level of severity gave better results?	Medium and Critical, followed by Low and High
Which ML algorithm performed better?	At low level, NB algorithm, At medium level, Boosting algorithm At high level, NB algorithm, At critical level, Boosting algorithm
What is the optimum value of N for achieving the best results?	After N = 100, performance becomes stable

algorithmic level, and hybrid strategy for data balancing. The second pathway is to develop a novel technique for FS so that the performance of the SVSPM can be enhanced. As we are working on a textual dataset that generates feature vectors of high dimension, therefore developing a novel FS technique is very crucial to deal with the curse of dimensionality and improve the performance of the prediction model. For this purpose, algorithms such as deep learning algorithms and evolutionary algorithms can be used. These algorithms are gaining popularity in literature and are used in various paradigms (Dong et al. 2018; Alqudah et al. 2021; Wu et al. 2020; Saha et al. 2022; Kaur and Khehra 2022). The third pathway aims toward generalization of the results. For that purpose, other than Mozilla, different datasets can be added, having a high number of vulnerabilities, investigating whether the proposed model gives good performance or not.

ARTICLE INFO

ABSTRACT

The comprehensive study on "The Influence of Color on Visual Psychology and Cognitive Behavior: A Study in Paediatrics Hospital Environment" explores the profound influence of color choices on paediatrics hospital management, with a focus on their effects on patients, staff, and families. The research findings reveal that color psychology plays a pivotal role in creating healing environments tailored to the unique needs of children. Warm and vibrant colors, such as yellows and reds, are shown to uplift the mood of young patients in play areas, while softer pastels like blues and greens can soothe and potentially aid in pain perception in recovery rooms. Color psychology extends to staff perceptions, where a well-designed hospital with carefully chosen colors can boost morale, enhance job satisfaction, and foster better communication and teamwork among healthcare professionals. For families, the study highlights the role of colors in alleviating stress and anxiety, advocating for comfortable and relaxing spaces in waiting areas and family rooms.

These findings have critical implications for hospital environment, including potential improvements in patient outcomes, staff satisfaction, and family experiences. The study underscores the need for future research on cultural variations, long-term effects, multi-sensory design, cost-effective solutions, and patient and family involvement in hospital design. Incorporating these insights can lead to more compassionate, supportive, and effective healthcare environments for paediatrics patients and their families.

KEYWORDS: Color Psychology, Paediatrics Hospital, Healing Environments, User Experience, Cognitive Behavior

INTRODUCTION

Paediatrics hospitals are institutions that are crucial for the comprehensive and specialized medical care of infants, children, and adolescents. With a focus on addressing the unique physical, emotional, and developmental needs of young patients, these hospitals play a vital role in promoting the health and well-being of the paediatrics population. From neonates, who are the most vulnerable and delicate, to adolescents on the brink of adulthood, the spectrum of care offered in these hospitals encompasses various stages of growth and development.

In the nurturing environment of a paediatrics hospital, the aim is not just to provide medical treatment but also to create a space that is comfortable, engaging, and conducive to the emotional healing of young patients. Such an environment is carefully crafted, keeping in mind the principles of color psychology and the profound impact that different hues can have on individuals, especially children. Researchers and healthcare

professionals recognize that the atmosphere in which medical treatment is provided can significantly influence the emotional state and well-being of patients, families, and staff. The following objectives were considered for the study.

1. The first objective involves conducting a comprehensive review of the existing literature on color psychology within healthcare environments. This review will place a special emphasis on understanding how colors influence emotions, behavior, and overall well-being. By synthesizing this body of knowledge, we aim to establish a foundation for the subsequent research.
2. The second objective is to closely examine the critical role of color selection and design in the environment of hospitals. This examination will illuminate the connection between color choices and the outcomes experienced by patients. By exploring this relationship, we aim to shed light on the potential benefits of strategic color design in healthcare settings.
3. The third objective recognizes the unique challenges and considerations that arise when designing paediatrics healthcare environments. Creating spaces that are child-friendly and supportive requires a distinct set of guidelines and approaches. Understanding these factors is crucial in ensuring that paediatrics hospitals meet the specific needs of young patients.
4. The fourth objective involves a rigorous investigation into the influence of colors within paediatrics hospital settings. This investigation will rely on a combination of surveys and observational data to comprehensively explore how colors impact the emotions, behaviors, and experiences of patients, healthcare staff, and families. With the accumulated knowledge and insights.
5. The fifth objective is to provide practical color recommendations for the strategic design of paediatrics hospitals. These recommendations will encompass considerations such as age-appropriate color palettes, effective lighting strategies, and overall design principles aimed at optimizing the healing environment.
6. The sixth objective is to illustrate these findings and recommendations through a compelling case study. This case study will spotlight a paediatrics hospital that has implemented color psychology principles in its design and environment.

By assessing the real-world impact of these changes on patients, staff, and families, we aim to provide tangible evidence of the benefits associated with incorporating color psychology into hospital environment.

The significance of this research lies in its potential to contribute to the enhancement of paediatrics healthcare environments, ultimately benefiting the physical and emotional well-being of young patients, their families, and healthcare providers. By exploring the relationship between color and emotions in hospital settings, this study can offer valuable insights for hospital administrators, designers, and healthcare professionals tasked with creating and managing paediatrics healthcare facilities. Furthermore, the findings of this study can have broader implications for the field of hospital management and healthcare design. While the focus is on paediatrics hospitals, the principles of color psychology can be adapted and applied to healthcare settings for adults as well. Understanding how color choices can positively influence patient and staff experiences may lead to improved patient satisfaction, shorter hospital stays, and potentially better treatment outcomes.

LITERATURE REVIEW

The impact of the physical environment in healthcare settings, particularly within the context of children's hospitals, has garnered increasing attention in recent years. The use of color in hospital design has emerged as a pivotal factor affecting patients' well-being, comfort, and overall experiences. This literature review examines various studies that explore the role of color in paediatrics hospital environments, its implications for patient care, and the influence of color psychology on hospital design.

Color Psychology in Hospital Environments: Color psychology, the study of how colors can affect human emotions and behavior, plays a vital role in healthcare settings. In the study conducted by Sara Nourmusavi Nasab, Amir Reza Karimi Azeri, and S. Mirbazel (2020), the authors emphasized that children prefer hospital environments with entertainment facilities. This highlights the significance of creating visually engaging spaces that contribute positively to the emotional state of young patients (Nourmusavi Nasab et al., 2020).

Thematic Color Design for Children's Hospitals: Thematic color design, as discussed by Ali AbuLawi (2021), is deemed appropriate for children of all age ranges. This approach recognizes the importance of thematic and visually engaging environments that can enhance children's experiences in hospitals (AbuLawi, 2021).

Preferences of Thematic Design and Color: The preference of thematic designs and colors among children and young people was explored by J. Coad and N. Coad (2008). Their study, published in the Journal of Child Health Care, indicated that children and young people in a new children's unit preferred thematic designs of walls, doors, and floors. This underscores the importance of tailoring the hospital environment to meet the preferences of its younger occupants (Coad & Coad, 2008).

Psychological Wellbeing of Paediatrics Patients: In the research conducted by Valentina Marques da Rosa, P. Brust-Renck, and L. Tonetto (2022), the authors highlighted the impact of the hospital environment on all components of children's psychological well-being. This underscores the potential for hospital design, including color choices, to support the emotional needs of paediatrics patients (Marques da Rosa et al., 2022).

Color Environment Design in Paediatrics Care Units: Color selection in paediatrics hospital design was explored by L. Hong-xia (2011). The study suggested that colors are associated with specific emotions in paediatrics hospitals, emphasizing the need for thoughtful color choices in healthcare environments (Hong-xia, 2011).

Color Perception in Paediatrics Patient Rooms: A study by Jin Gyu "Phillip" Park (2009) compared the color preferences of healthy children and paediatrics outpatients. Healthy children exhibited higher mean scores of color preferences, underscoring the importance of considering color psychology in the design of paediatrics patient rooms (Park, 2009).

Appropriate Colors in Children's Rooms: Ajilian Maryam and T. Ali (2014) emphasized the diverse impacts of color, including its ability to inspire, soothe, heal, and agitate. Their study highlighted the multifaceted role of color in paediatrics hospital environments, suggesting its potential to create varied emotional responses (Maryam & Ali, 2014).

Child-Friendly Hospital Architecture: A child-friendly hospital environment was explored by Laure Verschoren, M. Annemans, I. V. Steenwinkel, and A. Heylighen (2015). Their research highlighted the importance of a child-friendly atmosphere that supports daily life, both socially and spatially, reinforcing the notion that hospitals should be designed with the unique needs of children in mind (Verschoren et al., 2015).

Role of Hospital Design in Reducing Anxiety: J. Cartland, H. Ruch-Ross, L. Carr, Audrey E. Hall, R. Olsen, Ellen Rosendale, and Susan Ruohonen (2018) investigated the impact of hospital design on anxiety levels among paediatrics patients. Children in the new facility experienced less anxiety than in the old facility, emphasizing the therapeutic potential of well-designed hospital spaces (Cartland et al., 2018).

Interactive Design in Children's Hospitals: The study conducted in 2022 emphasized the importance of interactive design in children's hospitals, suggesting that children feel much better in environments that incorporate emotional factors through interactive design (Anonymous, 2022).

Cross-Cultural Perspectives on Color Preferences: Jin Gyu "Phillip" Park and Changbae Park (2013) explored the differences in color preferences between American and Korean paediatrics patients. Korean paediatrics patients showed significantly higher preference scores for white than their American counterparts, underscoring the influence of culture on color perceptions in healthcare environments (Park & Park, 2013).

Light and Color in Healthcare Environments: Research by Navid Khaleghimoghaddama (2023) emphasized the importance of the proper use of color and light in healthcare environments. These elements were found to have a significant impact on healthcare outcomes, suggesting their potential to enhance the healing process (Khaleghimoghaddama, 2023).

Comprehensive Impact of Color in Healthcare: H. Ghamari and Cherif Amor (2016) summarized the extensive effects of color in healthcare environments. Their research highlighted color's role in reducing medical errors, promoting well-being, reducing stress, improving sleep, shortening hospital stays, enhancing spatial orientation, increasing patient satisfaction, and improving staff morale and productivity (Ghamari & Amor, 2016).

Color Selection and Patient Well-Being: Arezou Eshaghabadi, Pirhossein Koulivand, and H. Kazemi (2017) explored the impact of color selection on patient well-being in hospital design. Their study emphasized the significance of color choices in contributing to patients' overall experiences and outcomes (Eshaghabadi et al., 2017).

Environmental Graphics in Children's Wards: The analysis conducted by L. Jeddi, Fereidoon Kasrayee, S. Jeddi, and M. Taghipour (2016) focused on the role of suitable color in graphical design in children's hospital wards. Their research highlighted the importance of coordination between architectural and graphical design to improve the hospital's atmosphere and quality of care for children (Jeddi et al., 2016).

Environmental Psychology in Children's Hospitals: Lu Feng-hu (2010) discussed the association of colors with specific emotions in the decorative design of children's hospitals, underscoring the potential psychological impact of color choices in healthcare settings (Feng-hu, 2010).

Cultural Significance of Color: Jain Kwon (2010) explored the cultural meaning of color in healthcare environments, emphasizing the importance of considering cultural perspectives when choosing colors for hospital design (Kwon, 2010).

Lighting and Color in Hospital Design: Research by Hilary Dalke, Jenny Little, Elga Niemann, Nilgun Camgoz, Guillaume Steadman, Sarah Hill, and Laura Stott (2006) emphasized the importance of a well-balanced and attractive environment in patient health. Their study highlighted the potential for color and lighting to positively affect patient recovery and staff performance (Dalke et al., 2006).

Quality of the Visual Hospital Environment: H. Dalke, P. Littlefair, and D. Loe (2004) discussed how the quality of the visual hospital environment can have a positive psychological effect on patient recovery and staff performance, reinforcing the importance of visual elements like color in healthcare design (Dalke et al., 2004).

Children's Emotional Associations with Colors: A study by C. Boyatzis and Reenu Varghese (1994) explored children's emotional associations with colors. Their findings revealed that children's emotional reactions to bright colors became increasingly positive with age, suggesting the developmental nuances in color preferences among paediatrics patients (Boyatzis & Varghese, 1994).

Colors in Public Places: Parisa Zraati (2013) discussed the influence of colors in public places, emphasizing that colors can affect users. This highlights the significance of color choices in spaces like hospital waiting areas (Zraati, 2013).

This literature review highlights the multifaceted role of color in paediatrics hospital environments, emphasizing its potential to influence the emotional state, preferences, and well-being of young patients. The studies reviewed collectively underscore the importance of thoughtful color selection and design in creating hospital spaces that are conducive to healing, comfort, and the overall well-being of paediatrics patients and their families.

The Significance of Color Psychology in Paediatrics Hospital Design

The impact of color psychology in paediatrics hospital management, certain studies suggest that colors can have psychological effects on both children and adults. In the context of paediatrics hospitals, the use of certain colors can potentially contribute to creating a more comforting and soothing environment for young patients. For example, some hospitals use calming, warm colors such as light blues, greens, and pastels to create a relaxed atmosphere, which can help reduce stress and anxiety in children. These colors are often associated with feelings of tranquility and can have a positive impact on the emotional well-being of young patients. Additionally, some paediatrics hospitals might use vibrant and cheerful colors in play areas or waiting rooms to create an engaging and lively environment for children. This approach aims to promote a sense of joy and positivity, potentially aiding in the overall healing process and creating a more child-friendly atmosphere.

METHODOLOGY

This study employs a mixed-methods research design to analyze the impact of color on pediatric healthcare environments. By integrating quantitative and qualitative approaches, the study aims to comprehensively understand color preferences, emotional associations, and perceived environmental effects from the perspectives of hospital staff, young patients, and their families/visitors.

A. The research seeks to answer the following questions:
1. How do different colors in hospital environments affect the emotional well-being of pediatric patients?
2. What specific colors are perceived as most comforting by children in a hospital setting?
3. How does healthcare staff perceive the impact of color on their work environment and stress levels?
4. What are the experiences of families regarding the color schemes in pediatric hospitals?
5. How does the use of color in pediatric hospital design influence the behavior of young patients during their stay?
6. What are the cultural considerations in choosing colors for pediatric healthcare environments?
7. How do adolescents perceive color differently from younger children in hospital settings?
8. What role does natural lighting play in enhancing the effects of color in pediatric hospitals?
9. How do different age groups respond to various color palettes in a healthcare setting?
10. What are the key design elements, aside from color, that contribute to a healing environment for children in hospitals?
11. How do pediatric patients' emotional responses to color compare with those of their parents or guardians?
12. What are the most significant challenges faced by designers when implementing color psychology principles in pediatric hospitals?
13. How do colors impact the perceived safety and security within pediatric hospital spaces?
14. What feedback do pediatric patients and their families provide about color schemes during their hospital experience?
15. How do specific colors in pediatric hospital rooms influence the length of stay or recovery time for young patients?
16. What are the psychological effects of color changes over different times of the day in a pediatric hospital setting?
17. How do colors in waiting areas versus treatment rooms affect patient anxiety levels?
18. What are the perceived benefits of incorporating nature-inspired color schemes in pediatric hospitals?
19. How do different colors in hospital environments affect the interaction and communication between patients and healthcare staff?
20. What case studies or examples illustrate the successful implementation of color psychology in pediatric hospital design, and what lessons can be learned from them?

B. Data will be collected from three groups: hospital staff, young patients, and families/visitors using surveys, interviews and observations.

Surveys

1. Participants: Hospital staff, young patients, and families/visitors.
2. Instruments: Structured questionnaires developed based on the research questions.
3. Variables: Color preference, emotional association, and perceived effect on the environment.

Interviews

1. Participants: Selected individuals from each group to gain in-depth insights.
2. Instruments: Semi-structured interview guides.

Observations

1. Setting: Pediatric hospital environments.
2. Focus: Interaction with color schemes in different areas (e.g., play areas, recovery rooms, waiting areas).

C. Data analysis will be done using the available data.

The study aims to provide evidence-based recommendations for the use of color in pediatric hospital environments to enhance emotional well-being, improve staff morale, and support families. Insights from this study will inform hospital design strategies, contributing to more effective and compassionate pediatric healthcare settings. This methodology ensures a comprehensive and systematic approach to understanding the complex impacts of color on the pediatric healthcare environment, facilitating data-driven design decisions.

RESULT AND ANALYSIS

From the moment a child steps into the hospital, they are greeted with a lively and colorful setting. Playful and vibrant toys adorn the waiting areas, creating a sense of wonder and distraction. The walls are painted in soothing hues, carefully selected to instill a feeling of calm and reassurance, mitigating the anxiety often associated with medical settings. These deliberate color choices are not random but are based on a deep understanding of the psychological impact of colors on human emotions.

Moreover, the importance of color psychology extends beyond the visual appeal. Studies have shown that specific color schemes can significantly influence mood, behavior, and even physical well-being. In paediatrics hospitals, this understanding translates into the strategic use of colors to facilitate healing and improve the overall hospital experience for young patients. In recovery rooms, where children recuperate from procedures and surgeries, the emphasis is on creating a serene and tranquil environment. Soft, pastel shades of blue and green are often used, as these colors are known to evoke feelings of serenity and relaxation. This calming effect can help reduce stress and discomfort, contributing to a more positive recovery experience. By integrating these subtle yet impactful color schemes, paediatrics hospitals aim to create a supportive and nurturing space where children can heal both physically and emotionally.

Fig 4. Maternal & Child Health Care Room

Fig 5. Imaging Room for Childrens

Fig 6. Paediatric Treatment Room

Fig 7. Paediatric Intensive Care Unit (PICU)

Contrastingly, in play areas and activity zones, vibrant and energetic colors take center stage. Bright reds, yellows, and oranges stimulate energy and enthusiasm, fostering a lively and joyful ambiance. These vibrant settings are designed to encourage engagement, promote social interaction, and uplift the spirits of young patients. By immersing children in an environment filled with stimulating colors, paediatrics hospitals aim to create a positive and uplifting atmosphere that aids in the emotional well-being and overall recovery of the patients.

Furthermore, the impact of color psychology extends to the well-being of the hospital staff and families of the patients. By creating an environment that is visually appealing and emotionally supportive, paediatrics hospitals foster a sense of positivity and optimism among the caregivers, contributing to a more conducive work atmosphere.

It should be understood from the above that the integration of color psychology in paediatrics hospitals serves as a powerful tool in creating a holistic healing environment for young patients. Through careful consideration and implementation of color schemes, these hospitals strive to enhance the well-being and comfort of children, their families, and the healthcare professionals involved in their care. By leveraging the psychological impact of colors, paediatrics hospitals continue to pave the way for a more compassionate and effective approach to paediatrics healthcare.

Moreover, the study highlights that the impact of color extends to the hospital staff. A well-designed hospital with carefully chosen colors can foster a positive work atmosphere, leading to higher staff morale and job satisfaction. Colors can also be used for wayfinding, making it easier for staff to navigate the hospital efficiently and collaborate effectively. Families, too, benefit from the thoughtful application of color psychology in paediatrics hospitals. Comfortable and relaxing spaces with soft, neutral colors in waiting areas and family rooms can significantly contribute to their well-being. Muted blues and greens, in particular, help alleviate the stress and anxiety that often accompany a child's hospitalization.

Paediatrics hospitals are indeed playful and colorful, but their vibrant design elements are not just for show. They are a manifestation of the intricate relationship between color psychology and hospital Environment. The careful selection of colors contributes to a healing environment that supports the emotional needs of young patients, ensures staff satisfaction, and eases the burden on families during challenging times.

Healthcare environments, by their very nature, are spaces of vulnerability and emotional sensitivity, where patients and their families grapple with illness, uncertainty, and distress. As the healthcare industry continues to evolve, one critical aspect gaining recognition for its influence on patient well-being and outcomes is the physical environment itself. This environment encompasses various elements, including architecture, design, and spatial organization, but it is the use of color that forms a subtle yet powerful aspect of the hospital's atmosphere. In particular, paediatrics hospitals, dedicated to caring for children and adolescents, face the unique challenge of creating spaces that are not only medically efficient but also emotionally supportive, engaging, and calming for their young patients and their families. This study delves into the multifaceted role of color psychology within the context of hospital management, with a particular emphasis on its application in paediatrics healthcare settings.

The physical environment in healthcare settings has long been recognized for its potential to impact patient outcomes. Florence Nightingale, the founder of modern nursing, highlighted the importance of the environment in her groundbreaking work, "Notes on Nursing," published in 1859. She emphasized the significance of clean, well-ventilated spaces and suggested that the surroundings themselves could contribute to or hinder the process of healing. Over the decades, this understanding has evolved, leading to a growing awareness of how various environmental factors, including lighting, layout, noise, and aesthetics, influence the emotional state and overall well-being of patients and healthcare providers. In recent years, the healthcare industry has placed increasing importance on the concept of patient-centered care. This approach recognizes the patient as an active participant in their healthcare journey, and it seeks to provide an environment that not only promotes physical healing but also addresses emotional and psychological needs. In this context, the role of color psychology has gained prominence as an essential element in designing healthcare spaces that support the holistic well-being of patients.

Table 1: Color Palette in Paediatrics Hospital Design

Name	Hex Code	Color	Usage
Sky Blue	#87CEEB		Recovery Room Walls
Soft Green	#98FB98		Recovery Room Accents
Sunshine	#FFD700		Playroom Walls
Bubblegum	#FF69B4		Playroom Accents
Serene Gray	#D3D3D3		Waiting Areas and Corridors
Sunny Yellow	#FFFF00		Paediatrics Room Doors

As this study suggests, the power of color in paediatrics healthcare environments is profound, enriching the lives of those it touches.

The purpose of this study is to investigate and elucidate the role of color psychology in hospital management, with a particular focus on its application in paediatrics hospitals. It aims to explore the various ways in which color can influence the emotional state, comfort, and overall experience of young patients, their families, and healthcare staff. By delving into the science of color psychology and its practical application, this study seeks to provide hospital administrators, designers, and healthcare professionals with evidence-based insights that can inform the strategic use of color in paediatrics healthcare environments. This study is driven by several specific objectives that collectively guide the investigation into the relationship between color psychology and hospital management, particularly in the context of paediatrics healthcare settings.

The table 2 provides a reference for the association between emotions and colors. Common colors associated with happiness include bright yellow and red, while calmness is often linked to light blue and green. Vibrant red and orange are associated with excitement, while soft green and blue represent tranquility. Anxiety is often linked to bright red and yellow, while serenity is associated with pale blue and lavender. Bright orange and pink are associated with energy, while warm yellow and beige represent comfort.

Table 2: Illustrating emotion-color associations based on color psychology

Emotion	Associated Color	References
Happiness	Bright Yellow, Red	Stumpf, C. (2014). Color psychology: Everything you need to know. AVA Publishing.

The subsequent visuals depict envisioned color schemes implemented for particular healthcare rooms, inspired by the significant insights derived from the study titled " The Influence of Color on Visual Psychology and Cognitive Behavior: A Study in Paediatrics Hospital Environment ." These proposals are crafted to leverage the constructive influence of color psychology, with the goal of elevating the overall well-being and experiences of patients, families, and healthcare professionals within specific medical environments.

In alignment with the nurturing essence of maternal and child health care, the recommended color palette embraces soft pastels such as calming blues and gentle greens. Introducing accents of warm tones, such as light yellows or peach, is suggested to establish a comforting and supportive ambiance, fostering a sense of care and reassurance. To transform the imaging room into a more child-friendly space, an energetic and playful color scheme is proposed. The incorporation of bright, cheerful colors like blues, greens, and yellows is envisioned to contribute to a visually engaging atmosphere. Additionally, the introduction of child-friendly themes, such as murals or artwork, is suggested to enhance the overall welcoming nature of the room.

For paediatric treatment rooms, the suggested color scheme amalgamates soothing and uplifting tones. Soft blues and greens are recommended to promote a calming effect, while bursts of warmer tones, such as light oranges or soft purples, aim to maintain a positive and supportive ambiance. This approach is designed to create a therapeutic environment tailored to the unique needs of paediatric patients.

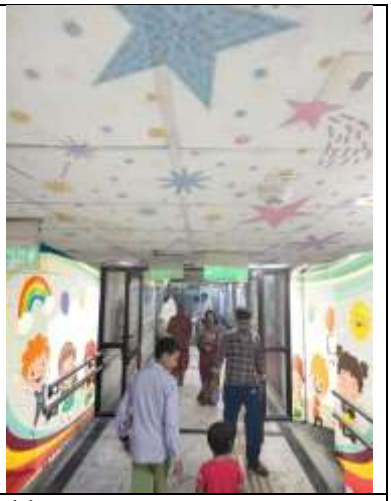
(b)



(c)

Fig 9 Redesigned Paediatric room gallery

These proposed color schemes take into account the psychological impact of colors on emotional well-being, with the intention of contributing to more compassionate, supportive, and effective healthcare environments for both patients and their families. It is crucial to evaluate these suggestions within the context of the hospital's overall design scheme, considering practicality and cultural preferences. Input from stakeholders is also essential to ensure a holistic and patient-centric approach to healthcare space design.

Mean Perceived Effect: 1.38 Median Perceived Effect: 2 Mode Perceived Effect: 2 (Neutral)	Mean Perceived Effect: 1.42 Median Perceived Effect: 2 Mode Perceived Effect: 2 (Neutral)	Mean Perceived Effect: 1.44 Median Perceived Effect: 2 Mode Perceived Effect: 2 (Neutral)

The comprehensive study on the impact of color psychology in paediatrics hospital environment reveals significant insights into how color choices influence the experiences of patients, staff, and families in healthcare environments. Hospital Staff showed a relatively higher mean color preference score of 3.0, indicating a preference for the chosen color palette. Young Patients had a slightly lower mean color preference score of 2.3, suggesting a preference for different colors compared to the staff. Families/Visitors had a mean color preference score of 2.58, aligning more closely with Young Patients. The most preferred color across all groups

was Blue, indicating its universal appeal. Hospital Staff, Young Patients, and Families/Visitors predominantly associated the selected colors with positive emotions, with 'Happy' being the most common emotional association. This positive emotional association suggests that the chosen colors have a generally uplifting effect on the mood of all groups.

Table 6: summarizing the findings of the study, highlighting the impact of colors on young patients, hospital staff, and families in paediatrics hospitals

Aspect	Impact on Young Patients	Impact on Hospital Staff	Impact on Families/Visitors
Emotional Well-being	Engaging and comforting atmosphere, alleviating anxiety during medical procedures and hospital stays.	Positive work atmosphere, potentially higher staff morale and job satisfaction.	Comfortable and relaxing spaces, stress and anxiety reduction during a child's hospitalization.
Atmosphere	Enhances overall atmosphere, promotes positive emotions and boosts mood.	Fosters a positive work environment, aiding staff morale and satisfaction.	Creates a supportive and inviting environment for families and visitors.
Wayfinding	Improves wayfinding for young patients, making navigation more intuitive.	Enhances wayfinding for staff, leading to efficient hospital operations.	Eases navigation and reduces stress for families trying to find their way within the hospital.
Color Preferences	Preferences for bright and cheerful colors in play areas.	Preferences for a well-thought-out color palette in the workplace.	Preferences for soft, neutral colors in waiting areas and family rooms.
Overall Impact	Creates an engaging and comforting environment for paediatrics patients.	Fosters a positive work atmosphere and supports staff well-being.	Provides a welcoming and stress-reducing atmosphere for families and visitors.

CONCLUSION

The findings have several implications for hospital environment, design, and the overall well-being of individuals involved.

The study highlights the potential for color psychology to enhance the experience of young patients in paediatrics hospitals. Colors like Blue, which are commonly preferred, can be strategically used to create more engaging and comforting environments in play areas. Well-designed hospitals with carefully chosen colors can foster a positive work atmosphere for healthcare professionals. This can lead to higher staff morale, job satisfaction, better communication, and effective teamwork. Comfortable and relaxing spaces with appropriate color choices in waiting areas and family rooms can significantly alleviate stress and anxiety for families during a child's hospitalization. The finding that Blue is a universally preferred color suggests its versatility in creating positive environments in paediatrics hospitals. The generally neutral perceptions of the environment by all groups indicate that the chosen colors do not have strong negative effects, which can be considered a positive outcome.

Paediatrics hospitals should consider a strategic approach to color design, tailoring it to specific areas like play zones, recovery rooms, and waiting areas to meet the emotional needs of patients, staff, and families. Collaboration between healthcare professionals, designers, and color psychologists is crucial in selecting the most suitable color palettes for paediatrics hospital environments.

Color Recommendations for Paediatrics Hospitals

Color Recommendations for Paediatrics Hospitals involves selecting and implementing color schemes that support the emotional well-being of young patients, enhance the work environment for hospital staff, and create welcoming spaces for families and visitors. Based on the study's findings:

1. Emotional Well-being: Consider using vibrant and engaging colors in play areas to alleviate anxiety during medical procedures and hospital stays. Soft, soothing colors in recovery rooms can contribute to a calming environment for young patients, aiding pain perception and recovery.
2. Atmosphere: Create a positive and mood-boosting atmosphere in paediatrics hospitals with strategically chosen colors. Incorporate bright and cheerful colors in spaces dedicated to play and recreation. Opt for a well-thought-out color palette that fosters a positive work environment for hospital staff. In waiting areas and family rooms, use soft, neutral colors to provide comfort and reduce stress for families and visitors.
3. Wayfinding: Utilize color as a tool for wayfinding within the hospital. Differentiate departments or areas with distinct colors to make navigation more intuitive for young patients. Similarly, use color for wayfinding cues for hospital staff to enhance operational efficiency. For families and visitors, color can play a role in easing navigation and reducing stress.
4. Color Preferences: Take into account the preferences of various groups within the hospital. Young patients often prefer bright and cheerful colors, while hospital staff may appreciate a well-designed color palette that contributes to a positive work atmosphere. Families and visitors tend to prefer soft and neutral colors in spaces where they seek comfort and support.

5. Play Areas: Utilize bright and vibrant colors like yellows, reds, and playful pastels to create engaging and cheerful play areas. These colors can help uplift the mood of young patients and promote a sense of excitement and wonder.
6. Patient Rooms: Opt for softer pastels, such as calming blues and soothing greens, in patient rooms. These colors can create a peaceful and serene ambiance, potentially aiding in pain perception and recovery. Pastels are also versatile and can be used as a base for other design elements like murals or decals.
7. Hallways and Common Areas: Maintain a cohesive and welcoming atmosphere in hallways and common areas with a harmonious color palette that includes both vibrant and calming colors. This balance ensures that the hospital environment remains engaging but not overly stimulating.
8. Nature-Inspired Palette: Consider incorporating nature-inspired colors, such as soft sky blues, leafy greens, and earthy tones, into various hospital spaces. These colors can help connect young patients to the natural world, providing a sense of comfort and tranquility.
9. Proper Lighting: Enhance the impact of colors by ensuring proper lighting in different areas. Soft, diffused lighting can complement calming colors, creating a soothing atmosphere. In play areas, consider dynamic lighting options that can adapt to different activities and moods.
10. Texture and Depth: Use texture to add depth and richness to the color scheme. Textured wallpapers, upholstery, or decorative elements can enhance the sensory experience and make the environment more engaging for children.
11. Balancing Stimulation and Calmness: Maintain a thoughtful balance between stimulating and calming spaces. While play areas and activity zones can feature brighter and more energetic colors, quieter spaces like patient rooms and family waiting areas should prioritize calming hues. This balance ensures that the hospital environment caters to the diverse emotional needs of young patients.
12. Customization: Consider allowing young patients to personalize their immediate surroundings with removable, washable, or easily changeable elements like posters or decals. This customization can give children a sense of control and comfort during their hospital stay.
13. Multisensory Design: Explore multisensory design elements, such as interactive walls with color-changing LEDs or tactile surfaces, to engage children and provide a sensory-rich experience that aids in distraction and comfort.

These color recommendations for paediatrics hospitals aim to create a healing environment that supports the emotional well-being of young patients, enhances staff morale, and eases the stress experienced by families.
By carefully selecting and implementing colors in different areas of the hospital, healthcare facilities can create a more compassionate, supportive, and effective healthcare environment for paediatrics patients and their families.

Journal of Capital Markets Studies

The rise of passive investing: a systematic literature review applying PRISMA framework

Priya Malhotra
USME East Campus, Delhi Technological University, Delhi, India

Received 3 December 2023
Revised 14 March 2024
23 March 2024
Accepted 8 April 2024

Abstract

Purpose – Passive investing has established itself as the dominant force in the world of professionally managed assets, surpassing the concept of index funds. Its meteoric rise is fueled by investors' preference for its dual benefits of strong diversification and low cost. A comprehensive study of the economic model, addressed areas and market structure has not yet been conducted, despite the existence of numerous studies on more specific topics. To address this gap, this paper examines 943 articles on passive investing published between 1998 and 2022 in SCOPUS and Web of Science.

Design/methodology/approach – The study utilizes the most pertinent tools for conducting a systematic review by the PRISMA framework. This article is the result of SLR and extensive bibliometric analysis. Contextualized systematic literature review is used to screen and select bibliographic data, which is then subjected to a variety of bibliometric analyses. The study provides a bibliometric overview of works on passive investment research that are indexed in Scopus and Web of Science. Bibliometrix, VoS Viewer and Cite Space are the tools used to conduct content and network analysis, to ascertain the present state of research, as well as its focus and direction.

Findings – Our exhaustive analysis yields important findings. One, the previous decade has witnessed a substantial increase in the number of publications and citations; in particular, the inter-disciplinary and international scope of related research has expanded; Second, the top three clusters on "active versus passive funds," "price discovery and market structures" and "exchange-traded funds (ETFs) as an alternative" account for more than fifty percent of the domain's knowledge; Third, "Leveraged ETFs (LETFs)" and "environmental, social and governance (ESG)" are the two emerging themes in the passive investing research. Fourth, despite its many benefits, passive investing is not suitable for everyone. To get the most out of what passive investing has to offer, investors, intermediaries and regulators must all exercise sufficient caution. Our study makes a substantial contribution to the field by conducting a comprehensive bibliometric analysis of the existing literature, highlighting key findings and implications, as well as future research directions.

Research limitations/implications – While the study contributes significantly to the field of knowledge, it has several limitations that must be considered when interpreting its findings and implications. With our emphasis on academic journals, the study analyzed only peer-reviewed journal articles, excluding conference papers, reports and technical articles. While we are confident that our approach resulted in a comprehensive and representative database, our reliance on Elsevier Scopus and Web of Science may have resulted in us overlooking relevant work accessible only through other databases. Additionally, specific bibliometric properties may not be time-stable, and certain common distribution patterns of the passive investing literature may still be developing.

Practical implications – With this study, it has been possible to observe and chart the high growth trajectory of passive investing research globally, especially post-US subprime crisis. Despite the widespread

adoption of passive investing as an investment strategy, it is not a one-size-fits-all proposition. Market conditions change constantly, and it frequently requires an informed eye to determine when and how much to shift away from active investments and toward passive ones. Currency ETFs enable investors to implement a carry trade strategy in their portfolios; however, as a word of caution, currency stability and liquidity can play a significant role in international ETFs. Similarly, LETFs may be better suited for dynamic strategies and offer less value to a long-term investor. Lastly, the importance of investor education cannot be underestimated in the name of the highly diversified portfolio when using passive alternatives, for which necessary efforts are required by regulators and investors alike.

Social implications – The inexorable trend to passive investing creates numerous issues for fund management, including fee and revenue pressure, which forces traditional managers to seek new revenue streams, such as illiquid and private assets, which also implies increased portfolio risk. Additionally, the increased transparency and efficiency associated with the ETF market indicates that managers must rethink the entire value chain, beginning with technology and the way investments interact. Passive investments have triggered changes in market structure that are still not fully understood or factored in. Active management and a range of valuation opinions on whether a price is "too low" or "too high" provide much-needed depth to a market as it attempts to strike a delicate balance between demand and supply forces, ensuring liquidity at all price points.

Originality/value – I hereby certify that I am the sole author of this paper and that no part of this manuscript has been published or submitted for publication.

Keywords Passive investing, ETF, Index funds, Benchmarking, Bibliometric, Systematic

Paper type Literature review

1. Introduction

Globally, and particularly in developed countries like the United States, there has been a substantial shift in investor preference toward passive investing. Passive asset management, commonly known as passive investing, is an investment approach that monitors a market-weighted index (Sharpe, 1991). It can be accomplished by holding any or a combination of index funds, exchange-traded funds (ETFs), Index future contracts, Index futures options or Stock Market Index Swaps (Hasbrouck, 2003; Stoll and Whaley, 1990; Constantinides *et al.*, 2011) Passive investing, which is most widespread in equities, is gradually becoming more popular in other investment categories such as bonds, commodities and hedge funds (Jaeger and Wagner, 2005). When compared to actively managed funds, it provides good diversification, minimal transaction costs and lower turnover (Baks *et al.*, 2001; Pézier and White, 2008).

Passive investing is founded on the efficient market hypothesis (EMH), which was developed in the 1960s and contends that shares always trade at their fair market value and that persistent alpha generation is impossible. This theory rejected the efficacy of stock selection and market timing and represented the earliest school of thought on passive investing. Index funds were introduced in the 1970s and have been restricted to large pension and social security institutions since then (Sorensen *et al.*, 1998; Clark and Hebb, 2004; Elton *et al.*, 2007; Ayres and Curtis, 2014). Gruber (1996) brought attention to the paradox that investors purchase actively managed funds even though they underperform index funds on average. With growing investor dissatisfaction with active fund underperformance (Sorensen *et al.*, 1998; Malkiel, 2005; Sorensen *et al.*, 1998) and a desire to reduce costs across social benefit schemes, the relative appeal of passive investments has increased by multiple degrees in the aftermath of the 2008–2012 subprime crisis (Elton *et al.*, 2002). This has piqued the interest of industry, academia, and researchers alike, resulting in a slew of studies examining their performance (Avellaneda and Lee, 2010). The literature on passive investing, hence, has exploded in recent years.

The testing of the EMH, the comparative performance assessment of passive portfolios to curated folios, and investor biases in passive investing have all been topics of discussion in the past (Frino and Gallagher, 2001; Elton *et al.*, 2004; Choi *et al.*, 2010; Guercio and Reuter, 2014; Cremers *et al.*, 2016; Fahling *et al.*, 2019). Multiple studies addressing various characteristics of index funds, such as fee expense (Hortacsu and Syverson, 2004; Elton *et al.*, 2012), return

volatility (Goetzmann and Massa, 2003), tracking error (TE) (Meade and Salkin, 1990; Chen *et al.*, 2006), liquidity, investor purchase and redemption patterns (O'Neal, 2004), price discovery (Chen and Gau, 2009), hidden costs (Petajisto, 2011) and portfolio allocation (Fan *et al.*, 2016) have been conducted since the inception of index funds. Recent research on index funds has progressed to sparse portfolios (Takeda *et al.*, 2013), goal programming (Wu *et al.*, 2007), algorithm-assisted allocations (Schoenfeld, 2017) and financial innovations (Cremers *et al.*, 2016).

Lo (2007) integrated the EMH with behavioral finance to create the adaptive market hypothesis (AMH), which states that rational investors can swiftly become irrational in reaction to increased market volatility. In the aftermath of the US Subprime crisis, index funds were heavily criticized for causing the 2007–2008 spike in commodity futures prices, consequently, numerous studies examined the effect of index funds on the prices of underlying assets (Malkiel and Radisich, 2001; Michał Falkowski, 2011; Irwin and Sanders 2011; Ivanov, 2013; Hamilton and Wu, 2015).

ETFs, which manage trillions of dollars (USD) in capital flows in developed economies, are the most recent and significant development in modern capital markets after index funds. Since their introduction, various barometers of ETF performance have been explored in depth, including TE (Johnson, 2009; Shin and Soydemir, 2010; Chu, 2011), pricing efficiency (Israeli *et al.*, 2017) and fund flows (Clifford *et al.*, 2014). As ETFs gained prominence, their role in price discovery and information transmission (Tse and Martinez, 2007; Levy and Lieberman, 2013; Haslam *et al.*, 2018), volatility in prices of underlying (Gleason *et al.*, 2004), market liquidity (Boehmer and Boehmer, 2003; Ben-David *et al.*, 2017), market microstructures (Gao *et al.*, 2018), market co-integration and error correction (Chou and Chung, 2006; Delcoure and Zhong, 2007; Broman, 2016), volatility spillover (Krause and Tse, 2013; Inci, 2018) has been investigated in detail. With growing environmental consciousness, ETF research has shifted to evaluating the efficacy of investments in alternative energy (Miralles-Quirós and Miralles-Quirós, 2019). Furthermore, inter se comparison between index funds and ETFs on a variety of criteria, including substitutability, cost structure, investor types and risk-adjusted returns have been conducted (Beneish and Gardner, 1995; Kostovetsky, 2003; Harper *et al.*, 2006). Leveraged ETFs (LETFs) are one of the most recent financial developments in the ETF realm, and various studies have been conducted to explain this concept (Avellaneda and Zhang, 2010; Charupat and Miu, 2011).

Notwithstanding economic challenges, unpredictability and an initial upheaval precipitated by the coronavirus disease 2019 (COVID-19) pandemic, the asset management sector rebounded in 2022 and produced favorable returns. The assets under management (AUM) of passive funds are projected to reach USD 34 trillion by 2025, according to the Global Asset Management Report, (2021) by Boston Consulting Group. Systematic reviews serve the purpose of identifying particular domains that necessitate further research. Additionally, they enable professionals to obtain a comprehensive understanding (Randhawa *et al.*, 2016). Previous studies have conducted literature reviews on distinct aspects of passive investing strategies, such as fixed-income and index investing (Tang and Xu, 2017), the effects, trading, and institutions of ETFs (Madhavan, 2012; Joshi and Dash, 2024), and an overview of Indian index funds (Sarkar *et al.*, 2013). Despite the expanding corpus of scholarly work concerning specific facets, a comprehensive overview of the overarching passive investing strategy remains extremely scarce. Our research is most closely aligned with the findings of the Fisch *et al.* (2019) study. In light of the market mechanism, the study offers a comprehensive analysis of the theoretical framework from institutional, policy and regulatory standpoints to enlighten passive investors. However, a review of the existing literature in this field is not included in the study. Given these overarching concerns, the expansion and development of the corpus of research in numerous disciplines emphasizes the need for a quantitative investigation to establish a comprehensive framework, identify noteworthy trends and determine directions for future research. Our study investigates the subsequent research

inquiries by employing a systematic literature review (SLR) and a rigorous bibliometric analysis.

RQ1. What characterizes the current research trend in passive investing?

RQ2. Which sources, articles and authors are the most influential in this research domain?

RQ3. What are the dominating themes in this field of study?

RQ4. What has been the evolution of the conceptual and intellectual structure (IS) over time?

RQ5. What is the future research scope?

2. Data and research methodology

This article is the result of SLR and extensive bibliometric analysis. Contextualized SLR (Tranfield *et al.*, 2003) is used to screen and select bibliographic data, which is then subjected to a variety of bibliometric analyses (Zupic and Čater, 2015). Bibliometric analysis as a technique entails the application of statistical tools to the examination of the bibliographic attributes of a body of literature. We follow Pattnaik *et al.* (2020) as a methodical approach for data selection and research design as depicted in Figure 1.

Figure 1.
Data selection and research design

2.1 Search criteria and data retrieval

The collected data adhered to a systematic research methodology that outlined the essential stages required to perform a literature review following the PRISMA framework. For the presentation of evidence in systematic reviews and meta-analyses, PRISMA is the acknowledged standard. Journals that underwent peer review were the only sources considered for this study. The evaluation process excluded reports, conference proceedings, publications and theses. Analyses of 943 articles indexed by Scopus and WoS were conducted to address the aforementioned research questions. In selecting these documents, five criteria were considered: (1) Refereed academic journals (to ensure the highest quality of refereeing), (2) Articles published between 1998 and 2021, (3) Indexed by Scopus and WoS, (4) Filtered using keywords and Boolean operators: "passive investing or passive invest*," or "index fund*," or "exchange-traded fund" or "ETF*" or "indexing,"; (5) The study includes all eligible non-duplicate publications in the English language that met the filtration criteria. The process of retrieving meta-data is summarized in Table 1.

2.2 Research methodology

Bibliometric approaches or analyses are now firmly established as an essential component of research evaluation methodology, particularly in scientific and applied disciplines (Ellegaard and Wallin, 2015). It helps to eliminate subjective bias in qualitative literature synthesis (Nerur *et al.*, 2008) and has been widely used in the past to analyze massive amounts of bibliographic content on topics (Blanco-Mesa *et al.*, 2017), universities (Merigó *et al.*, 2019), countries (Mas-Tur *et al.*, 2019) and journals (Donthu *et al.*, 2020). Citation and co-citation analysis are two of the most commonly used bibliographic approaches for uncovering differences in the intellectual landscapes of cited sources (Kessler, 1963; Small, 1973).

Bibliometrix, VoS Viewer and Cite Space are the tools used to conduct content and network analysis and to ascertain the present state of research in this sector, as well as its focus and direction. The descriptive analysis summarizes the trend in publications and citations (Tsay, 2009). The most influential sources, articles and authors are selected based on *h-index*, *g-index* and *m-index* (Hirsch, 2005; Ding and Cronin, 2011). Keyword analysis is used to elucidate the study domain's knowledge framework, emerging patterns and evolving themes (Hu *et al.*, 2018). The conceptual structure is deduced using word-tree analysis (WTM) (Callon *et al.*, 1983). Network analysis is performed using the bibliographic coupling (B-C) principle and network centrality strength to uncover interconnected communities (Bastian *et al.*, 2009).

Steps	Filtration criteria	Excluded	Accepted
Identification	Record identified through database screening (Boolean Operator)		1,320
Screening	Filtration on the basis of the subject (Business, Economics, Econometrics, Finance, Management, Accounting and Social Science)	308	1,012
	Duplicates removed	5	1,007

3. Descriptive statistics

3.1 Trend in research and scientific productivity

Addressing RQ1 on the research trend in passive investment, Figure 2 shows that the number of annual publications has been increasing since 2007. To be specific, over 90% of the literature included in this study was published after 2008, implying that the majority of intellectual debates in the area of passive investment occurred in the aftermath of the 2008–2012 global economic crisis.

3.2 Most influential authors, documents and sources

This section addresses the RQ2 concerning the prominent authors, articles, and sources in the field of Passive Investing. Table 2 summarizes the most influential authors on passive investing, arranged by the number of publications; additional metrics are included in the table. Tse Y is ranked first with 14 articles between 1998 and 2001, an h-index of 9, and 241 citations. Gruber MJ is the most prominent author on passive investing, with a TC count of 1,520, followed by Irwin SH (TC: 776) and Elton EJ (TC: 667). The h-index metric measures both citation and productivity impact at the author level; Irwin SH, with an h-index of 10, g (12) and m (0.833), is the most influential author in the field of passive investment, followed by Tse Y (9, 14 and 0.474).

Note(s): The table above enlists the top 10 authors contributing to the extant literature based on three distinct impact factors: h-index, g-index and m-index (*h*, *g* and *m* respectively). It also presents the total citation count (TC) accredited to the author along with the number of papers (NP) by the author

Source(s): Authors' own work

Table 2.
Most influential authors on passive investing based on three impact factors

As assessed by NP, Table 3 summarizes the top journals in the field of passive investment. The *Journal of Portfolio Management* tops the list with 35 contributions to the current body of knowledge, followed by Managerial Finance (NP: 28) and the *Journal of Banking and Finance* (NP: 25). It's worth noting that the top ten journals account for more than a quarter (26%) of the papers examined in this study, while the top twenty journals account for almost 40% of the total articles examined. While the Journal of Banking and Finance is the most widely cited source in the domain of passive investment, according to the *h* and *g* indexes (14 and 23 respectively), the Journal of Finance (not included in the table below) ranks first with 1,684 citations using TC as a measure of influence. Publications in reputable journals demonstrate the study domain's growth, inspiring additional research endeavors (Acedo *et al.*, 2006). The aforementioned considerations, hence, justify the remarkable increase in research in this area.

Based on the citation score, Table 4 presents the most influential papers and references on passive investing. Local citations (LCs) are based on a dataset included in the study, whereas global citations (GCs) are based on a large dataset available on Google Scholar and Web of Science. The top most influential article (GC:853) is Gruber J.'s "*Another Puzzle: The Growth in Actively Managed Mutual Funds*" (1996), followed by Shleifer A.'s "*Do Demand Curves for Stocks Slope Down?*" (1986) (GC: 589). Using LC as a metric of influence, Elton J., "*Spiders: Where Are the Bugs?*" (2002) ranks first (LC:71), followed by GruberJ., "*Managed Mutual Funds*" and Ben-David *et al.* (2018) "*Exchange-Traded Funds*" (LC: 49).

3.3 Most dominating themes in research on passive investing

In response to RQ3, Figure 3 offers an overview of the thematic evolution seen in the literature on passive investing. The frequency with which keywords appear in the literature from 1998 to the current day is used to extract the most prominent themes. Time slices were created using significant economic events that affected the development of financial markets in

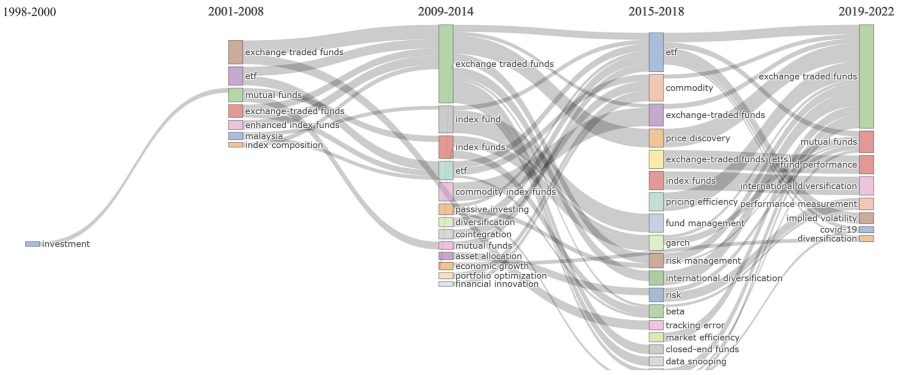

Figure 3. Thematic evolution in passive investing research

Note(s): Figure 3 presents the thematic evolution of research in the area of passive investing across four time slices, the frequency of occurrence is the qualifying criteria for the ranking of themes
Source(s): Authors' own work

general and passive investments in particular. The first time slice, from 1998 to 2000, illustrates the closed character of financial investments before the US IT boom. With the turn of the twenty-first century and the integration of financial markets, *exchange-traded funds* and *enhanced index funds*, which seek to boost the returns produced by strict index funds, were added to the broader basket of passive investments, which index funds previously dominated. The rapid post-global financial crisis (GFC) economic recovery of the Malaysian economy [1], bolstered by robust government spending and the strengthening of foreign trade, attracted the research community's attention, as evidenced by its inclusion in the prominent themes in the period spanning 2001–2008. Passive investments experienced

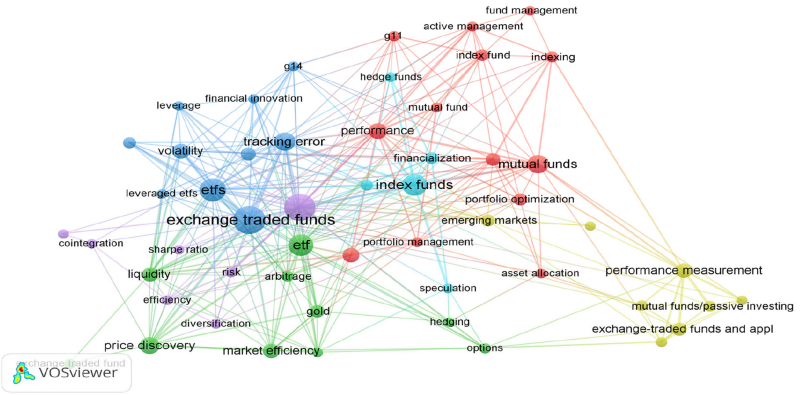
substantial growth in the aftermath of the GFC of 2007–2008, gaining extensive academic interest with the addition of *commodity index funds*, *financial innovations* and *asset allocation* to its repertoire. The increased availability of soft liquidity after quantitative easing (QE) has resulted in developing economies emerging as favored investment destinations. This development provides further rationale for the inclusion of *diversification* in the most prolific themes, alongside *portfolio optimization*. Additionally, heightened risk management awareness is a consequence of the GFC; as a result, international investors have redirected their attention toward attaining *international diversification* via ETFs that replicate global indices. The aforementioned developments have also prompted the incorporation of *TE* and *pricing efficiency* metrics into ETF performance evaluations, the implementation of *data snooping* and *GARCH* to identify patterns and the rise of leveraged ETFs (LETFs) as a novel concept in passive investing from 2015 to 2018. In 2019, asset markets experienced significant disruption and dislocation following the outbreak of COVID-19, the deadliest threat of the century. The fourth time slice commenced in that year. As a consequence, investigations into *implied volatility* in *performance evaluation, price discovery, portfolio construction* and other ETF-related studies were augmented to incorporate the quintessential *COVID-19* perspective. As environmental and sustainability concerns have grown, environmental, social and governance (ESG) orientation has emerged as a prevalent topic in passive investment research and a popular catchphrase.

4. Empirical findings

This section elaborates on the conceptual and intellectual framework of the existing literature concerning RQ4. It accomplishes this by employing a range of methodologies, including keyword analysis, B-C, keyword co-occurrence and content analysis, to identify key clusters of scholarly work in the domain of passive investing.

4.1 Network visualization of the literature

4.1.1 Keyword network analysis. In the form of a keyword co-occurrence network of the top 53 terms, Figure 4 depicts the conceptual structure of the scientific literature under investigation. Six clusters make up the network. The top cluster has 25% of all frequently co-occurring keywords in the literature, whereas the second and third clusters have 19% of all co-occurring keywords. While the fourth, fifth and sixth positions, respectively, contain 15, 13



Source(s): Authors' own work

Figure 4.
Keywords co-occurrence network

and 9% keywords. Each keyword is a node, the size of which is determined by its frequency of occurrence. The terms "exchange-traded funds," "tracking error," "index funds," "mutual funds," "performance measurement," "exchange-traded funds" and "etf" dominate in terms of network strength, implying the most prolific empirical themes in passive investing research.

4.1.2 Bibliometric content analysis of the network. Figure 5 shows the network illustrating the B-C of the top 251 articles. The network comprises nine clusters, each of which contains articles with a minimum of ten citations. The first three clusters represent more than half of all articles examined for the B-C, whereas the first five clusters represent more than 70% of all articles. The top three most popular articles in each cluster are listed in Table 5, sorted by page rank (Ding, 2011).

4.1.3 Clusterwise content analysis. With the arrival of the Science Citation Index (SCI) on the bibliographic landscape, the technique of analyzing vast scientific literature on the basis of the relationship between published papers (measured by co-referencing) has garnered huge research interest (Martyn, 1964). The B-C combined with the cluster method could provide valid depictions of the interrelationship between articles with similar referencing (Kessler, 1963). This section gives a clusterwise depiction of research in passive investing.

Cluster 1: active funds vs passive funds

The first cluster consists of 44 studies conducted from 1996 to 2019. The cluster's overarching theme is the comparative performance assessment of active funds with index funds and other passive benchmarks. The cluster is founded on the work of Gruber (1996), a research that compared active and passive funds and casts doubt on active mutual funds' meteoric expansion despite delivering lackluster performance on average (Moore *et al.*, 1999). The empirical inquiry is complemented by Elton *et al.* (1996)'s discussion of the persistence and predictability of risk-adjusted returns and fund flows as also how modern portfolio theory may be used to construct optimal portfolios generating economically significant expense-adjusted returns. The performance differential between active and passive funds (primarily index funds) has been examined from a variety of perspectives, including portfolio allocations (Keim, 1999; Baks *et al.*, 2001; Ahmed and Nanda, 2005; Bollen and Busse, 2006; Gil-Bazo and Ruiz-Verdu, 2009; Choi *et al.*, 2010; Cuthbertson *et al.*, 2010) and, non-portfolio differentiators such as fund fee expense, cash flows, trading costs and the fund management (Baks *et al.*, 2001; Gastineau, 2004; Golec, 2003; Hortacsu and Sveyorson, 2004; O'Neal, 2004; Houge and Wellman, 2007; Rompotis, 2009; Elton *et al.*, 2012; Bogle, 2014; Cremers *et al.*, 2016). Numerous studies have investigated anomalies such as in fund flows (Białkowski *et al.*, 2013) and fund

Note(s): The table lists the most prolific top 3 articles of the nine bibliographic clusters created on the basis of total citations (TC). PageRanks (PR) are used to rank the articles. Publishing year (PY) and First Author name are also mentioned in the table

Source(s): Authors' own work

Table 5.
Most prolific articles on passive investing

manager names (Kumar *et al.*, 2015). Brown *et al.* (2007) and distribution channels found no conclusive evidence of underperformance relative to index funds (Guercio and Reuter, 2014). The cluster also covers quintessential comparative performance assessment studies. Lettau and Madhavan (2018) conducted an in-depth examination of the structure and organization of ETFs and various advantages offered by them with a brief reference to the disadvantages arising from market frictions. Kostovetsky (2003) discovered that ETFs are more suitable for long-term investors and that flows to ETFs are determined by individual investor characteristics and risk tolerance (Clifford *et al.*, 2014; Mikhaylov *et al.*, 2019). Deviations from the underlying benchmark, TE, its determinants and persistence have been the most researched dimension in ETF studies (Frino *et al.*, 2004; Gastineau, 2004). Blitz *et al.* (2012) expanded the analysis to include Emerging Market Economy (EME)-focused ETFs and reported much higher TE in ETFs with a developed economy focus. Notably, ETFs deliver on their underlying objective of tracking indexes and the addition of active components adds no value to ETFs Sherrill *et al.* (2017).

Cluster 2: effect of market structures

The second cluster consists of 43 publications published between 2002 and 2019. The cluster's major focus is *price formation, price discovery, market structure, and its effect on volatility and liquidity*, with ETFs as the dominant investment type. Except during periods of extreme volatility, the contribution of ETFs tracking the broad market is considerable in a complex financial market environment comprised of equity indexes, ETFs and micro future contracts (Hasbrouck, 2003; Tse and Erenburg, 2003; Chen *et al.*, 2016; Chen and Tsai, 2017). The role of spot market dynamics in comparison to futures markets has been extensively studied, and it has been determined that the introduction of small tick sizes (Beaulieu *et al.*, 2003; Wu *et al.*, 2007; Chen and Gau, 2009), market microstructure and fragmentation (Hendershott and Jones, 2005; Tse *et al.*, 2006) are economically significant. Before the introduction of computerized trading, the futures markets dominated the process of price discovery (Schlusche, 2009). Notably, ETFs now enabled by in-kind creation and redemption activity in the stock market are now leading price discovery in commodity markets (Ivanov, 2013). Increasing institutional ownership and algo-trading using high-frequency data is further aiding the price discovery mechanism (Elton *et al.*, 2002; Charupat and Miu, 2011; Chen *et al.*, 2016; Nugroho, 2021). Volatility measurement both before and after the introduction of ETFs (Hansen *et al.*, 2012) has been another frequently researched dimension, as has market fragmentation. Volatility-return relationship (Daigler *et al.*, 2014), volatility spillover and leverage effects on returns (Chen and Huang, 2010; Krause and Tse, 2013; Dedi and Yavas., 2016), as well as return predictability (Shynkevich, 2016) have been the subject of research under numerous studies. While modeling ETF returns, multiple realized volatility measures outperform single realized volatility measures, and when multiple forecasting approaches are compared, algorithmic methods and Bagging (Bootstrap aggregation) are found to be more accurate (Brownlees *et al.*, 2011). The impact of the advent of these modern trading platforms on price variations, price formation and liquidity in the ETF market, particularly with an EME concentration, remains an open subject of intellectual dispute.

Cluster 3: ETF as an investment alternative

The third cluster contains 41 publications published during 17 years beginning in 2002. The cluster's major issue is the *ETFs as an investment alternative*, with a particular emphasis on trading strategies for passive investing. ETFs combine the characteristics of closed-end funds (CEFs) and open-end funds (OEFs) (Harper *et al.*, 2006). While CEFs and ETFs are similar in terms of trading and organization, liquidity and arbitrageability set these apart (Hughen and Mathew, 2009). Both fund types overreact to domestic results; however, ETFs

more closely track the underlying index (Aber *et al.*, 2009). The gap between the net asset value (NAV) and ETF price, indicating pricing efficiency can be explained by measurement errors. However, the rate of error correction is faster in domestic ETFs compared to international ETFs with implications on portfolio diversification (Jares and Lavin, 2004; Engle and Sarkar, 2006). Price deviation (premium/discounts) has been a subject of continual investigation in ETF research; ETFs are more likely to trade on a premium basis than on a discount basis. Delcoure and Zhong (2007) argue that factors such as institutional ownership, bid-ask spread, trading volume, currency volatility, geopolitical crisis and conditional correlation between markets contribute to the formation of iShare premiums. Trading methods based on passive investments are a major focus of research in this cluster. Avellaneda and Lee (2010) examined the efficacy of model-driven statistical arbitrage and determined that strategies based on exchange-traded funds yielded a higher Sharpe ratio. Cross-border spillovers (Lee and Chen, 2020), serial dependence in returns (Baltussen *et al.*, 2019), feedback trading (Chau *et al.*, 2011) and the use of ETFs to capitalize on industry and country momentum have all been examined to determine the international diversification benefits that passive investments may provide. While ETFs have a reduced average bid-ask spread (Andreu *et al.*, 2013), index funds provide greater diversification benefits due to their lower correlations with the underlying index (Khorana *et al.*, 1998). Individual investors can easily include carry-trading into their asset allocation strategy through the use of ETFs (Das *et al.*, 2013). Gold ETFs and other index funds tracking Gold offer hedging and safe-haven features (Pullen *et al.*, 2014). Leveraged exchange-traded funds (LETFs) are the most sophisticated ETF concept. However, when Gold is used as the underlying, these exhibit tracking incapability (Leung and Ward, 2015). By and large, LETFs underperform static strategies and are regarded as unsuitable for long-term investors (Avellaneda and Zhang, 2010). The role of behavioral characteristics or investor sentiment in ETF and index fund mispricing presents future research opportunities.

Cluster 4: pricing and market efficiency

The fourth cluster consists of 28 studies that span 16 years, from 2002 to 2018. With commodities at the center of the argument, research in this cluster examines the *impact of passive investment on future prices, risk premia, market efficiency* and EMH testing. Index funds have long been blamed for increasing volatility, distorting price relationships and fueling asset commodity price bubbles (Sanders *et al.*, 2010). Empirical studies examining the relationship between index fund positions and commodity futures prices, however, found no conclusive evidence of index fund positions' impact on returns and volatility (Capelle-Blancard and Couibaly, 2011; Stoll and Whaley, 2011; Hamilton and Wu, 2015), Büyükşahin and Robe (2014) reported similar results during periods of market stress. A novel study by Gilbert and Pfuderer (2014) provided greater evidence that changes in index positions offer prognostic information for commodity prices. The financialization of commodities results in the blurring of the distinctions between commodities and stock markets (Michał Falkowski, 2011). Ordu *et al.* (2018) cited variables such as currency appreciation, availability of liquidity and the expansion of developing markets contribute to the increased volatility in raw and soft commodities markets. This problem has also been discussed with the risk premia accessible to commodity investors. Main *et al.* (2018) assert that before and after financialization, the average unconditional return on individual commodity futures markets is equal to zero.

Cluster 5: market regimes and pricing

The fifth cluster has 26 articles spanning eight years from 2010 to 2020. This cluster's central theme is *market structure, market niches and the effect of various market regimes* on the performance and pricing efficiency of passive investments. The 2010 flash crash served as a

proving ground for a variety of economic theories. Madhavan (2012) revealed that market fragmentation was a significant factor in the propagation of the liquidity shock and how securities were affected by the flash crash. Price deviations and mispricing in ETFs have been thoroughly researched since then across a range of market environments. While Wong and Shum (2010) concluded that ETF returns are not proportionate to volatility, Shanmughama and Zabiulla (2012) discovered a substantial variation in alpha generation between bearish and bullish markets, with TE and average premium being larger in bearish conditions and vice versa. As markets become more integrated, the changing market dynamics have been a continuing source of inquiry. Petajisto (2017) found that funds that invest in overseas or illiquid equities experience more price variations. Ackert and Tian (2008) assert that when country ETFs' fund premiums are compared to US ETFs' fund premiums, country ETFs demonstrate a high degree of positive autocorrelation. Their undervaluation is a result of scale effects, momentum, and illiquidity. In the Asian markets context, Shin and Soydemir (2010) found greater persistence in TEs, with currency rates playing a substantial role in the failure to track along with commonly cited market liquidity factor (Osterhoff and Kaserer, 2016; Camilleri *et al.*, 2020). On the other hand, Charteris *et al.* (2014) provide compelling evidence that ETF premiums and discounts encourage feedback trading in EMEs, which becomes more prevalent as premiums rise. LETF is a derivative-based exchange-traded fund that seeks daily returns that are a multiple of the underlying index's return. According to Tang and Xu (2013), market frictions and inefficiency greatly contribute to the LETF's return deviation. On the other hand, Li and Zhao (2014) examined how LETF trading affects the market quality of component stocks and reported a positive correlation between the trading volumes of the LETF and the stocks. ETFs have attracted enormous investor interest, making them one of the most significant financial innovations. Empirical research has discovered a strong correlation between Information and Communications Technology (ICT) penetration and ETF popularity and adoption as an investment class. The dark side of financial innovation in the domain of high-frequency data, algorithmic trading and information diffusion, on the other hand, remains a relatively untapped field of study.

Cluster 6: portfolio strategies

This cluster includes 26 studies that examine portfolio construction and optimization methodologies for passive investing. The cluster dates back more than three decades, with Ippolito (1989) providing the first evidence of the efficiency of costly information in mutual fund returns consistent with optimal trading in efficient markets. Numerous studies found that portfolios constructed using stock-specific criteria (Meade and Salkin, 1990), diversity-weighted index (Fernholz *et al.*, 1998), enhanced index investing (Wu *et al.*, 2007) and heuristics (Takeda *et al.*, 2013) generated higher returns than portfolios constructed using the market capitalization method. Estrada (2008) demonstrated that low-cost value-based strategies outperformed both price-insensitive passive and capitalization-based indexes in global portfolio building. Thompson *et al.* (2006) conducted exploratory data analysis and found data-driven programming to be superior to the several fundamental models of neoclassical computational finance. In the ETF context, numerous studies found that ETFs provide fewer diversification benefits than implied by the benchmark index's return characteristics (Bhattacharya *et al.*, 2017; Buetow and Henderson, 2012; Pedersen, 2018). Huang and Lin (2011), on the other hand, concluded that ETFs have a higher Sharpe ratio than the target market index, particularly in EMEs. With growing awareness of the interdependence of ESG challenges, sustainable investment has gained traction, allowing investors to benefit from investing in ETFs tracking firms with sustainable development goals (Miralles-Quirós and Miralles-Quirós, 2019). Analyzing hedge strategies based on

restricted passive portfolios, smart beta strategies, alternative energy and ESG investment in general gives further scope for research.

Cluster 7: varying composition of underlying indices

A total of 24 studies examining *changes in the composition of broad market indices* such as the S&P 500, the Russell 2000, the FTSE100, and the DJIA, as well as the associated price effects, form the heart of this cluster, which spans over 2 decades (1994–2018). Index funds, ETFs and other passive funds collectively represent a sizable and important institutional investor class for stocks trading on global stock markets. Any change in the composition of the larger indices tracked by index funds and ETFs causes rebalancing of index fund portfolios and so affects returns (Shleifer, 1986; Lynch and Mendelhall, 1997; Chen *et al.*, 2006), providing vital insight into market efficiency (Madhavan, 2003). This effect could be transient, consistent with the price pressure hypothesis (Woolridge and Ghosh, 1986; Vespro, 2006), or it could be permanent, consistent with Scholes's (1972) price shift followed by considerable abnormal trading volume, confirming downward-sloping demand curve hypothesis (Biktimirov, 2004). Beneish and Gardner (1995) suggested that information symbolism, price pressure, imperfect alternatives and information cost could all be explanatory variables for the stock market consequences of DJIA revisions. On the other hand, Malkiel and Radisich (2001) find no evidence that indexing has a persistent effect on the pricing of securities. According to Masse *et al.* (2000), the information content of inclusion does not fully explain the share price response. Numerous studies examined the effect of changes in the composition of market benchmarks on stock betas (Hau, 2011), the liquidity provision of index funds (Green and Jame, 2011), the demand for component stocks (Kappou *et al.*, 2010), and the home currency (Hau *et al.*, 2010). On the day of index inclusion, NYSE equities saw less severe price effects than NASDAQ stocks, demonstrating the superiority of the expert system over the dealer system in minimizing price effects (Elliott and Warr, 2003).

Cluster 8 and 9: contribution of passive investments to market volatility

This cluster focuses on the *impact exerted by passive investments on market volatility*, which is fueled by both misguided investor decisions and ETF market action driven by arbitrage. This cluster is comprised of 17 articles dating from 2002 to 2018. Herding behavior has been extensively studied during periods of market stress and volatility, and momentum flows during these periods are significant for securities pricing (Goetzmann and Massa, 2002). Investor behavior, on the other hand, is not symmetrical between bull and bear markets (Gleason *et al.*, 2004; Gopane *et al.*, 2023). Stocks with a higher proportion of ETF ownership exhibit much more volatility, which adds another layer of non-diversifiable risk to stock prices (Ben-David *et al.*, 2017). Increased ETF ownership is accompanied by increased trading costs, diminished information acquisition benefits, and an increase in voluntary disclosures (Israeli *et al.*, 2017; Schoenfeld, 2017; Lin *et al.*, 2018). ETFs, hedge funds and other institutional investors provide aggressive liquidity at competitive prices (Aitken *et al.*, 2007). Index funds have been implicated in causing the asset price bubbles and ensuing financial crisis. With the growing popularity of passive investing, the situation is likely to deteriorate further due to increased financialization via ETFs and high-speed automated algorithmic trading, as well as accumulating unfunded obligations (Sornette and Cauwels, 2014). However, the magnitude of the crash is highly dependent on the proportion of uneducated investors and the amount of unsophisticated passive investing in the market (Barlevy and Veronesi, 2003). The effect of stock inclusion in ETFs on price correlation and stock betas remains largely unknown in the EME environment, despite rising cross-sectional commonality in equities. This also highlights the importance of developing innovative risk management solutions.

Nineth cluster is the smallest cluster, consisting of three publications that make significant contributions to the literature on the dynamic role of passive investments in global financial markets. With the growing popularity, passive investments account for a sizable portion of the total AUM in the developed markets. These funds are ready to amass massive positions as their combined ownership in the most widely followed broad indices such as the S&P 500 and DJIA continues to grow at a breakneck pace (Bebchuk and Hirst, 2019). Three mega-funds in the United States control more than 40% of voting rights in companies listed on S&P and dominate the broader index. Their full potential is anticipated to manifest itself in the shift to sustainability, with passive management eclipsing active fund management in socially responsible investing (Chen and Scholtens, 2018; Fisch *et al.*, 2019). The extent to which passive funds contribute to ESG objectives remains an unanswered question.

4.2 Conceptual analysis

The conceptual model illustrated in Figure 6 summarizes a thorough content study of the literature in nine bibliographic clusters. The structure largely illustrates the various antecedents of passive investments and their impact on two major performance attributes, with liquidity, degree of financialization and capital flows serving as mediating factors. Bi-directional arrows suggest potential endogeneity in financial variables, while the link denotes the nature of the relationship studied in the available literature.

The investors' rationale for choosing active funds despite their historical underperformance in comparison to passive benchmarks and index funds has been constantly scrutinized (Goetzmann and Massa, 2003; Lichtenstein *et al.*, 1999; Fortin and Michelson, 2005; Boldin and Cici, 2010). Passive funds are intended to replicate a market-linked benchmark, and deviations from the benchmark define tracking efficiency (Johnson, 2009; Chu, 2011; Rompotis, 2011). Transitions in the macroeconomy dictate market regimes. Furthermore, market volatility is substantially influenced by corporate actions, including investor disclosures and expanding ICT penetration. Expansionary developments tend to generate more pronounced surges, as forecasting errors escalate (Lunde and Zebedee, 2009; Nguyen *et al.*, 2007; Aggarwal *et al.*, 2014). The market for passive investments reflects the cumulative impact of these forces in three broad dimensions: Market liquidity, Capital Flows and Degree of Financialization. Although the term "financialization" began to appear with increasing frequency in the early 1990s, its origins remain elusive. However, since the late 1960s, the fundamental issue of a gravitational movement toward finance in capitalism as a whole has existed. Financialization essentially implies the increasing role of financial motives, financial markets, financial actors, and financial

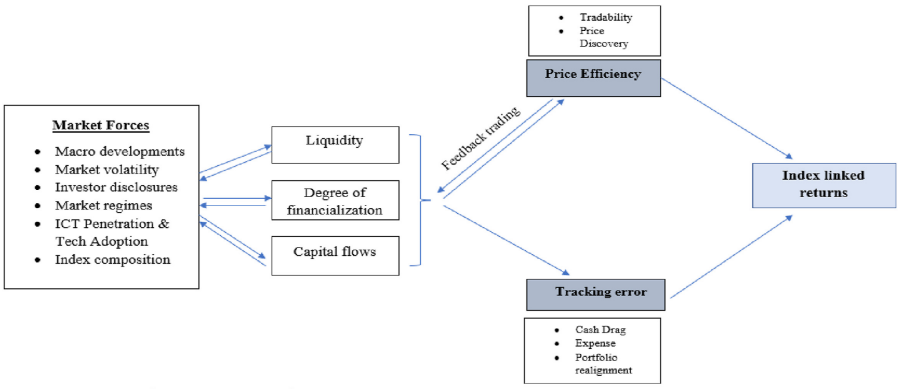

Figure 6.
This figure represents the conceptual structure developed based on analysis of the content of passive investing literature

Source(s): Authors' own work

institutions in the operation of domestic and international economies. This equally holds for passive investments.

ETFs, the most popular passive alternative, allow for secondary market trading. Authorized participants' in-kind redemption and creation processes result in price discovery in ETF markets, defining the pricing efficiency (Shanmughama and Zabiulla, 2012; Petajisto, 2017). The market's liquidity (Ackert and Tian, 2008), as well as overall volatility, determine the success of in-kind creation and redemption processes, thereby influencing the degree of financialization (Irwin and Sanders, 2011, 2012; Michał Falkowski, 2011; Ivanov, 2013). With the financial markets landscape evolving, contemporary issues such as the impact of ICT and social change on ETF performance (Lechman and Marszk, 2015), international diversification (Huang and Lin, 2011) and emerging economies perspectives (Blitz *et al.*, 2012) have become research focal points. Passive investments are gaining popularity and are establishing a dominant position as a source of investible surplus. ETFs have been instrumental in reducing market volatility (Lin and Chiang, 2005) and increasing liquidity (Hegde and McDermott, 2004; Ben-David *et al.*, 2017), and are now the primary source of price discovery (Ivanov, 2013), resulting in long-term convergence of stock betas (Sullivan and Xiong, 2012). Madura and Ngo (2008) concluded that ETFs had a sizable and beneficial effect on the valuation of their constituent equities. Petajisto (2011) coined the term "index turnover cost" to examine the effect of ETF price deviations on investment behavior. Charteris *et al.* (2014) concluded that ETF discounts/premiums encourage feedback trading, whereas Da and Shive (2018) concluded that correlations between ETF returns and stock-lagged beta provide evidence for price reversal. This also reflects the endogeneity of variables such as liquidity, capital flows and financialization degree.

5. Limitations

While the study contributes significantly to the field of knowledge, it has several limitations that must be considered when interpreting its findings and implications. With our emphasis on academic journals, the study analyzed only peer-reviewed journal articles, excluding conference papers, reports, and technical articles. As a result, contributions published in other formats that had an effect on the body of knowledge are excluded. Additionally, our keyword-based approach to article selection may introduce subjectivity bias into the process. While we are confident that our approach resulted in a comprehensive and representative database, our reliance on Elsevier Scopus and Web of Science may have resulted in us overlooking relevant work that is only accessible through other databases. Additionally, specific bibliometric properties may not be time-stable, and certain common distribution patterns of the passive investing literature may still be developing. Furthermore, it is worth noting that the graphs and citation networks were interpreted subjectively. With passive investing's growing popularity and the number of publications at an all-time high, it's clear that intellectual debate in this field has not yet reached saturation. As a result, the study's findings may not be exhaustive, and there is considerable room for additional research, as detailed in Sections 6 and 7.

6. Research implications

With this study, it has been possible to observe and chart the high growth trajectory of passive investing research globally, especially post-US Subprime crisis. The phenomenal growth story of passive investments may be attributable to increasing investor dissatisfaction with active investing which comes at a higher price. The findings of our study have key implications for various stakeholders: investors, regulators and managers, these are discussed in detail below:

6.1 Implication for investors

Despite the widespread adoption of passive investing as an investment strategy, it is not a one-size-fits-all proposition. Market conditions change constantly, and it frequently requires an informed eye to determine when and how much to shift away from active investments and toward passive ones. Active managers may outperform more frequently than passive managers in volatile markets or when the economy is weakening. On the other hand, passive strategies may be preferable when the index's constituent securities move in lockstep or when stocks have more consistent valuations. Depending on the opportunity in different sectors of the capital markets, investors may gain from a combination of passive and active techniques.

While active investing may be more profitable in cases where international diversification is required, such as investing in emerging market stocks, passive investing may make more sense in the domestic investing landscape. Additionally, an active fund manager may be better suited to manage a portfolio of illiquid securities or one that is tailored toward a specific objective, such as limiting the downside risk. It's also worth noting that investors, on average, place a higher premium on risk, return and liquidity than on cost. This is especially true for those with high net worth who have access to private equity, hedge funds and other curated alternative investments. While investing in ETFs, investors should bear in mind the effect of market regimes on TE, as deviations from the benchmark typically increase more during bearish than bullish regimes. Currency ETFs enable investors to implement a carry trade strategy in their portfolios; however, as a word of caution, currency stability and liquidity can play a significant role in international ETFs. Similarly, LETFs may be better suited for dynamic strategies and offer less value to a long-term investor. Lastly, the importance of investor education cannot be underestimated in the name of the highly diversified portfolio when using passive alternatives, for which necessary efforts are required by regulators and investors alike.

6.2 Managerial implications

The inexorable trend to passive investing creates numerous issues for fund management, including fee and revenue pressure, which forces traditional managers to seek new revenue streams, such as illiquid and private assets, which also implies increased portfolio risk. Additionally, the increased transparency and efficiency associated with the ETF market indicates that managers must rethink the entire value chain, beginning with technology and the way investments interact. ETFs outperform closed-ended funds in terms of tracking ability. Both, however, exaggerate their reactions to domestic news. Index funds may be more suitable for international diversification.

According to the research, ETF discounts and premiums promote feedback trading, which may result in panic redemptions during times of market stress. Additionally, managers must develop novel risk management strategies to reduce their reliance on cash holdings, which are a major cause of portfolio TEs. This is truer than before with the more integrated character of the world economy necessitating quicker portfolio realignments as indices reel under pressure. ETFs are now at the forefront of price discovery, and managers must adopt better volatility metrics that take macroeconomic and investment disclosure factors into account. Algorithmic approaches and bootstrap aggregation (Bagging) with superior predicting abilities may prove to be more effective in this area. With increasing sustainability and environmental concerns; however, ETFs are set to overtake active funds in the fulfillment of ESG objectives.

6.3 Implications for regulators

The passive investing phenomenon has shaken the financial industry by assuming dominance on the most closely followed global indices, which contradicts the tenet of

diversification. Passive funds are now having an impact on the creation and composition of the indices they were designed to follow, as trackers' holdings exercise significant influence over voting rights and flow momentum. Passive investments have triggered changes in market structure that are still not fully understood or factored in. Active management and a range of valuation opinions on whether a price is "too low" or "too high" provide much-needed depth to a market as it attempts to strike a delicate balance between demand and supply forces, ensuring liquidity at all price points.

Passive investments, on the other hand, have a straightforward mandate of buying on fund inflows and selling on fund outflows. If passive investments were to dominate, markets would be shallow, with liquidity available only to the extent that prices remained constant. Beyond the current price, the presence of bids and offers rapidly diminishes, increasing the risk of stocks being locked limited up/down and liquidity evaporating as price changes increase in magnitude. As previously stated, NYSE equities saw fewer price repercussions than NASDAQ equities during the index inclusion process, demonstrating the superiority of expert systems over dealer systems based on machine learning. Thus, with passive investing assuming a large role in the financial landscape, regulators will need to devise novel monitoring and discrepancy detection approaches in addition to reinstating a focus on investor education.

7. Conclusion and future scope

The study's objective is to synthesize available knowledge about passive investing and to highlight innovative advancements in this field on a worldwide scale. We analyzed 943 research publications (published between 1998 and 2021) and provided a thorough overview of the characteristics that determined the expansion of passive investment as a result of the twin benefits of diversity and low cost. The collection of studies has major managerial implications, particularly in terms of portfolio allocation, trading methods, price discovery and subsequent investment behavior. As detailed in the cluster analysis section, passive investment has become a dominant force in global financial markets, with passive funds together controlling more than two-fifths of the voting rights in the world's most widely tracked equity indices. ETFs, the most recent financial innovation in passive investing, are currently at the forefront of price discovery. With the increasing popularity of digital platforms, high-frequency trading and market interconnectedness; the impact of market regimes, microstructures and macroeconomic developments on underlying indices and stocks may define fund managers' portfolio optimization strategy. Managers must be alert and creative in weighing the costs and benefits of various options to maximize the performance of their portfolios. Furthermore, this research summarizes the available literature in terms of publication date, citations, geographic scope, intellectual environment, theories applied and research procedures. Additionally, this paper discusses some of the research issues associated with passive investing and suggests future research opportunities in this emerging field of study. Future studies pertaining to the clusters under consideration may be guided by the findings gathered in this study. The effect of contemporary trading platforms and algorithmic trading on price volatility, price formation and liquidity in ETF markets is a relatively uncharted territory within the broader category of market structures. The impact of behavioral characteristics on mispricing, future prices, risk premiums and market efficiency are all aspects that deserve attention within the pricing and market efficiency cluster. Although the number of empirically tested and generalizable studies is on the rise, further research in this area is required. Given the increasing significance of developing nations in international financial markets, there are potential areas for further academic investigation within the portfolio strategies cluster, including the impact of stock inclusions in ETFs, price correlations, stock betas and the variable composition of the indexes

tracked by these funds. Given the heightened awareness surrounding climate risk and sustainability, any discourse concerning ETFs as an alternative investment strategy must also consider the emergence of ETFs with an ESG focus. This represents a substantial aspect that merits further research, especially within the EME context.

Notes

1. The Malaysian government executed an initial monetary and fiscal stimulus package totaling RM 7 billion (USD 0.98 billion). This was succeeded by a more comprehensive stimulus package of RM 15 billion (USD 2.1 billion), which invested in locally-oriented initiatives with multiplier effects and accounted for nearly 9% of the country's GDP. In addition, tax incentives, private finance initiatives, and off-budget ventures were incorporated into the package. The stimulus package was the most comprehensive in the annals of the nation's economy and ranked second among ASEAN nations, behind only Singapore. The circumstances in Malaysia exhibited an unusual pattern, given that the worldwide financial crisis predominantly materialized as an export crisis as opposed to a currency or banking crisis. The significant repercussions were predominantly experienced inside the stock markets, resulting in a rapid outflow of portfolio investments. As a result of avoiding exposure to hazardous property asset bubbles, Malaysian banks encountered limited consequences in other financial sector domains and served as an illustrative case study of insights gained from prior crises.

ABSTRACT The application of UAV-aided MEC well-suited for the execution of the data-intensive and latency-sensitive tasks in the infrastructure-deprived regions. However, the growing number of UAVs and smart devices causing a major difficulty in the devising an effective scheme for the task offloading and resource allocation in multi-UAV-aided MEC networks. Furthermore, the resource deficient environments unable to sustain prolonged resource-intensive activities, additional complexities are posed on the optimum utilization of the resources. In this paper, we introduced a multi-agent deep reinforcement learning scheme for the task offloading in the multi-UAV-assisted networks (MUAVDRL). In this configuration, the mobile users fetch computational resources from the UAVs with the goal of minimizing the computation cost which incorporates both the energy consumption and the computation delay. Initially, we start with the optimization problem which is defined as the minimizing the computational costs. Through modelling it as MDP, we aim to reduce the computational costs for mobile users. Leveraging the dynamic and high-dimensional nature of the challenge, the MUAVDRL algorithm solves this problem efficiently. Comprehensive simulation results exhibit the efficacy and superiority of our projected framework when compared to existing state-of-the-art methods, illustrating its potential in the practice.

INDEX TERMS DRL, MEC, Resource allocation, Task offloading, UAV.

I. INTRODUCTION

The swift progression of the Internet of Things (IoTs) and information and communication technology has propelled smart applications like virtual reality (VR), augmented reality(AR), and autonomous driving [1] into the spotlight. As a result, the demand for minimal latency and considerable computational power has risen with the emergence of these applications, thereby posing substantial challenges for IoT mobile devices. These problems can be solved by Mobile edge computing (MEC) which provides the resources like the cloud at the network edge.. However, traditional MEC servers are costly to deploy and may not be viable in areas lacking infrastructure. To reinforce MEC's adaptability, UAV-assisted MEC has emerged as a promising paradigm [2]. However, prevalent solutions for optimization problems lean on centralized frameworks, reliant on the computational capacity of a central controller. With rising IoT and UAV numbers, complexity, and computational costs surging, they are urging the need for distributed decision-making methods to alleviate this computational burden in UAV-assisted MEC networks.

While mobile devices within UAV-assisted networks increasingly run real-time applications, their operational scope remains significantly restricted due to limited computational resources [3]. Introducing task-offloading strategies has expanded their capabilities by enabling application execution task delegation to nearby computational nodes [4]. However, this enhancement faces challenges, notably the potential hin-

drance caused by insufficient mobile battery energy [5]. This limitation often leads to service disruptions, as mobile applications may prematurely terminate [6]. The uninterrupted function of contemporary wireless networks necessitates prolonged battery life for sustained energy availability, alongside effective energy utilization by edge devices [7]. These issues collectively impede the network's ability to process real-time applications within designated time slots. Moreover, [8] focuses on optimizing caching in a cellular network where mobile devices are powered by harvested energy. It aims to minimize the proportion of file segments retrieved from the base station (BS) by optimizing file placement on devices. In another study, Lu et al. [9] investigate the placement of unmanned aerial vehicle base stations (UAV-BSs) in mobile UAV networks to minimize UAV-recall-frequency (UAV-RF) and enhance energy efficiency. Considering various power consumptions and ground user density, they employ a pattern formation system to capture the unstable nature of user density. Additionally, [10] delves into trajectory planning for UAVs in UAV-aided IoT networks with mobile sensor nodes (SNs), focusing on priority-oriented time-sensitive data collection. By assigning different delay sensitivities to each SN, the aim is to minimize UAV energy consumption and SN average delay through trajectory optimization. A proposed heuristic trajectory planning algorithm leverages RL but may introduce oscillations in convergence models, potentially impacting stability and effectiveness in specific scenarios.

Deep Reinforcement Learning (DRL) has gained significant traction, especially within network resource allocation problem domains. Its success in video games [11], continuous action control [12], and now in network resource allocations is noteworthy. Researchers are increasingly exploring DRL's potential in these domains, recognizing that optimal resource allocation is essentially an optimal decision-making challenge. When network dynamics exhibit certain regularities, DRL agents can discern these patterns and learn effective policies accordingly [13]. Chen et al. [14] delved into designing computation offloading policies in Edge Computing (EC) through deep Q-networks, integrating task queue state, energy queue state, and channel state information. Meanwhile, Ye et al. [15] focused on resource allocation a DRL-based scheme within V2V communications, treating V2V links as agents making informed decisions regarding optimal power levels and sub-band for transmissions. Sun et al. [16] examined the computation migration as a crucial issue in vehicular cloud scenario, employing polynomial estimation for value functions and SARSA algorithm training to address missions with linear inter-dependency topology. Conversely, Zhu et al. [17] explored research on UAV-supported edge computing for missions with different inter-dependence topology structures using only single agent Actor-Critic (AC) algorithm for selecting target UAVs, albeit without accounting for parallel transmission and energy constraints. Additionally, Min et al. [18] came up with another offloading algorithm based on RL for IoT devices with energy harvesting, considering factors like current battery levels, previous radio transmission rates, and predicted harvested energy. However, the authors overlooked the time delay factor concerning energy consumption, potentially limiting the comprehensive nature of their approach.

There has been substantial research into UAVs aiding mobile edge computing, covering aspects like energy efficiency [19], trajectory design [20], and the joint optimization of communication and computation [21]. However, few of these studies account for scenarios involving multiple UAVs. A single UAV, constrained by a limited payload, possesses restricted computing resources. Moreover, several recent studies have explored multi-UAV-assisted MEC. specifically, Huang et al. [22] delve into offloading scenarios within multi-UAV-enabled aerial edge computing. The authors addressed a scenario where users have interdependent tasks, and multiple UAVs process these tasks centrally. Using a multi-objective optimization approach, they aim to optimize completion time and energy balance among UAVs. However, this study overlooked computing resource allocation, and practical constraints, like limited resources, could indirectly affect its optimization objectives.Consequently, UAV-assisted mobile edge computing necessitates a collective effort among UAVs to share the computation workload. Diverse computing capabilities among UAVs result in varying processing and communication times. Additionally, differences in energy conditions between UAVs and mobile users directly impact offloading outcomes. Within the dynamic network environment, efficiently offloading tasks for mobile users during ground network emergencies poses a significant challenge. The local ground MEC server might become overwhelmed as mobile users demand varied resources within the UAV network. Moreover, the mobile nature of some users causes them to fall outside the network coverage. Considering UAV-assisted networks' complex and dynamic conditions and resources, the task offloading policy should be carefully designed to minimize computation costs.

Due to the limitations of preceding works and the challenges stated above, in this article, we introduced a multi-agent DRL into a UAV-enabled network to propose intelligent task offloading. We offer task offloading and resource allocation, where mobile users offload their tasks to UAVs to perform task offloading. We develop the problem and transform it into a Markov decision process (MDP) model to attain optimum offloading decision policies. Given the presence of multi-objective problems and the dynamic nature inherent in UAV-enabled network environments, we incorporate the capabilities of advanced DRL techniques. This approach allows us to effectively grasp the dynamic network conditions, paving the way to devise an optimal task offloading algorithm that efficiently manages interactions between mobile users and UAVs.

This work's pivotal contributions can be encapsulated as follows:

1) We proposed a MUAVDRL scheme for task offloading among mobile devices within a multi-UAV-assisted

content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411022

network. The primary aim is to minimize computation costs, specifically targeting energy consumption and computation delay. This scheme empowers mobile devices to acquire environmental insights, enabling them to empower optimal task-offloading decisions within the network.

2) We developed a resource allocation and task offloading problem for mobile devices into a Markov MDP model and utilize a multi-agent model-free deep deterministic policy gradient algorithm for multi-UAV-assisted networks (MUAVDDPG). This method manages the expansive and continuous action space to maximize long-term rewards and determine the most efficient task-offloading strategy.
3) We extensively simulate and compare the performance of our proposed algorithm against three benchmark algorithms. These simulations demonstrate that our proposed algorithm significantly minimizes computation costs within a dynamic network setting.

The rest of this paper is arranged as follows. In Section II, the system model is presented. In Section III, the problem is formulated is presented. The MUAVDRL scheme and the algorithm are presented in Section IV. The simulation results are given in Section V. Finally, Section VI presents the conclusion.

II. SYSTEM MODEL

TABLE 1: List of Notations

Notations	Description
M	Set of UAVs
N	Set of mobile users
D_n	Set of computation task demand
S_n	Task Size
C_n	Required CPU cycles
τ_n	Delay Constraint
W	Bandwidth
d_{mn}	Distance between UAV m and user n
G_{mn}	Channel gain from user n to UAV m
r_{mn}	Transmission rate between mobile user n and UAV m
$T^{off}_{n,m}$	Transmission delay of user n offloading tasks to UAV m
$E^{off}_{n,m}$	Energy consumption of user n for offloading to UAV m
$T^{re}_{n^{(i)},m}$	Queuing Delay
$T^{tot}_{n,m}$	Total Delay
C^{tot}	Total system cost

The illustration in Fig. 1 delves into a comprehensive analysis of a Multi-UAV-assisted MEC network, constituting a collective of M UAVs and N mobile users. The UAVs are concisely labeled within this network structure in the set $M = \{1, 2, \ldots, m, \ldots, M\}$. At the same time, the mobile users are categorised explicitly in $N = \{1, 2, \ldots, n, \ldots, N\}$, which provides a structured and scalable representation, allowing for systematic coordination and efficient communication among the various entities present in the network. Owing to limited computational capabilities, mobile devices must transfer their computation tasks to UAVs for processing. Employing a comprehensive offloading model is essential to minimize the time and energy consumption of the user's equipment. Each UAV has a maximum capacity to connect with up to N_{max} mobile users concurrently, while each user is limited to offloading tasks to only one UAV during a specific time.

Each mobile user $n \in N$ contributes a computational task described by $D_n = (S_n, C_n, \tau_n)$, here S_n, C_n, and τ_n represent the task size, necessry for CPU-cycle frequencies, and for the imposed delay constraint, respectively. The parameter $\alpha_n \in \{1, 2, \ldots, M\}$ serves as the association policy for user n, indicating the selection of a UAV by user n for offloading purposes. This association policy is crucial in optimizing resource allocation, enabling each user to select a UAV strategically based on factors such as proximity, resource availability, and computation efficiency, ensuring efficient task offloading and timely processing within the multi-UAV environment. The notation used in the system model are illustrated in Table 1.

A. CHANNEL MODEL

The overall system bandwidth, denoted as W, is distributed among M unmanned aerial vehicles (UAVs), each utilizing a bandwidth of W_m. To prevent interference among these UAVs, the combined bandwidth across all UAVs must not surpass the overall system bandwidth, i.e., $\sum_{m=1}^{M} W_m \leq W$. Moreover, an equal distribution of bandwidth allocation is assumed among users connected to a particular UAV. This means that users connected with UAV m evenly divide the overall bandwidth W_m allocated to that specific UAV m. To ensure optimal utilization of bandwidth, the collective bandwidth used by all UAVs should not fall below the total system bandwidth W [23], which can be represented as follows:

$$\sum_{m \in \mathcal{M}} W_m = W, 0 < W_m < W. \tag{1}$$

The coordinates defining the position of UAV $m \in M$ and user $n \in N$ are specified as $L_m = (x_m, y_m, h)$ and $L_n = (x_n, y_n, 0)$, respectively. To determine the Euclidean distance in a three-dimensional space between two points UAV m and user n, an approach detailed in [2] is adopted, which can be expressed as:

$$d_{mn} = \sqrt{(x_m - x_n)^2 + (y_m - y_n)^2 + h^2} \tag{2}$$

Under the assumption, communication link among UAVs and mobile users is primarily Line of Sight (LoS), as highlighted in [24], the channel gain between mobile user n and UAV m is defined as per [25]:

$$G_{mn} = (d_{mn})^{-\lambda}, \tag{3}$$

where, the symbol λ illustrates the path loss exponent, serving as a parameter in the characterization of path loss for the communication link between the mobile user and the UAV.

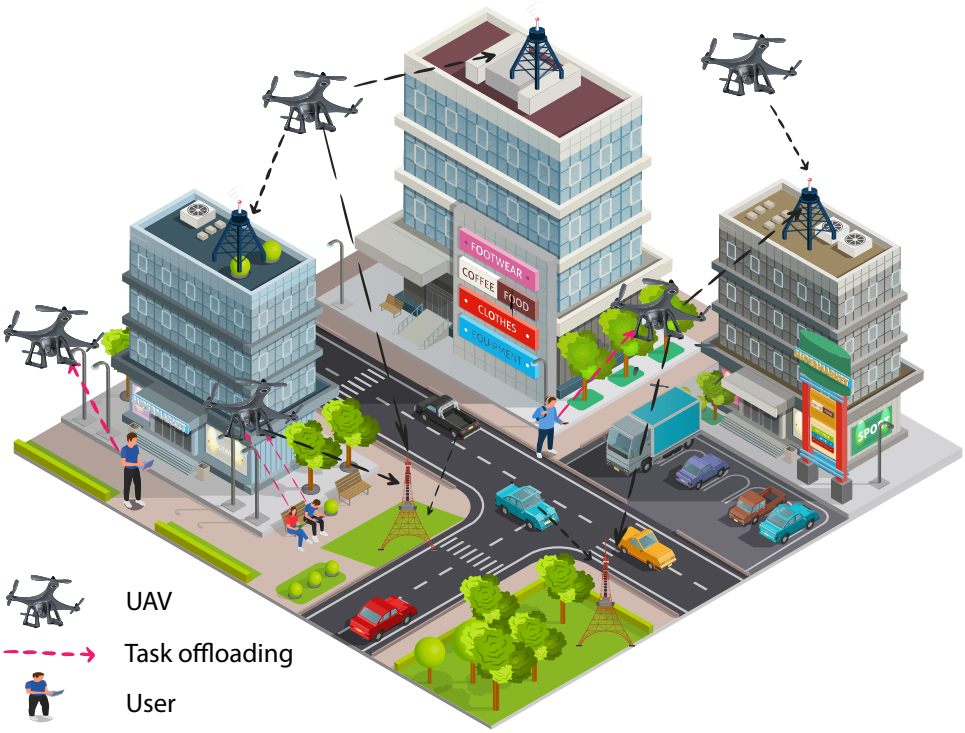

FIGURE 1: System model showcasing Multi-UAV-assisted MEC network.

B. OFFLOADING MODEL

The expression for the transmission rate between UAV m and mobile user n for the offloaded task D_n to UAV m is represented as:

$$r_{mn} = \frac{W_m}{|\mathcal{N}_m|}\log_2\left(1 + \frac{p_n G_{mn}}{N_0}\right), \tag{4}$$

where, W_m stands for the total bandwidth allocated to UAV m. $\mathcal{N}_m$ signifies the count of users associated to UAV m, with N_m representing this set of users as $N_m = n1, n2, \ldots, n|N_m|$. ensures an equitable distribution of available bandwidth resources among the users connected to UAV m. Additionally, the variable p_n refers to the transmission power of user n, while N_0 encompasses the background noise within the system.

The time taken for user n to transfer tasks to UAV m, referred to as the transmission delay, can be represented as:

$$T^{off}_{n,m} = \frac{S_n}{r_{mn}}. \tag{5}$$

The energy consumption related to user n during the process of offloading tasks to its respective UAV can be formulated as:

$$E^{off}_{n,m} = p_n T^{off}_n. \tag{6}$$

C. QUEUING MODEL

Once all computation tasks are received from their corresponding users, each UAV m organizes these tasks based on their order of arrival within the set of user $\mathcal{N}_m = \{n^1, n^2, \ldots, n^{|\mathcal{N}_m|}\}$. Consequently, the computation delay for user n at MEC m includes both queuing and computation delay. The queuing delay, crucially dependent on the order of task arrival, aggregates the computational delays of all tasks handled prior to the current task in the sequence. Tasks arriving earlier experience a longer queuing delay as they wait for previously arrived tasks to be processed. For instance, considering user $n^{(i)} \in \mathcal{N}_m$, processing delay pertaining to $n^{(i)}$ is outlined in [26].

$$T^{re}_{n^{(i)},m} = \begin{cases} \frac{C_{n^{(i)}}}{f_m}, i = 1 \\ T^{re}_{n^{(i-1)},m} + \frac{C_{n^{(i)}}}{f_m}, i > 1 \end{cases}, \tag{7}$$

Therefore, accounting for the available computation frequency of UAV m, denoted as f_m, the comprehensive latency incurred in processing tasks from user n encompasses both the queuing delay and the computational time. As defined in (7) the remaining processing time $T^{re}_{n^{(i)},m}$ for tasks from user $n^{(i)}$ at UAV m. It comprises two cases: firstly, when $i = 1$, indicating the first task from user n, the remaining processing time is straightforwardly computed as the computational time of the initial task $C_{n^{(i)}}$ divided by the computation frequency of UAV m as f_m. Subsequently, for tasks beyond the first $i > 1$, the remaining processing time is determined by adding the computational time of the current task $C_{n^{(i)}}$ divided by f_m to the remaining processing time of the previous task $T^{re}_{n^{(i-1)},m}$. This formulation enables tracking of the time required for task completion, considering

This work is licensed under a Creative Commons Attribution-NonCommercial-NoDerivatives 4.0 License. For more information, see https://creativecommons.org/licenses/by-nc-nd/4

This article has been accepted for publication in IEEE Access. This is the author's version which has not been fully edited and
content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411022

both the computational demands of individual tasks and the processing capabilities of the UAV. Hence, the total latency is calculated as the sum of the queuing delay and the time required for computation on UAV m, which is defined as follows.

$$T_{n,m}^{tot} = T_{n,m}^{off} + T_{n,m}^{re}, \tag{8}$$

The variable $\beta_n = \{0, 1\}$ functions as a binary indicator, signifying whether user n gratifies the stipulated delay requirement. When $T_{n,m}^{tot} \leq \tau_n \cdot \beta_n = 1$, it indicates that the user meets the specified delay constraints. This condition ensures that the total time taken for task processing by user n at UAV m does not exceed the designated maximum time threshold, thus adhering to the latency requirements.

Consequently, the total amount of the system cost amalgamates the energy consumption and time utilization from all users whose computational tasks are completed successfully. The representation of the total amount of the system cost is formulated as the summation of energy and time costs across all users in the system whose task computations are within the stipulated time constraints:

$$\begin{aligned} C^{tot} &= \delta^e E^{tot} + \delta^t T^{tot} \\ &= \delta^e \sum_{n\in\mathcal{N}} \sum_{m\in\mathcal{M}} \beta_n p_n T_{n,m}^{tot} + \delta^t \sum_{n\in\mathcal{N}} \sum_{m\in\mathcal{M}} \beta_n T_{n,m}^{tot}. \end{aligned} \tag{9}$$

III. PROBLEM FORMULATION

The primary objective is to minimize the cost of the system in multi-UAV-assisted network scenarios. The system cost is expressed as energy consumption and computation delay. For this, we formulate an optimization problem to minimize the system cost of the system through optimizing task offloading strategy and resource allocation to eventually reduce the overall system cost and is mathematically expressed as:

$$\begin{aligned} &P1: \min_{T,E} C^{tot} \\ &s.t. \sum_{m\in\mathcal{M}} W_m = W, \forall m, && \text{(10a)} \\ &\alpha_n \in \{1, 2, \ldots, m, \ldots, M\}, \forall n, m, && \text{(10b)} \\ &|\mathcal{N}_m| \leq N_{\max}, , \forall m, && \text{(10c)} \\ &p_n \in \{1, 2, \ldots, n, \ldots, N\}, \forall n. && \text{(10d)} \\ &E_n^{off} \leq E_n^{max}, \quad \forall n. && \text{(10e)} \\ &T_n^{tot} \leq T_n^{max}, \quad \forall n && \text{(10f)} \end{aligned}$$

The optimization problem (*P1*) revolves around key variables: the user association vector, transmit power vector, and UAV bandwidth allocation vector. These variables are defined as follows:

1) User Association Vector (α): The $\alpha = [\alpha_1, , \alpha_n, \ldots, \alpha_N]$ represents the user association vector. Each α_n denotes the choice of a UAV by user n for task offloading.
2) Transmit Power Vector (p): The $p = [p_1, \ldots, p_n, \ldots, p_N]$ represents the transmit power vector. The p_n corresponds to the transmission power of individual users.
3) UAV Bandwidth Allocation Vector (W): The $W = [W_1, \ldots, W_m, \ldots, W_M]$ denotes the UAV bandwidth allocation vector. W_m stands for the total bandwidth allocated to each specific UAV m in the system.

These variables set the foundation for the optimization problem, which is further defined by the following constraints:

1) Bandwidth Restriction ($\sum_{m\in\mathcal{M}} W_m = W, \forall m$): Constraint (10a) ensures that the aggregate bandwidth usage across all UAVs does not exceed the total system bandwidth W.
2) User Association ($\alpha_n \in \{1, 2, \ldots, m, \ldots, M\}, \forall n, m$): Constraint (10b) represents the user association indicator governed by the user association vector α. It imposes a limit on the maximum number of users a UAV can associate with, denoted as $N_{\max}$.
3) Maximum User Association ($|\mathcal{N}_m| \leq N_{\max}, , \forall m$): Constraint (10c) regulates the number of users connected to each UAV, aiding in workload management and optimization for individual UAVs within the network.
4) Transmit Power Range ($p_n \in \{1, 2, \ldots, n, \ldots, N\}, \forall n$): Constraint (10d) signifies the permissible range for users' transmit power.
5) Energy Limitation ($E_n^{off} \leq E_n^{max}, \quad \forall n$): Constraint (10e) outlines mobile users' energy limitation, ensuring that each computing device's battery energy remains adequate.
6) Time Constraint ($T_n^{tot} \leq T_n^{max}, \quad \forall n$): Constraint (10f) sets the time constraint for mobile users, stipulating that the total time T_n^{tot} should not surpass the maximum delay constraint for the task, denoted as T_n^{max}.

The proliferation of mobile devices is experiencing rapid exponential growth, coupled with the dynamic network scalability, thereby elevating the complexity of problem P1. This complexity stems from its classification as a mixed-integer and non-convex optimization problem. It revolves around the offloading decision vector α and features a nonconvex objective function, a characteristic that renders it NP-hard and poses challenges in directly deriving an optimal solution. An algorithm in polynomial time would not be able to unveil the best decision.Hence, we are providing a simplified DRL algorithm that minimizes the system offloading cost while maximizing resource allocation efficiency.

IV. MULTI-AGENT DRL SCHEME

A. MUAVDRL BASED TASK OFFLOADING

In this paper, we explore the task offloading paradigm within a multi-UAV-supported network operating within a dynamic environment where multiple agents are actively involved. The complexities of optimizing solutions in such a setting using traditional single-agent approaches have been acknowledged

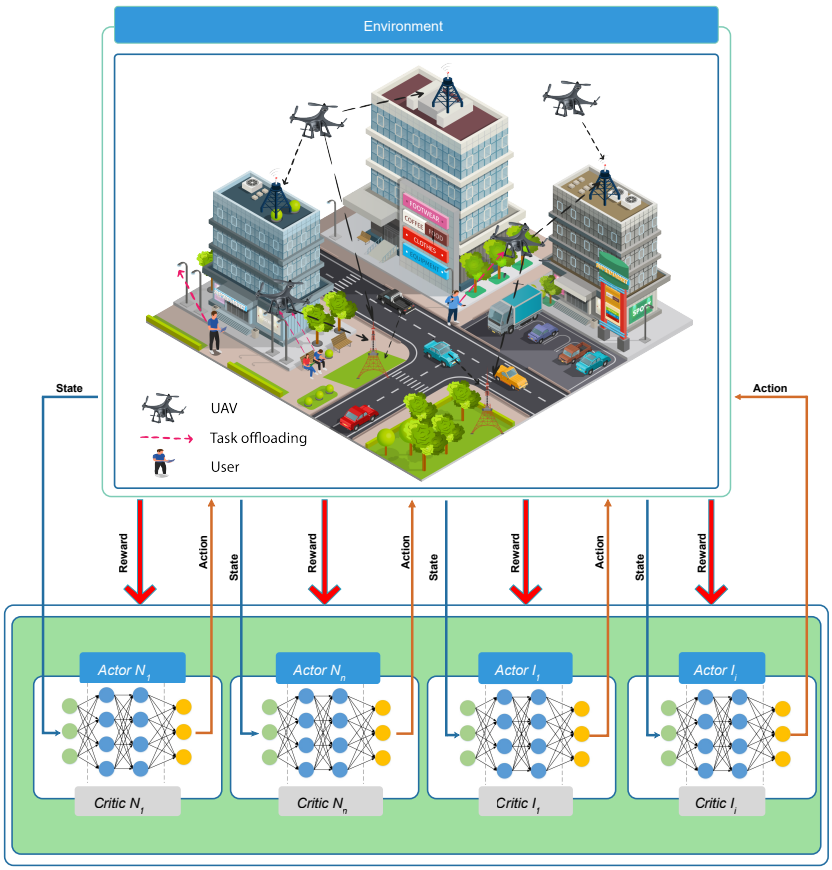

FIGURE 2: MUAVDRL Scheme for multi-UAV-assisted MEC Network.

as challenging [27]. To overcome these hurdles, our contribution introduces the MUAVDRL algorithm, tailored explicitly to address multiple problems within a multi-agent system. This algorithm is a strategic response to the complexities of optimizing task offloading across a network supported by multiple UAV agents.

We have formulated the problems within a Markov decision process framework in a multi-agent setting. Our approach introduces a MUAVDRL-based task offloading scheme aimed at minimizing the computation costs of mobile users while concurrently maximizing the rewards accrued by UAVs. Within this scheme, mobile devices and UAVs function as agents, engaging in a competitive interplay to accomplish their objectives. As illustrated in Fig. 2, agents compete during each stage, gaining experiential insights from others by observing the environmental state. The rewards acquired by UAVs and mobile users constitute the system's overall reward. To execute the MUAVDRL method effectively, we define the state space, action space, and rewards as follows:

- **State space:** The learning agents within the system acquire experiential knowledge and refine their decision-making policies by observing the environmental states. Their decisions are selected by optimization objectives within the environment, relying on the state space $s(t)$. This state space $s(t) = (r_{mn}, E^{off}_{n,m}, f_m, p_n)$, comprising elements such as the transmission rate r_{mn} between user n and UAV m, user energy consumption $E^{off}_{n,m}$ during task offloading, UAV computation frequency f_m, and user transmit power p_n, serves as the cornerstone for these agents' adaptive decision-making, enabling them to optimize strategies based on the current environmental conditions.

- **Action space:** The vector of offloading decision $B = [\beta_1, \beta_2, \ldots, \beta_N]$, vector of transmit power $p = [p_1, \ldots, p_n, \ldots, p_N]$, and computation resource allocation is represented as $F = [f_1, f_2, \ldots, f_N]$. The complete action vector at time 't' is indicated as $a(t) = [\beta_1, p_1, f_1, \ldots, \beta_N, p_N, f_N]$.

- **Reward function:** The overarching aim of the reward function is to enhance offloading decisions, mitigating computation costs encompassing delays and energy consumption. This optimization is crucial for ensuring QoS while extending the battery lifespan of mobile users. The reward function for mobile users is formulated as:

content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411022

$$r_{n,m}(t) = -(\delta^e E^{tot} + \delta^t T^{tot}). \quad (10)$$

The reward function for UAVs is defined as:

$$r_m(t) = R_m(t). \quad (11)$$

The comprehensive reward function for the system is formulated as:

$$r(t) = \sum_{n\in\mathcal{N}} \sum_{m\in\mathcal{M}} \Big(r_{n,m}(t) + r_m(t)\Big). \quad (12)$$

B. MUAVDRL ALGORITHM

Fig. 2 illustrates the MUAVDRL framework within a multi-UAV-supported network. The MUAVDDPG algorithm, an adapted actor-critic network incorporating the DQN method, demonstrates its efficacy in managing dynamic environments. Particularly suited for cooperative policy learning among multiple agents operating within a continuous action space, this algorithm stands as a valuable tool. It is essential to highlight that this system facilitates centralized training of the action-value function, known as the critic network while promoting decentralized execution. The critic function utilizes action policies from other agents, enabling each agent to decide its actions autonomously based on individual strategies and observations. The update of policy parameters is carried out individually by each agent within the framework.

The scheme involves a collection of J agents, encompassing both UAVs denoted as M_m and mobile users denoted as N_n, each equipped with distinctive observations, actions, and reward mechanisms. Within this context, each agent, indexed as J among the J agents, possesses a distinct set of states denoted as $\mathcal{S} = \{S_1, S_2, \ldots, S_J\}$, an array of actions denoted as $\mathcal{A} = \{\mathcal{A}_1, \mathcal{A}_2, \ldots, \mathcal{A}_J\}$, and a series of observations represents as $\mathcal{O} = \{\mathcal{O}_1, \mathcal{O}_2, \ldots, \mathcal{O}_J\}$. In this scheme, agents are empowered to select an action utilizing a stochastic policy $\pi_{(\theta_j)} : \mathcal{O}_j \times \mathcal{A}_j \rightarrow [0, 1]$ to select an action based on its own observations and available actions. The transition to the subsequent state is facilitated by the state transition function $\mathcal{T} : \mathcal{S} \times \mathcal{A}_j \times, \ldots, \times \mathcal{A}_J \rightarrow S$. Every agent receives rewards centered on their current states and the actions taken, depicted as $r_j : \mathcal{S} \times \mathcal{A}_j \rightarrow \mathcal{R}$. Additionally, each agent privately acquires their specific observation $\mathcal{O}_j : \mathcal{S} \rightarrow \mathcal{O}_j$. Each agent j operates with the primary goal of maximizing its expected cumulative rewards, denoted as $\mathbb{E}\left\{\sum_{j=0}^{\infty} \gamma^j r_j, t + k\right\}$. Here, $r_j, t + k$ signifies the reward obtained by agent j at a time k episodes into the future, considering the discount factor γ. Within the MUAVDDPG framework, the fundamental concept revolves around learning a centralized critic function, namely the action-value function, designated as $Q_j^{\pi}(\mathcal{J}, \alpha_1, \ldots, \alpha_J)$ for the j-th agent. This function involves representations of actions from all agents $\{\alpha_1, \ldots, \alpha_J\} \in \mathcal{A}$, and each agent possesses comprehensive information regarding global training weights.

Moreover, the collective policies' set utilized by agents is denoted as $\pi = \pi_1, \ldots, \pi_J$, each accompanied by its respective policy parameter represented as $\theta = \theta_1, \ldots, \theta_J$. This centralized learning approach underpins the MUAVDDPG framework, facilitating coordinated learning among multiple agents within the system. Within the MUAVDDPG algorithm, updates are performed on both the actor and critic-network upon completing every training episode. More precisely, the actor-network undergoes an update using a gradient method computed in the following manner:

$$\nabla_{\theta_j}(\theta_j) = \mathbb{E}_{\mathcal{J},a\sim\mathcal{D}}[\nabla_{a_j}\theta_j^{\mu}(\mathcal{J}, a_1, \ldots, a_J) \nabla_{\theta_j}\mu\theta_j(\mathcal{O}_j)|_{aj} = \mu\theta_j(\mathcal{O}_j)], \quad (13)$$

where, the variable $\mathcal{D}$ signifies the replay buffer, responsible for storing tuples of experiences encountered by all agents, consisting of $(\mathcal{J}, \mathcal{J}', a_1, \ldots, a_J, r_1, \ldots, r_J)$. The update process for the critic function θ_j^{μ} is represented as follows:

$$\mathcal{L}(\theta_j) = \mathbb{E}_{\mathcal{J},\mathcal{J}',a_1,\ldots,a_J,r_1,\ldots,r_J}[(\theta_j^{\mu}(\mathcal{J}, a_1, \ldots, a_J) - y)^2], \quad (14)$$

where, $y = r_j + \gamma\theta j^{\mu'}(\mathcal{J}', a1', \ldots, a_J')|ak' = \mu k'(\mathcal{O}k)$ denotes the computation for updating the critic function. Here, the target policies' set, characterized by delayed parameters, is represented as θ_j', represented as θ_j', is depicted as $\mu' = \mu\theta_1', \ldots, \mu\theta_J'$. This calculation involves incorporating the rewards received by agent j alongside evaluating the next state-action values utilizing the target policies, considering the delayed parameters.

Algorithm 1 outlines the proposed MUAVDDPG algorithm tailored for task offloading within a multi-UAV-supported network. It comprises two essential procedures: Collecting the observed data and the training process. The algorithm commences with an initialization phase (lines 1-4), establishing the replay buffer and initializing parameters for the actor-network and critic-network along with their respective weights. This phase also sets the groundwork by defining the total number of episodes and training steps for the agents (lines 5-10). This preliminary step ensures that the algorithm starts with a defined structure and clear parameters before the actual training begins. Collection of observed data by agents: Execution of actions, reward acquisition, and generation of new states (lines 11-21). The experiences gained are stored within the experience replay buffer. Training phase (lines 22-28): Policy training involves batch sampling from the replay buffer. Subsequently, the actor-network and critic-network undergo updates based on randomly selected samples. This algorithm orchestrates the collection of data from the environment by agents, storing experiences for later training. During the training phase, samples from these experiences to update the actor and critic networks, facilitating policy learning within the multi-agent system.

C. COMPUTATIONAL COMPLEXITY

The proposed MUAVDDPG algorithm outlines the computational complexities for actor and critic networks. For the

end for

actor-network with P layers and the critic network with U layers, the computational complexity of each layer is expressed as $\mathcal{O}\left(Z_{p-1}^a Z_p^a + Z_p^a Z_{p+1}^a\right)$ and $\mathcal{O}\left(Z_{u-1}^c Z_u^c + Z_u^c Z_{u+1}^c\right)$ respectively. Consequently, the overall training complexity of the proposed algorithm can be expressed as:

$$\mathcal{O}\left(J * T * E * \left(\sum_{p=2}^{P-1}\left(Z_{g-1}^a Z_p^a + Z_p^a Z_{p+1}^a\right) + \sum_{u=2}^{U-1}\left(Z_{u-1}^c Z_u^c + Z_u^c Z_{u+1}^c\right)\right)\right) \quad (15)$$

Each agent's execution complexity is $\mathcal{O}\left(J * E * \left(\sum_{p=2}^{P-1}\left(M_{p-1}^a Z_p^a + Z_p^a Z_{p+1}^a\right)\right)\right)$. The algorithm's convergence analysis considers UAV agents' interaction, influencing subsequent user agent actions while supporting policy changes among agents.

V. SIMULATIONS RESULTS AND DISCUSSIONS

In this section, we analyze the outcomes of our algorithm's simulations across various parameter configurations. Our simulations were executed in a Python 3.7 environment utilizing Tensorflow 2.0. The computations were performed on a system powered by a Core i7 CPU operating at 2.4GHz and equipped with 16GB RAM. We consider our analysis to involve a range of 2 to 12 UAVs and 10 to 60 mobile users unless specified otherwise. These UAVs are positioned at an altitude of 100m above ground level. Within our devised multi-agent algorithm, we established 3000 episodes during the training phase, each comprising 200 steps. The neural network employed in this algorithm is a fully connected architecture featuring both a critic network and an actor-network. Specifically, every agent within the system operates with a neural network structure comprising two hidden layers in the actor as well as critic neural networks. These layers consist of 256 neurons in the initial hidden layer and 128 neurons in the subsequent layer. A mini-batch size of 256 was employed to manage the learning process. Other simulation parameters are summarized in Table 2.

TABLE 2: Experimental Parameters.

Parameters	Value
Task Size	[150-1500] KB
CPU cycles required for task	[150-2000] Mcycles
Maximum processing time delay	[0.1-2] Sec
Mobile Transmission Power of	0.1 W
Task Size	[150-1500] KB
Bandwidth	40 MHz
Learning rate of actor-network	$1e^{-4}$
Learning rate of critic-network	$3e^{-4}$

The proposed MUAVDDPG algorithm is evaluated against the following baseline algorithms.

(a) Average Cost (b) Average Time Delay (c) Energy Consumption

FIGURE 4: Effects of UAVs on Cost, Time, and Energy Consumption

1) Deep Deterministic Policy Gradient (DDPG) [28]: A DDPG-based scheme wherein each agent learns from prior offloading experiences and dynamically fellows the nearest computational UAV node.
2) A3C [28]: Both the A3C and DDPG algorithms belong to the paradigm of model-free DRL and follow an actor–critic framework. However, their distinct advantages come to light in various applications, especially in achieving efficient convergence during training.
3) DQN [29]: DQN exhibits strengths in dynamically allocating computational tasks among heterogeneous resources. DQN learns from experience and navigates high-dimensional state spaces contributing to effective decision-making in dynamically changing network conditions.

The convergence analysis depicted in Fig. 3 illustrates the performance of various DRL algorithms. Specifically, the proposed MUAVDDPG algorithm demonstrates superior performance compared to the three baseline algorithms. Convergence for the MUAVDDPG algorithm occurs before the 550-episode mark, while the other three algorithms converge around the 700-episode range. This points to the successful alignment of interests between UAVs and mobile users, effectively maximizing rewards and minimizing computation costs through optimal offloading decisions. An observed trend reveals an increase in average rewards proportional to both the number of episodes and the number of agents. Remarkably, the proposed MUAVDDPG algorithm yields an overall reward increase of 16%, 26%, and 33% compared to DDPG, A3C, and DQN, respectively. This notable enhancement in reward values signifies the efficacy of the MUAVDDPG approach in optimizing both UAV and mobile users' objectives within a dynamic network environment.

In Fig. 4, our focus initially centers on analyzing the performance of the proposed algorithm concerning the escalating number of UAVs. As observed in Fig. 4a, a trend emerges, indicating a decrease in the average computation cost across all algorithms with an increase in the number of UAVs. Notably, the MUAVDDPG algorithm showcases a swifter reduction in average cost, surpassing the performance of the three baseline algorithms. This pattern suggests that under the MUAVDDPG framework, agents collaborate more effectively, leading to reduced resource consumption compared to other algorithms. DDPG and A3C exhibit superior performance to DQN due to their enhanced support for distributed learning. Particularly noteworthy is the MUAVDDPG's remarkable reduction in average cost by 30%, 49%, and 70% compared to DDPG, A3C, and DQN, respectively. This demonstrates the MUAVDDPG algorithm's effectiveness within a multi-agent system, surpassing baselines by optimizing agents' decisions. Additionally, Fig. 4b and 4c portray a notable trend: as the number of UAVs increases within the MUAVDDPG algorithm, optimal time delay and energy consumption decrease. This trend is also observed, to a lesser extent, in DDPG, A3C, and DQN. Thus, across various numbers of UAVs, the MUAVDDPG algorithm consistently outperforms the three baseline algorithms by efficiently minimizing time delay and energy consumption.

In Fig. 5, our investigation delves into the average cost, time delay, and energy consumption across various data sizes from 1 to 16 MB. This analysis aims to assess how offloading data sizes impact system performance. Fig. 5a graphs the average cost across diverse data sizes. The observed gradual increase in the average cost across all algorithms is attributed to larger offloading data sizes demanding more time and energy consumption. Tasks with increased data sizes require higher computational time and resources from UAVs. Once the offloading task size reaches 4 MB, there's a rapid spike in the average cost for the three benchmark algorithms. However, under the proposed algorithm, the average cost escalates significantly slower. The algorithm's collaborative nature facilitates information sharing among agents, enabling efficient cost minimization. Comparatively, the proposed algorithm demonstrates a significant reduction in the average cost, showcasing a decrease of 45%, 52%, and 65% when compared to the DDPG, A3C, and DQN algorithms, respectively. Moving to Fig. 5b and 5c, the analysis focuses on time delay and computation energy consumption, encompassing the transmission and execution of mobile users' tasks. Fig. 5b demonstrates a proportional increase in computation time delay with rising offloading data sizes. However, the proposed algorithm consistently maintains lower time delays compared

(a) Average Cost (b) Average Time Delay (c) Energy Consumption

FIGURE 5: Effects of data size on Cost, Time, and Energy Consumption

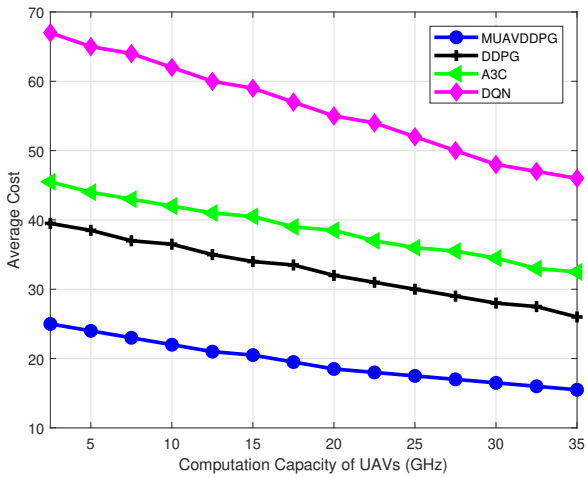

FIGURE 6: UAV Computation Capacity vs Average Cost

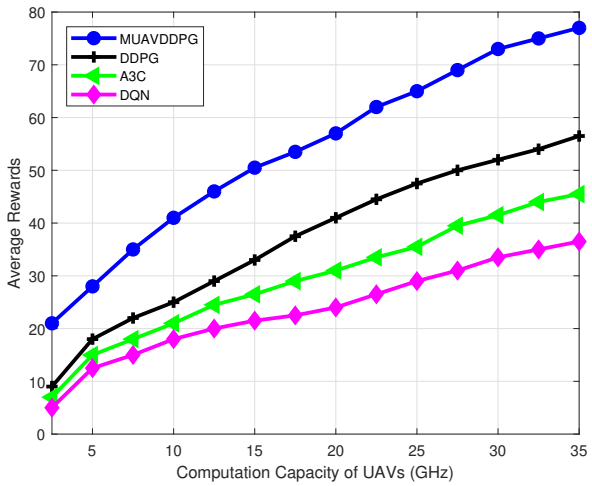

FIGURE 7: UAVs Capacity vs Average Reward

to the three baseline algorithms. Meanwhile, Fig. 5c reveals a general uptrend in total energy consumption across all algorithms as offloading tasks expand. Remarkably, the proposed algorithm exhibits a notably slower increase in energy consumption compared to the three baseline algorithms. This highlights the algorithm's capacity to effectively minimize computation costs concerning time delay and energy consumption across varying offloading data sizes.

The research analyzes how the computational capabilities of UAVs impact the computation cost mobile users incur when offloading tasks. As indicated in Fig. 6, an evident pattern emerges: as the computational capacity of UAVs rises, there is a gradual decline in average costs observed across all algorithms. This decline in average costs demonstrates a consistent, albeit slow, reduction. To elaborate further, it is important to note that the average cost associated with the three fundamental algorithms exceeds that of the proposed MUAVDDPG algorithm. Upon closer examination by evaluating each algorithm's performance concerning the maximum computation capacity, substantial reductions in average costs are evident. Specifically, when comparing the MUAVDDPG algorithm to the DDPG, A3C, and DQN algorithms, there is a notable decrease in average costs by 40%, 52%, and 66%, respectively. This comparison underscores the significant efficacy of the MUAVDDPG algorithm in significantly reducing costs compared to the established algorithms studied.

Fig. 7 and Fig. 8 demonstrate how the computation capacity of UAVs influences the performance metrics of various benchmark algorithms in multi-UAV-assisted MEC environments. Specifically, Fig. 7 illustrates the relationship between UAVs' computation capacity and the average reward achieved by each algorithm, highlighting the increasing trend in average rewards as the computation capacity grows. Notably, the MUAVDDPG algorithm shows the most significant performance enhancement, suggesting that it is particularly effective at utilizing increased computational resources to maximize rewards. This outperformance is consistent across varying capacities, indicating MUAVDDPG's robustness in different computational scenarios. Moreover, Fig. 8 explores the impact of UAVs' computation capacity on the offloading rate, which is a critical measure of how effectively computing tasks are transferred from mobile devices to UAVs. It can

content may change prior to final publication. Citation information: DOI 10.1109/ACCESS.2024.3411022

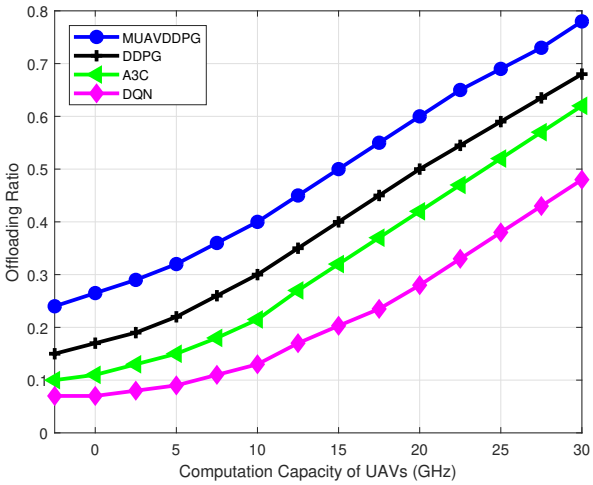

FIGURE 8: UAVs Capacity vs Offloading Rate

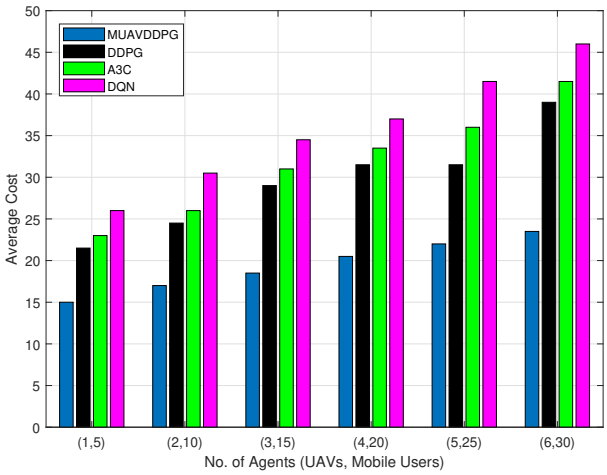

FIGURE 9: Varying No. of UAVs and Mobile Users vs Average Cost

be observed from Fig. 8 that all algorithms benefit from increased computation capacities, achieving higher offloading rates. The superior performance of MUAVDDPG in achieving higher offloading rates further confirms its enhanced ability to efficiently manage and utilize UAV computational resources, which is crucial for task offloading in complex environments. The consistency of MUAVDDPG's superior performance in both average reward and offloading rates under varying computational capacities supports its stability and robustness, making it a promising option for optimizing UAV-assisted operations in diverse MEC settings.

As the demand from mobile users for resources from UAVs rises, so does the average cost. Collaboration intensifies within the ever-changing network setting when there's a growth in the number of agents - including UAVs and mobile users. This collaboration leads to improved rewards for UAVs and cost reductions for mobile users. To confirm the scalability of our proposed framework, we varied the number of agents in our scenario, ranging from 1 UAV and 5 mobile users to 6 UAVs and 30 mobile users across all algorithms, as depicted in Fig. 9. The proposed MUAVDDPG outperforms the three alternative algorithms. Our observations revealed that average costs also escalate as the number of agents rises. However, the cost associated with the MUAVDDPG algorithm remains lower than the others and sees a more gradual increase. Under MUAVDDPG, agents exhibit higher cooperation and a more favorable experience in contrast to DDPG, A3C, and DQN algorithms as the number of participants grows. Hence, in our proposed scenario, the MUAVDDPG algorithm exhibits greater scalability than the other benchmark algorithms and proves its relevance in multi-agent system scenarios.

A. PRACTICAL IMPLEMENTING AND EVALUATING OF THE PROPOSED ALGORITHM

The evaluation of the proposed MUAVDDPG algorithm against various practical scenarios and benchmark approaches reveals its efficacy in optimizing resource allocation and minimizing computation costs in dynamic network environments. Compared to baseline algorithms such as DQN, A3C, and DDPG, the MUAVDDPG algorithm demonstrates superior performance, as illustrated by convergence analysis and average reward increases. Notably, the MUAVDDPG algorithm converges faster, aligning the interests of UAVs and mobile users to maximize rewards and minimize computation costs through optimal offloading decisions.

Furthermore, across different network scales, including varying numbers of UAVs and offloading data sizes, the MUAVDDPG algorithm consistently outperforms baseline algorithms by efficiently minimizing time delay, energy consumption, and average cost. This performance advantage is attributed to the collaborative nature of the MUAVDDPG framework, which facilitates effective information sharing among agents, reduces resource consumption, and ensures optimal resource allocation.

Additionally, the scalability of the MUAVDDPG algorithm is demonstrated by its ability to maintain lower average computation costs even as the number of agents, including UAVs and mobile users, increases. Overall, these findings underscore the practical utility and generalizability of the proposed algorithm in multi-agent system scenarios, highlighting its potential to address complex task offloading and resource allocation challenges in dynamic network environments.

VI. CONCLUSIONS

In this paper, we explored task offloading and resource allocation within a resource-constrained multi-UAV-assisted MEC network. Our focus centered on optimizing compu-

tation costs, encompassing energy consumption and computation delay, by enabling mobile users to access computational resources from UAVs. Leveraging an optimization problem modeled on dynamic preferences and employing the MDP framework, our goal was to minimize computational demands for mobile users.The MUAVDRL algorithm effectively addresses this challenge by efficiently navigating its dynamic and high-dimensional nature. Rigorous simulation results validate our proposed framework's superior performance and effectiveness when compared to existing state-of-the-art methods, highlighting its substantial potential in practical scenarios. Notably, the simulation outcomes underscore the efficacy of the MUAVDRL algorithm, showcasing its ability to significantly enhance system utility while meeting stringent latency and energy requirements, surpassing the capabilities of other baseline algorithms.

Abstract
The urban transport rail network is represented by operational lines and associated variables such as the origin/destination matrix, ridership, and speed. In railway planning, operators always desire to maximize profit by evaluating the effects of different train lengths and service frequencies, whereas passengers aspire to minimize travel expenses. This study analyses the effects of train length and service frequency on economic expenses related to passengers' travel expenses and the critical impact on the health costs incurred due to acute stress. An optimization model for maximizing the operator's profit and minimizing passenger travel expenses, along with a health costs model related to travel expenses, is presented. A simplified algorithm is developed to analyse the impact of train length variation on the infrastructure cost, which is tested and compared over a set of real implemented projects. The scenarios of short trains, high frequency trains over long trains, and low service frequency are analysed. It is observed that longer trains with lower service frequencies optimize the operator's profit and passenger travel expense for intercity travel. The findings indicate that selecting a balance factor of approximately 0.6 is crucial for maintaining optimal passenger expenses. Moreover, within the range of 0.7 to 0.9, passenger benefits reach a peak while slightly compromising the operator's profit. It is evident that the 9-car train length with a service frequency of 16 and an optimum headway of 15 min, over a 4-hours observation duration, yields superior benefits for both passengers and operators. The effectiveness of the optimization model is further analysed with respect to the operator's performance, which is adversely affected by keeping the frequency and train size constant during the peak and off-peak periods.

Keywords Train length · Service frequency · Optimum profit · Passenger travel expense · Travel stress · Nonlinear optimum model

1 Introduction

With the speed and scale of urbanization, accelerated population and economic activities have generated a potential rise in the demand for rapid, affordable, and efficient metro transportation systems. Leveraging benefits such as rapid, clean, and efficient ways to transport passengers through urban metro transportation systems has relieved the traffic pressure on many clusters of metropolitan cities. The policy dimensions of the urban rail transportation network include the length of lines, the distance between stopping stations, service pricing, the operating frequency of trains, and train length. Passenger arrival flow is the key factor in making decisions about these policy dimensions for a public transport operator. Specifically, during peak hours of any working day, the passenger arrival flow is enthusiastically large. During such a large flow improvement, the main objective of planning for the operator is to improve the total travel time, maintain headway regularity and minimize passengers' generalized travel expenses [1].

With large policy dimensions, a vast research area is available about public transportation planning. In the areas of network design, crew management, trip demand evaluation, etc., issues have been addressed through many approaches. In metro cities with painful traffic congestion, parking may lead car drivers to opt for public transport if

an affordable and service-quality system is offered. In [2], the author performed a cluster analysis through a customer satisfaction survey on mass transit rail in Tehran in which satisfaction with public transit was influenced by trip characteristics and sociodemographic groups. *Structural equation modelling* (SEM) was utilized to identify the most effective attributes in each group. The results showed that both clustering and segmentation based on individuals' characteristics were efficient. Rail transport operators are responsible for planning and providing transport systems that maximize the quality of service to passengers and ensuring minimum *operation and maintenance* (O&M) costs by adopting novel initiatives in an urban rail transit system. In one of the rail-based urban transit systems of China, for service quality improvements, the author analysed operational strategies such as optimizing coach composition, energy consumption, and relative traction capacity [3]. Similarly, in [4], the author tried to ameliorate the train schedule and timetable rationalization by exploring human intervention and adopting innovative ways of matching supply with demand.

The user desires rapid rail transport services to be cost friendly, comfort providers for train and transfer terminals, and punctual; to have broader service coverage; and to have a higher frequency level. The operator, on the other hand, thrives on maximizing profit and plans to employ larger trains [5]. However, planning with only this policy dimension will be unfavorable to passengers, leading to low frequencies, high schedule delay costs, more waiting times, and additional time losses for boarding and alighting. The planning objective for rail transport is to obtain an equilibrium between the objectives of these two conflicting stakeholders [6, 7].

Equilibrium or optimization of these two objectives can be achieved by a two-step process in which the first step is line planning, which includes selecting and constructing terminal stations, tracks, and trains [8–10]. The service frequencies of the trains are planned in the second step. Mostly, the actions are planned jointly, but because the passenger flow is time dependent and elastic, service frequency planning needs to be performed for different periods or demand changes. The demand variations trigger the need for modification in the frequency and length or composition of trains.

Traditionally, longer trains with reasonable service frequencies have been introduced to meet the objective of meeting the elastic passenger demand of rail operators, including high-speed railway systems worldwide. Globally, networks of high-speed rail and intercity rapid rail transit systems have manifolded, so the service frequency and train length choices are planned, and test cases are available. The choice of train length and service frequency has a considerable impact on the operator's infrastructure and operating costs; hence, there is considerable research interest in this optimization challenge.

Researchers have presented different optimization methodologies [11] and maximizing the number of direct trips has been found to be the most common objective [12]. Headway flexibility and the augmentation of line capacity to increase the attractiveness of rail networks were also considered [8, 13]. Primarily, the solutions are focused on minimizing the passenger travel expense mapped to the waiting and other comfort-related factors.

The rail transportation sector and passenger behavior are directly related to our fast-paced world engrossed by microwave speed culture in daily life. Our complete life has become deadline-oriented, and all tiny activities are sequential and linked to another activity in such a manner that if the deadline of one activity is missed, then the deadline for completing the next sequence of activities collapses.

Apart from generating high acute stress due to putting off a task until its deadline, researchers have also found dead brain cells, depleted creativity, and debilitating effects on one's health due to deadlines or timeline-based living [14]. Urban or metropolitan transportation is primarily linked with passengers travelling for work and normally treats travelling as a task to be completed during a scheduled duration or at a scheduled time. After the completion of this task, the main important task related to work is taken up, which sets up the context for the developed acute stress of honoring phased deadlines. Consequently, the task of urban travel can be termed a rush-recurring deadline, which is critically linked with the completion of all the timelines of subsequent activities. Hence, for urban rail transport passengers, travel expenses include direct fare or ticket costs and detrimental health costs due to acute stress because of waiting time, schedule delay costs and congestion. Therefore, in addition to mapping economic aspects, passenger travel expenses must essentially be associated with consequential health cost expenditures [15, 16].

1.1 Related Work: Choice of Service Frequency and Train Length

The rapid metro rail system is a vital transit mode in modern metropolises and has attracted significant attention from researchers in recent decades. The literature on urban rail transport includes two main categories: rail line planning, e.g., line length, number of stations, train length, etc., and the service frequency of trains. These studies have focused primarily on the train timetabling problem, aiming to determine a preoperation schedule or train rescheduling model that needs to adjust the preoperative timetable effectively to counter the effects of any disturbances [17].

The urban rail passenger desires to minimize the total travel expense [18], and at the same time, the operator wants to maximize the profit, which leads to an optimization challenge between the choice of train length and the service

frequency. In [19], the author addressed the effect of train length and service frequency on the determination of train timetables, where the service strategies of different operators, such as short trains with high frequency and long trains with low frequency, were analysed, in which a maximum profit model with elastic demand was solved using an analytic method. Early work [20] proposed a nonlinear dynamic programming model with headway and passenger costs as two dynamic equations. The model presented an iterative hierarchical multilevel decomposition method. This study focused primarily on headway rescheduling; i.e., service frequency referenced to fluctuations in passenger demand and passenger travel expense was not considered. In [21], the authors presented an optimization model using dynamic and stochastic transit assignment that accounted for variations in headways and crowding and their consequences for passenger flow distribution. The supply-setting problem is formulated as a system cost minimization problem consisting of service users' (generalized travel) costs and service providers' (fixed and variable) costs. In [22], the authors optimized the quality of service with the mean time spent by the passengers and safety constraints on the headway of trains as variables. The case of nonsmooth arrival rates of passengers was focused on headway optimization. The authors in [23] proposed a linear programming-based model predictive control formulation methodology for computing the optimal train schedules. The methodology could generate optimal schedules for the whole day and between two separate periods.

Real-time scheduling and routing of trains were implemented through an algorithm, and several theoretical and practical results were discussed [24]. In [25], the authors discussed train schedules that minimize the total passenger waiting time by utilizing a nonlinear integer programming model with linear constraints. A mixed-integer linear programming approach was used to design dynamic passenger demand-oriented metro train scheduling to minimize energy consumption and waiting time [26]. A mixed-integer nonlinear programming model using a novel linearization approach was also used to explain the train service configuration and passenger assignment problems to minimize operators' costs, passengers' waiting time costs and transfer costs [27]. The same optimization model was also used for Beijing URT line capacity utilization and trip time reduction without additional operating costs and investments. The results revealed that the number of transfers can be reduced by reducing travel time and operating costs when the crossline express delivery operating mode is properly adjusted [28].

Different methods for setting service frequency and train length were presented to address the trade-off between operational and passenger travel costs [29–31]. Most analyses were performed for a line with two stations and were generalized to the network. The different lengths of stations and passenger flow variabilities at different stations were not considered. In [32], the author explained the relationship between high-speed train service level and passenger flow variation with the help of the logit and gravity model on the Beijing-Shanghai high-speed rail line by classifying the stations in the large, medium and small station categories based on ridership; the results revealed that large station origin–destination (OD) should reduce train stops and increase travel speed overall to attract more transferring passengers; and medium and small station OD should increase train stops and increase service frequency to attract more potential passengers.

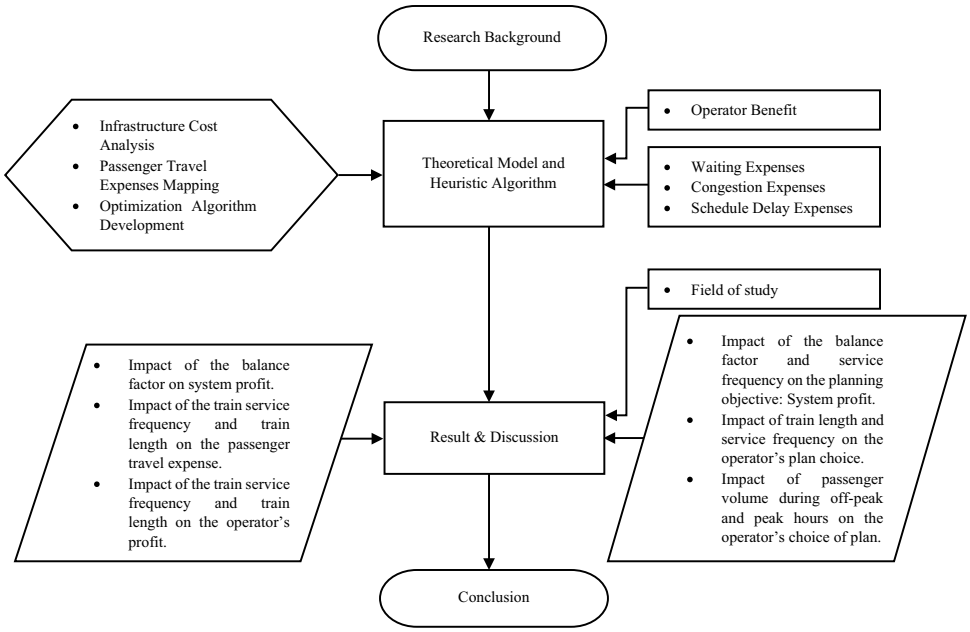
A similar optimization issue was addressed in [33], where a model was proposed for solving the trade-off between the service frequency and the number of coaches per train. In [34], a model was formulated in which elastic passenger demand and social benefits were maximized by using train length, service frequency and cost as control variables. The empirical data showed that length and frequency change approximately with the square root of demand. In [35], the authors considered two forms of schedule delay: one with very high frequencies and passengers generally ignoring the timetables and another where timetables are consulted. It was observed that two types of schedule delay have different effects on choice service frequency. The authors proposed an optimization model based on the behavior of passengers when choosing which train to board [36]. The relationship between the train operation frequency and train formation length was shown to be an s-continuous p-median problem, and the train scheduling optimization problem was simplified [37].

Although the traditional models discussed above simplify the optimization of trade-offs faced in capacity management in rail operations, the effect on the operator's benefit through variations in the infrastructure cost of rail networks, referenced to the variation in train length and frequency, and mapped to passenger travel expenses, e.g., waiting time, schedule delay, and congestion, on the health costs incurred by the passenger and a simplified optimization algorithm to analyse the impact of train length and service frequency on the overall system profit are open issues.

To the best of our knowledge, a novel approach comprising train length and frequency impact on an operator's infrastructure cost, health cost mapping of passenger travel expenses and simplified optimization analysis of complete lines with different passenger arrival flows at different stations elevated or *underground* (UG) is illustrated in this paper.

The objectives of this research primarily involve steps carried out in the study as demonstrated in Fig. 1. The remainder of this paper is structured as follows: Section 1 presents the research background and related works on the service frequency choice and train length. Section 2

Fig. 1 Research workflow



formulates the proposed theoretical model and heuristic algorithm to optimize the operator's profit and passenger generalized travel expense for variations in the size and frequency of trains. In Section 3, analyses, results and discussion are presented based on empirical data from the *Regional Rapid Transit System* (RRTS) project of the *National Capital Region Transport Corporation* (NCRTC). The conclusions are presented in Section 4.

2 Theory and Method

This research paper focuses on optimizing train length and service frequency to increase overall system profit. This involves minimizing passenger travel expenses while maximizing the operator's profit. The train length, which represents the number of coaches, and service frequency play crucial roles in optimizing railway schedule planning at the tactical level, which is one of the three hierarchical levels of time interval-based schedule planning, alongside strategic and operational procedures. The primary objectives and novel contributions of this paper are outlined as follows:

- **Infrastructure Cost Analysis:** The variation in train length and frequency affects infrastructure costs, including factors such as viaducts, tunnels, and platform lengths. To analyse these effects, this study introduces a novel method that assesses how train length and frequency impact infrastructure costs, which are pivotal in evaluating operator profits.
- **Passenger Travel Expenses Mapping:** Passenger travel expenses encompass waiting times, schedule delays, and congestion-related costs. This paper delves into a comprehensive analysis of these expenses and proposes models to connect them with the health costs borne by passengers.
- **Optimization Algorithm Development:** To comprehensively examine the influence of train length and service frequency on the overall system profit, this research presents an innovative optimization algorithm. This algorithm enables a thorough evaluation of how changes in these parameters impact the entire system's financial performance.

Through these contributions, this research enhances our understanding of optimizing train operations by considering both infrastructure costs and passenger experiences, ultimately leading to improved profitability for operators.

2.1 Modelling the Objective

A novel optimization algorithm for the RRTS network plan is proposed with two objectives: minimizing the passengers' total travel expense and maximizing the operator's profit. The effects of train length and service frequency on the overall system profit are analysed. The "overall system profit" pertains to the combined financial outcome of the Rapid Rail Transit System (RRTS) network plan. This outcome is influenced by two primary objectives: reducing the total travel expenses incurred by passengers and increasing the profit earned by the operator. The effects of train length and service frequency on this overall system profit are then examined. To enable the demonstration of the fundamental

concepts without loss of generality, the following primary considerations are made in this paper.

- One of the objectives of this paper is to observe the relationship between train length and service frequency; hence, the ticket price is assumed to be fixed, although passenger flow is partially related to the fare component of overall travel expenses.
- To reveal the relationship between train length and service frequency in terms of system profit, the network is assumed to be linear with multiple stations in between, and the distance between two adjacent stations is treated as a line for modelling, as shown in Fig. 2.
- For a complete network, the profit is maximized using all analyses for all lines cumulatively. As the RRTS network progresses through different stations between cities, the passenger flow for each station varies. The passenger flow for each station is assumed to be the same as that projected through the survey conducted during the detailed project planning phase.
- The passenger's comprehensive travel expenses encompass various factors, including the fare cost and the health-related costs associated with acute stress or tight deadlines that arise from the physical and psychological toll of prolonged waiting times, the anxiety and pressure resulting from schedule disruptions, and the physical discomfort and mental strain endured due to congested travel conditions. In essence, the passenger's total travel expense calculation considers not only the direct monetary costs but also the less tangible and equally significant health-related expenses incurred during the journey.
- The observation period (t_{obp}) is assumed to be a chosen period within which the intensity of passenger demand is unified at a specific station. This is taken as the peak period where the passenger density is the maximum during running hours per day.
- The train service frequency and length are chosen in such a manner that the capacity generated during the observation duration must be sufficient to allow all passengers to arrive during that period.

Under these assumptions, the effects of the ticket cost, planned stopping schedule and variations in demand on the train service schedule are ignored. Hence, the relationship between train length and service frequency on system profit can be effectively revealed. The urban transport system desires planning objectives to minimize passengers' total travel expenses ($p_{totaltravexp}$) and maximize total operator profits (op_{prft}). The two conflicting requirements are transformed into a single objective of maximizing system profit (sys_{prft}) by introducing the balance factor (bal_{fact}), which confirms a balance between the operator's profit and the passengers' total travel expenses. The objective is simplified to maximize (sys_{prft}) with a determination of the number of trains (trn_n) and the length of the train (trn_l) for an observation duration (t_{obp}). Thus, the optimization model of system profit for the RRTS network is formed as in Eq. (1):

$$sys_{prft} = bal_{fact} \text{x} p_{totaltravexp} + \left(1 - bal_{fact}\right) \text{x } op_{prft} \tag{1}$$

2.2 Operator Benefit

The time fluctuation characteristic of the passenger volume of the railway network is echoed in the planning horizon by determining the train schedules for each specified observation duration (t_{obp}). From the perspective of urban rail transport, an operator's benefit is primarily derived from ticket income. When the price of a ticket is (p_{tkt}) or the passenger flow is (p_{vol}) during the observation duration (t_{obp}), the operator's benefit (op_{bnft}) is derived as per Eq. (2):

$$op_{bnft} = p_{tkt} \text{ x } p_{vol} \tag{2}$$

By providing train services to passengers, the cost incurred by the operator can be divided into two types: one infrastructure and another operation cost. Hence, the operator's cost is the sum of the infrastructure cost and O&M cost.

The infrastructure requirement needs modification with the variation in train length. The fixed infrastructure required to operate the RRTS rail network comprises different subsystems, namely, Civil Infrastructure, Track, General Electrical, *Overhead Equipment* (OHE) in Electric Traction, *Signalling*

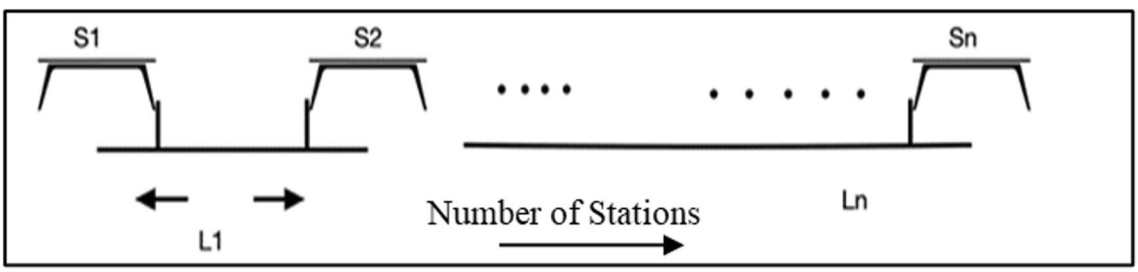


Fig. 2 RRTS station and line network

and Telecommunication (S&T), and *Platform Screen Door* (PSD). The civil infrastructure may further be dependent upon the variation in platform length, viaduct and tunnel volume for the station area referenced to the variation in required train length. Similarly, the straight track length, length of sidings and terminals, *Inspection Bay Line* (IBL), and *Stabling Bay Line* (SBL) required for maintenance and depot length also vary. This impact occurs because, for shorter trains, such as those with the same length as mentioned above for sidings, the IBL is also shortened, which significantly affects the cost component. The cost impact of such variations in the civil and track subsystems echoes that of the general electrical, S&T cable and traction subsystems. The effect on the PSD system is consequently apparent owing to the lower requirement of doors for shorter trains and consequential provision of infrastructure, such as cabling.

The RRTS rail network is taken as a linear network with several stations from start to end. The starting end of the network assumes station S_1 to be the first station, followed by S_2 and the end station S_n. The distance between the stations is also not uniform; hence, the length of the rail network between two stations is taken as lines L_1, $L_2 \ldots L_n$ for pairs of stations S_1—S_2, $S_2 - S_3$, … $S_{n-1} - S_n$, as shown in Fig. 2.

Apropos of the above considerations, an *infrastructure cost determination algorithm* (ICDA) with pseudocode is designed as explained in Table 1 below to determine the infrastructure cost required for running a specific train-length service.

As the rail network is continuously put into passenger service for approximately 80% of the day, the system needs dedicated maintenance to re-energize for the next day. Hence, the operator must incur maintenance expenditures apart from operation expenditures, e.g., crew, station staff, and power logistics. Concerning variations in the length of trains and service frequency operation costs related to crew management and energy requirements for running trains are significant variables. As the infrastructure cost varies for trains of different lengths, the maintenance efforts required also vary; however, coach maintenance is considered a nonvariable assuming that the total number of coaches remains the same only when the length of trains and service frequency are optimized within this constraint. From the above deliberations, the *O&M cost determination algorithm* (OCDA)

Table 1 ICDA

```
Input:
{
   location: [S1, S2, S3, ..., Sn],
   unit-cost: Infra subsystems,
   unit coach length: u_cl,
   no_ug_stn: no_ug_stn
}

//Define platform lengths for three different trains
platform_lengths: [pl_3, pl_6, pl_9]

//Calculate total platform length for each iteration
total_platform_length: []
for each pl_iteration in platform_lengths:
   total_platform_length.append(pl_iteration x 1.5 x no_ug_stn)

//Calculate total track length for each iteration
total_track_length: []
for each pl_iteration in platform_lengths:
   total_track_length.append(sum(N_L, depot_length x fct_iteration, terminal_length x fct_iteration))

//Map all the above lengths to total units corresponding to all subsystems
total_units_iteration: []
for i in range(len(platform_lengths)):
   tunl_iteration = total_platform_length[i]
   vdctl_iteration = total_platform_length[i] - total_platform_length[(i + 1) % len(platform_lengths)]
   trkl_iteration = total_track_length[i]

   total_units_iteration.append(map{tunl_iteration, vdctl_iteration, trkl_iteration, N_L})

//Calculate Infrastructure cost for each iteration

   Infra_cst_iteration.append(sum(mul{unit-cost: Infra subsystems}, total_units_iteration[i]))

End

Output: { Infra_cst_iteration }
```

with pseudocode is formulated as explained in Table 2 below to obtain the O&M cost required for running a specific train length and with a particular service frequency.

Considering trains of length (trn_l) with a service frequency of (trn_n) should suffice to carry a load of passengers in the (t_{obp}) duration for the lines so that no passengers are left out, the infrastructure cost determined by ICDA, *Infra_cst_iteration* needs to be mapped to the duration of the study (t_{obp}). Assuming that the operator creates the infrastructure for running trains to the minimum possible headway for a fixed number of years before heavy replacement is needed, the mapping of the infrastructure cost is performed in reference to the number of trains running during the observation duration. Similarly, the O&M cost, *O&M_cost_iteration,* is mapped to the duration of the study (t_{obp}). Hence, the operator's profit is determined from Eq. (3):

$$op_{prft} = op_{bnft} - trn_n \text{x} \left| infra_{cost_{iteration}} \right|_{t_{obp}} + trn_n \text{x}\ trn_l \text{ x}\ unit_{coach_{cost}} + O\&M_cost_iteration \quad (3)$$

2.3 Passenger's Travel Expense

The traditional approach of considering the time spent by passengers in transportation may involve allocation to other activities and has pecuniary value. As urban transport systems have higher speeds and service frequencies are also high, the financial mapping of the waiting time, travel time, etc., is small in comparison to the actual fare expenses.

However, urban rail travel can be categorized as a rush-recurring deadline task that directly impacts the completion of all the timelines of subsequent activities planned by the passenger. Hence, for urban rail transport passengers, this rush-recurring-deadline task can cause acute stress due to waiting time, schedule delay costs and congestion. Therefore, in addition to economic valuation, passenger travel expenses must essentially be considered in reference to the substantial health cost expenditures incurred due to developed acute stress. The passenger's travel expenses due to travel time, congestion expense and schedule delay expense are modelled to map this cost in terms of the health expenditure incurred by the passenger.

2.3.1 Waiting Expenses

The monetary mapping of travel expenses such as waiting time, scheduled departure time or congestion expenses may not be directly perceived or appreciated by the passenger due to the high service frequency, i.e., less headway of RRTS. The health costs referenced in the above travel expenses are real perceptible expenses incurred by the passengers whom they observe during the entire engagement period with RRTS. During the waiting time, acute stress develops during the state of health, as passengers may need to reach a place at a certain time, and then waiting for travel will lead to an escalated level of anxiety transformable into acute stress. Subsequently, the passenger's body reacts by releasing hormones, which makes the passenger's brain more alert, causing the muscle to tense and increasing the heart rate and blood pressure, which vary depending upon how much waiting time the passenger is observing. If the waiting time in terms of headway considered (15 min in the present case) increases from 0 to 80%, the acute

      crew_cst_iteration x trn_n
   }
End

Output: {O&M_cost_iteration}
```

stress shown in Fig. 3 does not affect passengers much; however, during the remaining 20% of headway, a sharp increase in acute stress puts the passenger at risk for health problems, in turn increasing the travel expense, i.e., the health cost.

The phenomenon effect of deadline rush is described by a hyperbolic function [38], as shown in Eq. (4):

$$with_{wt} = \frac{without_{wt}}{1 + k\text{x } wt} \tag{4}$$

where $with_{wt}$ is the cost after waiting time, wt is exhaust, $without_{wt}$ is the base expenditure without any waiting time, wt is the waiting time, and k is the passenger-dependent parameter. The higher k is, the more impulsive the passenger is, and the steeper the curve is. For research analysis, the mean k value is taken as 0.1 [39].

For a mass transit system, as the headway is lower than that for long-distance mainline trains, the passenger arrival may be assumed to be uniformly distributed during the waiting period. For the RRTS system, trains run on a fixed headway; thus, the waiting time (wt) is related to the service frequency and cost after waiting, as given in Eq. (5):

$$with_{wt} = \frac{without_{wt}}{1 + \frac{k\text{x } p_{distribution}\text{x } t_{obp}}{trn_n}} \tag{5}$$

where $p_{distribution}$ is the passenger distribution parameter and, for a uniform distribution, is taken as 0.5. Considering the base expenditure as unity, Eq. (5) is simplified, and the total cost referenced to the waiting time is determined as in Eq. (6):

$$cst_{wt} = \int_0^{wt} \frac{1}{1 + k\text{x } t} dt \tag{6}$$

$$cst_{wt} = \frac{1}{k} \ln\left(k\text{x } \frac{p_{distribution}\text{x } t_{obp}}{trn_n}\right) \tag{7}$$

Fig. 3 Acute stress and waiting time

2.3.2 Congestion Expenses

During the observation duration (t_{obp}), a fixed number of identical passengers opts for the line of the RRTS network to work. When a train approaches the station, all passengers on the platform thrive to board it so that their waiting time expense is minimized. The passengers of a train encounter the expected crowding discomfort ($ds_{cmfrt(np)}$), where np is the number of users taking the same train. Discomfort is caused by additional passengers encroaching on the minimum area (approx. 1 m2) occupied by passengers for comfortable travel [40]. The function $ds_{cmfrt(np)}$ is strictly increasing for approximately two-thirds of the total number of stations for intercity travel because at stations close to the end of the network, passengers start deboarding the train. The discomfort function is modelled as in Eq. (8):

$$ds_{cmfrt(np)} = \frac{p_{vol}\text{x } t_{obp} - trn_n\text{x } trn_l\text{x } cc_c}{trn_n\text{x } trn_l\text{x } c_l\text{x } c_w} \tag{8}$$

The coach carrying capacity ($\boldsymbol{cc_c}$) is taken as 180 for comfortable travel, and the available area per coach is taken as a product of coach length ($\boldsymbol{c_l}$) 23.54 m long) and coach width ($\boldsymbol{c_w}$) 3.24 m wide coach, ignoring the area occupied by fittings, etc., of the coach. The congestion cost function is minimal and approximately zero at the origin station when the train is empty. Travelling in crowded trains is associated with increased mental acute stress since the passenger perceives less control over the environment. The impact on mental health outweighs that of other urban acute stressors, such as pollution and noise [41].

The acute stress developed due to congestion increases slowly at the initial stations and then increases sharply immediately after a couple of stations, as shown in Fig. 4.

The acute stress can be modelled as in Eq. (9):

$$stress_{congestion} = (ds_{cmfrt(np)})^2 \tag{9}$$

Therefore, the total congestion expense for the complete network during the observation duration t_obp is given by Eq. (10):

$$congestion_{cost} = \sum_1^n (ds_{cmfrt(np)})^2 \tag{10}$$

2.3.3 Schedule Delay Expenses

In an ideal scenario, the departure times of trains must coincide with the passengers' expected boarding times to ensure that the rail network is suitable for passengers. However, trains run with a fixed headway in urban rail transport, and there is a difference between the passenger's desired boarding time and the operator's provided boarding options [42]. If the passenger arrives early to

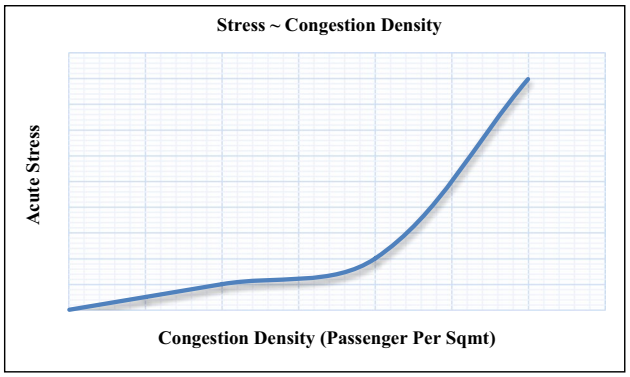

Fig. 4 Acute stress and congestion density

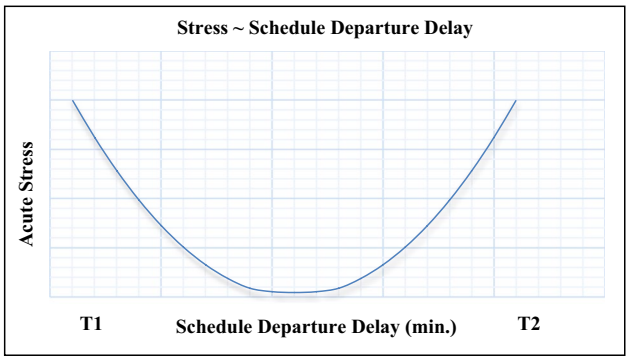

Fig. 5 Acute stress and schedule departure delay

the arriving train (T2), there is an anxiety that he should have arrived a little later and may have completed other tasks apart from exactly matching the train time. This spike in anxiety is reflected in the development of acute stress, which affects the health costs incurred. Similarly, if the passenger arrives a little late to the train that has just departed (T1), then the acute stress is increased to the level that passengers analyse all previous events and tasks in a short time, exposing themselves to a sudden spike of higher anxiety, which is shown in Fig. 5.

This anxiety stress is an expense to the passenger and follows Eq. (11):

$$sde_{stress} = \begin{cases} \frac{1}{e^{\frac{t_{obp}}{trn_n}}}, 0 < pass_{arrival_{time}} \leq \frac{t_{obp}}{2*trn_n} \\ e^{\frac{t_{obp}}{trn_n}}, \frac{t_{obp}}{2*trn_n} < pass_{arrival_{time}} \leq \frac{t_{obp}}{trn_n} \end{cases} \tag{11}$$

Assuming that the passenger flow between headways is uniformly distributed, the total schedule delay cost can be determined as in Eq. (12):

$$sde_{cost} = p_{distribution} \text{ x} \left\{ \int_0^{\frac{t_{obp}}{2\text{x } trn_n}} \frac{1}{e^{\frac{t_{obp}}{trn_n}}} d(trn_n) + \int_{\frac{t_{obp}}{2*trn_n}}^{\frac{t_{obp}}{trn_n}} e^{\frac{t_{obp}}{trn_n}} d(trn_n) \right\} \tag{12}$$

Using Taylor series expansion and ignoring the minimal effect of higher-order terms on sde_{cost}, the schedule delay cost may be approximated as in Eq. (13):

$$sde_{cost} = p_{distribution} \text{x } t_{obp} \text{x } trn_n^{-2} \tag{13}$$

Considering the above discussion, a passenger's total travel expense, which consists of the fare, waiting time, congestion expense and schedule delay expense, can be determined by the *passenger expense determination algorithm* (PEDA) with pseudocode, as explained in Table 3.

The passenger's total travel expense is determined by combining the ticket cost, waiting expense, schedule delay expense and congestion expense. Costs other than the ticket cost are mapped in financial terms with transformation factors *q1*, *q2*, and *q3* for the waiting expense,

Table 3 PEDA

   {cst_wt, 〖congestion〗 _cost, sde_cost},
   {p_distribution, t_obp},
   {mapping factor: q1, q2, q3}
}

For iteration: trn_n and trn_l in different steps
//Iteration steps should ensure the capacity generated, trn_n x trn_l x capacity_coach must be sufficient to
carry all passengers in the observation duration t_obp
do
   p_tr_expns_ite: p_tkt + q1 x cst_wt +  q2 x congestion_cost + q3 x sde_cost)
End

Output: {p_totaltravexp: p_tr_expns_ite}
```

schedule delay expense and congestion expense, respectively, and expressed as in Eq. (14):

$$p_{totaltravexp} = p_{tkt} + q1 \times cst_{wt} + q2 \times congestion_{cost} + q3 \times sde_{cost} \quad (14)$$

The planning objectives of the operator can be achieved by minimizing the passenger's total travel expense ($p_{totaltravexp}$) and maximizing the total operator's profit (op_{prft}) determined through the deliberations mentioned above.

3 Results & Discussion

The Delhi-Ghaziabad-Meerut (NCRTC) RRTS corridor is approximately 82 km in length and has 23 scheduled stoppages between two Intercity trips; this corridor is used for the analysis of optimization issues, as shown in Fig. 6 [43]. The observation duration *t_obp* is taken as the window of peak or rush hours of 4 h. length from the daily running hours. During these rush hours, the passenger flow is at its maximum, and all the passenger expenses are at their peak, which leads to the fair assumption that at other times, the optimization solution will reduce the passenger travel expense compared to that of the peak hour analysis.

The length of the viaduct, platform, depot, tunnel, sidings and other relevant infrastructure parameters affected by the train length of the 9 coaches are explained in Table 4. Similarly, parameters for other train length parameters are also determined and put in as input to the ICDA algorithm for the calculation of infrastructure cost.

The per unit cost of the above variables for the 9-car train length is also determined from the real implemented project data in the metro rail sector in India and referenced from the Report on Operations and Maintenance Systems for Metro Railways, Ministry of Urban Development, and formulated in Table 5. The capacity of the coach is taken as 180 (no. of passengers) for a standard gauge network, and the coach length is 23.54 mt with a width of 3.24 mt. The unit of expense and system profit is taken in the INR, and the transport demand is taken in the number of passengers [44].

The balance factor (*bal_fact*) is varied from 0 to 1 in steps of 0.1 for comprehensive analysis. The effects of train length and service frequency on system profit, operator profit and passenger travel expense with respect to variations in the balance factor are analysed and discussed.

3.1 Impact of the Balance Factor on System Profit

The system profit (in INR) decreases sharply as the balance factor increases because for higher values of the balance factor, the objective is aligned toward maximizing the operator's profit, and passengers' travel expenses are not given due weightage. The effect of the system profit on the balance factor is shown in Fig. 7.

A set of ten service frequencies based on the minimum and maximum headways planned are analysed, and it is observed that when the service frequency is higher, the rate of decrease in system profit is lower, providing minor compensation for passenger expenses. Thus, a very high value of the balance factor should not be chosen to maintain the passenger expenses at an optimum level.

3.2 Impact of the Train Service Frequency and Train Length on the Passenger Travel Expense

Figure 8 shows the effect of train service frequency on passenger travel expenses relative to intercity travel. As the train service frequency (number of trains running in an hour) increases, the passenger travel expense decreases. Additionally, longer trains with high frequency are inferred to offer maximum benefits to passengers as the congestion cost is minimized along with other travel expenses. However, a short train with a high service frequency provides similar benefits to passengers as does a long train with such a high service frequency. The mode of a short train with a higher frequency is suitable for the case of abundant transport capacity and high service frequency demand, whereas the operation cost is minimized for long trains with less frequency.

3.3 Impact of the Train Service Frequency and Train Length on the Operator's Profit

As shown in Fig. 9, with an increase in service frequency, a decrease in the operator's profit is observed for a given train length. This observation is in line with the fact that as the service frequency increases, the operator must deploy additional system resources to maintain and run the trains at such a frequency. The reduction in the operator's profit is greater for the 9-car train than for the 3-car train, which indicates that a large train formation with less service frequency can improve the operator's profit.

3.4 Impact of the Balance Factor and Service Frequency on the Planning Objective: System Profit

The balance factor ensures a balance between the operator's train running cost and the passenger travel expense. Figure 9 illustrates the effect of the balance factor on the system benefit concerning a particular service frequency. The passenger benefit is more significant for a higher balance factor, and the operator's profit is reduced. In

Fig. 6 NCRTC Delhi-Ghaziabad-Meerut RRTS Corridor

general, the region of interest shown in Fig. 10 describes the rational range of the balance factor observed between 0.4 and 0.6, where the decrease in system profit concerning the service frequency maintains the maximum system profit. If the balance factor is set higher in the range from 0.7 to 0.9, the passenger benefits are maximized, whereas the operator incurs a heavy reduction in profit. Although this approach ensures more benefits to passengers, this network operation is sustainable only if the operator is supported through enough financial subsidies from the government.

3.5 Impact of Train Length and Service Frequency on the Operator's Plan Choice

The operator's decision about train length and frequency is generally related to the plan's profitability for running trains. The influence of train length and frequency are embodied in

the objective function, which is described as system profit. The effects of train length and service frequency are illustrated in Fig. 11.

When the train service frequency is increased, the system profit increases and approaches nearly the same values at very high service frequencies. When the train length and service frequency are very small, the operator's cost for running trains is low, the service capability is also low, and the service quality is poor. With increased service frequency and train length, passengers' travel expenses are reduced, so operators' profit also decreases. However, for the operator's selection, the region of interest shown in Fig. 11 is impacted by the frequency in the range of 10 to 20, which provides the maximum system profit. Within those frequencies of interest, a 9-car train length with a service frequency of 16 optimizes the benefits for both the operator and passengers. When the observation duration is considered to be 4 h, the optimum headway observed is 15 min with a 9-car train, for which the operator's profits are maximized and the passenger travel expense is minimized.

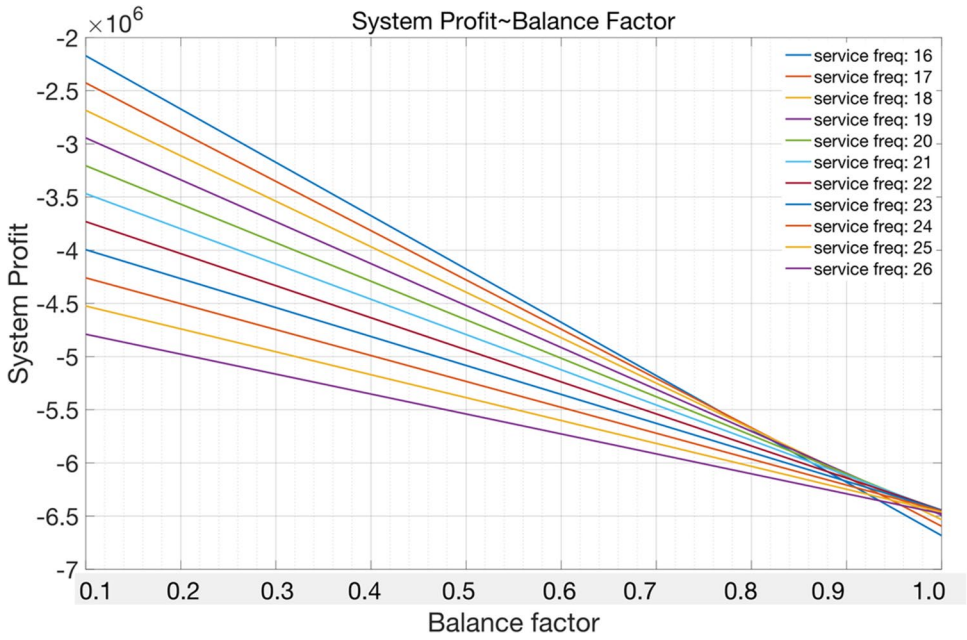

Fig. 7 System profit and balance factors

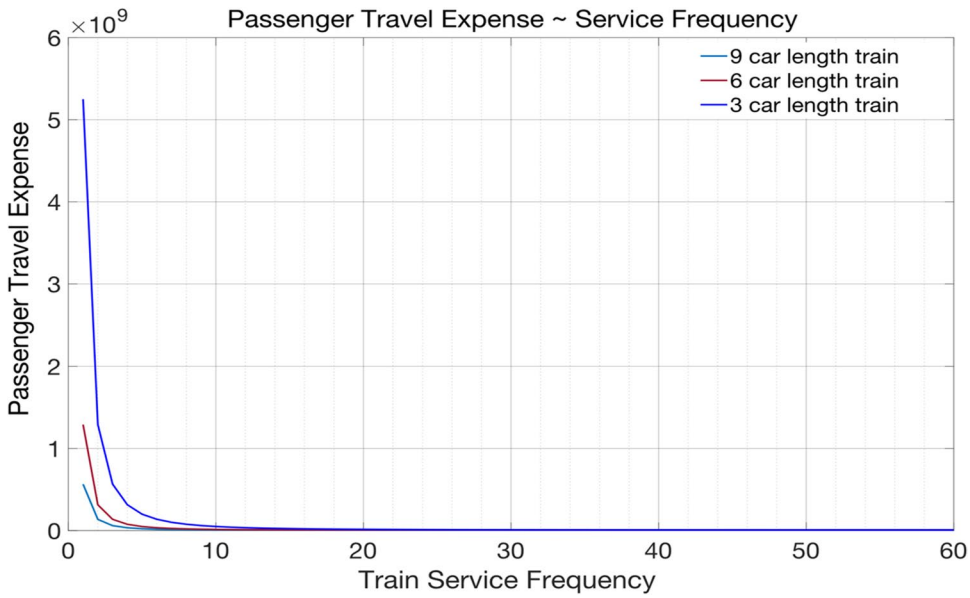

Fig. 8 Passenger travel expense and service frequency (per hour) and train length

3.6 Impact of Passenger Volume During Off-Peak and Peak Hours on the Operator's Choice of Plan

The passenger volume reaches a maximum during the rush hours when the day starts, and most passengers desire to reach the workplace; similarly, during the evening, they desire to reach home from the workplace. However, during the middle hours of the day or early start, the passenger flow is comparatively low compared to that during rush or peak hours. These durations are termed off-peak hours. In general, the operator's decision about train length and frequency should cater to the available passengers with acceptable system profits and hence need to be dynamic in accordance with the passenger flow. The effects of off-peak and peak-hour passenger volumes are illustrated in Fig. 12.

The off-peak hour system profit approaches the peak hour system profit for a specific train service frequency. Notably, in comparison to the peak-hour system profit, the off-peak-hour system profit approaches the same values for lower service frequencies. Hence, if the operator continues to maintain the same service frequency and train size during off-peak and peak hours, the operator's performance will be adversely affected. For the operator's selection, the region of interest, as shown in Fig. 12, observes that a frequency in

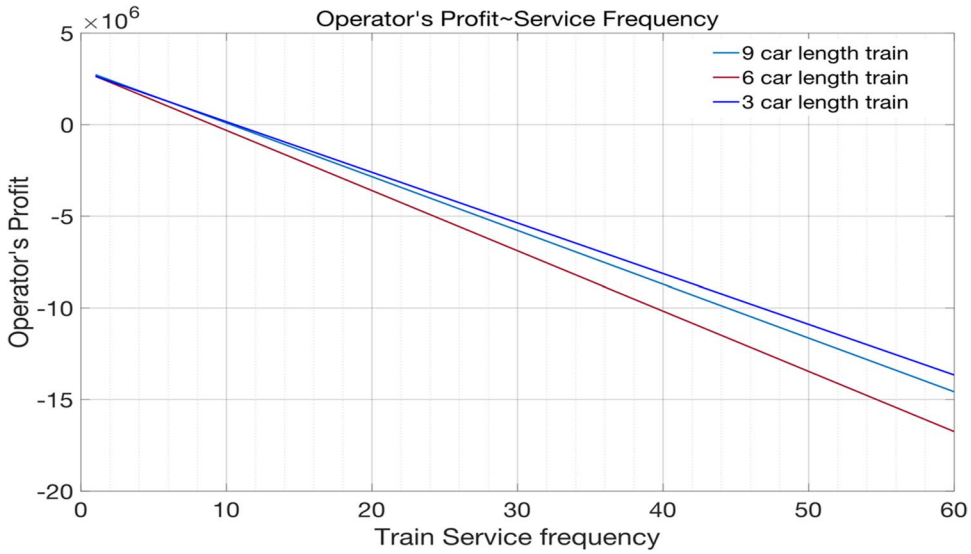

Fig. 9 Profit and service frequency (per hour) and train length of the operator

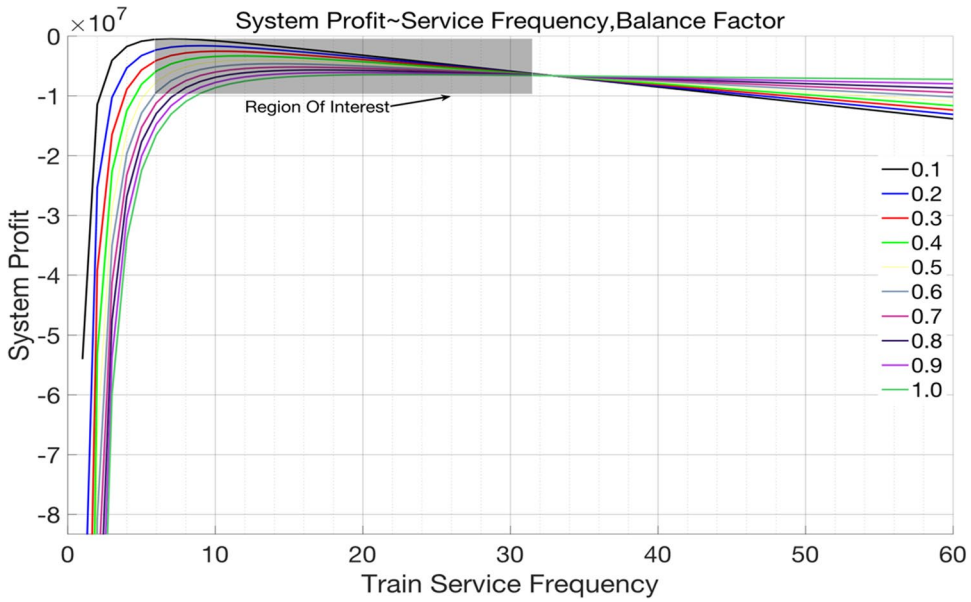

Fig. 10 System profit and service frequency (per hour) and balance factor

the range of 5 to 10 provides maximum system profit during off-peak hours compared to a service frequency range of 10 to 20 in peak hours.

4 Conclusion

The objective of the study is to choose the train length and service frequency so that the operator's profit and passenger expense are optimized. The variation in the infrastructure cost of rail networks due to variations in the viaduct, tunnel, and platform length owing to the train length and service frequency is embodied in the analysis. The acute stress that passengers experience due to travel expenses such as waiting time, schedule delays and congestion expenses is mapped. The study analysed and presented acute stress models to map these expenses to the health costs incurred by passengers.

The results of the optimization model reveal that a balance factor of approximately 0.6 should be chosen to maintain the optimal passenger expenses. If the balance factor is considered to be between 0.7 and 0.9, the passenger benefits are maximized on the verge of the operator's reduced profit. The region of interest observes that a service frequency in the range of 5 to 10 provides maximum system profit in off-peak hours compared to a range of 10 to 20 in peak hours. Thus, it is evident that a 9-car length train has a service frequency of 16 and an optimum headway of 15 min for an observation duration of 4 h. optimize the benefits for both the operator and the passengers.

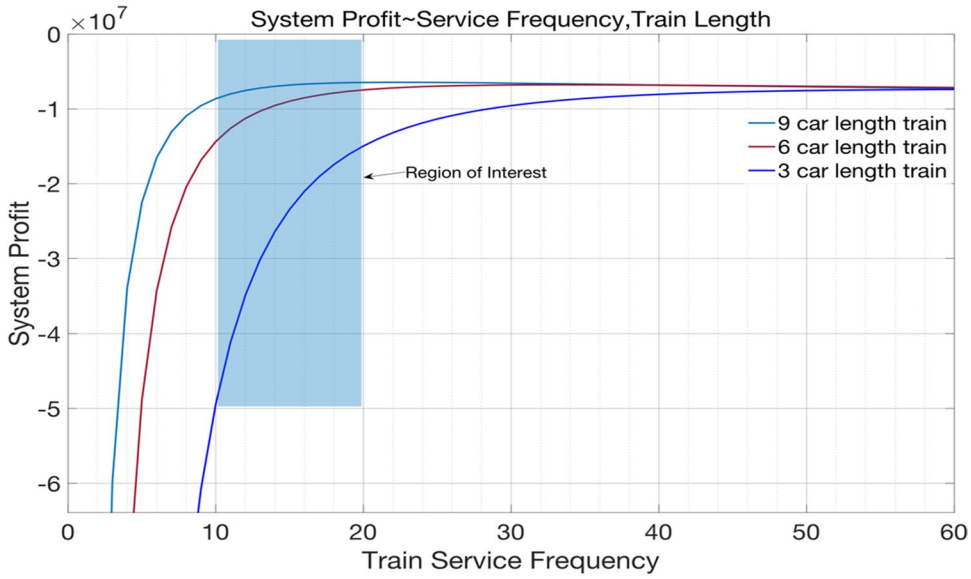

Fig. 11 System profit and service frequency (per hour) and train length

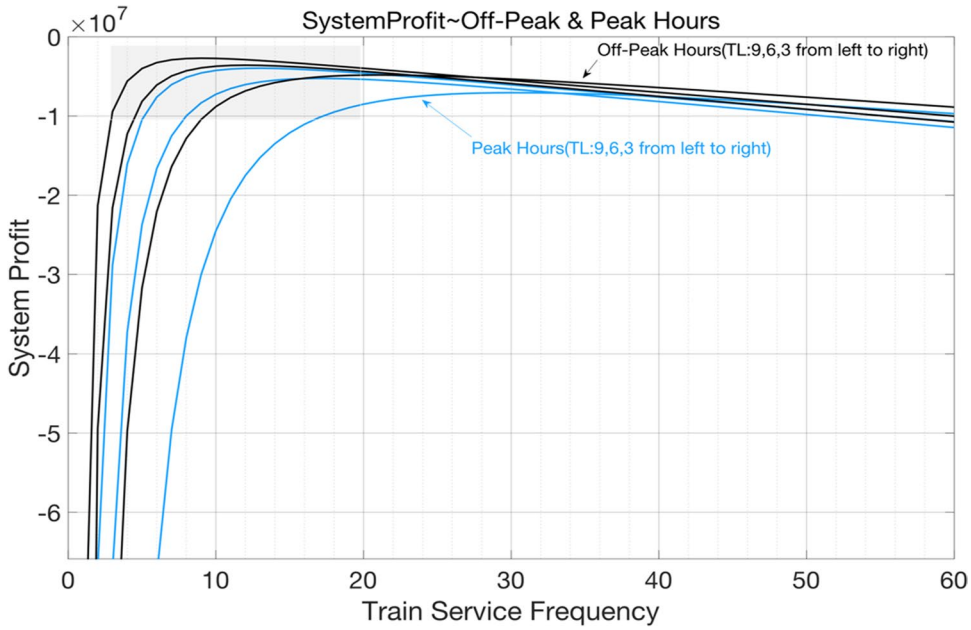

Fig. 12 System profit and service frequency (per hour): Off-peak and peak-hour passenger volumes

The study demonstrated that the model of a short train with a higher frequency is suitable only when transport capacity and high service demand are available and when operators' decision to opt for a long train length with a low frequency is the optimal operation decision for intercity travel. Furthermore, the operator should not opt for a constant train length or service frequency plan during peak and off-peak periods.

Despite the abundant research literature on rail-based transportation, there is still a gap in the study of how the choice of train length and service frequency are correlated with psychological stress. During the research study, both the constraints, ticket price and passenger flow, are considered constant and uniformly distributed, but over time, both of these constraints are variable in nature and require further deliberation. Thus, future research work should include the analysis of train formation and scheduling with the variability factor of these constraints.

Abstract
Ho^{3+}-Yb^{3+} activated $Sr_9Y_2W_4O_{24}$ (SYW) phosphors were synthesized using a traditional solid-state reaction method. X-ray diffraction (XRD), scanning electron microscopy (SEM), and Fourier transform infrared spectroscopy (FT-IR) investigations were conducted to assess the phase, morphology and bond structure in the as-synthesised samples. To determine the optical bandgap values, diffuse reflectance spectra (DRS) for the as-titled phosphors have been obtained. Preliminary photoluminescent studies on the as prepared phosphors focus on UV–visible excitation and emission spectra, as well as observations of decay lifetimes. Secondly, the up-conversion (UC) emission spectra of as-titled phosphors, excited by a 980 nm laser were also recorded. The UC findings show that there are three bands at 488 nm and 551 nm, and 668 nm, corresponding to transitions of Ho^{3+} ions from $^5F_3$ to $^5I_8$, $^5F_4/^5S_2$ to $^5I_8$, and $^5F_5$ to $^5I_8$, respectively. UC luminescence is entirely a two-photon absorption process, as demonstrated by the fitting results of the curve exhibiting the relation between pump power and UC luminescence intensity. Furthermore, the emission spectra data yielded CIE coordinates that are located in the green region. The high thermal activation energy of the SYW phosphor substantially improves its thermal stability, as indicated by temperature dependent PL (TD-PL) spectra. Furthermore, the fluorescence intensity ratio (FIR) was employed to explore the optical sensing properties. Through the research, the bidirectional energy transmission in the UC mechanism was better understood, potentially leading to applications in solid state lighting and temperature sensors and UC applications of this phosphor.

1 Introduction

Rare earth (RE) ions doped phosphor materials have seen a lot of usage recently because of their distinctive photoluminescence characteristics. These materials exhibit promising prospects in many domains, including fluorescent lamps, solid state lasers, light emitting diodes (LED), cathode ray tubes, optical thermometry, drug delivery, and bio-imaging [1–5]. The lanthanide ions exhibit rich multi-modal photoluminescence, including up-conversion (UC), downshifting (DS), contingent upon the various excitation radiations employed. UC refers to nonlinear optical processes that progressively absorb two or more photons and transform them into light emissions at a wavelength shorter than the excitation wavelength [1, 2, 6]. The UC phosphors often employ RE ions as their luminescence centres due to their abundance of electronic states, extended duration of intermediate meta-stable states, and energy levels stacked in a ladder-like manner [7]. However, in some specific applications, such as optical thermometry, the plentiful 4f electronic states of dopant ions typically result in multicolor emission with many emission peaks from f-f transitions. The behaviour of optical temperature sensors based on UC emission has been extensively researched in recent years due to its excellent sensitivity and accuracy. Optical thermometry is a fundamental term that refers to some lanthanide ions with thermally coupled energy levels (TCELs) [1, 8, 9]. The fluorescence intensity ratio (FIR) approach, that involves two thermally connected levels, is currently the most widely used mechanism for optical temperature detection. The thermally connected amounts of RE ions have narrow energy gap (100-2000 cm^{-1}), which varies depending on the lanthanide

ions [10]. Vega et al. investigated the near-infrared to visible up-conversion and second harmonic production in the $BaTiO_3$ phosphor doped with Ho^{3+}/Yb^{3+}[11]. Lojpur et al. also reported temperature sensing characteristics for Ho^{3+}/Yb^{3+}:Y_2O_3 phosphor [12]. Furthermore, to the best of our knowledge, temperature sensing characteristics have not been explored in the SYW: Ho^{3+}/Yb^{3+} ions co-doped phosphors.

Meanwhile, down-conversion (DC) is the opposite of up-conversion (UC), and it can be utilized in numerous applications such as solid-state lighting (SSL), lasers, optoelectronic devices, and plasma devices when an appropriate host lattice is doped with RE ions [13–17]. Compared to traditional fluorescent and incandescent light sources, SSL devices offer a number of improved features, including a longer lifespan, lower production costs, and an environmentally friendly design [18–21]. Currently, the most widely used commercial w-LEDs are created by combining a blue LED semi-conductive chip with a YAG: Ce^{3+} phosphor that emits yellow light. Many problems, including low colour rendering index (CRI) and high correlated colour temperature (CCT) values, are caused by the absence of red colour component [22, 23]. Phosphors that emit green, red, and blue (RGB) light in n-UV chips were created as a feasible method that could be applied for production of w-LEDs. This method is not widely used, though, as the commercial red phosphor (Y_2O_2S: Eu^{3+}) used in it is not very good at absorbing light from the n-UV semiconductor chip.

In material science, doping is a commonly used technical procedure that includes adding atoms to obtain hybrid materials with desired features and capabilities. Since rare earth (RE) ions usually generate multicoloured emissions in UV to IR regions due to numerous ladder-like energy levels, long-lived excited states, and outstanding green emission, they are typically thought of as suitable options for lighting and display fields[24–27]. However, due to its limited absorption, the singly doped Ho^{3+} UC phosphor has very low pump efficacy and emission intensity under NIR stimulation. Since Yb^{3+} ions have a greater absorption cross-section at around 980 nm and can effectively transmit the excitation energy to Ho^{3+} ions, they can serve as excellent sensitizers for Ho^{3+} ions [28–31]. As a result, combining Ho^{3+} with Yb^{3+} may significantly increase Ho^{3+}'s emission efficacy. The distance between the acceptor and donor ions will often vary with different doping concentrations. Thus, it is very important to maximise the Ho^{3+}/ Yb^{3+} doping concentration and boost energy transfer efficiency.

For the creation of promising materials, the choice of an appropriate lattice is significant. A wide range of host materials have been thoroughly investigated, such as phosphates, titanates, tungstates, aluminates, and molybdates etc. Tungstates are a considerable class of host material by virtue of the numerous benefits they offer, particularly their simplicity of preparation, low cost, remarkable chemical strengths, and excellent optical characteristics [32–35]. When exposed to UV light, tungstate, a type of self-activated phosphor, emits a wide range of hues. The low phonon energy of tungstate helps to prevent highly competitive non-radiative decay for dopants and improves luminosity, making it a good host for phosphors. Thus, the LBGW:0.12Sm^{3+} was revealed by Pei et al. to serve as an orange-red phosphor in an LED field [36]. Kamal et al. conducted study on the sample (BWO: 0.07Tb^{3+}) for latent fingerprint identification and anti-counterfeiting applications [37]. Zhao et al. investigated $LiCaYb(WO_4)_3$:Er^{3+}/Tm^{3+} with very sensitive thermometry for thermometer applications [38]. On the other hand, SYW: Ho^{3+}/ Yb^{3+} phosphor has not yet been thoroughly studied for DC & UC mechanism.

In the present work, we utilised an intuitive high-temperature solid-state technique to synthesis a range of Ho^{3+}/ Yb^{3+} activated SYW phosphors. Using XRD, SEM & UV–vis-NIR techniques, we have examined the structural, morphology & optical properties of the as synthesised phosphors. To examine the many vibrational bands that are present in the lattice, FT-IR investigations were carried out. PL spectra measurements were used to investigate the luminous characteristics of the co-doped SYW phosphors. For excitation wavelengths at 454 nm and 980 nm, the DC & UC spectra of the samples were captured. The stability of intense high purity green UC emission was investigated at various pumping powers and dopant concentrations. We provide a detailed illustration of the potential energy transfer mechanism of the co-doped Ho^{3+}/ Yb^{3+} phosphors. Temperature dependence of the UC spectra under 980 nm excitation was recorded and the activation energy of the host material was estimated thereby providing an idea about the thermal stability of the phosphor. FIR calculations were used to obtain maximum relative sensitivity (S_R) and absolute sensitivity (S_A) values. These aforementioned UC PL features of Ho^{3+}/ Yb^{3+} co-doped SYW phosphors have not been reported yet.

2 Synthesis and instrumentations

The phosphor samples for this study were synthesised using the high temperature solid-state reaction technique. A range of phosphors have been produced, including SYW: x Ho^{3+} (x = 1.0, 3.0, 5.0, 7.0, & 9.0 mol%) and SYW: x Ho^{3+}/ y Yb^{3+} (x = 7.0 mol% & y = 1.0, 3.0, 5.0, & 7.0 mol%). For the phosphor synthesis, the high-purity raw ingredients $SrCO_3$ (98%), Y_2O_3 (98%), WO_3 (99.9%), Ho_2O_3 (99.9%), and Yb_2O_3 (99.9%) were utilised. The raw materials for each composition were measured out using an electric balance, then combined with a pestle and agate mortar for one hour to achieve a homogenous combination. The sample was then well mixed and heated for

4 h at 1300 °C, 5 °C per minute, in an alumina crucible. After the mixture had naturally cooled to ambient temperature, the resultant powder was ground for a second time to conduct appropriate characterizations.

Using a Bruker D-8 Model Advance diffractometer that comes with a nickel-based filter and Cu-Kα as source, XRD was utilised to examine the crystal phase of the Ho^{3+}/ Yb^{3+} co-doped samples. The PerkinElmer Spectrum 2 equipment was utilised for FT-IR spectroscopy. The JEOL 7610 F Plus microscope was used to capture SEM and EDX images. With a resolution of 2.0 nm, a Jasco V-770 spectrophotometer was used for diffuse reflectance spectroscopy (DRS). To assess the DC spectra, Xenon lamp was employed as the excitation source having resolution of 1.0 nm along with a Jasco 8300 FP spectrofluorophotometer. Using a 980 nm laser, Horiba PTI Quanta Master has been utilised for up-conversion PL. A 150 MHz digital oscilloscope (HM 1507 Hameg Instruments) was used to measure the PL decay.

3 Result and discussion

3.1 XRD analysis

XRD patterns were utilised to identify the phase formation of the samples, and the results obtained from all of the as-prepared samples were identical. Figure 1(a) shows a series of XRD patterns of SYW: Ho^{3+}/ Yb^{3+} phosphors with varying doping concentrations in the diffraction 2θ range 15°-60° as well as the JCPDS Card No. 49–0568. The presence of broad, strong peaks indicates that the phosphor particles are well-crystallized after being synthesised. There were no peaks from impurities, and all of the diffraction peaks showed good coincidence with the JCPDS data. This result shows that doping Ho^{3+} and Yb^{3+} ions in SYW phosphors has been accomplished.

Using the most prevalent diffraction peak and the provided Debye Scherrer formula, the crystallite size has been calculated [39].

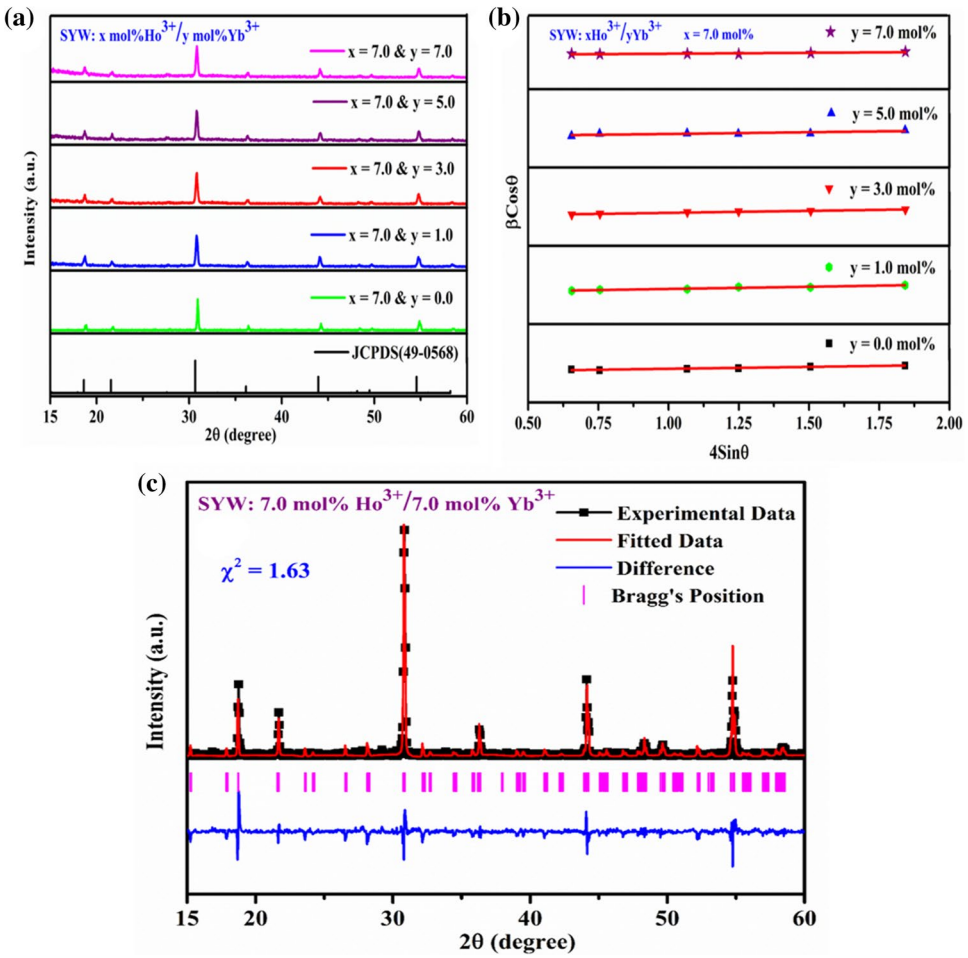

Fig. 1 (**a**)XRD patterns of SYW: xHo^{3+}/ yYb^{3+} (x = 7.0 mol% and y = 1.0, 3.0, 5.0 and 7.0 mol%) phosphors along standard JCPDS card. (**b**) their respective W–H plot of SYW phosphors & (**c**) show reitveld refinement recorded for SYW: 7.0 mol% Ho^{3+}/ 7.0 mol% Yb^{3+}) phosphors respectively

$$D = \frac{k\lambda}{\beta cos\theta} \quad (1)$$

where λ is the wavelength of the X-ray utilised, β indicates the full width at half maximum, and θ represents the diffraction angle, D is the crystallite size, and K is the form factor (0.9). The estimated crystallite sizes range from 22 to 27 nm.

It has been noted that the lattice strain (ε) and crystallite size may be affected by the β, (FWHM) of the XRD diffraction peak. This can be readily explained by the Williamson–Hall equation [39, 40],

$$\beta cos\theta = \frac{k\lambda}{D} + 4\varepsilon sin\theta \quad (2)$$

W–H plots are depicted in Fig. 1 (b). W–H plots and Debye Scherrer's formula have both been used to determine the crystallite size (D) and strain effect on SYW: Ho^{3+}, Yb^{3+} samples. Scherrer's analysis and W–H plots indicate that there isn't much fluctuation in crystallite size. This is due to the common assumption that the strain factor in Scherrer's equations is zero. The estimated strain in the as-synthesised phosphors in this instance is extremely small which has little influence on the doped samples' PL-intensity.

The Rietveld refinement analysis of SYW:x Ho^{3+},y Yb^{3+} (x = 7.0 mol% and y = 7.0 mol%) phosphor was conducted via the FULLPROF suit programme. The pseudo-Viogt function has been applied to fit different data point settings. The Rietveld refinement SYW:x Ho^{3+},y Yb^{3+} (x = 7.0 mol% and y = 7.0 mol%) is shown in Fig. 1(c). The calculated XRD pattern is shown by the solid line in the refinement diagram; the observed XRD patterns are represented by dots; the Bragg's positions of the cubic phase are represented by vertical bars; and the variation between the calculated and observed XRD patterns is displayed in the lower profile. Lower values for goodness of fit (GOF) = $\chi 2$ for the best refining results predicted the quality of the refine data Table 1.

Table 1 Rietveld refinement parameters with JCPDS data for SYW: 7.0 mol% Ho^{3+}/ 7.0 mol% Yb^{3+}) ion doped phosphor

Parameters	Standard data JCPDS (49–0568)	SYW phosphor
a(Å)	11.642	11.615
b(Å)	11.642	11.615
c(Å)	16.465	16.489
α = β = γ (°)	90	90
χ^2	–	1.63
Cell Volume (Å^3)	2231.60	2224.50

3.2 FESEM and EDX

To explore the atomic structure and particle size of the as-titled samples in further detail, FESEM has been employed. SEM micrographs of the Ho^{3+} doped and Ho^{3+}/Yb^{3+} co-doped SYW phosphors are displayed in Fig. 2(a & b). The uneven size and irregular polyhedron forms of SYW particles are clearly visible. Moreover, some phosphor particles exhibit very minimal agglomeration as a result of the high-temperature reaction process and hand grinding.The SYW phosphor's particle sizes as estimated from ImageJ software lay in the range of 4-9 µm...

An EDX analysis is used to identify the constituent elements of various materials. The single Ho^{3+} ion doped sample's EDX spectrum is displayed in Fig. 2(c), whereas the co-doped Ho^{3+}/ Yb^{3+} sample's spectrum is displayed in Fig. 2(d). The elements Sr, Y, W, Ho were detected in the analysis of singly doped e Ho^{3+} ions sample, and the elements Sr, Y, W, Ho, and Yb were detected in the Ho^{3+}/ Yb^{3+} ions co-doped sample. As a result, all of the components that were utilised for producing these samples are confirmed by the EDX record. The elemental mapping of the Ho^{3+}/ Yb^{3+} co-doped phosphor is displayed in Fig. 3. Every element occurs in the matrix, and the doping ions are evenly spaced over the surface, as can be seen from the elemental mapping.

3.3 FT-IR spectral analysis:

The nature of bonding and their stretching and bending vibrations in the as-titled phosphor was investigated using FT-IR analysis. The attenuated total reflectance mode (ATR) spectra of un-doped, SYW: 7.0 mol% Ho^{3+} and co-doped SYW: 7.0 mol% Ho^{3+}/ 7.0 mol% Yb^{3+} phosphors are shown in Fig. 4. There are bands around 564, 791, 857, 1062, 1470, 2892, and 2974 cm^{-1} in the spectra. Bands in the 470–735 cm^{-1} range are assigned to metal–oxygen (Y–O) bond vibrations, and the peak at 791 cm^{-1} is ascribed to the W–O-W stretching vibration mode. The peaks at approximately 857 cm^{-1} is due to the W–O bond's asymmetric stretching vibration. An infrared band located between 1062 and 1470 cm^{-1} indicates the existence of Sr–O. The occurrence of a hydroxyl group may be indicated by the band at 2892 cm^{-1}, and the antisymmetric stretching of adsorbed water molecules can be seen at 2974 cm^{-1}. Numerous functional groups have been observed to be the same in both doped and un-doped as-prepared phosphors.

3.4 DRS analysis and band gap energy

An important parameter of phosphors used in w-LEDs is their optical band gap (Eg). Figure 5 displays the DRS of undoped, 7.0 mol% Ho^{3+}, and 7.0 mol% Ho^{3+}/ Yb^{3+} doped SYW phosphors from 200–1400 nm. The spectra reveal

جامعة قطر QATAR UNIVERSITY

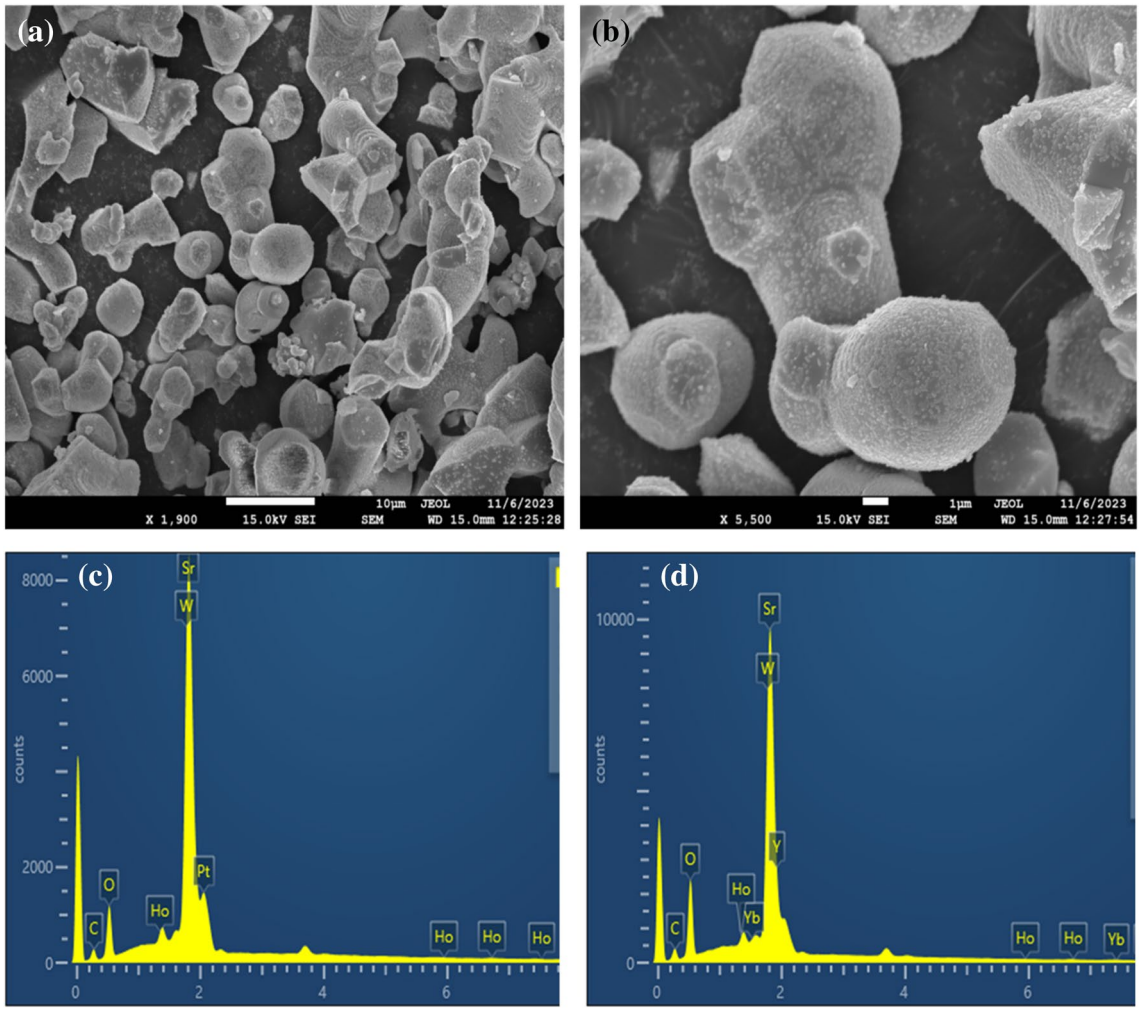

Fig. 2 SEM micrographs (**a**-**b**) of 7.0 mol% Ho^{3+} & 7.0 mol% Ho^{3+}/ 7.0 mol% Yb^{3+} co-doped SYW phosphors (**c**-**d**) and their corresponding EDX images

that the distinct, strong absorption bands at 454, 542, and 646 nm in the visible area are triggered by transitions from $^5I_8 \rightarrow {}^5G_6$, $^5I_8 \rightarrow {}^5F_4/{}^5S_2$, and $^5I_8 \rightarrow {}^5F_5$, in that order. In addition to this, the host also exhibits a prominent, broad absorption band in the UV area at 305 nm due to the charge transfer band (CTB) [41]. After converting the DRS spectral data into the Kubelka–Munk function, the optical band gap (E_g) was computed using the subsequent formulae [42, 43].

$$F(R) = \frac{(1-R^2)}{2R} = \frac{\alpha}{S} \tag{3}$$

The sample reflectance is denoted by R, the scattering coefficient by S, and the absorption coefficient by α.

$$F(R)h\nu = C(h\nu - E_g)^n \tag{4}$$

Here, h denotes Planck's constant, v represent the frequency of incident light, and C is an energy-independent constant (in this case, = 1). For direct & indirect allowed transitions, the value of n can be ½ and 2, respectively. The direct allowed optical bandgap (n = 1/2) for the current scenario has been computed. The graph $(\alpha h\upsilon)^2$ vs hυ of the undoped, Ho^{3+} doped, and Ho^{3+}/ Yb^{3+} co-doped phosphors is displayed as a Tauc plot in Fig. 6. By extrapolating the linear part of the plot, the optical band bap value for the samples was found to be between 4.36 and 4.52 eV. A lower band gap value leads to a greater number of ions being excited, which increases the intensity of photoluminescence.

3.5 PL properties

Figure 7(a) shows the PL excitation spectra of SYW: x Ho^{3+} (1.0, 3.0, 5.0, 7.0, & 9.0 mol %) phosphor, which was obtained by observing green emission at 551 nm. It has several bands that depict transitions from the ground state, $^5I_8$, to distinct excited states, $^3H_5$ (363 nm), $^5G_4$

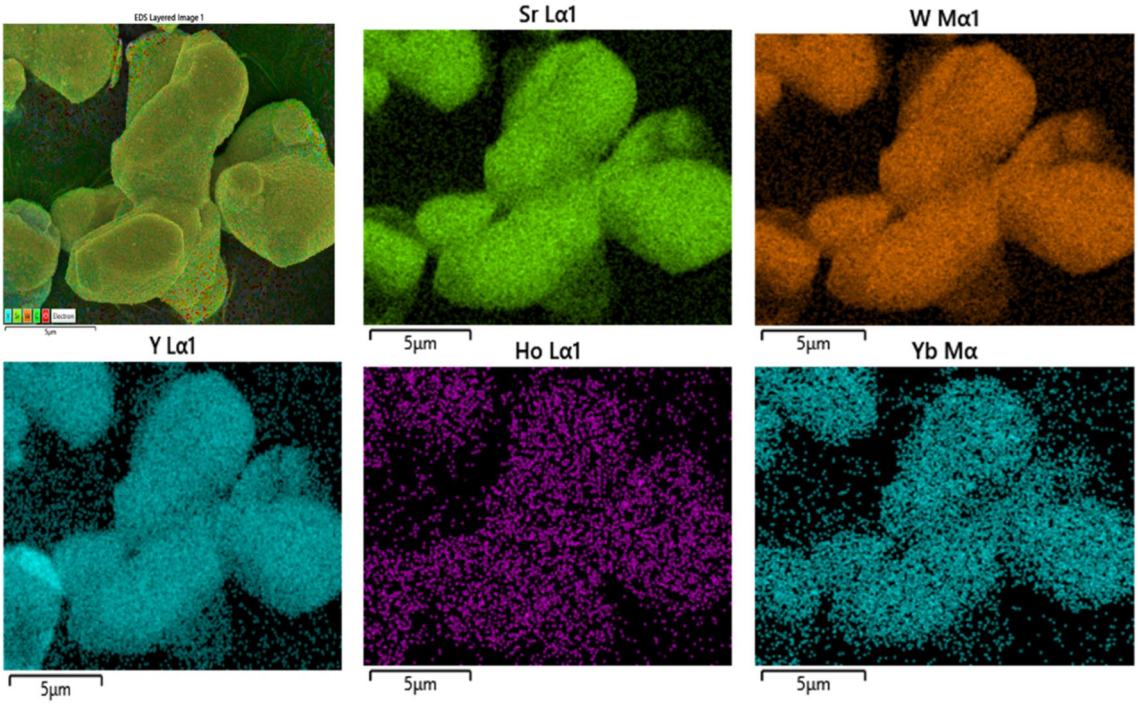

Fig. 3 Elemental mapping of 7 mol% Ho^{3+}/7 mol%Yb^{3+} co-doped SYW phosphor

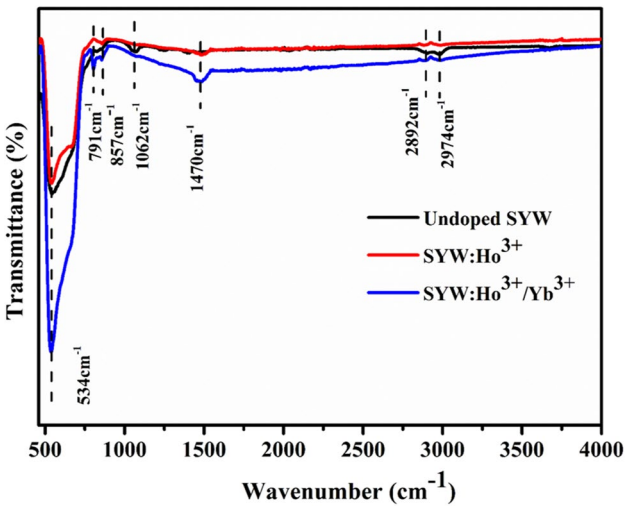

Fig. 4 FT-IR spectra of an un-doped, SYW: 7.0 mol% Ho^{3+} and co-doped SYW: 7.0 mol% Ho^{3+}/ 7.0 mol% Yb^{3+} phosphors

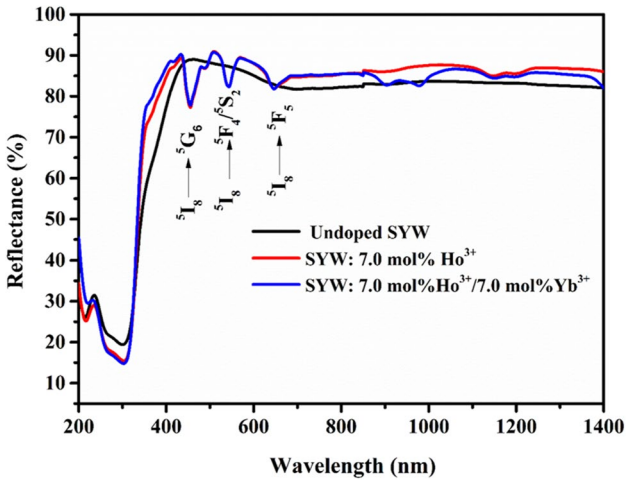

Fig. 5 DRS spectra for of the un-doped, 7.0 mol% Ho^{3+}, and 7.0 mol% Ho^{3+}/Yb^{3+} doped SYW phosphors

(387 nm), $^5G_5$ (421 nm), $^5G_6$ (454 nm), $^3K_8$ (476 nm), and $^5F_2$ (489 nm) [44, 45]. These transitions were noted in accordance with data reported by Carnall et al. [46, 47]. From these bands, the band at 454 nm ($^5I_8 \rightarrow {}^5G_6$) exhibited high intensity; thus, this transition wavelength was chosen to examine the visible photoluminescence (PL) spectra for varying concentrations of Ho^{3+} ion doped SYW phosphors. Figure 7(b) displays the PL emission spectra of Ho^{3+} doped SYW phosphors at different concentrations that were excited by blue light with a wavelength of 454 nm. The emission spectra shows emission band, exhibiting a maximum at 551 nm that is ascribed to the Ho^{3+} ion's $^5F_4/^5S_2 \rightarrow {}^5I_8$ transition [48–50]. Furthermore, the emission bands associated with the transition from excited states $^5F_5$ (667 nm) to ground state $^5I_8$ are much weaker than the bands assigned at 551 nm in the current emission spectra.

جامعة قطر QATAR UNIVERSITY

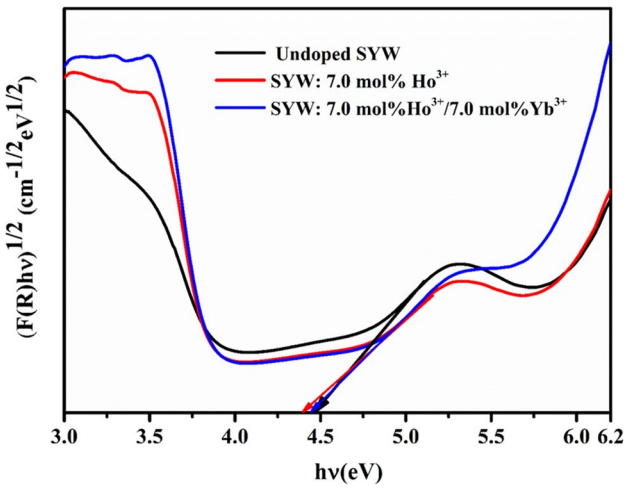

Fig. 6 The tauc's plot for direct band for SYW phosphors

The linear emission spectra obtained under 454 nm excitation for the SYW: x Ho^{3+}/y Yb^{3+} (x = 7.0 mol%, & y = 1.0, 3.0, 5.0 & 7.0 mol%) phosphors are displayed in Fig. 8. The co-doped SYW phosphors exhibit visible emission as well when excited with blue light. Three emission peaks are evident at wavelengths of 488, 551 and 668 nm, which corresponds to the transitions $^5F_3 \rightarrow {}^5I_8$, $^5F_4/{}^5S_2 \rightarrow {}^5I_8$, and $^5F_5 \rightarrow {}^5I_8$, respectively [24, 51]. As the Yb^{3+} concentration increases, it is evident from Fig. 8 that the emission intensity also increases. This could be because of the ET from Yb^{3+} to Ho^{3+} ions in the emission, and the cross relaxation between Ho^{3+} and Yb^{3+} ions. Furthermore the investigation on the UC behaviour of Ho^{3+}/ Yb^{3+} co-doped SYW phosphors carried out, since the Ho^{3+} ions exhibit very low or insignificant emission at excitation 980 nm.

Figure 9 demonstrates the UC spectra of the as-synthesised SYW: Ho^{3+}/ Yb^{3+} phosphors using 980 nm laser illumination in the 425–725 nm range. In the spectra, three distinct bands were seen in the blue, green, and red sections, at wavelengths of 488, 551, and 668 nm respectively. The subsequent transition of the Ho^{3+} ions from their $^5F_3$,$^5F_4/{}^5S_2$, and $^5F_5$ excited states to the $^5I_8$ ground state, is attributed by these blue, green, and red bands respectively [24, 52, 53]. The figure also clearly shows that as the Yb^{3+} concentration rises, so does the intensity of the UC emission. Ho^{3+} ions are known to have an extremely weak absorption cross-section when excited by a 980 nm laser. Consequently, Yb^{3+} ions are serving as a sensitizer in the current study and transmit energy to Ho^{3+} ions (the activator). Furthermore, it is evident from Fig. 9 that the UC emission produced by Ho^{3+} ions increases steadily up to 7 mol% when Yb^{3+} ion concentrations (1.0, 3.0, 5.0, and 7.0 mol%) rise. Doping Yb^{3+} ions causes energy to flow from Yb^{3+} ions to Ho^{3+} ions, which affects luminescent effectiveness. This is the cause of the increased red and green emission of Ho^{3+} ions. We have examined the power pump dependence PL studies to acquire additional confirmation for this up-conversion process.

3.6 Power pump dependent PL analysis

SYW: x Ho^{3+}/y Yb^{3+} (x = y = 7.0 mol%) was illuminated by variable power 980 nm laser to investigate the process of ET

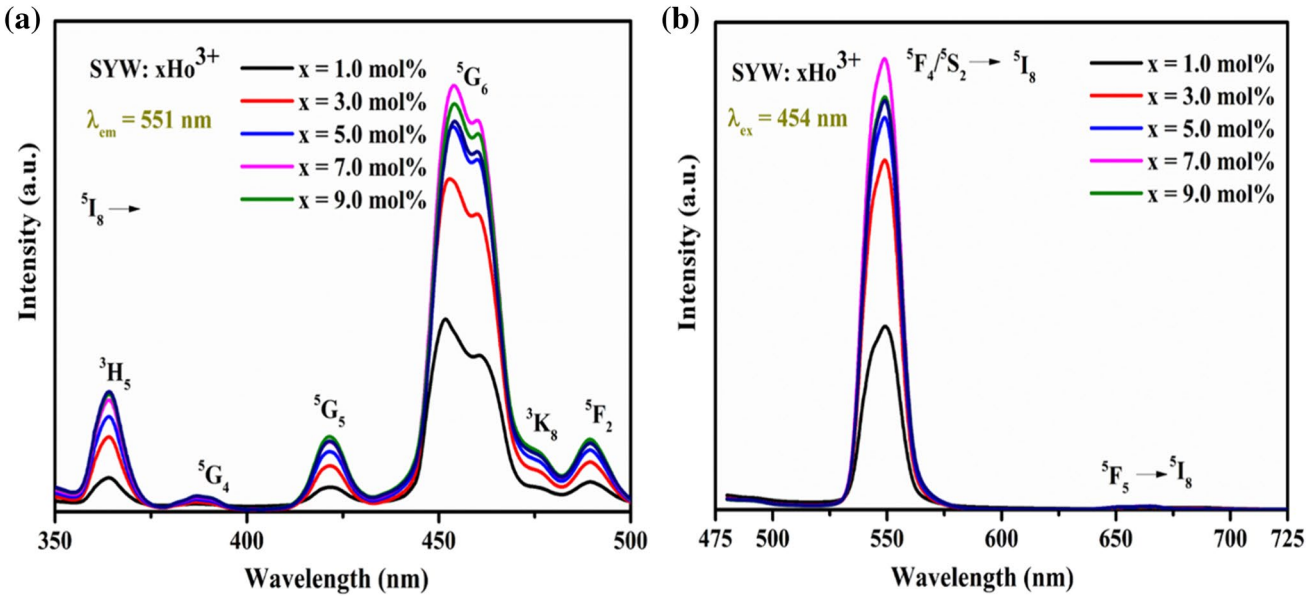

Fig. 7 (**a**) PL excitation spectra for SYW: xHo^{3+} (1.0, 3.0, 5.0, 7.0, & 9.0 mol %) doped phosphors at 551 nm wavelength. (**b**) PL emission spectra of SYW: xHo^{3+} (1.0, 3.0, 5.0, 7.0, & 9.0 mol %) doped phosphors under excitation wavelength 454 nm

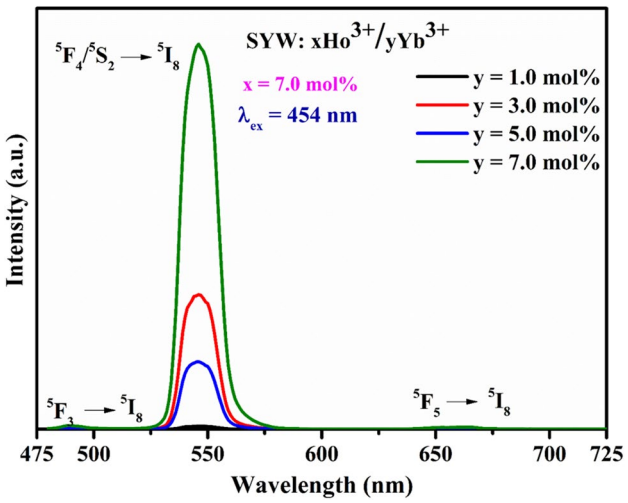

Fig. 8 Linear emission spectra under 454 nm excitation for the SYW: xHo^{3+}/yYb^{3+} (x = 7.0 mol%, & y = 1.0, 3.0, 5.0 & 7.0 mol%) phosphors

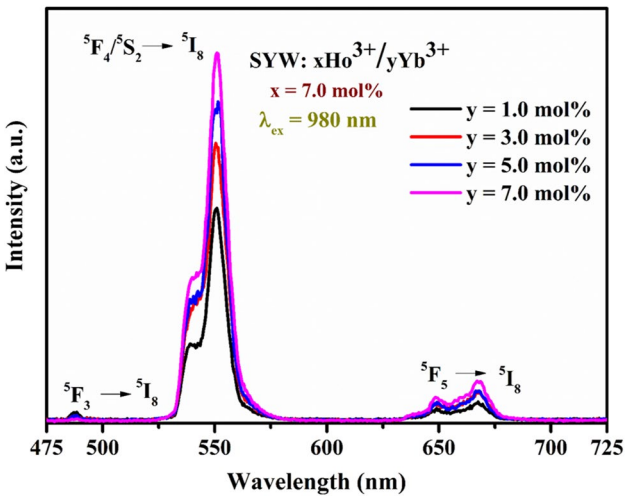

Fig. 9 UC spectra of the SYW: xHo^{3+}/yYb^{3+} (x = 7.0 mol%, & y = 1.0, 3.0, 5.0 & 7.0 mol%) phosphors under 980 nm excitation

between Yb^{3+} and Ho.$^{3+}$ ions in the sample. The variability in green and red band intensity with pump power is depicted in Fig. 10(a). In this up-conversion spectra, the green band is more intense than the red band. The UC intensity rises with increasing pump power at first, then saturates slightly. This intensity saturation can be the result of the material heating at more pump power. The emission intensity is directly related to nth power of pump power [54, 55]

$$I_{up} = (P_{in})^n \tag{5}$$

The variables I_{up}, P_{in}, and n represents the intensity of UC luminescence, pump laser, and number of needed pump photons, respectively. Figure 10(b) displays the outcomes of a logarithmic graph between power and intensity of the phosphor. For the emissions at 551 and 668 nm, the slope (n) values were 1.48 and 1.87, respectively. In the case of the two photon processes that are responsible for the observed green and red emissions, n ought to be almost equal to 2 which is confirmed from the plot. These findings suggest that the red and green emissions in phosphor are produced by two-photon processes.

3.7 Energy transfer mechanism

Using the aforementioned data as well as the Ho^{3+} and Yb^{3+} energy level diagrams, Fig. 11 illustrates potential mechanisms and population processes in the SYW: Ho^{3+}/ Yb^{3+} phosphor. When an infrared photon is absorbed by Yb^{3+} under the excitation of a 980 nm laser diode, electrons in the ground state of $^2F_{7/2}$ jump to the excited state of $^2F_{5/2}$. Ho^{3+} ions go through ground state excitation (GSA), which involves lifting an electron from the $^5I_8$ level to the $^5I_5$ level[56]. An additional lift of the electron from the $^5I_5$ level to the $^5F_2$ level occurs. The excited state absorption (ESA) of the $^5I_6$ level to the $^5S_2/^5F_4$ levels is also caused by the ET from Yb^{3+} to Ho^{3+} ions. Their population is increased by a non-radiative (NR) decay from the $^5I_5$ levels to the $^5I_6$ and $^5I_7$ levels, which also initiates the ESA from these levels to the $^5F_4$ and $^5F_5$ levels, respectively. Energy transfer (ET) from Yb^{3+} ions boosts each of these ESA even more. Green photon emission is produced when the highly populated $^5F_2$ level decays non-radiatively to the $^5F_4$ level, which decays radiatively[57]. Although the green emission predominates, the $^5F_2$ level also exhibits some radiative decay leading to an NIR photon emission. The non-radiative decay of $^5F_4$ level contributed slightly to the $^5F_5$ level, which is mostly populated by the ESA of $^5I_7$ level. As a result, there are fewer atoms at the $^5F_5$ level, and it releases a red photon as it relaxes to the ground state[51]. Conversely, the densely occupied $^5F_4$ level would rather relax to the ground level $^5I_8$ than to the $^5I_7$ level and release a green photon. As a result, the entire UC process is dominated by the emission of green photons.

3.8 CIE coordinates estimation

The CIE coordinates for the SYW: Ho^{3+}/ Yb^{3+} doped phosphors has been calculated using PL data from 1931CIE. The CIE diagram for SYW: Ho^{3+}/ Yb^{3+} doped phosphors with excitation wavelengths of 454 nm and 980 nm are displayed in Fig. 12(a) and (b), and Table 2 presents each of their estimated values. According to the CIE diagram, the coordinates of the as-synthesised phosphors are located close to the green region. Therefore, SYW: Ho^{3+}, Yb^{3+} could be a

جامعة قطر QATAR UNIVERSITY

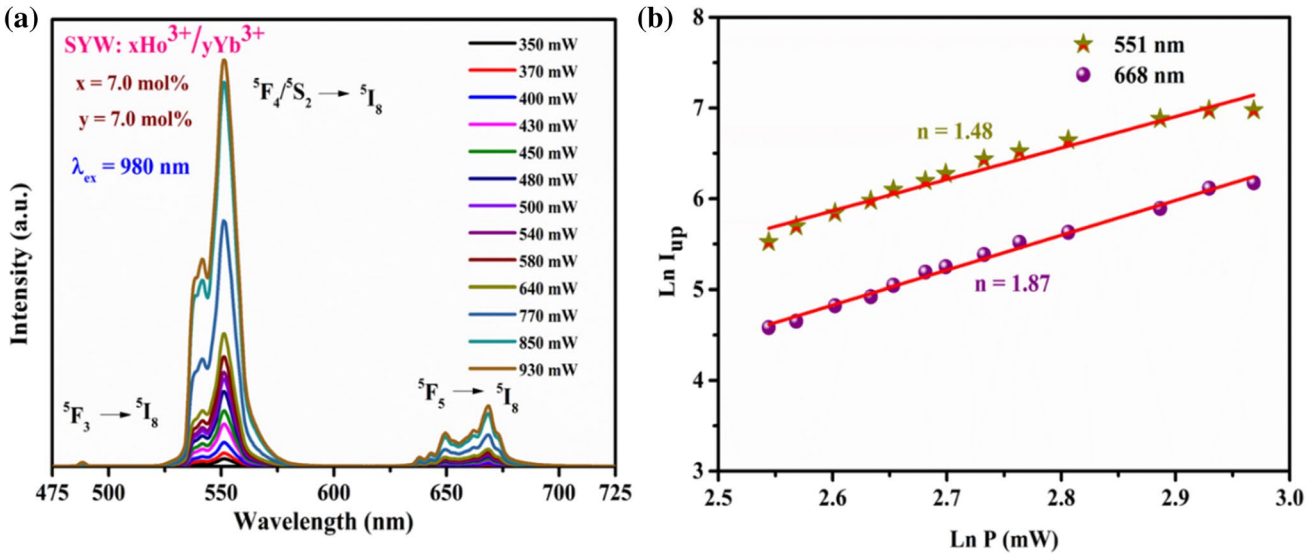

Fig. 10 (**a**)Power dependence PL spectra of SYW: xHo^{3+}/yYb^{3+} (x = 7.0 mol%, & y = 7.0 mol%) phosphor under 980 nm laser excitation and (**b**) plot of Ln I_{up} & Ln P

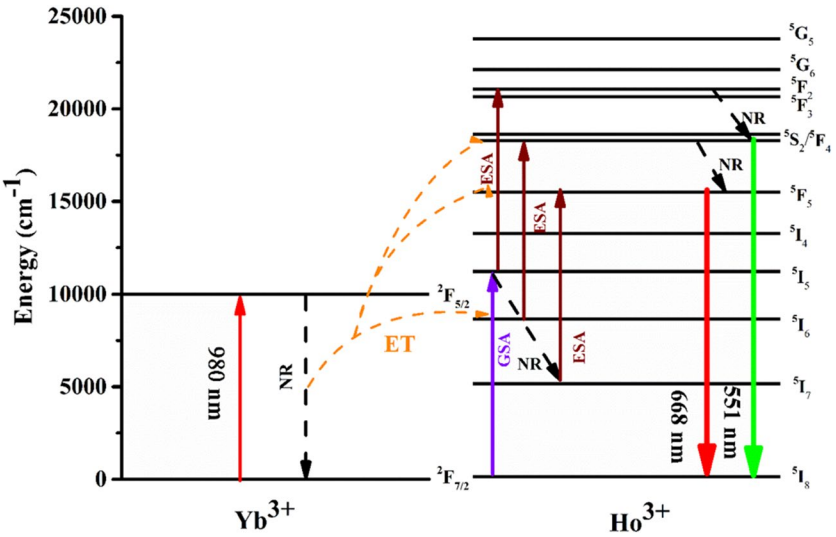

Fig. 11 Energy level diagram for Ho^{3+} & Yb^{3+} ions

good option with promise for lighting and multicolor display applications.

Typically, CCT is a useful metric for assessing the quality of a light source. The values of CCT can be calculated using McCamy's empirical formula, which is provided below [58, 59].

$$CCT = 449n^3 + 3525n^2 - 6823.2n + 5520.3 \quad (6)$$

Here, and xe = 0.332, ye = 0.186. The CCT values of Ho^{3+}/ Yb^{3+} doped SYW phosphor at λex = 980 nm are tabulated in Table 2.

Furthermore, one of the crucial factors for the w-LEDs application is colour purity. For the phosphor samples, the colour purity was determined using the following relation [17, 60].

$$Colorpurity = \frac{\sqrt{(x - x_{ee})^2 + (y - y_{ee})^2}}{\sqrt{(x_d - x_{ee})^2 + (y_d - y_{ee})^2}} \quad (7)$$

In this case, (x, y) represents the CIE coordinates of the SYW phosphor; (x_{ee}, y_{ee}) stands for the CIE coordinates of the standard white colour; and (x_d, y_d) represents the CIE coordinates of the dominant wavelength. The value of (x_i,y_i) was (0.33, 0.33). Table 2 also displays the computed colour purity values for the samples. It is noted that the Ho^{3+}, Yb^{3+} doped SYW samples colour purity lies between 97.4

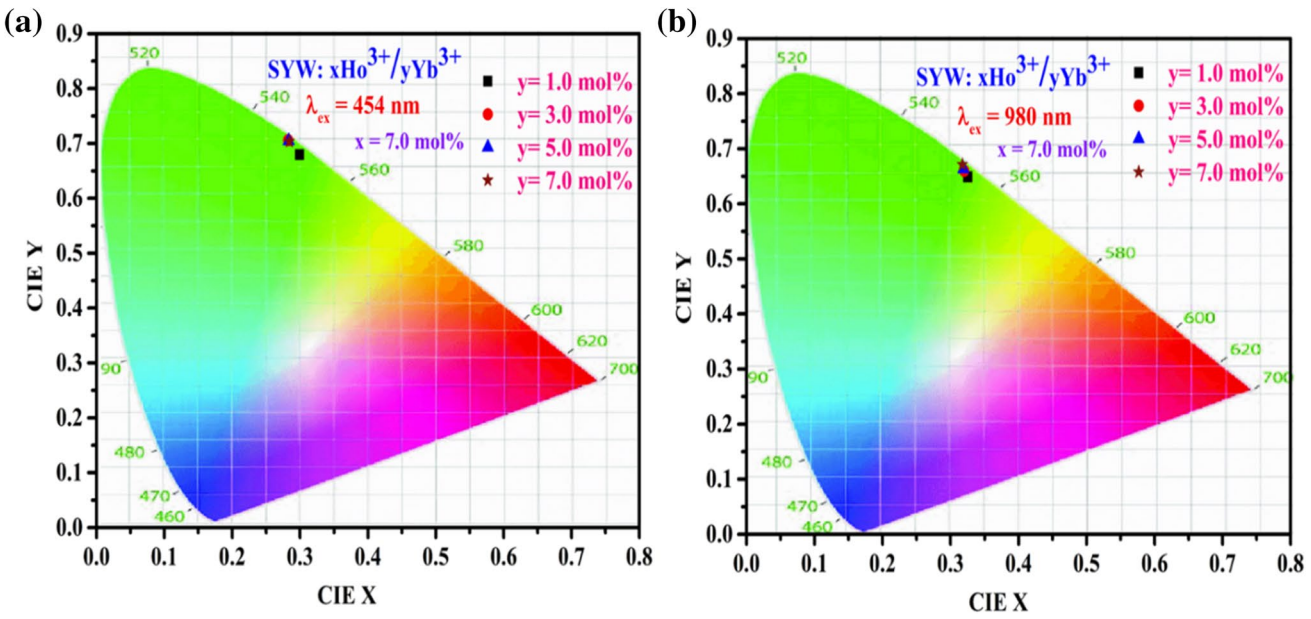

Fig. 12 CIE diagram for SYW:Ho^{3+}/Yb^{3+} doped phosphors with excitation wavelengths of 454 nm and 980 nm

Table 2 CIE coordinates, CCT values & color purity of SYW: xHo^{3+}/yYb^{3+} (x = 7.0 mol%, & y = 1.0, 3.0, 5.0 & 7.0 mol%) phosphors under 454 nm & 980 nm excitation

Sample ID SYW	CIE coordinates (x, y) λ_{ex} = 980 nm	CCT values (K) λ_{ex} = 980 nm	CIE coordinates (x, y) λ_{ex} = 454 nm	CCT values (K) λ_{ex} = 454 nm	Color purity (%)
y = 1.0 mol%	(0.3382, 0.6520)	5433.13	(0.2993,0.6795)	5994.13	97.6
y = 3.0 mol%	(0.3412, 0.6508)	5390.01	(0.28268,0.7058)	6209.19	97.9
y = 5.0 mol%	(0.3477, 0.6453)	5294.23	(0.2835,0.7048)	6197.77	98.2
y = 7.0 mol%	(0.3503, 0.6427)	5254.67	(0.2842,0.7038)	6188.50	97.4

and 98.2%. High colour purity values strongly imply that the synthesised samples have a lot of potential for use in w-LED applications. Therefore, SYW: Ho^{3+}, Yb^{3+} could be a good option with promise for lighting and multicolor display applications.

3.9 Decay profiles

Figure 13 illustrates the fluorescence decay profiles of the SYW: x Ho^{3+}/y Yb^{3+} (x = 7.0 mol % and y = 1.0, 3.0, 5.0, & 7.0 mol%) phosphors in Ho^{3+}/ Yb^{3+} co-doped samples, which were recorded at 980 nm excitation. Many exponential equations were used to fit the decay curves; in the present scenario, the bi-exponential equation fit the data the best [61].

$$I = I_0 + A_1 * exp\left(-\frac{t}{\tau_1}\right) + A_2 * exp(-\frac{t}{\tau_2}) \quad (8)$$

where I_0 & I signify the luminescence intensities at time t = 0 and at some other time, respectively, τ_1 & τ_2 are the components for rapid and slow decay, A_1 and A_2 are the fit constants for bi-exponential fitting. The average lifetime values for the bi-exponential fit are given by [62]

$$\tau_{exp} = \frac{A_1\tau_1^2 + A_2\tau_2^2}{A_1\tau_1 + A_2\tau_2} \quad (9)$$

SYW: x Ho^{3+}/y Yb^{3+} phosphors have an effective average decay time of 69.89, 67.61, 53.88, and 41.23 µs for x = 7.0 mol% and y = 1.0, 3.0, 5.0, & 7.0 mol%, respectively. As the concentration of Yb^{3+} ions rises, the decay time of Ho^{3+} ions decreases progressively, implying that ET from sensitizer to activator ions. Because of the presence of an ET channel, the Yb^{3+} ions transferred their energy to Ho^{3+} ions in the phosphor lattice.

3.10 Temperature sensing behaviour

One of the most important aspects in the high power w-LEDs and temperature sensing is the phosphor's PL thermal stability. The TD-PL spectra of SYW: x Ho^{3+}/y

جامعة قطر QATAR UNIVERSITY

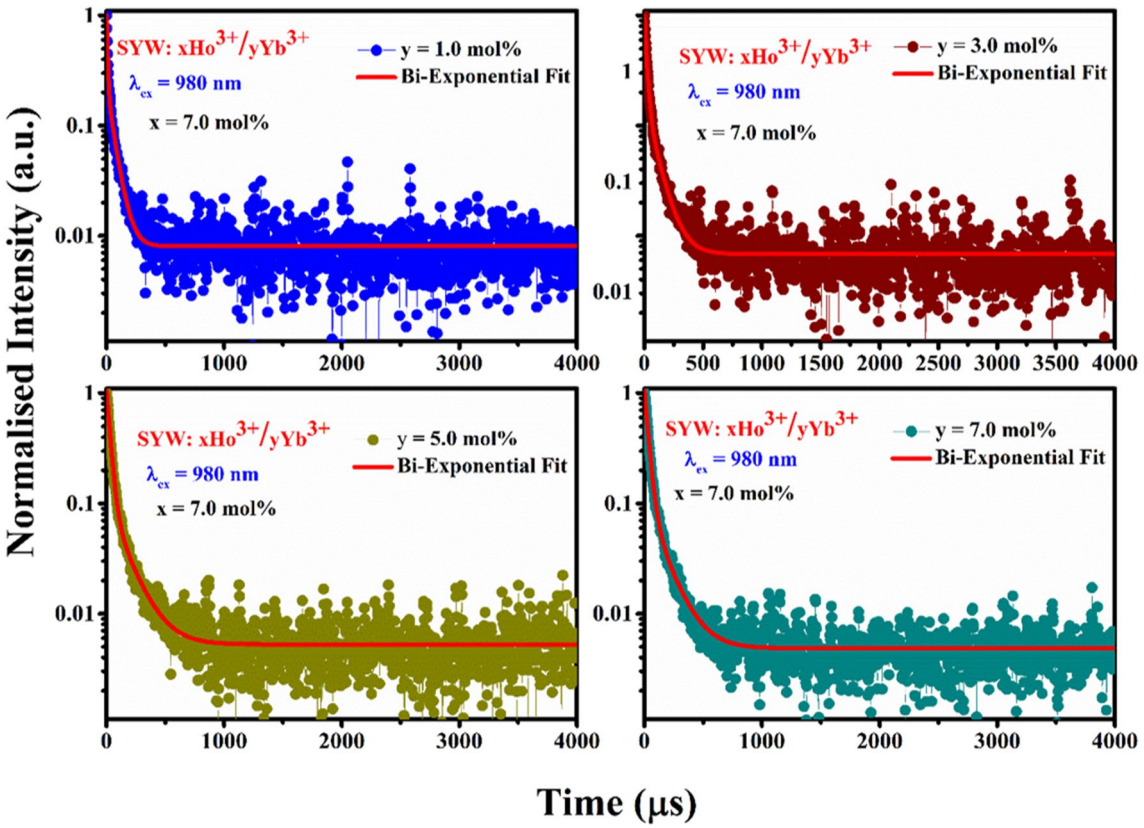

Fig. 13 The decay curves of SYW: xHo^{3+}/yYb^{3+} (x = 7.0 mol%, & y = 1.0, 3.0, 5.0 & 7.0 mol%) phosphors under 980 nm excitation

Yb^{3+} (x = y = 7.0 mol%) of phosphor was monitored under the excitation of 980 nm, in the range of 303 K to 453 K. The TD-PL emission intensity change with temperature for this phosphor is depicted in Fig. 14(a). According to the data, it seemed that when temperature increased, the emission intensity decreased. The phosphor was found to retain around 57% of its original intensity (303 K) at 453 K. Therefore, it is safe to assert that this phosphor is thermally stable and appropriate for use in white-LED applications.

The Arrhenius equation's exponential form can be used to estimate the activation energy (ΔE) for the thermal quenching process [63].

$$I_T = \frac{I_0}{1 + Cexp\left(-\frac{\Delta E}{K_B T}\right)} \tag{10}$$

where T is the temperature, c denotes the constant term, k represents the Boltzmann constant, and I_0 and I_T are the initial and emission intensity at different temperatures, respectively. Figure 14(b) displays a graph of ln [(I_0/I)—1] vs $1/k_BT$. Based on the plot, the activation energy, or ΔE, of SYW phosphor is 0.276 eV that is greater the other reported data [64–66]. The aforementioned findings indicate that the single phased phosphor can be used in w-LEDs and temperature sensing behaviour.

The population of the two thermally connected levels could be described using the Boltzmann distribution with temperature as a parameter. The intensity ratio of emissions from the two thermally connected levels can utilised to determine their respective populations. The FIR curve is formed by fitting the integral FIR of the two emission bands (at 551 nm and 668 nm), which can be used to determine how effectively the phosphor functions as a thermometer. Figure 15 depicts the fluctuation in integrated intensity as temperature increases.

Furthermore, the FIR curve is fitted using the equation shown below [67]:

$$FIR = \frac{I_0}{I} = Aexp(\frac{\Delta E_{TCEL}}{k_B T}) \tag{11}$$

Here, I_0 and I are the TD-PL intensities for the Ho^{3+}/Yb^{3+} ion transitions $^5F_4/^5S_2 \rightarrow {}^5I_8$ and $^5F_5 \rightarrow {}^5I_8$, respectively, A represents the fitting constant, ΔE is the splitting energy between TCELs, k_B stands for Boltzmann constant, and T denotes the temperature. Figure 16(a) depicts the I_{551}/I_{668} dependency on absolute temperature.

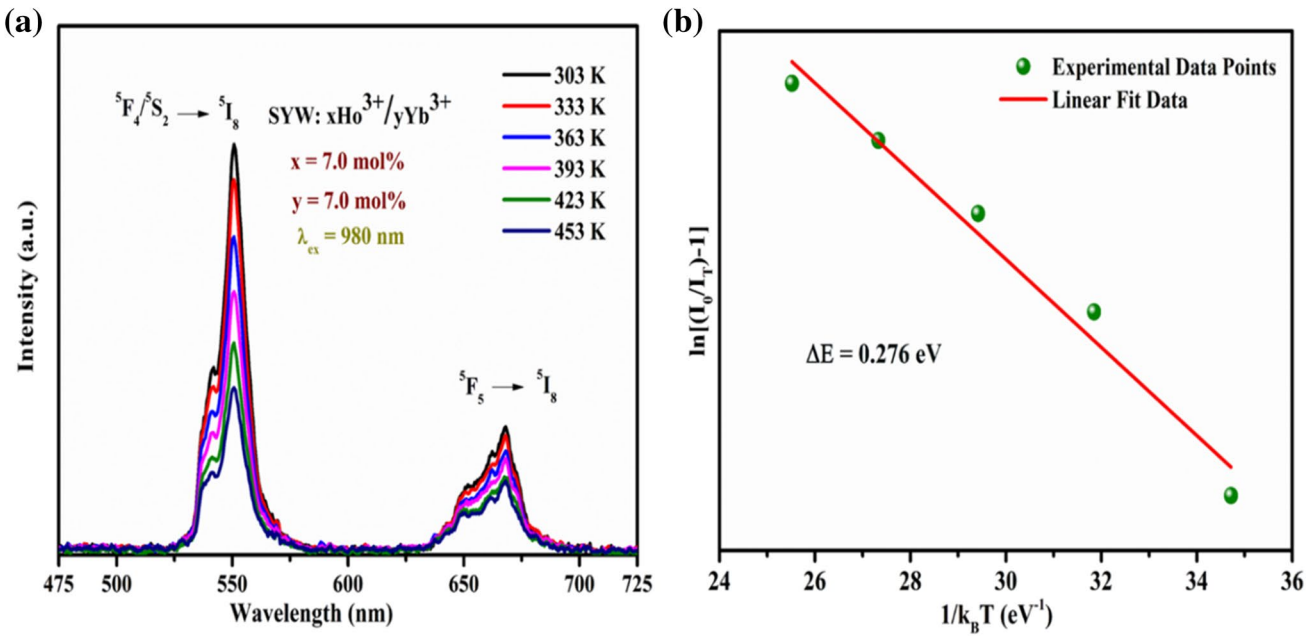

Fig. 14 (**a**) TD-PL spectra of SYW: 7.0 mol% Ho^{3+}/7.0 mol% Yb^{3+} phosphor using 980 nm laser source (**b**) Linear plot of ln $[(I_0/I_T)-1]$ vs $1/k_BT$ plot

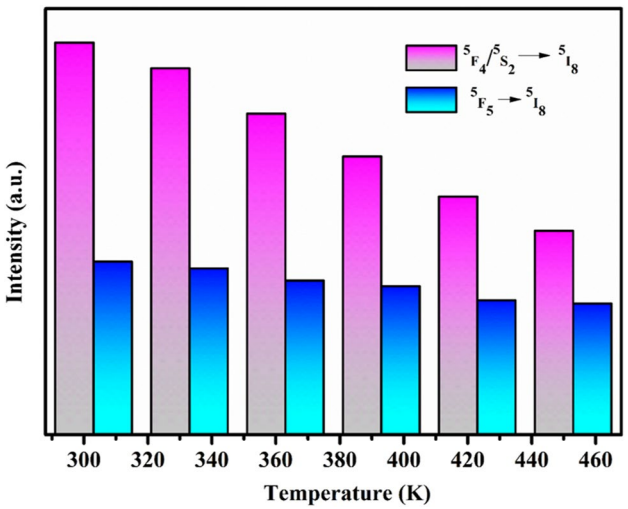

Fig. 15 Variation of the intensity of the emission peaks $^5F_4/^5S_2 \rightarrow {}^5I_8$ and $^5F_5 \rightarrow {}^5I_8$ with temperature

Fitting the experimental data can reveal a relation that is linear. The slope derived from the data points by linear fitting is 367.48. The energy difference between TCELs was calculated using the slope and k_B values and found to be 255.40 cm^{-1}. The estimated ΔE_{TCEL} values were almost completely related with the energy population in Ho^{3+}/Yb^{3+} ions.

The following equation represents temperature sensitivity, an important property in optical thermometric measurements that describes the rate of change in the FIR with temperature [68, 69].

$$S_A = \frac{dFIR}{dT} = FIR \times \frac{\Delta E_{TCEL}}{k_B T^2} \tag{12}$$

$$S_R = \frac{1}{FIR}\left(\frac{dFIR}{dT}\right) = \frac{\Delta E_{TCEL}}{k_B T^2} \tag{13}$$

Figure 16(b) depicts the variation of relative (S_R) and absolute (S_A) sensitivities with absolute temperature, with maximum values of 0.0091 K^{-1} and 0.0040 K^{-1}, respectively, at 303 K. Table 3 compares the optical temperature sensing capabilities of several UC hosts doped with Ho and Yb [10, 67, 68, 70]. The variation in sensitivity results could possibly be attributed to the diverse experimental circumstances of Ho^{3+}/Yb^{3+} UC lattices. Nevertheless, the as-titled phosphors used in this work can work as an effective optical temperature sensor as well.

4 Conclusion

In conclusion, a conventional high-temperature solid state reaction technique was utilised to successfully synthesise $Sr_9Y_2W_4O_{24}$: Ho^{3+} doped and $Sr_9Y_2W_4O_{24}$: Ho^{3+}/ Yb^{3+} co-doped phosphors. The formation of phase and crystal nature of the samples were verified using the XRD technique. The size of phosphor particles were found to be in the micrometre

جامعة قطر QATAR UNIVERSITY

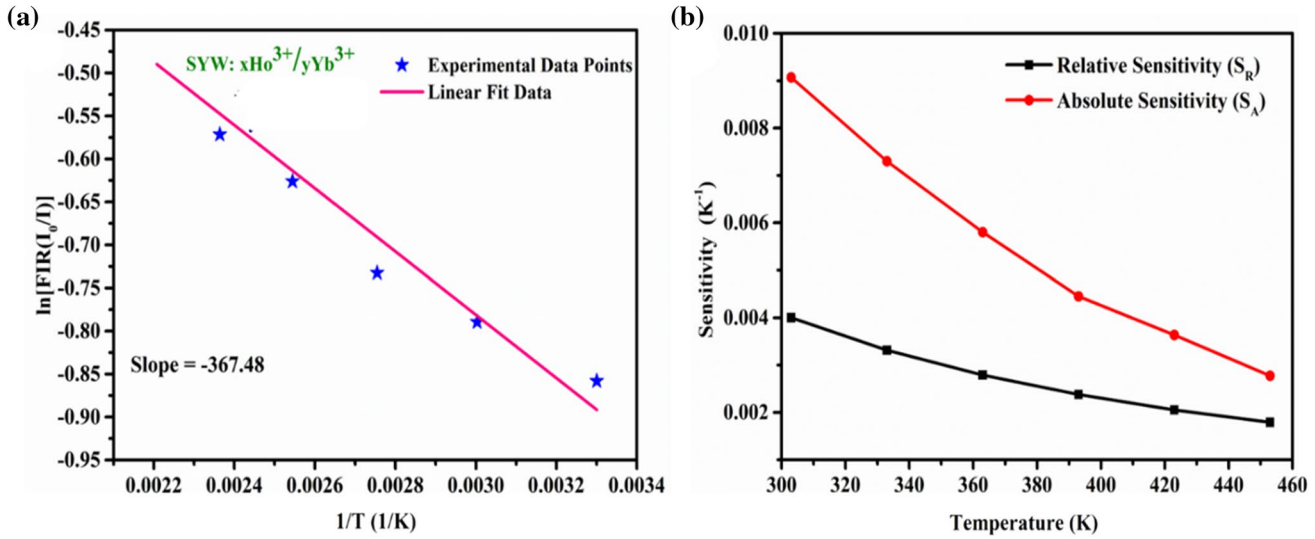

Fig. 16 (**a**) Plot of ln[FIR (I_0 /I)] vs 1/T (**b**) Relative sensitivity (S_R) & absolute sensitivity (S_A) values with temperature (K)

Table 3 Maximum S_R values of phosphor materials reported

Phosphor materials	Temperature Range (K)	S_R (% K^{-1})	References
$ZnGa_2O_4$:Ho^{3+}/Yb^{3+}/Bi^{3+}	303–600	0.0013	[10]
BaTiO3: Ho^{3+}/Yb^{3+}	305–515	0.0030	[65]
BYS: Ho^{3+}/Yb^{3+}	293–553	0.0049	[66]
NYSO: Ho^{3+}/Yb^{3+}	298–548	0.0153	[68]
SYW: Ho^{3+}/Yb^{3+}	303–453	0.0040	Present work

range, based on FESEM analysis and elemental mapping revealed that all of the essential elements required for synthesis were present in the lattice of the phosphors. Furthermore, it was been found that the components of the produced phosphor are evenly dispersed throughout its surface. The FT-IR spectra of the phosphors described the presence of different vibrational bonds and hydroxyl groups. The optical band gap values in the SYW host, determined by via Tauc plot, that turned out to be in the range of 4.36—4.52 eV. Under the excitation of 980 nm light, the green emission at 551 nm was seen, with a minimal red emission at 668 nm as well. This was due to the radiative transitions from $^5F_4$/ $^5S_2$ and $^5F_5$ excited states to the $^5I_8$ ground state, respectively. The amount of photons involved in the UC process can be obtained by analysing the variation in intensity and pump power. As the concentration of Yb^{3+} ions increased, the decay lifetime of Ho^{3+} ions at λ_{em} = 551 nm, which was monitored under 980 nm excitation, decreased. Every sample has CIE coordinates that are located in the green area under both 454 nm and 980 nm excitation. These samples also exhibit a high color purity. The TD-PL findings under 980 excitation demonstrates that the as-titled phosphor is relatively thermally stable having maximum relative sensitivity (S_R) and absolute sensitivity (S_A) values at 303 K temperature to be 0.0091 K^{-1} and 0.0040 K^{-1}, respectively. From the aforementioned results of the DC/UC studies conducted on the SYW phosphors, we wish to project these phosphors for usage in near-UV /IR stimulated white LEDs, temperature sensing and up-conversion applications.

***Abstract*—Sentiment analysis has historically concentrated on text-based data to investigate people's views towards objects. However, given how frequently visual content is shared on social media, a strong case exists to expand sentiment analysis to include image context. This research addresses the gap through a novel approach by comparing several deep learning methods—such as CNNs and transfer learning—on the Memotion dataset. Our approach is unique in that we carefully analyze performance indicators, paying particular attention to feelings associated with the offensive class and emotions in the images. Our study explores the subtleties of sentiment analysis in visual content by assessing accuracy, precision, recall, and F1-score.By evaluating accuracy, precision, recall, and F1-score, our study delves into the nuanced aspects of sentiment analysis in visual content. Notably, we contribute valuable insights by comparing ResNet, DenseNet, EfficientNet, and Swin Transformer models, revealing that DenseNet emerges as the superior choice, showcasing advancements in image sentiment analysis techniques. This comparative analysis not only highlights the effectiveness of different models but also underscores the innovation in our methodology, providing a significant contribution to the evolving landscape of sentiment analysis in the visual domain.**

Keywords—Sentiment analysis, Emotion recognition, ResNet,DenseNet,Swin Transformer,EfficientNet.

I. INTRODUCTION

Sentiments are feelings such as love, grief, happiness, and anger that impact others through emotion, and sentiment analysis categorizes them into positive, negative, or neutral classes[1]. Policymakers, for example, can utilize feelings to monitor public attitudes toward policies. The hotel staff uses client feedback to make improvements to the facilities. That is why emotional awareness is essential for understanding.

Traditionally, we may anticipate sentiments based on unimodality[2], the bulk of which is text in which the relationship between words and phrases is analyzed. Still, text alone is insufficient to extract people's feelings or sentiments. For example, in analyzing text sentiment, the word "amazing" is normally favorable, but when combined with "well," it signals doubt or sarcasm, indicating negative attitudes. To overcome the limitation of traditional text-based sentiment analysis, multimodal sentiment analysis[3] is offered, comprising a combination of two or three modalities with a massive quantity of social network data available in video, image, or voice.

People increasingly share their views and emotive memeson various platforms, including Instagram, WhatsApp, YouTube, and others, providing excellent data for sentiment analysis. Memes are new messages created by a caption on an image or text inserted into an image[4]. It can be an amusing notion or behavior that passes from person to person, but it can also be adverse in the context of sharing someone's private images without consent, misleading people by providing incorrect political informationor bullying them by forwarding it[5]. Consider a meme that includes the caption "she's fine" but in the image a woman is drunk and two men are helping her, which simply shows the sarcasm, thus meme analysis is important for growing research and we need sentiment analysis to precisely identify memes.Because it can be both a visual and textual representation, a meme is particularly multimodal. It can also be applied in a multimodal setting, where the memewith or without textis combined with textual remarks and exchanges to offer emphasis, more context, or an emotive reaction[6].The relationship between the two items may be used to determine the meaning of the word when an image of an apple is included to go along with the text. Within the framework of this essay, the meme is comparable to the apple picture, with the term "apple" standing in for social media communications. The meme offers more information on the text's meaning or response to it[7].At first, it was believed that the emotive level was subjective and that multimedia picture retrieval was based on real or objective data.As effective multimedia discovery developed further, it became clear that effective content could also be objective rather than subjective if the effect was a predictable outcome of the designer's intended actions or if the multimedia content elicited a widely shared affective response in society[8].

Fig 1: Visualization of Text in image, commonly known as Meme

Textual content analysis includes word, phrase, remarks, and discussion analysis. Images were categorized by use of pictures. In addition, if textual messages were embedded in the memes, they were identified and evaluated[6].

Various text and image-based deep learning methods are used for sentiment analysis. For detecting the linguistic patterns in text various supervised and unsupervised learning techniquesare used for the successful analysis of sentiments [9].We can use Early Fusion, Late Fusion,and Attention-Based Cross-Modal[10] models like CNN[11], RNN, and Transformers for images and LSTM[12], Bi-LSTM, and BERT for text sentiment analysis.

The main contribution of our work is that, since most work on this dataset focuses on CNN, BERT, and ResNet, we are offering a novel way for the Memotion dataset to compare multiple deep-learning approaches, such as ResNet18, ResNet50, DenseNet121, EfficientNet, and Swin Transformer. This allows us to achieve better results on various evaluation metrics using different transform learning techniques.Accuracy, Precision, Recall, and F1 score are just a few examples of the metrics that can be used to evaluate thedataset.

The remaining manuscript is structured as follows. The majority of the sentiment analysis study is highlighted in Section II. The procedure is described in Section III. The experimental details are covered in Section IV, and the study is wrapped up in Section V.

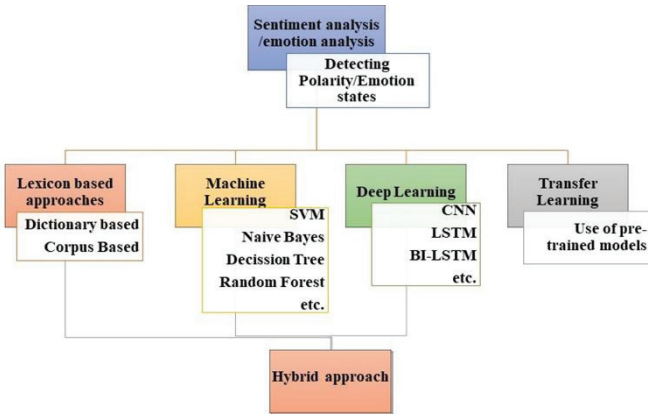

Fig 2: Techniques of Sentiment Analysis[13]

II. Related Work

This section represents the literature survey of deep learning techniques used for classifying meme emotions. Memes are spreading humor to target individuals or groups of people in a sarcastic or polite way, it is very difficult to classify memes.

Aggarwal et al. [14] proposed a model that can classify more than one modal by using two different approaches i.e., sequential and multimodal where the first approach classifies text and image sentiments and the second approach integrates the features of different modalities.Sherratt et al. [15] proposed an MC-CNN model for classifying memes in live data and wild data. To provide accuracy in data they used a Multi-channel system i.e. Text, image, and histogram which ranks the non-meme formats with textual attributes. Agarwal and Meel[16] proposed a deep learning framework using stacked BI-LSTM which incorporates embeddings from fine-tuned BERT model and provides highest accuracy of 0.99 on the Articles dataset and Kaggle dataset.

Barveen et al.[17] proposed a method of Extended LSTM-RNN which provides better results as compared to CNN and analyses features using HOG feature extraction which divides the image into smaller segments that classify the image as a good meme or not with an accuracy of 0.98%. Tang et al.[18]proposed a multimodal bi-directional dynamic-enhanced block that will reduce the redundancy and provide fine-grained auxiliary context modalities on the MOSI dataset. Intra-modality redundancy between the audio and video block is reduced by using this model which provides fine-grained sentiment contexts. Xue et al.[19] proposed a MAMN model whose performance is compared on the basis of 19 methods and provides noise reduction on multilevel granular data in an efficient way. Before reducing the noise, it first, extracts the granular features and then applies fusion methods for document and aspect-based sentiment analysis.

Zhu et al.[20] proposed a cross-modal ITIN network to capture the finer relationship between text and image on multimodal features for classifying the sentiments on the MVSA dataset. Zeng et al. [21] proposed a Gated Fusion Semantic Network to provide the inter and intra relationship between text and visual modalities. A cross-modal mechanism improves the result by 0.10% to 3.66% by employing cross-attention between the text embedding and images for the sentiment prediction on the Yelp and Flickr30k datasets. Meel and Kumar Vishwakarma[22] proposed a frameworkthat uses multi-modal fusion architecture for both textual and visual data and achieves 97.19% accuracy on Weibo[23], and the MediaEval16 dataset.

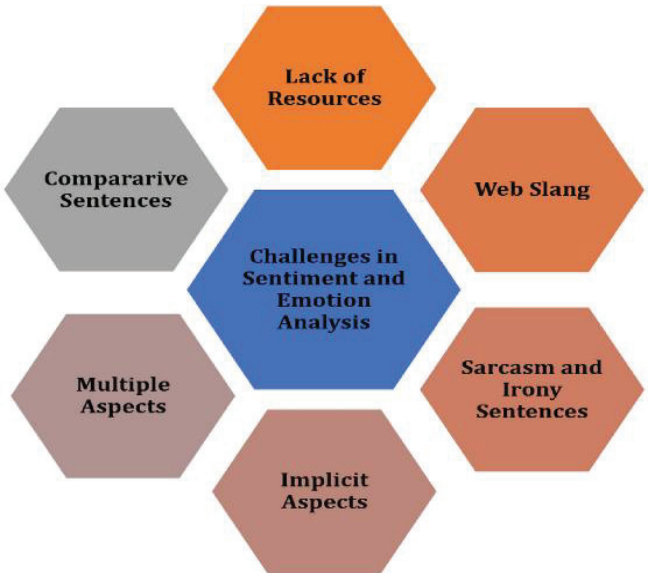

Fig 3: Challenges in sentiment analysis[13]

Yao et al.[24] proposed a sarcasm detection model M3N2 for mimicking the brain's perception using guided attention and attention pooling methods for capturing the modal information on Twitter images, Text embedded on images, and caption of tweets from different levels like singlewise, pairwise, triplewise, and tetradwise. Stappen et al.[25] proposed a multimodality solution that uses the MAHN modelto categorize the emotion from MuSe 2020 dataset which contains features in the form of Audio, Video, and text. Ye et al.[26] proposed a SMP framework for addressing the sentiment signals, it captures theinformation from text and images using cross-modal contrastive modules on VSO, MVSA, Twitter15, and Twitter17 datasets and provides fine-grained sentiment analysis. Zeng et al.[27] proposed a TATE network for handling the missing partially

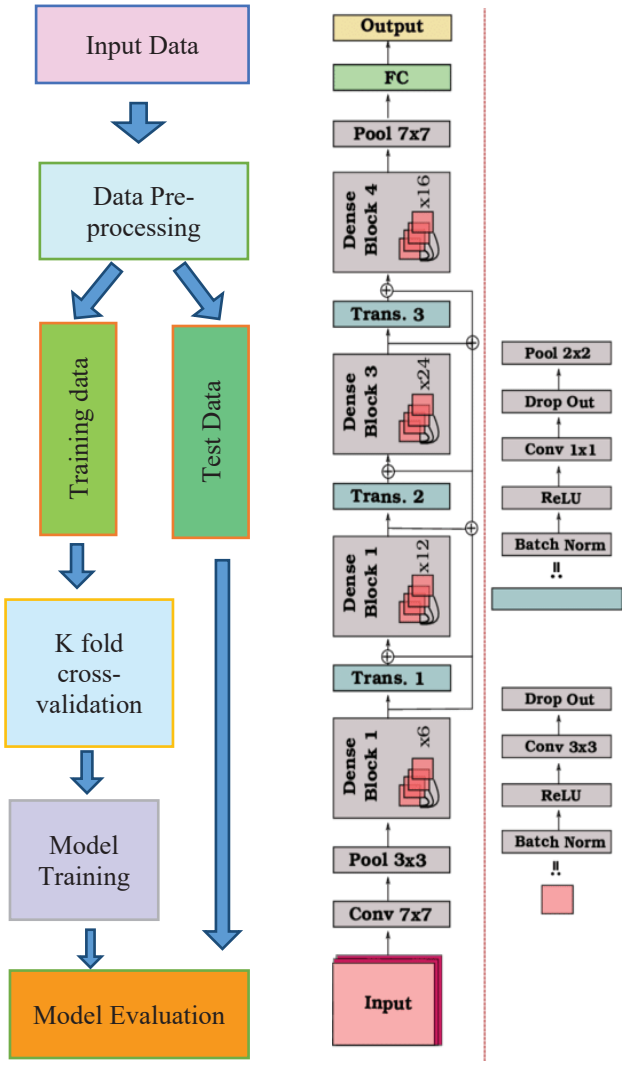
Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 18,2024 at 09:18:46 UTC from IEEE Xplore. Restrictions apply.

available multiple modalities instead of considering only the single modality. To learn the missing modality features, aligned vectors are fed into the transformer and then transformer encoder is used on CMU-MOSI and IEMOCAP datasets for classifying the sentiments.

After thoroughly survey the papers we conclude that there is a need of comparative study about deep learning methods on Memotion dataset.

III. Methodology

In this Section, we provide details about deep learning methods and explain the working of our model and their key components.



(a) (b)

Fig 4: (a)Procedure flow diagram for the proposed approach (b) Basic architecture of DenseNet-121

A. Overview

Our approach begins with the initial stage of processing the data, which is then followed by a phase of data pre-processing. Data pre-processing is essential for cleansing the image data, assuring its integrity, and preserving its quality. Afterward, the dataset is partitioned into several subsets for training and testing. The training data is further adjusted using k-fold cross-validation. Once the data is in optimal condition, several deep learning networks such as CNNs, RNNs, and Transfer Learning methods are employed to evaluate metrics such as accuracy and precision. The outcomes can be visually represented using a variety of charts and graphs to evaluate the effectiveness of the model. This helps to figure out which method or model works best for the task. Figure 4(a) shows the flow diagram for the proposed approach.

B. Image Models:

- ResNet: A residual network is used to solve the gradient problem that arises due to an increase in the number of layers in CNN. The skip connections technique is used in which the activation connection of a layer to another layer is done by skipping some layers between them, which is known as a residual block. Residual networks are inspired by VGG-19, which uses a 34-layer plain network and a shortcut connection to transform it into a residual network that improves the performance of deeper-layer networks[28].

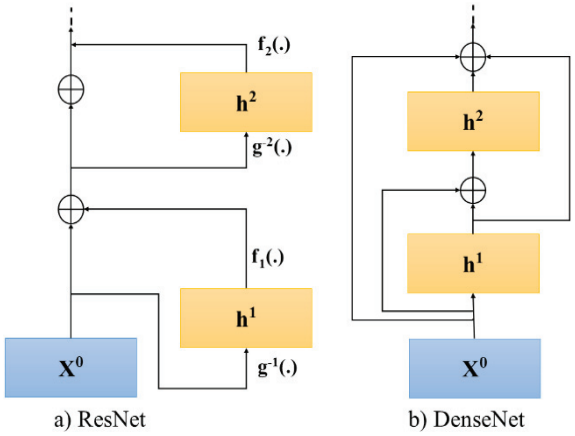


Fig5: ResNet and DenseNet

- DenseNet: Densely connected-convolutional network directly connects any layer to all subsequent layers unlike ResNet in which skip-connection is used to pass information from one layer to another layer[29].
- EfficientNet: DenseNet balances the depth of the network, for balancing the depth, width and resolution of the network we uses the EfficientNet[30].
- SwinTransformer: It is used for image classification and object detectionand provides better performance thanother vision networks like CNNs and ViTs. Its key features are first it is designed in hierarchical structure stages where each stage process image at different level. Secondly, it uses shifted windows to process image patches, then for creating relationships between these image patches multi-head-self-attention is used[31].

C. Abbreviations

DenseNet without transform (DN121), Resnet50 with transform (RN50 T), Resnet50 without transform (RN50), Resnet18 without transform (RN18), Resnet18 with transform (RN18 T), Efficienet without transform (EF), SwinTransformer without transform (ST).

IV. Experimental Details

A. Dataset

This online memedataset contains approx. 10K memes having labels such as sentiments based on (positive, negative, and neutral) and type of emotions such as humor, sarcasm, offensive and motivational.

Memotion dataset[32]are classified into different emotions such as humor, sarcasm, offensive and motivational and based on this an overall sentiment is labeled as positive, negative and neutral. For our experiment we are trying to classify memes into 4 levels of offensive class which are non-offensive, slight, very offensive and hateful offensive. Among these 10k samples of memes 80% samples uses as train data and 20% as test data. The percentage of data classification in offensive classes are mentioned in Table 1.

TABLE I. Offensive Class Percent Classification

Offensive Classes	Percentage in Data
Very offensive	20.97%
No offensive	38.80%
Hateful offensive	3.16%
Slight Offensive	37.07%

B. Data Pre-processing

In the data preprocessing phase, we implement a series of essential steps to enhance the quality and usability of our image dataset. Initially, we undertake a cleaning process, systematically removing unlabeled images to ensure the integrity of our dataset. Subsequently, we rescale the images to a standardized 128x128 resolution, facilitating consistent and efficient processing. To augment the dataset and diversify the training samples, we employ a range of transformation techniques. Some of the common operations that can be performed include horizontal and vertical flips, shift-scale rotations, RGB shifts, resizing, and random adjustments to brightness and contrast. These transformations enhance the learning of our dataset by using deep learning models.

C. Hyperparameters Tuning

To achieve better model performance hyperparameter tuningmethods are used. For the integration of 5-fold cross-validation with more than 100 epochs used to explore the model learning capability with a learning rate of 0.01 to achieve the highest accuracy. The implementation of all models is conducted using the PyTorch framework, to effectively utilize the computational power of Nvidia GPU. The detailed description of the models along with their parameters and accuracy are defined in Table 2.

D. Evaluation Metrics

In this section,a set of key assessment measures for the comprehensive comparative analysis of a given dataset is mentioned.Precision [1], Recall [2],F1-score [3], and Accuracy [4] are the assessment metrics used for the comparative analysis of this image dataset.Precision[33], calculated as the ratio of true positives to the sum of true positives and false positives highlights the model's accuracy

TABLE II. Model Description

Model	Parameterization	Acc. Scores
ResNet18	The model is pretrained on the IMAGENET1K_V1 dataset with the training epochs (100), batch size (500), learning rate (0.01), and the use of 5-fold-cross validation.	**56%**
ResNet50	We are getting better results using SGD optimizer with 5-fold-cross-validation and having epochs 100 with learning rate is 0.01.	**49%**
DenseNet121	The model process on image size of 128x128 having batch size 500 with learning rate 0.01 for SGD optimizer.	**95%**
EfficientNet	With batch size of 500, a learning rate of 0.01. The model was trained for 100 epochs using fivefold cross-entropy loss function. The model accuracy was discovered after third fold.	**49%**
Swin Transformer	For this model we use a batch size of 250 with 100 epochs using five folds and provides better accuracy after third fold for SGD optimizer.	**43%**

in identifying positive instances. Similarly, Recall[33], is determined by the ratio of true positives to the sum of true positives and false negatives which showcases the model's ability to capture all relevant positive instances.Accuracy[34], defined as the ratio of correctly predicted instances (both true positives and true negatives) to the total instances, provides an overall assessment of model correctness. The F1-score is a harmonic mean of Precision and Recall.By employing these standard metrics, we ensure a comprehensive and rigorous evaluation of the model's performance on the image dataset.

$$Precision = \frac{TP}{TP+FP} \quad (1)$$

$$Recall = \frac{TP}{TP+FN} \quad (2)$$

$$F1 = 2 * \frac{Precision * Recall}{Precision + Recall} \quad (3)$$

$$Accuracy = \frac{TP+TN}{TP+FP+FN+TN} \quad (4)$$

V. Results& Analysis

The result section provides a detailed comparative analysis of various deep learning models applied on the Memotion dataset. Table 3 offers an in-depth examination of the performance metrics, including accuracy, precision, recall, and F1 score, highlighting the subtle distinctions among ResNet, ResNet50, EfficientNet, Densenet121, Swin Transformer, and other models. Insightful observations emerge from our study, prominently illustrated in Figure6, where the comparative study graph showcases DenseNet's exceptional performance, achieving an accuracy of 95%, surpassing other vision transformer models. This superiority of DenseNet comes from its unique architecture which provides densely connected blocks that effectively addresses issues like the vanishing gradient problem and promote

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 18,2024 at 09:18:46 UTC from IEEE Xplore. Restrictions apply.

efficient features reuse.DenseNet121 consists of 120 convolutional layers and 4 average pooling layers as shown in Figure 4(b). Within each dense block, the weights are distributed across multiple inputs, enabling deeper layers to utilize the extracted features. In the second and third dense blocks, the output of the transition layers is given the lowest weight assignment. Even though the final layers use the weights of the whole dense block, more high-level features

may be created further into the model. This was seen in the tests, where there was more focus on the final feature maps. Due to its reduced parameter requirement and feature reuse capability, DenseNet yields more compact models in comparison to CNN or ResNet.

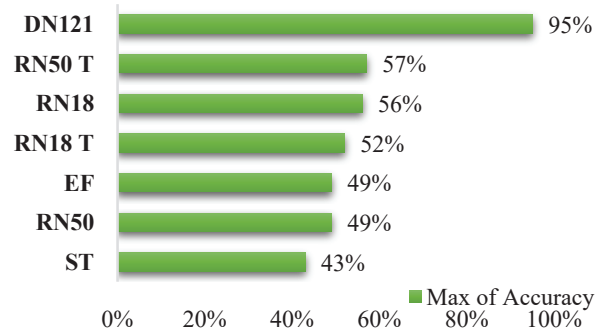

Fig 6: Accuracy graph for comparative models

Figure7 extends the comparison to different vision models on the IMAGENET1K_V1 pretrained dataset, visually representing the performance differences among Resnet18, Resnet 18 with Transform, RN50, Efficientnet, Densenet121, and Swin Transformer. Particularly, DenseNet stands out across multiple metrics, establishing its advantages in image sentiment analysis. Figure8 illustrates the positive correlation between the accuracy of the model and the amount of data provided to the model. This improvement in accuracy is achieved through the use of the five-fold cross-validation technique and the application of various transformers during the data pre-processing phase. These findings emphasize the durability and effectiveness of DenseNet, confirming its superiority over alternative models for sentiment analysis tasks using visual data.

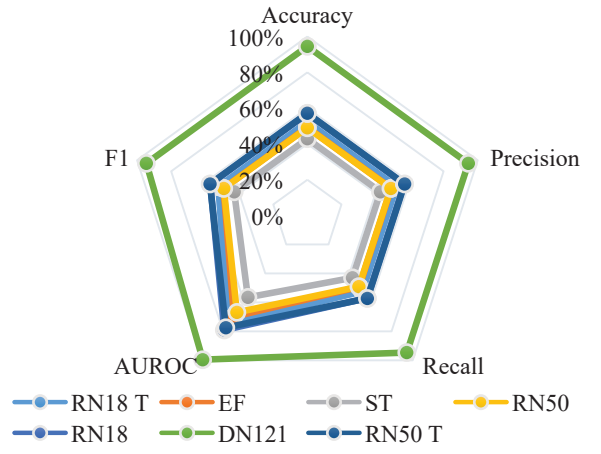

Fig7: Comparison between different models according to the assessment metrics

TABLE III. EXPERIMENTAL RESULTS

Model Name	Accuracy	Precision	Recall	F1
DN121	94.8%	94.6%	94.2%	94.0%
RN50 T	57.0%	56.1%	55.6%	55.8%
RN18	56.0%	56.2%	56.1%	56.3%
RN18 T	52.0%	51.6%	51.2%	51.3%
EF	48.6%	48.0%	47.0%	47.5%
RN50	48.5%	49.0%	47.2%	48.0%
ST	42.8%	42.0%	43.0%	42.3%

VI. CONCLUSION&FUTURE WORK

Thecomparative analysis of various deep learning methods proves instrumental in the informed selection of techniques tailored to specific dataset limitations, systematically unveiling the strengths and weaknesses inherent in each approach. The insights gained from this comparison not only aid in the current methodological choices but also guide future research endeavours. By identifying effective adjustments or novel combinations of techniques, the study contributes to the evolving landscape of sentiment analysis in the visual domain. Particularly noteworthy is the experimental finding that DenseNet outperforms other deep learning techniques on the Memotion dataset, achieving an impressive 95% accuracy compared to Swin Transformer and EfficientNet. This result highlights the efficacy of DenseNet for image sentiment analysis.Looking ahead, our methodology offers a versatile framework that can be extended to text models, image models, and their fusion, promoting the exploration of multimodal approaches for a more comprehensive understanding of sentiments and emotions.

Future research should utilize Densenet121's exceptional performance on the Memotion dataset by enhancing its capabilities through targeted transfer learning and fine-tuning. Looking into how interpretable Densenet121 is in meme analysis might help us understand more about the most important visual features, which would improve the overall interpretability of models in meme-related research. Furthermore, a study might be devised to examine the dissemination of memes throughout various communities by assessing the level of popularity or aversion towards a specific meme inside a particular community, such as

Authorized licensed use limited to: DELHI TECHNICAL UNIV. Downloaded on June 18,2024 at 09:18:46 UTC from IEEE Xplore. Restrictions apply.

Facebook, Instagram, WhatsApp, and others. This investigation expands to reveal political tendencies within memes, providing insights into the attitudes conveyed by different groups and contributing to a sophisticated comprehension of meme's influence on contemporary political communication.

Abstract
This research work aims to propose an ensemble model of different pre-trained CNN networks combined with LSTM to detect a set of routine human activities practiced by the elderly from the publicly available STAIR Actions Dataset. The prime objective of this work is to visualize the effect of using different networks for implementing activity detection for a set of five activities, compare them based on standard performance parameters and combine the best- performing models into a better-performing ensemble unit. Applying the transfer learning technique helped achieve shorter training times and promising classification results for the dataset. The hybrid CNN-LSTM model uses CNN to extract spatial features from the video frames, followed by classification using sequential learning by the LSTM network. For the set of five routine activities practised by the elderly taken up from the STAIR Actions dataset, we obtained an overall test set accuracy of 82.27%, 82.73%, 73.64%, 72.73%, 64.55%, 71.82%, 83.64%, 88.18%, 86.82% and 86.82% respectively on using VGG16, VGG19, ResNet50, ResNet101, ResNet152, Inception V3, Xception, DenseNet121, DenseNet169 and DenseNet201 models, pre-trained on the ImageNet dataset for feature extraction from the video frames. Apart from test-set accuracy, we evaluated the models using other performance metrics, including AUROC, AUPRC, sensitivity, specificity and precision. Using the best-performing model from each category of CNN networks employed, we developed a weighted voting ensemble that outperformed the best-performing individual model in terms of test set accuracy. The highest test set accuracy achieved by optimising the weights assigned to each model in the proposed ensemble was 93.18%.

1 Introduction

Modern-day applications of the advancements in 2D and 3D video technologies such as intelligent surveillance [1, 2] and security systems or smart home [3, 4] and healthcare systems [5, 6] have one aspect in common, i.e., Human Activity Recognition (HAR). HAR is one of the most crucial components in enabling systematic and personalized healthcare and life care systems. The ability to successfully monitor and track human activities correctly can make providing the elderly with premium quality healthcare services much easier and also help save a considerable amount of resources that would otherwise be required for healthcare expenditure. Such services can help prolong the life of the elderly by taking good care of them.

With the number of older people living by themselves increasing manifold, the use of human activity recognition to develop assistive robots could keep track of their daily activities [7, 8] and help them perform necessary activities such as taking medication at the right time, which by old age they themselves tend to forget. The ability to understand human activities and respond appropriately can completely transform robotic science to an entirely different level; as such, robots would no longer require instructions to perform tasks. They would rather be able to perform a follow-up task in response to an activity they detect, thus integrating them with human interactions.

With the emergence of the COVID-19 pandemic, people infected with the virus had to be isolated or home-quarantined to avoid further spread. On account of the more significant health risk faced by them, the elderly were subjected to complete home confinement to avert any chances of infection. This confinement, coupled with an acute shortage of healthcare staff raised the need to track their everyday activities [9] using vision-based methods to monitor their health. Keeping this scenario in mind, the activities chosen for this work are routine activities practised by the elderly in indoor environments.

Detection of human activities accurately can prove to be quite a challenging task for several reasons, including the presence of several other unnecessary objects or activities taking place in a particular frame captured to detect a particular activity and ambiguity in detection. Most human activities, such as drinking water or eating a meal, can be performed in a wide variety of body poses or orientations. While detecting activities, we come across inter-activity (this means that two or more activities being detected involve a somewhat similar body movement, thus creating confusion in detection) and intra-activity (these account for the differences that arise due to the same activity being performed differently by different subjects used for testing and training) variations [10, 11]. This makes video-based activity recognition a somewhat cumbersome task.

HAR has been carried out primarily using two broad approaches - sensor-based [12] and vision-based [13–16]. Wearable sensor-based HAR involves multiple sensors that are continually affixed to a person's body. The severable cable connections may prove to be uncomfortable for the user, along with other disadvantages such as high costs, energy consumption, and device setup. The dependability on sensors gets obliterated if we directly use the camera feed to detect activities using vision-based HAR. Additionally, adding activities to the vision-based model is easier without additional hardware requirements. Though, compared to the sensor-based methods, an elaborate setup is not required for vision-based detection before implementation and sensor cost gets eliminated, vision-based activity recognition has its own set of challenges, as discussed in detail in [14, 17].

According to the feature extraction process, vision-based human activity recognition methods can be classified into handcrafted and learning-based processes. Due to the

increased computational power required by deep learning-based approaches to process sequential image frames representing human actions, the field of activity recognition was initially dominated by handcrafted action representations. These methods involve three major steps – foreground detection, feature selection and extraction and classification of actions represented by extracted features using a generic trained classifier [18]. The feature learning processes can be classified into traditional and deep learning methods. Deep-learning methods are now being widely explored for activity recognition on account of their promising results and generalization ability for different types of data. Contrary to handcrafted feature extraction, these methods involve an automated feature extraction [13]. The primary challenges posed by these methods comprise the requirement of huge amounts of data to act as a training set and the increased computational complexity involved. The steps involved in deep learning methods for vision-based human activity recognition have been shown in Fig. 1.

1.1 Aim of the study and major contributions

This study aims to experiment with multiple cutting-edge CNNs to develop hybrid CNN-LSTM models for vision-based HAR and combine the front-running networks via weighted voting to generate an improved ensemble model. The major contributions of this paper are summarized as follows:

(a) Implementing a hybrid model that capitalizes on the strengths of state-of-the-art CNN and LSTM networks to efficiently encapsulate both the spatial and long-range temporal dependencies for vision-based HAR.
(b) Extensive comparison of ten hybrid CNN-LSTM models using various performance criteria such as precision, specificity, sensitivity, accuracy, AUROC, and AUPRC.
(c) A conclusive model that outperforms previous baselines in terms of test-set accuracy. This is achieved by assembling the top-performing hybrid models into a composite ensemble model. The final model predictions are determined through weighted voting of individual judgements, with the optimal weights established through an exhaustive grid search technique.

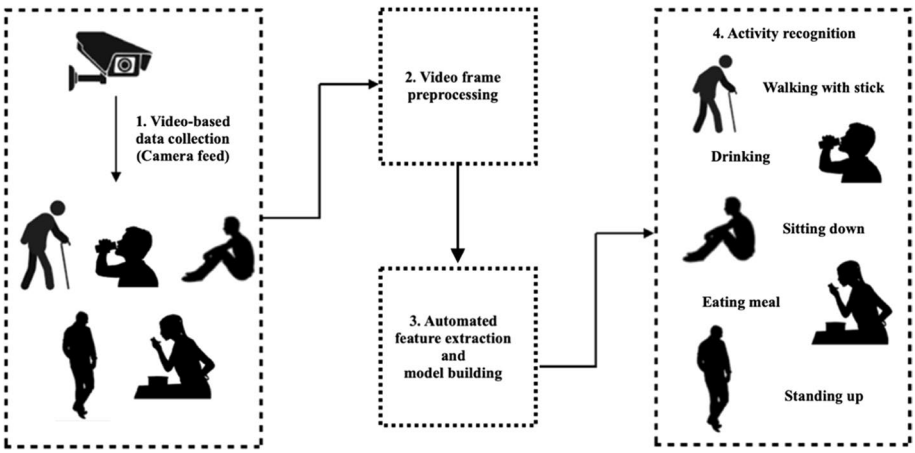

Fig. 1 Fundamental steps involved in deep learning approaches to vision-based human activity recognition

(d) Ablation study to further strengthen the experimental findings and confirm the importance of LSTM in the hybrid model.

1.2 Article organization

In the following sections, we discuss our aim and approach in more detail and provide further information. The rest of this paper is organized as follows: Section 2 highlights the related work carried out in the field of human activity recognition. Section 3 explains the proposed approach. Section 4 presents the experimental setup to conduct a detailed analysis and review of all individual models trained and the ensemble model proposed. Section 4.5 presents the results achieved using the individual hybrid models and the ensemble model. Section 5.6 delineates the merits and demerits of the proposed architecture. Finally, Section 7 concludes the paper and provides suggestions for future works.

2 Related work

With the tremendous amount of focus it has gained, HAR has acquired a very vast literature. Primarily, activity recognition has been performed using either sensor or visual data.

2.1 Sensor-based Human activity recognition

This is a crucial research field that focuses on wearable or smartphone-embedded sensors such as accelerometers, gyroscopes, GPS, and temperature sensors to identify and understand human activities [19–23]. Sri Harsha et al. [24] compared the performance of machine learning algorithms for smartphone-based HAR. Raj and Kos [25] proposed a multi-layered CNN architecture for activity recognition. Recurrent neural networks, including LSTMs, have been widely used for sensor-based HAR [26–30]. Kaya and Topuz [31] introduced a novel 1-D CNN that utilizes smartphone sensor data to identify human activities. Park et al. [32] proposed a novel grouped temporal shift network (GTSNet) that is designed to be adaptable by establishing the computing cost to align with budgetary limits on different wearable devices. Matey-Sanz et al. [33] curated a novel dataset to offer smartwatch and smartphone-based inertial data for sensor-based HAR. The data samples were gathered from a diverse range of individuals in terms of age and gender. Zhang and Yu et al. [34] proposed integrating a 1-D CNN with a BiLSTM model and an attention mechanism to enhance multi-sensor HAR. Ullah and Pirahandeh et al. [35] put forth a novel deep-learning architecture for sensor-based HAR. The authors employed sparse learning to retrain just the weak nodes and keep stronger nodes fixed in a fully linked layer before the final classification. By integrating CNN, BiGRU, and BiLSTM networks into a single architecture, Lalwani and Ramasamy [36] aimed at capturing both short-term and long-term patterns in sequential HAR data. Sansano et al. [37] experimented with several state-of-the-art deep-learning architectures such as CNN, LSTM, BiLSTM, GRU, and DBN for HAR using different types of sensors. Mallik et al. [38] presented a dual-phase approach to categorize activities into static and dynamic classes. While the first phase was based on SVM, the second used 2D and 1D CNN to identify static and dynamic activities. For sensor-based HAR, Serpush et al. [39] employed CNN and fuzzy SVM as the feature extractor and classifier, respectively. Noori et al. [40] explored different methods for integrating multiple

sources of sensor data for HAR. The authors compared the performance of data, feature, and decision-level fusion methods across three benchmark datasets. After extracting relevant features from sensor data using a fuzzy logic-based genetic algorithm, Jameer and Syed [41] used a CNN-LSTM framework to classify human activities. To combat the effects of defective sensors and missing data, Bagci Das and Birant [42] devised a flexible multi-instance learning framework for sensor-based HAR. Kumar and Murugan [43] suggested using a deep belief network for classification of sensor data while performing hyperparamter tuning using the cuckoo search optimization algorithm. Choudhury and Soni [44] provided a generic framework design for sensor-based HAR while analyzing cutting-edge methods and the challenges encountered by them. Imanzadeh et al. [45] collected a new dataset using gyroscopes, magnetometers, and accelerometers for sensor-based HAR. Thakur et al. [46] applied the grid search technique for hyperparameter tuning in a twin SVM framework. To reduce the training time and number of trainable parameters, Boudjema et al. [47] used cascaded training procedure with a CNN-based framework for HAR.

Gholamrezaii and AlModarresi [48] argued that eliminating pooling layers from 1D and 2D CNNs and incorporating strides in the convolutional layers could help reduce computational time without compromising the performance on sensor datasets. Geravesh and Rupapara [49] proposed a novel DS-MLP (Deep Stacked-Multi Layer Perceptron) model that employed MLP as a base learner while using an artificial neural network as a meta-learner. Hasan et al. [50] highlighted the positive influence of time series data augmentation on sensor-based HAR. Acknowledging that recurrent architectures for HAR may prove to be computationally burdensome, especially during deployment on embedded devices, Raja Sekaran et al. [51] devised a lightweight architecture by utilizing parallelly arranged convolutional heads. Based on the premise that random forests extract more interpretable features when compared with other methods, Thakur and Biswas [52] used a modified random forest for optimal feature selection from sensor data. Ghalan and Aggarwal [53] developed a novel stacked CNN framework to deal with semantically comparable daily activities. Ouyang and Pan [54] came up with a weighted voting model for HAR using single-axis and multi-axes correlation data extracted from wearable sensors. Zhang et al. [55] proposed a hybrid CNN-Transformer model to extract local and global information from sensor data. To forecast how much better a given HAR model will perform after retraining with more data, Tanigaki et al. [56] introduced a novel approach that does this before any new data is collected. Dua et al. [57] integrated the Inception CNN with GRU to capture both spatial and temporal features from sensor data. Ankalaki and Thippeswamy [58] proposed a novel activation function that overcomes the dying gradient problem faced by ReLu variants and demonstrated its ability to capture improved feature representation by using it in the hidden layer of a 1D CNN network. To overcome the problems posed by weakly annotated data and data distribution differences, Prabono et al. [59] proposed a multiple-instance domain adaptation approach for sensor-based HAR. Mhalla and Favreau [60] employed a particle filter theory-based domain adaptation approach to develop personalized HAR classifiers. Zebhi [61] used continuous wavelet transform and short-time Fourier transform to model the problem of sensor-based HAR as one of 3D volume classification. Lattanzi et al. [62] introduced a lightweight trigger to address the significant issue of limited battery life in sensor-based HAR. Liang et al. [63] presented a novel 3D attention module capable of incorporating both spatial and weight information of each channel in sensor data. Pareek et al. [64] eliminated the temporal global average pooling layer from the 3D CNN architecture and used an attention layer to capture temporal information for activity recognition. Bodhe et al. [65] proposed a hybrid model for HAR comprising CNN for extracting spatial

information, fuzzy C-means clustering for data reduction, and LSTM for capturing temporal dependencies. In [66], Stuchbury-Wass et al. investigated the suitability of multimodal attention networks for HAR using earables, i.e., wearable sensor devices for the ears.

2.2 Vision-based Human activity recognition

Technological advancements have made RGB and RGB-D cameras more accessible and affordable. Vision-based HAR systems aid surveillance for large regions. Rangasamy et al. [67] proposed a VGG-16-based transfer-learning framework for hockey activity recognition. When studying the use of LSTM in vision-based activity recognition, in an initial work, Baccouche et al. [68] used an LSTM-RNN approach to classify soccer actions of the MICC-Soccer-Actions-4 dataset using both visual and motion contents. Grushin et al. [69] demonstrated how LSTMs maintain classification performance even when subjected to unfavourable experimental conditions and how they outperform temporal pooling by taking into account the temporal ordering of video frames. In [70], Veeriah et al. proposed a differential RNN wherein handcrafted features concatenated from successive video frames were fed into the LSTM network.

Donahue et al. [71] proposed the long recurrent convolutional network, a hybrid model that brought together CNN and LSTM for visual feature learning and temporal recursion, respectively. Carreira and Zisserman [72], Ng et al. [73] and Qiu et al. [74] investigated the use of LSTMs in combination with CNNs for activity recognition amidst other prominent deep learning methods, including 3D CNN, a two-stream network, a two-stream inflated 3D CNN, and a 3D-fused two-stream network. Hybrid networks built using LSTM on top of CNNs have shown promising results in capturing spatio-temporal features. Núñez et al. [75] used a combination of CNN and LSTM for skeleton-based human activity recognition. Pandya et al. [76] obtained an accuracy of 94.20% on the UCF-101 dataset [77] using an LRCN model using the InceptionV3 pre-trained network. Negi and Kumar [78] employed ResNet-50 to perform vision-based HAR on the UTKinect dataset via transfer learning. Nguyen and Ribeiro [79] integrated CNNs with cutting-edge sequence learning models such as RNNs and transformers to recognize human activities from video sequences. To further boost the accuracy of video-based HAR, Ge et al. [80] proposed an attention-integrated CNN-LSTM architecture.

Vishwakarma and Dhiman [81] proposed a robust framework for HAR by combining Difference of Gaussian (DoG)-based spatiotemporal interest points (STIP) and Spatial Distribution of Gradients (SDGs). Nasir et al. introduced a real-time HAR model, HAR-EDNet [82], that can accurately identify human actions in unconstrained settings. Dharmalingam and Palanisamy [83] extracted and augmented features of location, shape, and speed of a person to formulate a novel feature descriptor for HAR. Shrivastava et al. [84] extracted interaction features to understand the role of each individual in multi-person activities. To reduce the computational complexity of CNN-based architectures for HAR, Kushwaha et al. [85] explored the impact of information fusion at intermediate network layers. Zhao et al. [86] encoded the 3D coordinate data of human body nodes into colour images for activity recognition using an improved CNN. By combining object appearance and motion information via feature fusion, Kushwaha et al. [87] developed a view-invariant feature descriptor for HAR. Vishwakarma and Jain [88] developed a computationally efficient framework for real-time 3D HAR using skeleton and point-based methods. Riahi et al. [89] proposed to utilize key frames from video sequences to generate dynamic images for HAR. Samma and Sama [90] optimized the YOLO computer vision system for HAR in

drone images using a two-layer particle swarm optimizer. Stressing the need to select representative frames from a given video instead of utilizing the entire frame sequence, Alfasly et al. [91] proposed a novel two-stage approach for HAR involving discriminative and representative frame selection. Varshney and Bakariya [92] designed a two-stream network for HAR, comprising a spatial stream based on an ImageNet-pretrained network and a temporal stream based on enhanced motion history images. Sun et al. [93] merged GAN and LSTM networks to accurately identify tennis activities. Sinha and Kumar [94] introduced an improved segmentation technique to extract features such as bag of visual words, local gradient threshold pattern, and grey level co-occurrence matrix for vision-based HAR. Kushwaha et al. [95] designed a computationally efficient CNN-based architecture to capture the complex and varied visual patterns in activity data. The authors stacked together small micro-networks, each catering to a distinct receptive field, to consider multi-scale features. Singh et al. [96] proposed a four-stream network for HAR by utilizing dynamic images and depth images from front, side, and top views.

3 Research gaps, challenges and key ideas

According to recent surveys [97], most HAR studies are based on sensor-based data instead of other types of data, including videos, Wi-Fi or RFID data. This can be attributed to the availability of sophisticated smartphone devices with embedded sensors and minimal privacy intrusion in capturing data. However, in light of the challenges posed by sensor-based HAR, including high costs, setup issues, and power consumption, it is necessary to develop improved techniques capable of accurately identifying human activities directly from video data. Video-based HAR studies also encounter several significant challenges [17]. A single activity might be performed in several different ways by people with varied body proportions. The angle or perspective with which the subject performing a particular activity is viewed also gives rise to multiple variations. The subject's appearance and motion patterns can vary considerable across different possible views. The environment in which videos are recorded for activity recognition also has a significant bearing on the performance of a framework. While most HAR frameworks developed in recent times work well in indoor environments, their performance degrades rapidly in cluttered and dynamic backgrounds of outdoor environments. The same subject might perform a given activity differently at different times. This type of intra-class variability caused by anthropometric disparities can complicate the framework design for a single activity. In some cases, several activities may be performed simultaneously, like brushing one's teeth while walking or talking on the phone while laying down. This further complicates both sensor and vision-based activity recognition. Collaborative activities involving multiple subjects interacting with each other constitute another challenging case. further boost the accuracy of video-based HAR, Ge et al. [80] proposed an attention-integrated CNN-LSTM architecture.

This study focuses on developing a high-performing ensemble model for video-based HAR. Our experimental findings demonstrate how the weighted voting ensemble approach can significantly boost the performance of a given architecture without the need for complex modifications. Combining the capabilities of the best-performing transfer-learning-based hybrid models helps achieve promising results with a simple and straightforward framework. To evaluate their approach, several studies based on vision-based HAR still use the UCF-101, Weizmann and KTH datasets. In order to simulate more research on similar

datasets, this paper demonstrates its findings on videos from the relatively less-explored STAIR Actions dataset.

4 Architecture for human activity recognition

This section seeks to elaborate upon the proposed ensemble architecture and the hybrid models constituting it.

4.1 Problem statement

Let us consider V as a representation of a visual sample space. With respect to vision-based human activity recognition, each dataset sample consists of a video. Further, each example is associated with a class label denoted as C^i. Simply put, each instance comprises two components: a video, and a classification label indicating the activity being performed in that video. The dataset can be represented as shown in Eq. (1).

$$H = \{(V^0, C^0), (V^1, C^1), \ldots, (V^i, C^i), \ldots, (V^{n-1}, C^{n-1})\} \tag{1}$$

where, H denotes the collection of dataset pairs, V^i denotes the data corresponding to visual modality, C^i stands for the class label of the i^{th} video, and n represents the total number of dataset samples. The proposed framework is designed to acquire a mapping function $F : V \rightarrow C$ from the inputs that constitute set H. For the activity classification task, $C^i \in \{walking\ with\ stick,\ standing\ up,\ sitting\ down,\ eating\ meal,\ drinking\}$.

4.2 Proposed Model

The ensemble learning process combines multiple models to get better classification accuracy. To prepare an ensemble model, we chose the best-performing hybrid models from each category of pre-trained CNN networks used. These models were – VGG19 + LSTM, ResNet50 + LSTM, Xception + LSTM and DenseNet121 + LSTM with test set accuracies of 82.73%, 73.64%, 83.64% and 88.18% respectively. A detailed comparison of the performance parameters of these models, including test-set accuracy, amongst others, has been given in Section 4.5. The sequence of steps undertaken to achieve the proposed weighted voting ensemble model is shown in Fig. 2. Fig. 3 illustrates the architecture for this ensemble model.

Before the weighted ensemble, a simple model averaging ensemble was also tested. The result obtained from this model served as a measure to compare the results

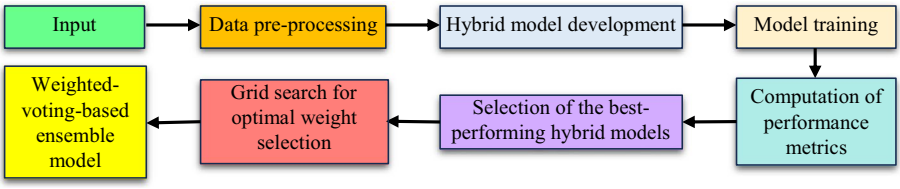

Fig. 2 Sequence of steps undertaken to devise the proposed ensemble model

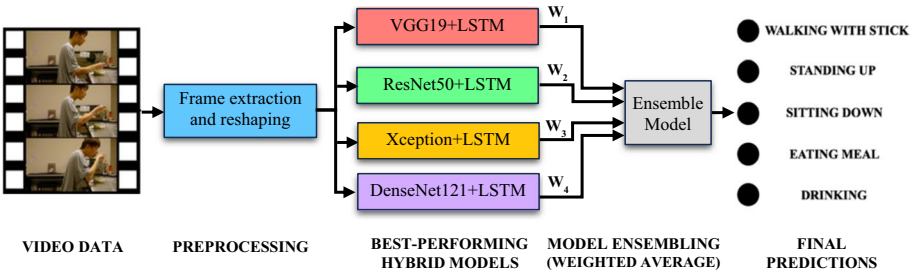

Fig. 3 Weighted voting ensemble model architecture

obtained from weighted ensembles. Under the simple model averaging ensemble, after obtaining the prediction probabilities for each activity from each of the four models, the probabilities for each class were added, and the class with the maximum value for the sum of predicted probabilities was chosen as the final prediction. In this approach, all the models have equal weights (equal to $\frac{1}{n}$ where n is the total number of models); hence, the model outputs are non-weighted.

Under the weighted average ensemble approach, the contribution of each ensemble member model is indicated by a weight value proportional to its performance. As opposed to directly adding the prediction probabilities in the simple ensemble model, a weighted sum is calculated in this method. The weighted sum is given by the value $\sum_{i=1}^{n} p_i w_i$, where n is the number of models constituting the ensemble, p_i the prediction probability as obtained from the ith model and w_i the weight assigned to it. The weight values chosen are typically between 0 and 1 and are assigned such that the sum of weights across all contributing models equals one. To reach the best possible accuracy using our trained models, we used the exhaustive grid search technique to calculate the combinations of the most optimal weights by testing all possible cases. In case the sum of the weights assigned by the grid search was not one, normalization was carried out to achieve the same. Table 14 in Section 4.5 summarizes the results obtained for different weight combinations.

4.3 Convolutional Neural Network (CNN)

CNNs are commonly employed in various image recognition applications [98, 99] due to their capacity to extract spatial characteristics from images. These networks can automatically learn and extract distinctive features from images, including those that may be challenging to characterize or quantify. CNNs are structured using a layered architecture comprising three types of layers: convolutional, pooling, and fully-connected. The multi-layered structure of CNNs allows them to capture low, mid and high-level features, thus emulating the hierarchical learning process of the human brain. Figure 4 seeks to categorize the CNNs used in this study on the basis of architectural configuration. Table 1 outlines the major contributions, strengths and limitations of the different architectures. Table 2 lists the ten different CNN models used in conjunction with LSTM and summarizes their key details.

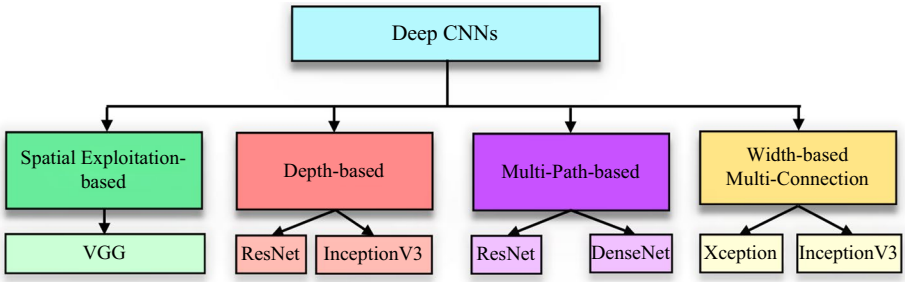

Fig. 4 Taxonomy of CNN architectures used in this study

4.4 Long short-term memory (LSTM)

LSTM has proven to be a boon to applications involving sequential relationships. It is a special type of RNN network proposed by Hochreiter and Schmidhuber [100] that utilizes memory cells to maintain state value over a long time and output information. Its architecture comprises memory blocks, with each block holding a number of memory cells. As shown in Fig. 5, a memory cell consists of three non-linear gates that control the flow of signals into and outside the memory cells. These gates are – the input gate to decide what new information is to be stored in each cell, the forget gate to decide whether to retain or forget certain information and the output gate to choose useful information from the current cell state to display as output. Mathematically, the functioning of an LSTM unit can be expressed as shown in Eq. (2), Eq. (3), Eq. (4), Eq. (5), and Eq. (6).

$$i_t = \sigma\left(W_i \otimes \left[h_{t-1}, x_t\right] + b_i\right) \tag{2}$$

$$f_t = \sigma\left(W_f \otimes \left[h_{t-1}, x_t\right] + b_f\right) \tag{3}$$

$$c_t = f_t \otimes c_{t-1} + i_t \otimes tanh\left(W_c \otimes \left[h_{t-1}, x_t\right] + b_g\right) \tag{4}$$

$$o_t = \sigma\left(W_o \otimes \left[h_{t-1}, x_t\right] + b_o\right) \tag{5}$$

$$h_t = o_t \otimes tanh\left(c_t\right) \tag{6}$$

where i_t, f_t, c_t, o_t, h_t, and x_t represent the input gate, forget gate, memory unit, output gate, hidden state, and input at time t respectively. W and b denote the response weight and bias respectively. *tanh* and σ stand for the hyperbolic tangent and sigmoid activation functions respectively while $\otimes$ symbolizes the multiplication operation of elements.

4.5 Hybrid CNN + LSTM architecture

This research work uses a combination of CNN and LSTM for 2D video human activity recognition. While CNNs alone do not take into account the temporal dependencies of the

Table 1 Summary of the different CNN architectures used to build the hybrid CNN-LSTM networks

Network	Major Contribution	Strengths	Limitations
VGG	Homogenous architecture with small kernels	**1.** Increased number of layers with smaller kernel size. **2.** Increased non-linearity.	**1.** High computational cost of fc layers. **2.** Vanishing gradient
ResNet	Residual learning and skip connections	**1.** Helped combat the vanishing gradient issue. **2.** Residual connections enable faster training and better convergence.	**1.** Complex architecture. **2.** Training can be computationally expensive.
InceptionV3	Replaced large-sized filters with smaller ones and tackled the issue of representational bottleneck.	**1.** Utilized asymmetric filter combinations and bottleneck layers to reduce the computational demands. **2.** Filters of different sizes aid in capturing a wide range of features in high-resolution images.	**1.** Increase in space and time complexity. **2.** Complex architecture. **3.** Lack of homogeneity.
Xception	Depth-wise separable convolutions	**1.** Introduced depth-wise separable convolutions. **2.** Learns good abstractions via cardinality.	**1.** Increased computational costs.
DenseNet	Cross-layer information flow	**1.** Allows maximum data flow across network layers. **2.** Eliminates redundancy of re-learning feature maps.	**1.** Computationally expensive. **2.** Memory-intensive.

Table 2 CNN architecture summary (https://keras.io/api/applications/)

Network	Depth	Size (in MB)	Parameters (in millions)	Top-1 Accuracy on ImageNet dataset (%)
VGG16	16	528	138.4	71.3
VGG19	19	549	143.7	71.3
ResNet50	107	98	25.6	74.9
ResNet101	209	171	44.7	76.4

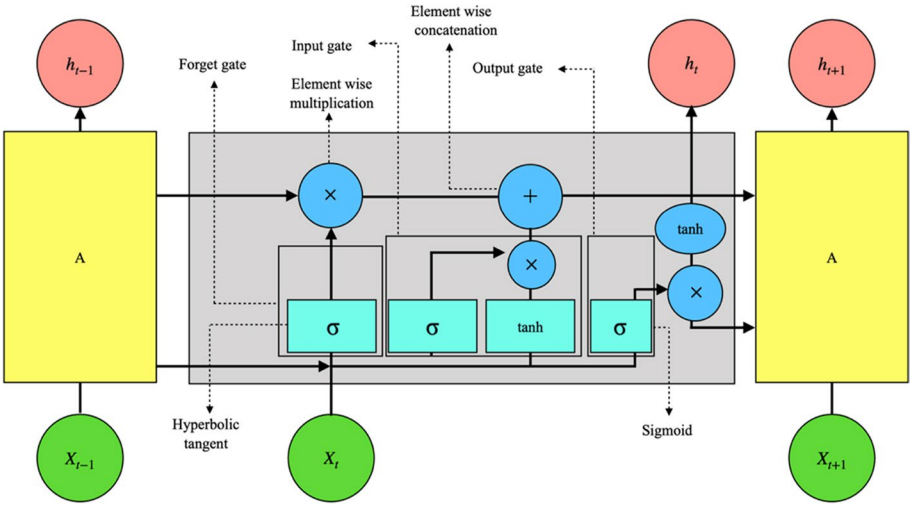

Fig. 5 Structure of LSTM unit. Here, X is the input of the memory, and h is the prediction at time t

different frames of a video, LSTMs, a special type of RNN, can make up for this shortcoming by maintaining observations in memory for extended periods using their gating mechanism.

For this study, ten CNNs have been used to process individual video frames. The LSTM network helps exploit the variations between frames to achieve more accurate predictions. As stated earlier, the LSTM network uses memory cells to store and output information. This leads to the better discovery of long-range temporal relationships and helps overcome the gradient vanishing and exploding issues encountered in training RNN networks. Twenty video frames with equivalent distance were extracted from each input video for feature extraction and temporal relationship classification. In the hybrid CNN+LSTM architecture, data transmission is efficient only when the data format remains consistent at the network junctions. The feature dimension of the LSTM

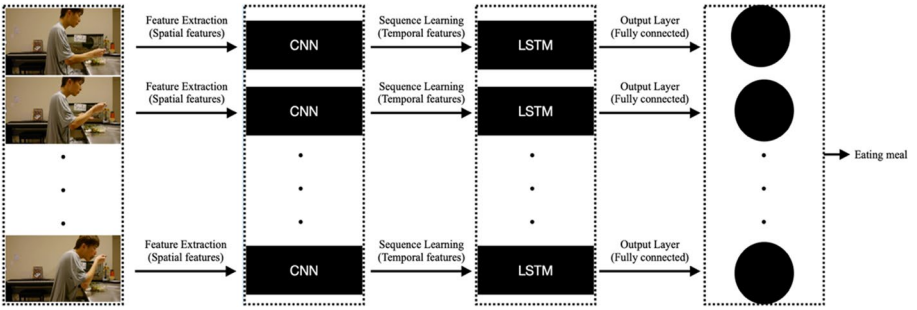

Fig. 6 Overall framework of the combination of CNN with LSTM. The extracted spatial features from the CNN pass through the LSTM to create the temporal features

model should be determined by the output of the CNN model to maintain consistency in feature extraction. Figure 6 depicts the core sequence of steps for the approach used. The reconfiguration of standard CNNs first entailed deleting the fully connected layers while keeping the convolutional and pooling layers as the core network. To regulate the number of output features, a global average pooling layer was used to obtain the CNN output. The sequential frames are encoded by the CNN model to generate a series of feature vectors, which are then supplied as input to an LSTM layer with 32 units.

4.6 Transfer Learning

For this work, we used different networks pre-trained on the standard ImageNet [101] dataset for feature extraction from input video frames by eliminating the top layer used for classification. Ten state-of-the-art deep learning models - VGG16, VGG19 [102], ResNet50, ResNet101, ResNet152 [103], Inception V3 [104], Xception [105], DenseNet121, DenseNet169 and DenseNet201 [106] were used as the pre-trained models for feature extraction. The output of the base CNN model passes through a global average pooling layer followed by a time-distributed layer wrapping to apply the feature extraction layer to each temporal slice or frame of input. This is followed by the LSTM to identify temporal features within the frame sequence. The combined features are then passed to a fully connected layer to predict a single activity for the given input sequence, as visualized in Fig. 7.

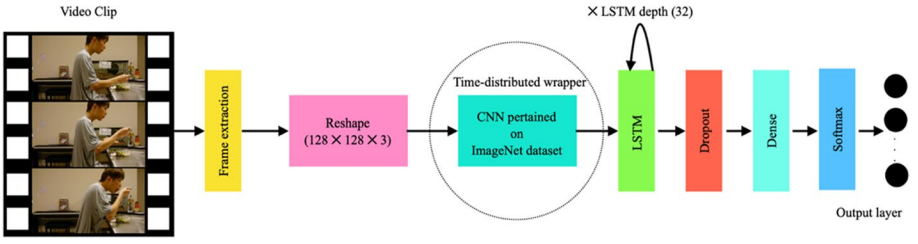

Fig. 7 Model architecture

Class/Activity	Drinking	Eating meal	Sitting down	Standing up	Walking with stick
Number of videos in dataset	408	441	886	503	923

5 Experimental Settings

This section describes the experimental settings and the methodology followed to establish the proficiency of the proposed framework.

5.1 Dataset Description

We used videos from the STAIR (Software Technology and Artificial Intelligence Research Laboratory) Actions dataset [107], a large-scale video dataset for activity recognition and classification. The dataset consists of trimmed video clips of 5-6 seconds each for everyday human activities, with each video clip being associated with a single label. The dataset video clips have either been procured from YouTube or prepared by crowdsourcing workers. For this paper, five classes of activities were chosen: walking with a stick, standing up, sitting down (from solo action set of activities), eating a meal and drinking (from kitchen related set of activities). Sample frames for these activities have been depicted in Fig. 8. The number of videos per class is shown in Table 3.

5.2 Performance Metrics

To evaluate the performance of the models, the metrics adopted include AUROC, AUPRC, precision, specificity, sensitivity (or recall) and overall accuracy. Section 4.5 discusses the need for these metrics and compares the values obtained for the different models.

The metrics are defined in Table 4, where TP, TN, FP and FN stand for true positives, true negatives, false positives and false negatives, respectively.

Table 4 Performance metrics

Performance metric	Description and Mathematical Formula
Precision	Precision, or positive predictive value, identifies the proportion of positive predictions that were actually true. It is the ratio of the true positives to the total positives predicted. $Precision = \frac{TP}{TP+FP}$
Specificity	Specificity, or true negative rate, identifies the proportion of true negatives that were correctly predicted by the model. It is the ratio of true negatives to all the negatives in the ground truth. $Specificity = \frac{TN}{TN+FP}$
Sensitivity	Sensitivity, or hit rate or true positive rate, identifies the proportion of true positives that were correctly predicted by the model. It is the ratio of true positives to all the positives in the ground truth. $Sensitivity = \frac{TP}{TP+FN}$
Accuracy	Accuracy is the measure of how often the classifier is correct. It is the ratio of the number of correct predictions to the total number of predictions. $Accuracy = \frac{TP+TN}{TP+TN+FP+FN}$
AUROC (Area under the ROC curve)	This is a metric that defines the degree to which the model is able to discriminate or separate the different classes. The higher the value, the better the model is at distinguishing between the different classes. The ROC curve is a TPR vs FPR curve with TPR on the y-axis and FPR on the x-axis. Since ours is a multi-class problem, we have used OvR (One vs Rest) method to plot the curves.
AUPRC (Area under the precision-recall curve)	This is a useful metric to evaluate output quality of a model for an imbalanced dataset. The higher the value, the higher the precision (low FPR) and higher the recall (low FNR). The precision-recall curve is a precision vs recall curve for different thresholds with precision on the y-axis and recall on the x-axis.

5.3 Video frame extraction

Video-based HAR requires us to extract frames to study the temporal relationships between them. The OpenCV library was used to extract 20 equidistant frames of dimension 128×128 for each video in the dataset. Figure 9 illustrates the frames extracted for a video of the class – 'eating meal'.

5.4 Hyperparameters

Ten different CNN + LSTM network models formed using ten different architectures, namely VGG16, VGG19, ResNet50, ResNet101, ResNet152, InceptionV3, Xception, DenseNet121, DenseNet169 and DenseNet201 were trained on the videos for five classes from the dataset. In order to determine and establish the best possible performance for the different models compared, we trained several models by experimenting with different values for frame dimensions, batch size, epochs, patience value for early stopping call-back and learning rate. All models have been compared, keeping the frame height and width 128, batch size 4, epochs 50, early stopping call-back with a patience value of 10 and using the Adam optimiser with cross-entropy categorical loss calculation [108]. Early stopping call-back based on validation loss helped prevent overfitting of the models on the training dataset so as to ensure that they are able to perform well on unseen inputs. The training process terminated when there was no improvement in performance for 10 consecutive

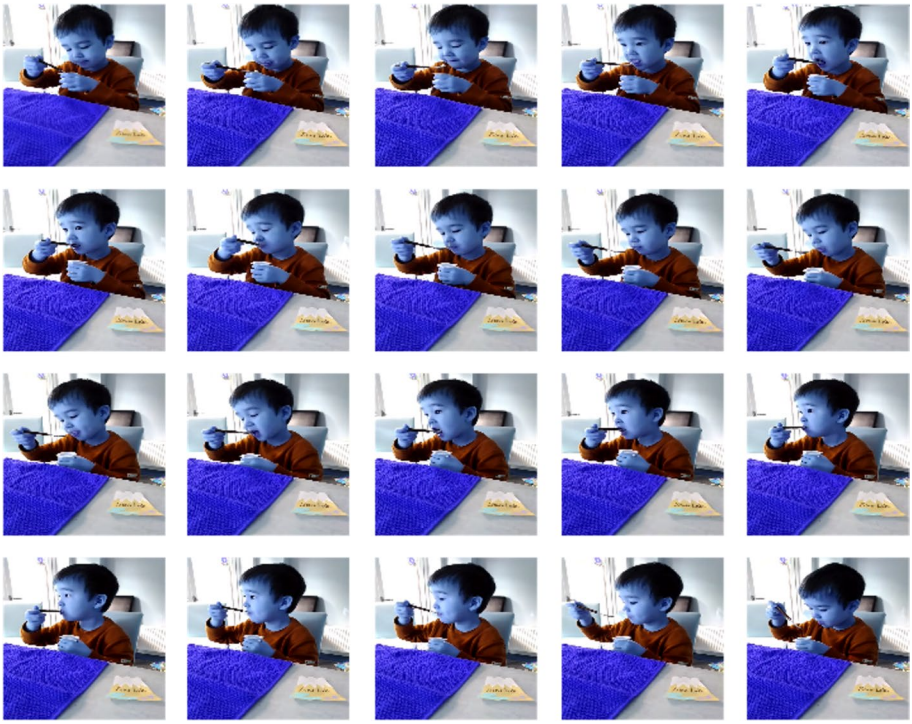

Fig. 9 Video frames extracted from a sample video from the class – 'eating meal'

Table 5 Number of parameters for each of the network architectures

Network	Total parameters	Trainable parameters	Non-trainable parameters
VGG16 + LSTM	14,785,669	70,981	14,714,688
VGG19 + LSTM	20,095,365	70,981	20,024,384
ResNet50 + LSTM	23,855,301	267,589	23,587,712
ResNet101 + LSTM	42,925,765	267,589	42,658,176
ResNet152 + LSTM	58,638,533	267,589	58,370,944
InceptionV3 + LSTM	22,070,373	267,589	21,802,784
Xception + LSTM	21,129,069	267,589	20,861,480
DenseNet121 + LSTM	7,174,021	136,517	7,037,504
DenseNet169 + LSTM	12,861,317	218,437	12,642,880
DenseNet201 + LSTM	18,573,189	251,205	18,321,984

epochs. The number of trainable and non-trainable parameters for each of the ten hybrid models has been stated in Table 5.

5.5 Implementation details

The models in this study were trained and tested using Google COLAB Pro+ equipped with NVIDIA V100 GPU, 52 GB of system RAM, 150 GB of hard disk space, and 16 GB of GPU RAM. The models were constituted and trained using Python programming language with Keras libraries.

6 Results and discussion

Under this section, we first present a review of the individual models based on the performance metrics defined in Section 4.2, following which the results of the ensemble model have been discussed.

6.1 Performance of the individual hybrid models

This section compares the results of the ten hybrid models on the five classes of activities chosen from the STAIR Actions dataset.

The CNN-LSTM models were tested on a set of 230 videos spread over the five classes. As depicted in Fig. 10, the dataset showed class imbalance (walking with a stick 29.2%, standing up 15.9%, sitting down 28.03%, eating meal 13.95% and drinking 12.9%). Thus, we used confusion matrices and graph plots of receiver operation characteristics (ROC) and precision-recall curves for each class to evaluate, analyze, and compare the trained models. Both AUROC and AUPRC values were calculated for each class for each model. The performance metrics calculated for each class include specificity, sensitivity, and

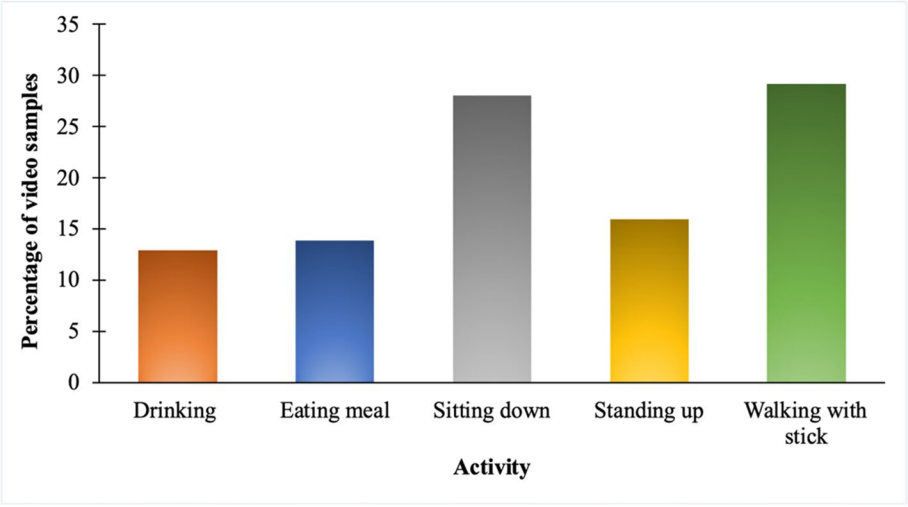

Fig. 10 Class imbalance in dataset

precision. After experimenting with different values for batch size, batches of 4 gave optimum results, so all models were compared using a batch size of 4.

The accuracy and loss values during training, validation and testing have been shown in Table 6. While comparing the number of epochs taken by each model to achieve the minimum value for validation loss, we observed that DenseNet169, DenseNet121 and Xception reached the lowest value at just 9, 12 and 9 epochs, respectively. Within these epochs, they reached accuracy values above 90%. When studying training parameters, it was found that five of the best-performing models, i.e., VGG16, Xception, DenseNet121, DenseNet169 and DenseNet201, were able to achieve a training accuracy of 100%. The model trained using Xception achieved the lowest value for training loss, followed by DenseNet121, DenseNet169 and DenseNet201. From this data, it can be inferred that all variants of DenseNet architecture exhibited the best performance for the task at hand. The confusion matrices shown in Fig. 11 display the number of video samples correctly and incorrectly identified by each model for each class.

Learning curves are graphical representations that depict the evolution of learning performance over time. They serve as valuable tools for evaluating the fitness of a model. Table 7 displays the curves of training and validation loss and accuracy as the number of epochs increases. The training and validation loss curves exhibit a consistent and gradual decrease, leading to the convergence of loss values at a stable point. The validation accuracy curves exhibit a steady increase as the number of epochs progresses. The learning curves impart empirical support for the adequacy of the models' fit and effectiveness of their training. Table 8, Table 9, Table 10 and Table 11 summarize the precision, sensitivity, specificity, and accuracy values.

When studying the individual findings for each model, the highest AUROC of walking with stick was achieved by DenseNet201 (1.0000), DenseNet121 (0.9994), DenseNet169 (0.9992) and VGG16 (0.9996). For recognition of standing up, the best models were DenseNet169 (0.9689) and DenseNet201 (0.9665). For sitting down, the highest AUROC values were obtained using DenseNet169 (0.9825) and DenseNet121 (0.9782). The activity of eating meal was most confidently predicted by DenseNet201 (0.9962) and DenseNet169 (0.9834). Finally, for drinking, the the models with best results were Xception (0.9862), DenseNet121 (0.9859) and DenseNet201 (0.9852). Figure 12 presents the ROC curves for each class and model, while Table 12 summarizes the AUROC values. The highest values of AUPRC for walking with stick were achieved by DenseNet201 (1.0000), DenseNet121 (0.9989) and DenseNet169 (0.9986) and for standing up by ResNet101 (0.9038). The best classification for sitting down was obtained using DenseNet169 (0.9425). DenseNet201 (0.9829) helped achieve the highest AUPRC for the activity of eating meal. Finally, for drinking, the models with the best results were Xception (0.9624) and DenseNet121 (0.9614). Figure 13 presents the precision-recall curves for each class and model, while Table 13 summarizes the AUROC values.

6.2 Ablation study

An ablation study aims to determine the essentiality of each component in a given architecture to validate its inclusion. This process is usually carried out by methodically removing each component and analyzing the effect of its absence on the overall model performance. This study utilizes a hybrid CNN-LSTM model to collect both spatial and temporal features for HAR. We conduct an ablation study to determine the efficacy of LSTM in this hybrid model. Figure 14 illustrates the outcomes achieved with and

Table 6 Loss and accuracy during training, validation and testing

Network	Best epoch	Train loss	Train accuracy	Validation loss	Validation accuracy	Test loss	Test accuracy
VGG16 + LSTM	29	0.0061	1.0000	0.3264	0.8939	0.5011	0.8227

without LSTM for each of the ten CNNs utilized in this study. There is a striking contrast in performance between the two scenarios depicted. Eliminating LSTM results in a notable decrease in test-set accuracy, demonstrating its capacity to extract the necessary temporal information for activity recognition. The CNN can only capture the spatial features on the frame level and does not account for the sequential relationships across frames. Since activities such as walking, sitting, standing, eating, and drinking are constituted by characteristic sequences of actions undertaken by a subject across successive video frames, it is imperative to employ a sequential learning model to recognize them accurately.

6.3 Weighted voting ensemble model

When a finite number of models are trained to perform the same task, ensemble learning is used to merge multiple models to improve performance and reduce instability and variance. The application of the weighted voting ensemble methodology (Fig. 15) outperformed the results of all individual hybrid models compared. The test set accuracy for the simple averaging ensemble model was 0.8954, a slight increase from the best performing individual model. Table 14 summarizes the best weight combinations along with their respective test set accuracies for the proposed model. The highest test set accuracy of 0.9318 was achieved using the set of weights {0.1333, 0.1333, 0.2667, 0.4667} for models ResNet50 + LSTM, VGG19 + LSTM, Xception + LSTM and DenseNet121 + LSTM respectively.

Xception + LSTM	0.9773	0.9272	0.8636	0.9409	0.9636
DenseNet121 + LSTM	0.9909	0.9454	0.9227	0.9454	0.9591
DenseNet169 + LSTM	0.9864	0.9318	0.9273	0.9545	0.9364
DenseNet201 + LSTM	0.9909	0.9409	0.9045	0.9591	0.9409

necessarily guarantee a higher accuracy. The hybrid models created using the ResNet architecture recorded the worst performance in terms of test-set accuracy. The underlying principle of the ResNet architecture is to allow for training deeper CNNs via skip connections between the front and back layers. These shortcut connections facilitate gradient propagation during model training. The DenseNet architecture, too, strives to function along the same fundamental concept, but it forms dense connections between all preceding and subsequent layers, as indicated by its name. This allows DenseNet to outperform ResNet while requiring lesser computational cost and fewer parameters. The least test-set accuracy achieved using a DenseNet variant (0.8682) exceeds the best score obtained using a ResNet variant (0.7364) by a significant margin.

ResNet variants, amongst other deep learning networks, exhibit a characteristic where the test-set accuracy of the model declines as the number of layers goes beyond a specific threshold. This trend can also be verified by the results outlined in Table 6. The test-set accuracy value declines from 0.7364 to 0.7273 as we move from ResNet-50 to ResNet-101 and further reduces to 0.6455 for ResNet-152. A similar pattern can also be seen with respect to the DenseNet variants. Therefore, it is vital that the depth of the model be chosen cautiously. Unlike its predecessors, the Inception architecture employs different-sized filters and max-pooling technique to decrease the dimensionality of input data and attain more complex feature representations. Though the hybrid models constituted using InceptionV3 and Xception possess the same number of trainable parameters, the depth-wise separable convolutions in the Xception architecture help achieve significantly better classification performance.

After having trained and evaluated the individual hybrid models, we developed an ensemble model that is capable of utilizing the strengths of diverse base learners via a weighted voting scheme. By aggregating the knowledge from acquired from various base models, the ensemble model enhances the overall predictive accuracy on the test-set. The ensemble model was constructed by selecting the best-performing variant of each of the base learner architectures, to allow for the inclusion of diverse modelling abilities and perspectives. The cumulative application of the strengths of multiple base classifiers boosts predictive accuracy, as seen in Table 14. The weighted voting scheme assigns a weight to each of the base learners to integrate their predictions and impact the final model prediction. Following extensive iterations of different combinations of weights computed using grid-search mechanism, the results in Table 14 were obtained. The most optimal weight

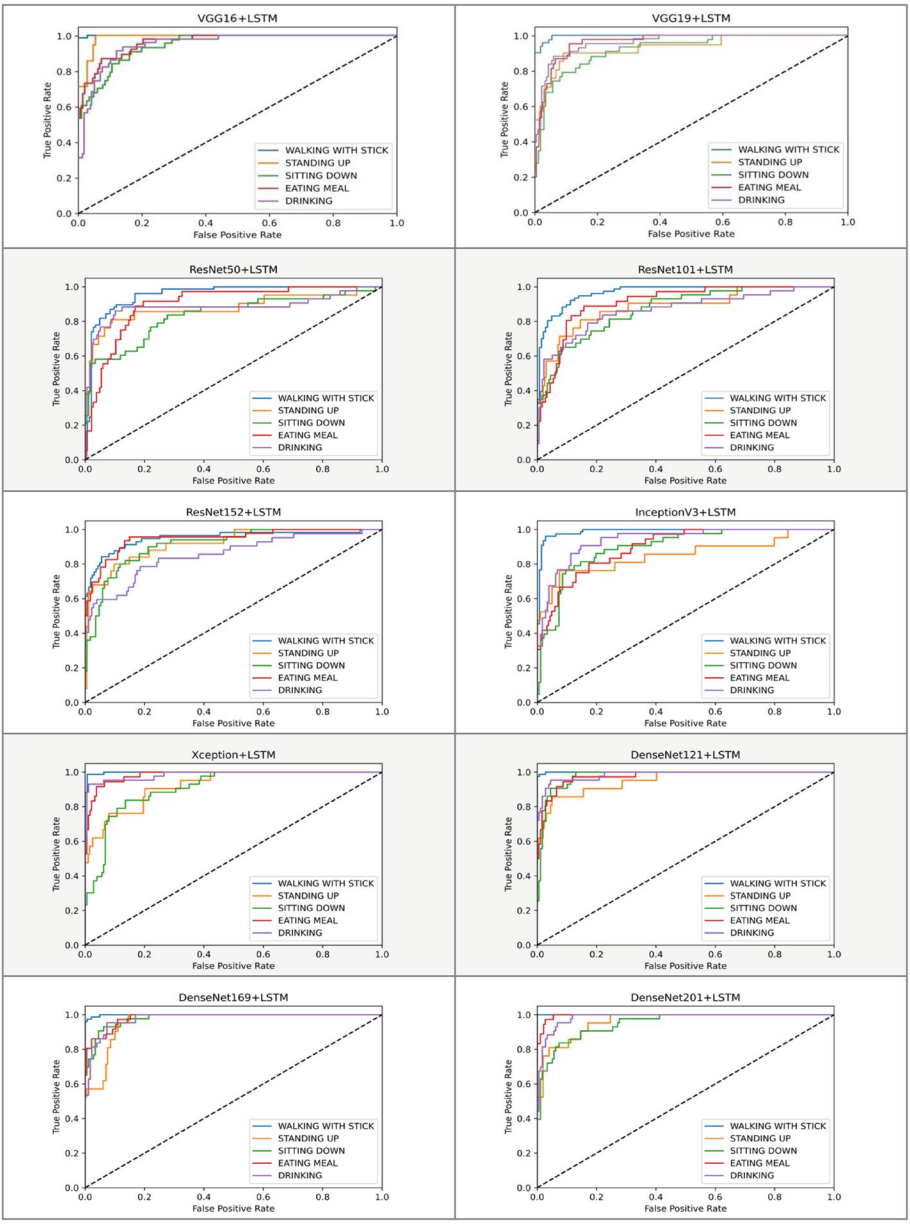

Fig. 12 ROC curves for each of the network architectures

allocation {0.1333, 0.1333, 0.2667, 0.4667} for the models ResNet50 + LSTM, VGG19 + LSTM, Xception + LSTM and DenseNet121 + LSTM respectively, helped achieve the highest test-set accuracy of 0.9318. This is a significant increase from the highest score achieved by an individual hybrid model (DenseNet121 + LSTM, 0.8818). This observation bears testament to the performance-enhancing abilities of ensembles, which are also quite

Table 12 AUROC for each of the network architectures

Xception + LSTM	0.9986	0.9222	0.9083	0.9828	0.9862
DenseNet121 + LSTM	0.9994	0.9572	0.9782	0.9748	0.9859
DenseNet169 + LSTM	0.9992	0.9689	0.9825	0.9834	0.9773
DenseNet201 + LSTM	1.0000	0.9665	0.9482	0.9962	0.9852

intuitive since they take the predictions of diverse top-performing base learners into consideration at the same time.

The chosen data sample also has significant bearing on the results achieved. The dataset in the present scenario is of a moderate size. If a larger data sample had been chosen, with a higher number of videos as well as classes, the simple yet sturdy model under examination could yield even better outcomes. Additionally, increasing the dataset sample size also enhances the model's generalization capabilities by allowing it to learn from a wider range of scenarios and examples for each activity. While larger datasets do demand increased computational resources required for training and testing, they are employed because they are capable of capturing varied instances of activities, thus allowing for development of robust models. Increasing the number of classes will facilitate the inclusion of a practical set of activities that can be applied in daily life, thus developing a suitable system for real-world applications. As the data sample grows in size, it becomes possible to explore more complex networks for extracting feature representations and predicting activities. Complex architectural designs have a tendency to overfit on small-sized datasets as the model may become too closely adapted to the training set, resulting in suboptimal performance on new data instances. Overall, the dataset size and model complexity are closely tied together and should be carefully selected in consideration of each other.

6.5 Comparison with SOTA approaches

This section presents a comparison of the performance of the proposed ensemble model in relation to previously published methods for vision-based HAR. According to the findings presented in Table 15, it is evident that the ensemble model outperforms existing techniques by acquiring the best accuracy score.

In [67], Rangasamy et al. proposed a transfer-learning framework for activity recognition using the VGG-19 network pre-trained on the ImageNet dataset. The primary disadvantage of utilizing solely a pre-trained CNN for HAR is that the temporal features across frames are not taken into account, thus leading to a low accuracy score for the dataset in this study. Singh et al. [109] proposed a CRNN model for vision-based HAR. A pre-trained ResNet-152 model was combined with an RNN (or LSTM) to capture the required spatio-temporal features. Deep and Zheng [110] experimented with three state-of-the-art pre-trained CNNs – VGG-16, VGG-19, and InceptionV3. Out of these three networks,

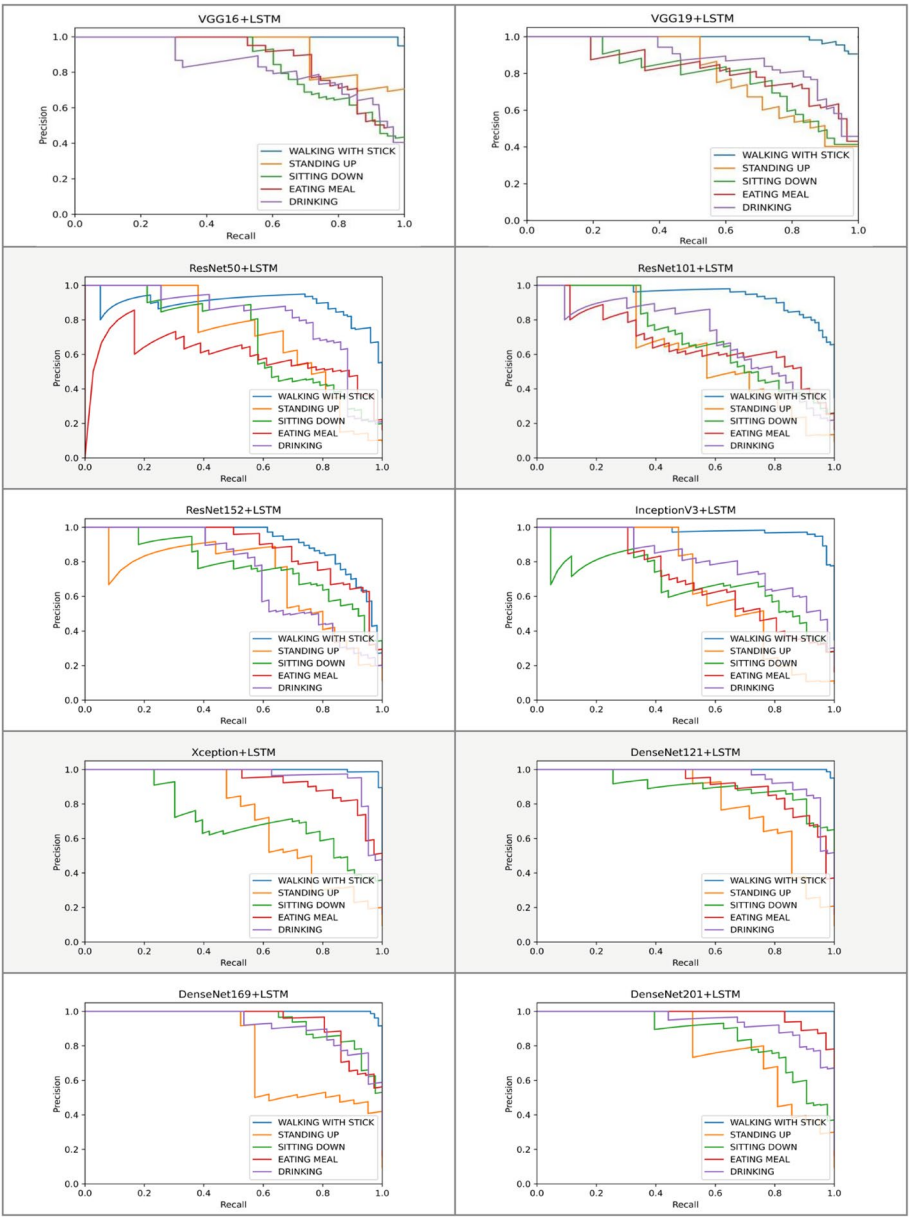

Fig. 13 Precision-recall curves for each of the network architectures

InceptionV3 helped achieve the highest accuracy score of 0.6364 on the dataset under consideration in this study.

Garg et al. [111] trained CNN and LSTM models for vision-based HAR in the KTH and Weizmann datasets. The authors concluded that the two types of models when brought together, were able to better understand and recognize activities than when they were used

separately. Verma and Singh [112] used VGG-19 as a feature extractor, followed by SVM as the classifier for activity recognition from the UCF Sports Action dataset. In [113], Putra et al. used the cyclical learning rate method with ResNet-50 to develop a vision-based HAR model. Kulkarni and Jadhav [114] employed VGG-16, InceptionV3, and MobileNet as feature extractors to develop a transfer-learning-based HAR model using the Collective Activity dataset [115].

6.6 Computational complexity and scalability

Computational complexity plays a critical role in evaluating the efficiency of deep learning models. The number of trainable parameters and inference time are often considered as measures of computational complexity. In this section, we analyze the trade-off between computational complexity, measured by the number of trainable parameters and inference time, and the test-set accuracy of the ten hybrid models.

Figure 16 portrays a bubble chart wherein the size of each bubble is proportional to the number of trainable parameters of the model. A larger bubble implies a greater number of trainable parameters. The test-set accuracies are plotted on the vertical axis, while the inference time (in seconds) has been specified along the horizontal axis. According to the plotted metrics, the models in the top-left region are optimal in terms of high test-set accuracy and low inference time. Despite having a lower trainable parameter count as compared to all ResNet variants, the hybrid models constituted using VGG variants achieve considerably higher test-set accuracies. The best-performing DenseNet121+LSTM model possesses an intermediate parameter count between those of models comprising VGG and ResNet variants. It is also the lowest parameter variant of the DenseNet architecture. Despite its complexity and high trainable parameter count, the ResNet architecture is unable to achieve comparable results when compared against the lower parameter alternatives such as VGG-16, VGG-19, and DenseNet-121. Upon examining the inference times, we observe that the ResNet variants, InceptionV3 and Xception, have contributed to the development of hybrid models with faster inference capability compared to those created using VGG variants. The graph clearly shows that the DenseNet 121+LSTM model, which achieves the highest test-set accuracy, also possesses a favourable balance between a low

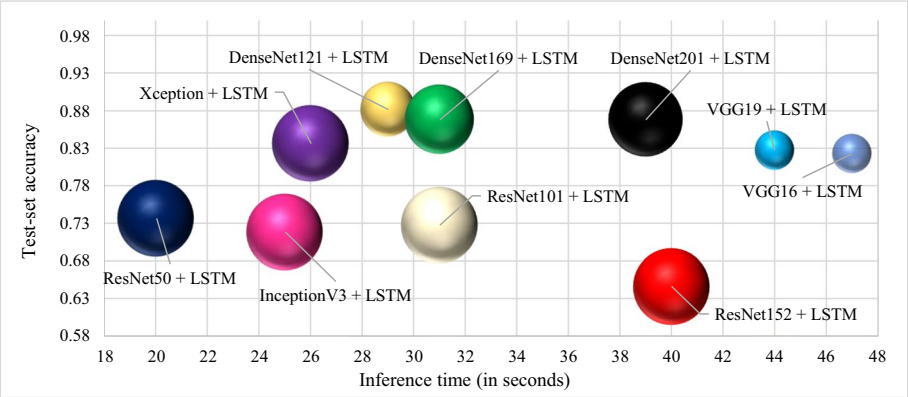

Fig. 16 Complexity analysis of the ten hybrid models analyzed in this study. The vertical axis specifies the test-set accuracy. The horizontal axis mentions the inference time (in seconds). The size of each circle is proportional to the number of trainable parameters of the model

trainable parameter count and a short inference time. Deep learning models possess a notable characteristic of scalability, enabling them to process large volumes of data effectively. Furthermore, it has been observed that larger datasets positively impact their performance. Considering this, the hybrid models and the ensemble model discussed in this paper can be applied to large-scale video datasets for human activity recognition, such as the ActivityNet and NTU datasets. Utilizing GPUs with greater processing power and larger memory capacity can significantly reduce training and inference times, thus augmenting the efficiency of the models.

7 Strengths, limitations and future research directions

The following subsections lay out the strengths of the proposed model while acknowledging its limitations that pave the way for future research endeavours.

7.1 Strengths of the proposed model

The hybrid model employs a combination of CNN and LSTM to automatically retrieve the pertinent features for human activity recognition. CNN is adept at image recognition and can extract valuable features from visual data, whereas LSTM is proficient at handling temporal information, such as the sequence of steps undertaken to perform an activity. The concurrent application of CNN and LSTM enhances the efficacy of activity recognition by accounting for both spatial and temporal connections in the visual data. Ensemble classifiers provide enhanced reliability and uniformity when applied to various subsets of the data. The stability provided by an ensemble model guarantees that the predictions are dependable and that the outcomes may be consistent, irrespective of the particular training data utilized.

7.2 Limitations, scope for improvement, and future opportunities

Though the proposed ensemble architecture helped achieve promising results for HAR, it is necessary to recognize the constraints of the current work in order to outline potential areas for future research. Firstly, the performance of the proposed method was validated using videos from a single dataset. Its performance must be tested using other publicly available video datasets for activity recognition. Secondly, the recent introduction of a variety of attention modules [116, 117] has greatly enhanced the performance and efficacy of deep learning architectures [118–120]. Future endeavours must be aimed at integrating these attention modules into the CNN-LSTM model to further facilitate activity recognition by focusing on the most crucial aspects pertaining to a particular activity. Thirdly, in order to develop generalizable architectures for HAR, it would be interesting to examine how models trained on other video datasets with overlapping activity classes perform on the STAIR Actions dataset. Lastly, keeping in mind the need to develop light-weight architectures for HAR that can easily be deployed on mobile devices, care must be taken to reduce the number of model parameters. Most current frameworks for HAR concentrate on achieving superior performance in terms of metrics like accuracy, precision, and recall but overlook the importance of model size, a critical factor for real-time deployment.

8 Conclusion

This research work experimented with several state-of-the-art pre-trained neural networks including VGG16, VGG19, ResNet50, ResNet101, ResNet152, InceptionV3, Xception, DenseNet121, DenseNet169 and DenseNet201 using transfer learning technique. The best individual model turned out to be the one trained using a combination of DenseNet121 pre-trained on the ImageNet dataset with LSTM with an accuracy of 88.18% on the test dataset, followed by DenseNet169 and DenseNet201 with an accuracy of 86.82% each. Despite the existence of numerous ensemble methods, determining the suitable ensemble configuration for a specific dataset can be challenging. The weighted voting ensemble technique is highly favoured for its straightforward concept, intuitive nature, and practical effectiveness. This technique merges a group of well-performing conceptually diverse base learners to offset their individual deficiencies and generate an improved learner. Given that the base models constituting an ensemble exhibit varying levels of performance, it is imperative to assign distinct weights to these base learners in order to enhance classification performance. On preparing a weighted voting ensemble model using the top-performing model from each category of CNN networks taken up, we obtained a test-set accuracy of 93.18%, a major improvement over the best performing individual model. This study brings out a detailed comparison and analysis and proves that human activity recognition models based on the integration of CNN with LSTM approach, when built using transfer learning methods, can give good results and save training time which would otherwise be required for training the CNN employed. The most significant aspects of our work include carrying out vision-based human activity recognition using a relatively unexplored dataset and then proposing an ensemble model after thoroughly evaluating the performance of different neural network architectures using standard metrics when incorporated as the feature extraction unit in the hybrid model described. Incorporating attention modules into the proposed

model presents promising future opportunities. With a suitable attention mechanism, the model can automatically adjust the importance of key features and reduce the influence of irrelevant noise. Light-weight architectures may be achieved, for instance, by employing computationally efficient multi-branch feature extractors such as those used in the ResNext [121] architecture.

Funding No funding was received to assist with the preparation of this manuscript.

Data availability The STAIR Actions dataset is available at https://actions.stair.center/.

Abstract
Blockchain Technology has grown exponentially in recent years due to its decentralized, immutable, transparent data storage, transaction sharing, and processing capabilities. With the emergence of different blockchain platforms, it is important to analyze and evaluate the performance of these platforms in various scenarios. The popularity of the public blockchain, i.e., Bitcoin and Ethereum, has increased manifold. But in distinction to a public blockchain, there is a permissioned and private blockchain that allows restricted involvement of users in the network. To make a well-informed decision regarding the selection of an appropriate platform for utilization, it is crucial to evaluate diverse performance metrics among the numerous available blockchain platforms. In this study, we assessed the performance of the Hyperledger Fabric blockchain (HLF), taking into account various metrics such as resource consumption, throughput, success rate, and latency. We have incorporated parameters such as the ordering service, programming language to write chaincode/smart contracts, number of transactions, transactions per second, and organizations to evaluate the system's performance. Along with our analysis, we also suggested potential areas of research for future development of blockchain technology.

Keywords Hyperledger fabric · Ordering services · Performance metrics · Hyperledger caliper · Chaincode · Benchmarking

1 Introduction

One of the most ground-breaking and ingenious advancements in recent years is blockchain technology. Blockchain is a solid platform that has a wide range of potential uses across many industries. It was first developed as the underpinning technology for the cryptocurrency Bitcoin. With no need for a central authority or middleman, blockchain technology essentially functions as a decentralized, distributed ledger that is well-kept and verified by a network of users. Increased security, transparency, efficiency, and cost-effectiveness are just a few advantages that this technology offers. Blockchain is a topic of tremendous significance for scholars, developers, and business leaders due to its potential to positively change industries, including finance, healthcare, and more. The launch of the Bitcoin network in 2009 helped popularise the technology that has subsequently been employed in many other cryptocurrencies [1].

Through a distributed system, these digital currencies enable the movement of electronic money. Users can use digital signatures to give others ownership of their data, and the transactions are publicly visible on the Bitcoin blockchain. This makes it possible for any user on the network to confirm the validity of transactions independently. The blockchain's decentralized structure makes it possible for the system to work without having a single point of failure that could cause the database as a whole to crash. In a blockchain system, a copy of the ledger is present on every computer in the network at once. This differs from a traditional business where client information is stored on a server farm in a single building. Data loss is a risk even with server farms if proper backups aren't

available. As a result, the blockchain can continue to function even if one or more nodes go offline. When new data, such as new transactions, are added to the blockchain network, they are first broadcast to the nodes on the network. The nodes then validate the transactions and add them to a pool of unconfirmed transactions. The miners then choose transactions from this pool and add them to the next block they are mining. The blockchain gets its name from the way these blocks are connected to create a chain of documents. When data is stored on a blockchain, it becomes immutable, meaning it cannot be altered or modified once added. To incorporate new information, additional blocks must be appended to the existing chain. Beyond just supporting Bitcoin, blockchain technology's fundamental objective is to deliver third-party advantages like non-repudiation, security, authenticity, and integrity in a decentralized and distributed setting [2].

It is appropriate for any transactional system utilized by numerous independent, trustless parties since it provides auditability, transparency, immutability (transactions cannot be altered once published), and pseudonymity to users. These characteristics apply to any systems that need a high level of decentralized trust, security, and dependability in addition to monetary systems. By imposing restrictions on their adoption, permissioned blockchains enable users to alter the behavior of network nodes. The number of users who can validate transactions is restricted on permissioned blockchains, in contrast to conventional blockchains, which can be completely open and decentralized [3].

Furthermore, alterations in protocols that enable the execution of Turing-complete codes have simplified the creation of distributed applications that are based on smart contracts. Yet, fully permissioned blockchains are similar to conventional shared databases in many aspects. Thus, it's possible that this intricate design is not required in all circumstances. Although blockchain technology has a lot of capabilities for the development of future internet systems, there are still several technical issues that need to be resolved. Due to their mining-based consensus process, poor transaction throughput, and delaying transaction finality, public blockchains like Bitcoin and other POW consensus-based blockchains experience performance and scalability concerns [4] [5]. In September 2022, the Merge represented the Ethereum network's transition from a mining-based consensus mechanism, known as Proof-of-Work (PoW), to a Proof-of-Stake (PoS) consensus mechanism. So, after the merge, Ethereum no longer relies on mining to achieve consensus. Ethereum, a prominent decentralized platform, has addressed scalability challenges through a multifaceted approach. While Layer 2 scaling solutions, such as rollups, currently play a significant role, future advancements like Danksharding and proto-danksharding promise even greater transaction throughput and cost reductions. Private permissioned blockchain platforms are utilized for Business-to-Business (B2B) and Business-to-Consumer (B2C) transactions between known parties as they provide higher throughput and more effective consensus techniques. In B2B interactions, businesses often share sensitive data like pricing models or trade secrets. Private blockchains provide a permissioned environment where only authorized participants can access this data, reducing the risk of breaches. While B2C applications are still emerging, private blockchains can offer value in specific areas like loyalty programs and product verification. To decrease transaction processing delay and boost performance and scalability, the DLT-based blockchain 3.0 platforms use cutting-edge validation and voting procedures in addition to data structures like Directed Acyclic Graphs (DAG).

One of the most critical issues is scalability, particularly concerning the limiting block size of the Bitcoin network, which is currently fixed at 1 MB for each block. Because of this, the transaction rate is limited to only 7 Transactions Per Second (TPS), which makes it unfit for high-frequency trading. As a small number of users are willing to sustain such a huge blockchain, increasing the block size can result in centralization by slowing network propagation and increasing storage needs. Hence, it is necessary to address the trade-off between block size and security. Another major issue is the potential for selfish mining tactics, such as hiding mined blocks for future gain, to let miners earn more money than is reasonable [6]. This could lead to a lot of branch occurrences, which would be bad for blockchain growth. Therefore, solutions are required to deal with this problem. Even when users exclusively conduct transactions using their public and private keys, there is a chance of privacy leakage.

Blockchain's need for anonymity introduces a trust risk because dishonest users may take advantage of it. To safeguard the integrity of the ledger, each transaction needs to be confirmed before being added to a block. Consensus algorithms are used to decide which blocks to add to the blockchain, taking advantage of users' common desire to keep the system honest. As the backbone of all blockchain transactions, consensus algorithms are crucial in building trust and ensuring the correct storage of transaction data [7]. In a blockchain network, a consensus mechanism is a collection of guidelines and procedures that enables nodes to concur on the ledger's current state. Each node in a blockchain network maintains a copy/duplicate of the ledger, which is dispersed throughout the network. Each node has the power to validate and add new transactions to the ledger. There is no central body in a decentralized network to validate or confirm the authenticity of transactions. This is where consensus mechanisms come into play, as they provide a way for nodes to reach an agreement on

the state of the ledger without the need for a centralized authority.

Consensus algorithms are an important aspect of blockchain technology because they enable network nodes to agree on the validity of transactions and the order in which they are added to the blockchain. These algorithms act as a safeguard to ensure the dependability and validity of transactions. Proof of Stake (PoS), Delegated Proof of Stake (DPoS) [8], Proof of Work (PoW) [9], and Proof of Activity (PoA) are the most commonly used consensus algorithms in public blockchain applications. However, it is important to note that each of these algorithms has distinct characteristics in computing cost, security, and consensus efficiency. Unlike public blockchains, where anyone can participate in the consensus process, permissioned blockchains only restrict participation to authorized parties. This allows for more control over who validates transactions on the network. Permissioned blockchains typically outperform public blockchains due to restricted participation. The performance of a permissioned blockchain network can be quantified in terms of transaction throughput, confirmation latency, and scalability.

1.1 Motivation

Many ways to improve the data protection and verbosity of contemporary information systems are provided by blockchain technology. Regarding customization and potential use cases, the HLF offers a variety of functions. It permits a developer to create a unique business network on blockchain that comprises various heterogeneous clients, each having a certain purpose. The motivation behind conducting this study is to identify the various areas where blockchain platforms can be made more efficient depending on the performance measure. With the analysis of the performance, it can be easy to identify the bottleneck and the factors affecting the performance of the blockchain platform.

1.2 Problem statement

Although blockchain technology presents an enticing substitute for centralized database systems with its emphasis on- security and transparency, its practicality is frequently hindered by performance limitations. Issues such as inefficiencies in transaction processing and the absence of standardized protocols can serve as substantial barriers to the widespread adoption of blockchain. These constraints materialize as scalability hurdles, increased transaction latency, and bottlenecks in throughput. Blockchains with limited scalability struggle to handle the high volume of transactions typical in enterprise environments. For example, Bitcoin processes around 7 TPS due to its small block size and Proof-of-Work consensus mechanism. This is insufficient for large-scale adoption as a digital payment system. While faster than Bitcoin, Ethereum still experiences congestion during periods of high activity, leading to an increase in latency. Also, previous works have primarily focused on delineating the architectural and conceptual frameworks for implementing blockchain across different domains. Nonetheless, the successful deployment of blockchain requires careful consideration of factors such as the number of transactions, transaction rates, and the number of participants. These variables can significantly influence performance metrics such as success rate, throughput, resource consumption, latency, and the function relating to the creation and querying of transactions.

1.3 Research contributions

Here, we have presented the key contribution of our work:

1. The work concentrates on evaluating the performance of Hyperledger Fabric, analyzing multiple key performance indicators to gauge the effectiveness of the blockchain platform. This research builds upon our prior work [10], which delved into the performance of three prominent blockchain platforms: Hyperledger Fabric, privately deployed Ethereum, and Hyperledger Besu. A comparison of the platforms revealed that Hyperledger Fabric surpasses Ethereum and Hyperledger Besu in terms of throughput and latency. This paper presents a comprehensive analysis specifically focusing on the performance attributes of Hyperledger Fabric.
2. The work examined the impact of increased workload, TPS, ordering services, and organizational factors on the scalability and performance of the blockchain platform.
3. The work investigates the various errors that lead to transaction failure.

The outline of the study is illustrated (Fig. 1) as follows. A general introduction to blockchain, its application, and its drawbacks are described in section one.

The survey of existing literature is provided in section two. Section three describes the tools and techniques to measure the performance and scalability of the HLF blockchain. Section four outlines the experimental design and reports the findings. Section five discusses the experimental outcome and our analysis. Section six of the paper summarizes the findings and conclusions drawn from the research and outlines potential areas for future work.

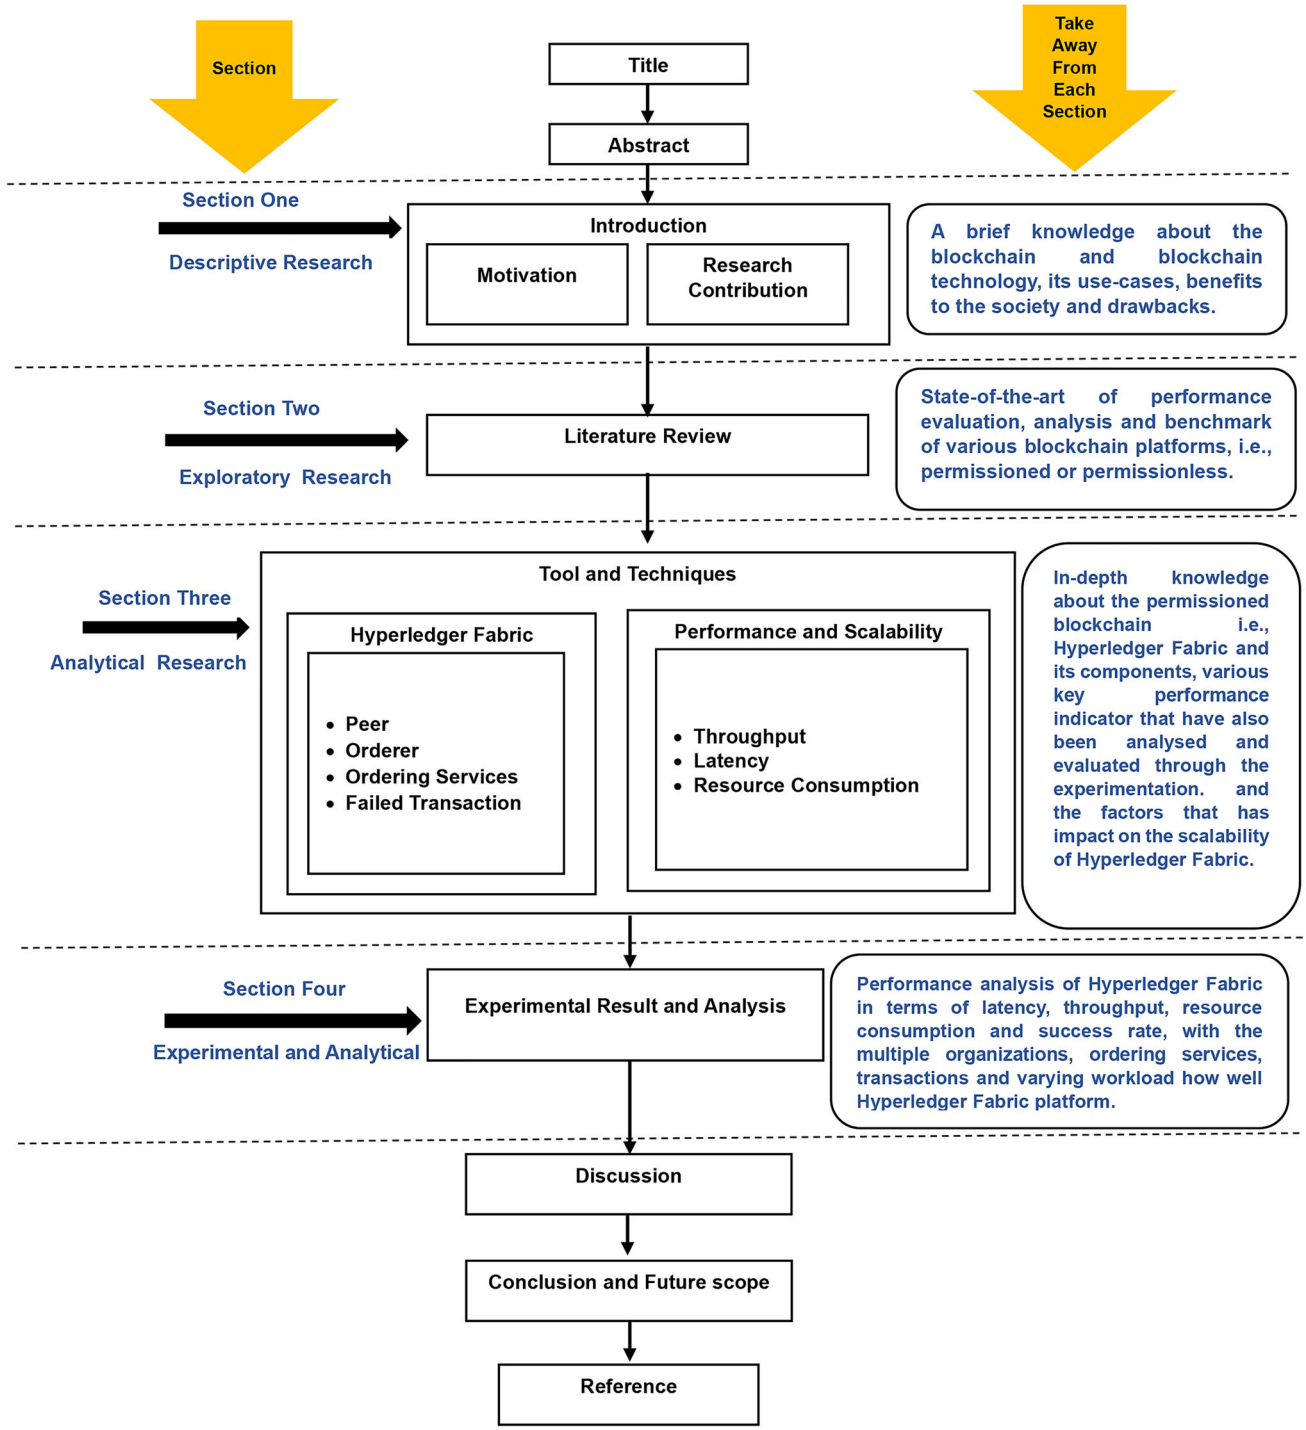

Fig. 1 Structure of our study

2 Literature review

This research employed a literature review to identify relevant scholarly work. We conducted an exhaustive search of print sources and publications across diverse publishers, encompassing works published between 2017 and 2023. To ensure the quality and relevance of the included studies, we used a rigorous methodological framework utilizing pre-defined exclusion and inclusion criteria, as illustrated in Fig. 2. Many performance evaluations have been carried out on the blockchain platform to gauge its effectiveness and pinpoint possible areas for improvement. These studies often employ benchmarking software to assess the platform's throughput and latency

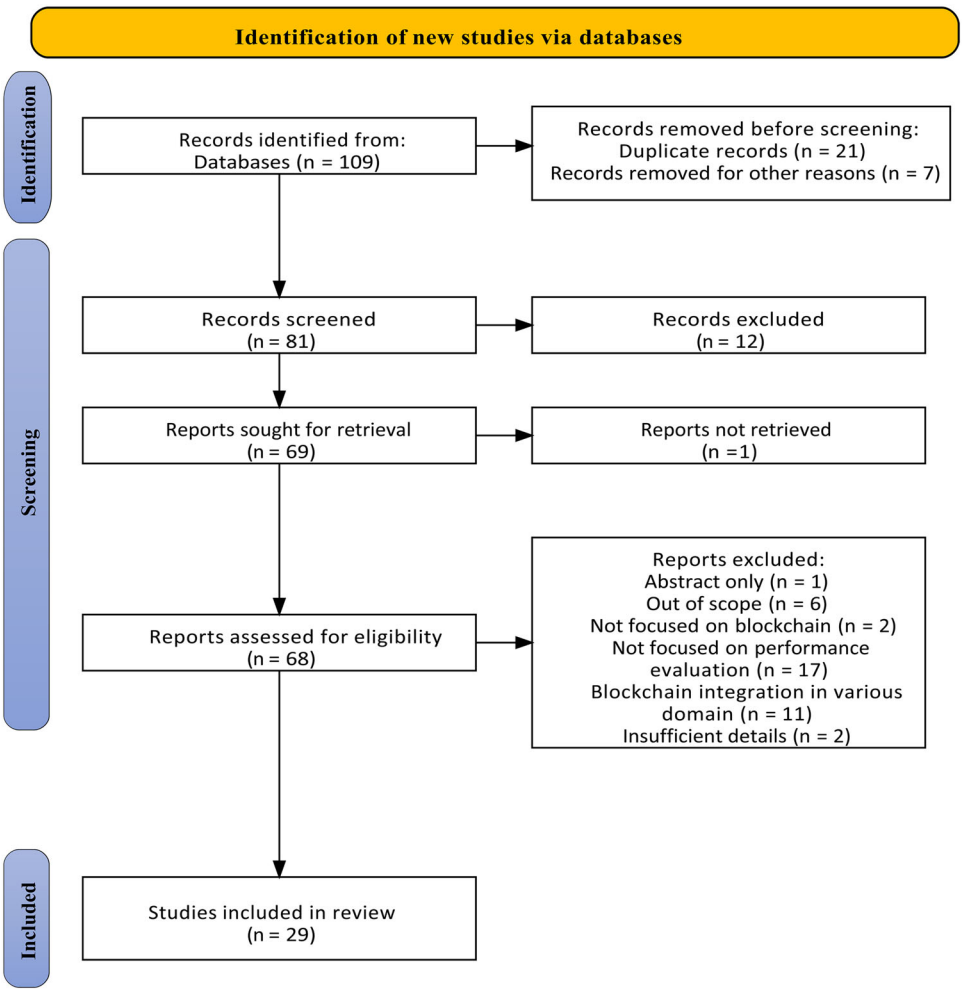

Fig. 2 PRISMA flow diagram for selection of studies

under several scenarios and identify the variables influencing its performance. Here, Table 1 outlines relevant studies concerning the performance analysis of blockchain platforms alongside our research, which encompasses various parameters.

2.1 Studies related to hyperledger fabric

To analyze the performance of HLF version 1.0 and version 0.6 and compare them in the article using a variety of measures, including latency, execution time, and throughput while altering the workload and the number of nodes, the study [11] illustrates that HLF v1.0 surpasses v0.6 in terms of scalability, execution time, latency, and throughput. While the study demonstrates that Hyperledger Fabric (HLF) version 1.0 outperforms version 0.6 in maintaining consistent performance across various metrics regardless of network size, it neglects to explore the impact of the underlying consensus mechanism on these results. HLF v1.0 exhibits superior scalability, supporting up to 26 nodes compared to v0.6's limit of 16. However, v1.0 struggles with 10,000 concurrent transactions when exceeding six nodes. Interestingly, the evaluation reveals better performance for v1.0 with two organizations across all measures compared to a single organization setup. A crucial missing element in this analysis is a detailed examination of the specific consensus protocol employed by each version and its demonstrable influence on the reported performance metrics. This exploration would significantly strengthen the research's conclusions.

To demonstrate that the number of peer nodes in the blockchain network and the number of transactions being completed have a significant impact on HLF's performance, the study [12] performs benchmarking of HLF and points out several architectural bottlenecks in the platform, such as the orderer nodes' use of the consensus method and the network's propagation of transactions. While this study identifies bottlenecks and proposes optimizations, it doesn't delve into how the number of ordering service nodes or the choice of consensus algorithm affects Hyperledger Fabric's performance. To gain a deeper understanding of scalability and fault tolerance, future

Table 1 Summary of various studies related to performance analysis of various blockchain platforms

Ref.	Year	C1	C2	C3	C4	C5	C6	Research gaps
[21]	2017	471	Ethereum, HLF	Yes	Yes	Varying number of transactions, Concurrent transaction	Latency, Throughput, Execution time	The study only examines the platforms' execution layer, Excluding the consensus layer, which can influence performance. No detailed analysis on scalability
[24]	2017	225	Ethereum client (Parity, Geth)	Yes	No	Different clients on the same (Ethereum) platform	Processing speed	Fixed node configuration
[11]	2018	349	HLF	Yes	Yes	Number of Transactions, Number of Nodes	Latency, Execution time, Scalability, Throughput	The impact of different ordering services and varied transaction rates in the network is not investigated
[12]	2018	657	HLF	Yes	Yes	Endorsement policy, Ledger database, scalability and fault tolerance, channels and resource allocation, Block size, and Transaction arrival rate	Throughput, Latency, CPU Utilization	Doesn't explore how varying ordering service nodes or using different consensus algorithms impacts performance in Hyperledger Fabric
[13]	2018	197	HLF	Yes	Yes	Number of input, Number of chaincode, Number of peers, Number of channels	Latency, Throughput	Study to investigate the impact of multiple organizations, ordering services and number of transactions in the network
[16]	2019	242	HLF	Yes	Yes	Transaction rate, Simultaneous transactions, Number of transactions	Throughput, Latency	The study does not delve into how the varying number of peers, organizations, and nodes in ordering services influences performance metrics
[25]	2019	276	Raft consensus algorithm	Yes	No	Number of nodes, Packet loss rate, Election timeout, Number of elections	Network split time	Lack of detailed analysis of Raft's scalability in private blockchain networks with increasing node count
[17]	2020	62	HLF	Yes	No	Batch time out, Batch size, Number of endorsing peers	Network throughput, Transaction Latency	Performance evaluation is done on a considerably small network. The influence of increased transaction volume, concurrent transactions, and the number of orderers on the network performance needs to be considered
[18]	2020	49	HLF (measured with tool HLF-GLDB)	Yes	No	BlockSize, ValueSize, NumBlocks, NumWrite, NumRead, Compression, StateDBSize, Bloomfilter	Execution time, Transaction per second	Small key and single signature
[19]	2020	47	HLF	Yes	No	Transaction arrival rate, Endorsing timeout rate	Throughput, Mean transaction response time, Transaction rejection probability	An attack or hardware/software crash could cause peer breakdown
[26]	2020	230	Consensus Mechanism	Yes	No	DAG, PoS, PoW	Transaction per second, Confirmation delay, Confirmation failure probability, Average time to generate a new block	Imact of Network latency, network size on the performance of the consensus mechanisms need to be considered

work will involve evaluating HLF with various network structures. This will include analyzing the impact of different consensus mechanisms and the number of ordering service nodes on performance under varying workloads.

To assess the performance and scalability powers of HLF's newest version (v1.0), authors [13] have experimented with HLF on different workloads and analyzed its throughput and latency characteristics. Using a set of fabric-specific microbenchmarks, authors optimize various transaction and chaincode parameters and investigate their effect on transaction latencies. It is analyzed that for write, throughput scales nearly linearly up to a transaction rate of 1000 tx/sec. However, throughput drops significantly beyond this point, and transaction delays and latency experience a significant increase. At higher workloads, they discovered that reducing the number of necessary

endorsements (a chaincode parameter) can improve throughput and reduce latency. A stochastic reward net-based performance model for HLF v1.0+ is developed by the authors [14], and the efficacy of the model is assessed by measuring mean queue length, throughput, and utilization at each peer and pivotal processing stage within a peer Increasing block size can potentially alleviate ordering service and ledger write performance bottlenecks, but it can also introduce other trade-offs. If the transaction endorsement process is the main bottleneck for performance, parallelizing it can considerably decrease the length of the endorser queue and boost the maximum throughput of the system. While these studies provided valuable insights into performance, a key limitation remains the lack of a method to determine the optimal configuration settings for a specific use case.

Androulaki et al. [15] has investigated the impact of peer CPU, storage type (SSD versus RAM disc), and block size on blockchain throughput and latency in HLF v1.1. This study also demonstrates the system's scalability through the expansion of peer numbers. Moving forward, it is crucial to explore the utilization of benchmarks for performance optimization and evaluation and assess scalability with significantly expanded deployments. According to the paper [16], network workload has a significant impact on the performance of a blockchain in the context of scalability and latency. The findings depict that the chosen AWS EC2 instance can support up to 100,000 HLF platform participants. Shalaby et al. [17] evaluated the performance of HLF version 1.4 by examining the impact of various configurable parameters such as the number of endorsing peers, batch size, and batch timeout on network throughput and end-to-end transaction latency. Altering the batch timeout impacts both latency and throughput as the number of concurrent transactions rises. Setting the batch size to 45 transactions offers a balance between efficiency and latency. This size avoids reaching the maximum batch size before the timeout and allows all transactions to fit within a single block. However, as the number of parallel transactions within the block increases, latency tends to rise, while throughput conversely benefits. These findings have significant implications for improving blockchain performance.

The HLF-GLDB benchmark tool is developed to replicate database access in HLF. The findings illustrated in [18] show that data compression in GoLevelDB is a significant performance bottleneck in the HLF network and increased the network's overall performance by 54% by disabling data compression. Furthermore, the study discovered that database size affects performance, and it is recommended to combine smaller values to be represented by a single key to minimize database access overhead in chaincode. These findings are critical for improving the performance of HLF-based blockchain networks. To scrutinize the performance of the transaction process in HLF version 1.4, study [19] incorporated a hierarchical modeling approach based on block timeout constraints and endorsement; they created equations to estimate the system's performance. It used extensive simulations and numerical analyses to validate its model. The research is focused on two timeout constraints, which resulted in the development of a hierarchical model to describe the process of HLF transactions, beginning with the submission of transactions by clients and ending with the validation and commenting of transactions as a block is completed. The study also formulated formulas for platform throughput, mean transaction response delay, and transaction rejection probability.

In order to investigate the Fabric platform's transaction performance by examining the factors that have the most significant impact on overall overhead, the study [20] focuses on the impact of programming language and the number of endorser peers on transaction latency. Furthermore, the study compares the performance overhead of various chaincode implementations across Fabric's three programming languages: GO, Node.js, and Java. The tests are carried out with different node counts (1,2,4,6,8,10,12,14,16), and the findings show that GO outperforms the other two languages. The performance of two popular blockchain platforms, HLF and Ethereum, is compared under varying workloads [21]. The empirical findings disclose that HLF continually outperforms Ethereum throughout all evaluation metrics, including execution time, latency, and throughput.

The performance measurements of HLF version 2.0 are illustrated in the study [22] found a significant improvement in HLF version 2.0 compared to older versions of the blockchain framework. Adopting an approach that involves collecting measurement data from the system being studied to determine the pattern of resource utilization or degradation in performance that could be triggered by software aging is discussed in [23]. While this approach has been widely used in other contexts, there is limited research on the impact of software aging on blockchain platforms. Only one study has been reported in the literature, which analyzed the effects of software aging on a PoW blockchain network, specifically HLF.

2.2 Studies related to consensus

The performance complexity of distributed systems has made it difficult to fully comprehend the impact of ordering services, scalability, and bottlenecks on HLF. To address this issue, the authors [33]conducted a thorough evaluation of HLF's performance and examined traits of the execution, ordering, and validation phases. The evaluation

included a comparison of three different ordering services: Raft, Kafka, and Solo. The findings revealed that the execution phase demonstrated satisfactory scalability with the OR endorsement policy, whereas the AND endorsement policy did not perform satisfactorily. Interestingly, the authors found no substantial differences in the performance of Raft, Kafka, and Solo ordering services. However, the validation phase was noted as the probable bottleneck due to the slower speed of chaincode validation. The study has primarily concentrated on measuring the performance of consensus algorithms, neglecting to assess their resource consumption.

A novel method for evaluating the effectiveness of consensus algorithms on Ethereum and HLF private blockchain platforms is presented in the study [34]unfolds the impact of consensus techniques on the overall performance of the blockchain network by conducting a rigorous quantitative examination of important performance measures, such as latency and throughput. The results provide compelling evidence that the selection of a consensus algorithm can exert a significant constraint on a blockchain network's overall performance. Furthermore, the research demonstrates that the Practical Byzantine Fault Tolerance (PBFT) consensus algorithm consistently outperforms the Proof-of-Work (PoW) algorithm in terms of both speed and transaction processing capacity, even under diverse workloads. However, the study would benefit from further exploration of two key areas. Firstly, the impact of varying node counts within the network on these performance metrics for both platforms remains unaddressed. Secondly, the ability of these platforms to manage concurrent transactions, a crucial factor for real-world usability, is not evaluated.

An innovative approach that considers both Byzantine and network failures when evaluating the effectiveness of consensus algorithms and blockchain platforms in adversarial network conditions is presented in the study [35]. The strategy entails using stochastic modeling methods to examine how consensus algorithms behave under various ideal and unfavorable operational circumstances. After that, the effectiveness of several consensus mechanisms is tested in a blockchain application using chaos engineering techniques. Analyzing four permissioned blockchain platforms and their corresponding consensus mechanisms serves as an example of the suggested technique.

The performance metric for evaluating the effectiveness of various consensus protocols, including proof-of-activity (PoA), PoS, DPoS, and PoW based on multiple parameters such as scalability, fault-tolerance rate, latency, and degree of decentralization in the study [36] indicates that PoA and PoW protocols have low degrees of decentralization and scalability, respectively. Additionally, DPoS exhibits the highest throughput, while PoW has the highest latency and average block time. Furthermore, the study suggests that the proof-of-authority protocol is the most effective in mitigating the risk of 51% attacks compared to the other protocols. The performance of the most widely used consensus algorithm, Raft, in networks experiencing a significant packet loss rate is investigated in the study [25]. The study proposes an analytical model that accurately calculates the probability of a distributed network split occurring. The model considers the election timeout period, packet loss rate, and network size as inputs to calculate the split probability at any given time. A Raft simulator is executed to confirm the model's accuracy and demonstrate that the analytical and simulation results match. This model makes it possible to theoretically predict network split probability and optimize the parameters within the Raft consensus algorithm.

The findings of the performance evaluation of three prominent consensus mechanisms in blockchain technology - PoS, DAG, and PoW based on several metrics, such as the average time required for generating a new block, confirmation failure probability, confirmation delay, and TPS in [26] demonstrate that the consensus agreement mechanism is influenced by both network load conditions and network resources (buffer size, computation power, coin age). Moreover, the study findings reveal that PoS and PoW are more responsive to changes in network resources, whereas DAG is susceptible to variations in network load conditions.

2.3 Studies related to other blockchain platforms

HLF and Ethereum are widely acknowledged blockchain platforms that have gained significant adoption within the industry. To compare the performance of these two platforms, a study [21] conducts performance evaluation in varying workload environments and reveals that HLF consistently surpasses Ethereum in the context of throughput, latency, and execution time. Although both platforms have made progress, they still fall short of current database systems when it comes to handling high workloads. However, Ethereum is capable of handling more concurrent transactions than HLF with similar computational resources.

A comprehensive experimental analysis of Hyperledger Besu in a private blockchain setting showcases the platform's performance traits from an application viewpoint, specifically in terms of scalability, resource utilization, latency, and transaction throughput. To achieve this, the study [31] adds a load balancer middleware and investigates three proof-of-authority consensus algorithms such as QBFT, Clique, and IBFT 2.0. The evaluation is carried out using the Hyperledger Caliper benchmark tool. The

findings reveal several key insights, including the significant impact of blockchain parameters like block time and block size on Besu performance, the bottlenecking effect of transaction execution and blockchain state updates, and the scalability potential of Besu networks with QBFT consensus, which can be increased up to fourteen validators without any evident decrease in performance.

The performance of two key components in HLF blockchain systems: modular functions and state databases, is evaluated using a range of configurations and workloads to assess the impact of different combinations of modular functions and state databases on system performance, and it has been observed from the study [32], that the performance of the state database is closely correlated with read-type transactions in HLF blockchain systems, while it has little to no impact on write-type transactions. This suggests that the choice of state database should be carefully considered, especially for applications that involve a high volume of read-type transactions.

In comparison to existing studies, our research offers a deeper understanding by focusing on a specific platform, Hyperledger Fabric. This research conducts an exhaustive exploration of the platform's performance characteristics under a variety of operational configurations Table 1. Our work investigates the influence of key factors on scalability and throughput, including transaction volume, ordering service, the number of participating organizations, and the programming language employed for smart contract development Table 2. This work focuses on Hyperledger Fabric. An in-depth examination of various factors provides valuable and actionable insights for optimizing its use in real-world deployments, addressing a gap in existing research primarily focused on broader architectural frameworks.

3 Tools and techniques

HLF offers a broad range of customizable features and potential applications for developers to establish a bespoke blockchain business network comprising heterogeneous clients with distinct roles assigned to them. Additionally, it facilitates the creation, deployment, and execution of chaincodes/smart contracts on the platform. The methodology adopted to conduct the experiment is shown below in Fig. 3.

To assess and quantify the effectiveness of the HLF platform, the utilization of Hyperledger Caliper is implemented (Fig. 4), which can produce a performance report tailored to specific use cases.

3.1 Hyperledger fabric

Hyperledger is a collaborative open-source project that originated from the Linux Foundation, intending to promote the development of blockchain technology across various industries. It involves the participation of leaders from different sectors worldwide, and its goal is to advance the application of blockchain collaboratively and innovatively. An open-source business application offers significant benefits, including a great deal of flexibility due to the availability of open-source code, modular components, and adherence to industry standards. This permits organizations to customize the technology to meet their special necessities and achieve maximum usability with minimal effort. HLF is a blockchain project under the Hyperledger umbrella that utilizes smart contracts and ledger to enable transaction management among participants. However, it differs from other blockchain systems in that it is permissioned and private. On the contrary, to open permissionless systems that allow unknown entities to join the network, HLF requires participants to conscript through an entrusted Membership Service Provider (MSP) to ensure the network's security. This means that it does not rely on protocols like "PoW" to validate transactions and maintain network integrity. To ensure transaction privacy within the HLF network, a system called a channel is utilized to isolate transactions and restrict access only to authorized nodes within that specific channel. The various roles concerned with the flow of transactions within a channel are described below.

3.1.1 Peer

Peers are a crucial component of the HLF network as they serve as hosts for ledger and chaincode instances. In blockchain technology, specifically on the Hyperledger Fabric platform, a chaincode refers to a smart contract. It's a small program that runs on the blockchain network and dictates the rules for transactions. These programs are written in languages like Go, Java, or Node.js and manage the data stored on the blockchain. Essentially, they automate and enforce agreements between different parties involved in a blockchain transaction. Essentially, chaincode acts as the business logic layer of a blockchain application, specifying how assets can be created, transferred, and updated on the ledger. Each peer has the capability to install multiple chaincodes and ledgers. While each peer doesn't need to install chaincode, peers can communicate with one another through the gossip protocol to update and modify the latest state of the ledger. This allows for efficient and decentralized communication among peers within the network. The organization peers

Table 2 Configurable parameter for HLF performance analysis

Examination	Parameters	Transaction rate (TPS)	Number of transactions (TXNs)
Impact of transaction rate TPS	Varying TPS and keeping TXNs constant	25,50,75,100,125,150,175,200,225,250,275,300,325,350	1000
Impact of TXNs (number of transactions)	Varying TXNs and keeping TPS constant	200	10, 100, 1000, 10,000, 100,000
Impact of ordering service	Varying TPS and keeping TXNs constant	25,50,75,100,125,150,175,200,225,250,275,300,325,350	1000
	Varying TXNs and keeping TPS constant	200	10, 100, 1000, 10,000, 100,000
Impact of programming language	Chaincode written in Go language also keeping TPS constant while varying TXNs	200	10, 100, 1000, 10,000, 100,000
	Chaincode written in Go language also keeping TXNs constant while varying TPS	50, 100, 150, 200, 250, 300,350	1000
	Chaincode written in Node.js also keeping TPS constant while varying TXNs	200	10, 100, 1000, 10,000, 100,000
	Chaincode written in Node.js also keeping TXNs constant while varying TPS	50, 100, 150, 200, 250, 300,350	1000
Impact of multiple organizations	Increased number of organizations with varied TPS and constant TXNs	25,50,75,100,125,150,175,200,225,250,275,300,325,350	1000
	Increased number of organizations with constant TPS and varied TXNs	200	10, 100, 1000, 10,000, 100,000

within the HLF network can be categorized into several types: leader, anchor, committing, and endorsing peers. Each peer is assigned specific behaviors and operations to carry out within the network. The role of a leader peer node is crucial in the network because it receives newly generated blocks from the orderer and distributes them to other peers through the gossip protocol. On the other hand, anchor peers are known to other organizations within the network, allowing them to communicate with each other using the gossip protocol. Endorsing peers are responsible for endorsing transactions that are sent to them by the ordering services. These peers play a vital role in validating the transactions before they are committed to the ledger. In contrast, committing peers do not execute transactions but receive the transactions from the orderer and commit those transactions to their local copy of the ledger. This ensures that the network maintains a consistent and accurate record of all transactions.

3.1.2 Orderer

The HLF network relies on the orderer to pack the transactions into blocks and send them to anchor peers across the network. The flow of transactions within the network consists of three distinct stages: The proposal stage, the packaging stage, and the validation stage. Although the orderer is primarily responsible for the packaging step, it also contributes to the validation step by sharing new blocks with the network. By doing so, the orderer ensures that the network maintains a precise and current ledger of all transactions. In the HLF network, the orderers package transactions into blocks and send them across the network and play a vital role in enforcing basic access control for channels. They control who has the authority to read and write data to the channels and configure them. It is important to note that the ability to modify configuration elements within a channel is subject to policies established by the relevant administrators during the creation of the consortium or the channel. By enforcing access control and adhering to established policies, orderers ensure that the network operates in a secure and efficient manner. The Fabric 2.0 version recommends the utilization of Raft ordering services, which have replaced the previously deprecated Kafka ordering services.

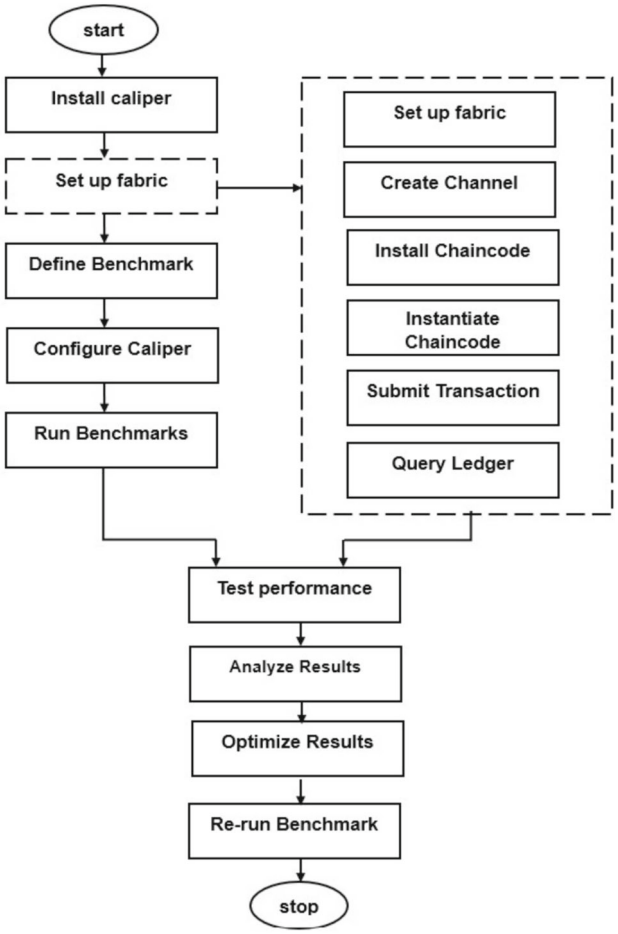

Fig. 3 Methodology employed in the experiment

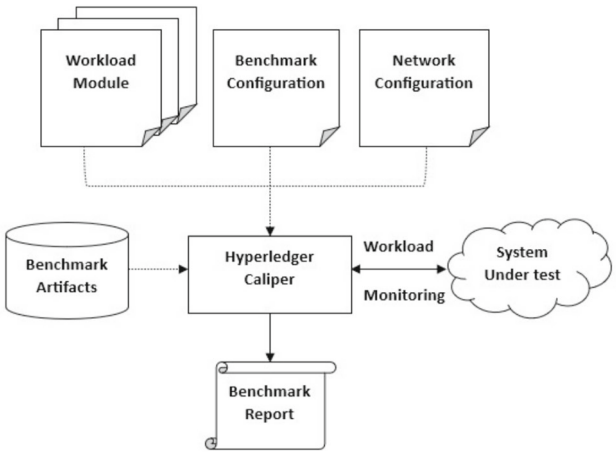

Fig. 4 Implementation of caliper for executing benchmark

3.1.3 Organization

An organization in HLF refers to a group of peers that work together towards a common goal in conducting business. These peers can be made up of one or more members who collaborate to maintain and operate the network. Each organization has its own MSP which oversees the identity and access control of its members. By dividing the network into separate organizations, HLF allows participants to transact and collaborate securely while still retaining control over their own data and operations.

3.1.4 Failed transactions

Blockchain transactions may get rejected or fail to be processed due to a variety of factors, including errors in syntax, errors in achieving consensus among nodes, and errors arising from the version of the blockchain software being employed. The consensus errors in blockchain occur when there is a dispute between the nodes in the network about the validity of a transaction. This can transpire due to various reasons, such as a network partition or a malicious node trying to manipulate the consensus [37]. In the case of HLF, validation logic errors can occur when the transaction's validation system endorsement policy is not satisfied and the peer nodes cannot reach a consensus on the validity of the transaction. This endorsement policy is defined by the chaincode and specifies the number of required endorsements, the identities of the endorsing peers, and the criteria for successful endorsement. If the policy is not realized, the transaction is not endorsed and will be rejected. For instance, in HLF, the endorsement policy specifies the required amount of signatures from endorsing peers who must agree that the transaction is valid. If the endorsement policy is not met, the transaction is deemed invalid and is rejected by the system. The policy ensures that transactions completed on the blockchain are valid and fulfill the network's predetermined requirements. Our experiment observed transaction failures related to endorsement policy, conflicts, and timeout. There are various reasons outlined for transactions to fail in the HLF blockchain, some of which are described below:

Insufficient Endorsement: Before a transaction can be added to the ledger, it needs endorsement from a certain number of peers, and not meeting the requirement of a specified number of endorsements leads to transaction failure.

Inadequate Resources: Due to the lack of resources available, such as processing power and network bandwidth, transactions may fail in HLF since it depends on the network of peers to validate transactions.

Versioning Conflict: Multiple versions of smart contract/chaincode deployment on the network are allowed by the HLF blockchain, but if the transaction submitted to the smart contract is not compatible with the network's version, then the transaction leads to failure.

Transaction Validation Failure: If the validation mechanism in the HLF smart contract is poorly described,

a validation fault results in transaction failure and unsuccessful transaction validation.

Network Congestion: Hyperledger blockchain network communicates in a peer-to-peer manner to reach consensus, and if the network is congested or encounters latency issues, the transaction in the network fails too.

3.2 Performance and scalability

Analyzing the performance of blockchain platforms is pressing in providing the guarantee to the users that it can help in delivering the required quality of service and meet the demands of its deliberated use cases. The user can distinguish limitations and bottlenecks in the scalability and performance of the system through performance analysis. The performance analysis can serve in optimizing the resource utilization of the system, such as network bandwidth, CPU, and storage, in order to enhance the overall efficiency [38]. Furthermore, performance analysis can assist in determining the possible security concerns as well as ensuring the system can manage high transaction volume without jeopardizing its integrity and security. This research aims to establish a framework for evaluating the performance of blockchain technology. The evaluation will encompass key metrics such as success rate, throughput, latency, and resource consumption (CPU and memory). The scalability of the HLF can be evaluated with the varying workloads, number of transactions, organization, and ordering services. Scalability aims to increase the network's capacity to process significant transactions without compromising its security and decentralized structure.

3.2.1 Throughput

Throughput under the frame of blockchain depicts the number of transactions that are successfully processed by the network within a specific time frame, typically measured in seconds. The throughput performance metric indicates the speed and efficiency of the blockchain network in processing transactions. Read throughput is a way to evaluate performance that measures how many successful read operations occur during a certain timeframe. The metric is typically expressed as reads per second and provides a specific count of completed read operations within the given interval [37].

Read Throughput = Total read operations / Total time in seconds

Transaction throughput is a measure of the speed at which valid transactions are confirmed and added to the blockchain during a specific timeframe, typically expressed as TPS. This performance metric evaluates the overall network's efficiency, taking into account all nodes rather than just a single node.

Transaction Throughput= Total valid committed transactions / Total time in seconds

By increasing the throughput, the network can manage more transactions, thereby improving the entire efficiency and scalability of the blockchain network.

3.2.2 Latency

The latency of a transaction is calculated by finding the difference between the time taken to complete the transaction and the time taken to deploy it. Latency is divided into two categories [37], transaction latency and read latency. Read latency is determined as the time between the response of the request and the submission of the read request.

Read Latency = Reply received time - Request submission time

On the other hand, the amount of time needed for a transaction to become available throughout the entire network is stated as transaction latency. This period encompasses the interval from the moment the transaction is first submitted and ends up being widely accessible on the network.

$$Transaction\ \ Latency = confirmation\ \ time \times network\ threshold - transaction\ \ submission\ \ time$$

The average latency measured in our work states the mean latency of all the transactions in a given data set.

3.2.3 Resource Consumption

During the test execution, transactions utilize the resources such as CPU, cache memory, disk, and RAM. Extreme consumption of these resources, e.g., disks, can induce a significant impact on the systems' performance [23]. The Resource Monitor allows initiation/termination of monitoring and obtaining information about the resource usage of the underlying blockchain system, such as network I/O, memory, CPU, and so on. The Docker resource monitor provides access to several performance metrics, including maximum and average memory usage, maximum and average CPU usage as a percentage, inbound and outbound network traffic, disk read operations, and disk write operations. This information can be used to monitor and manage the resource consumption of Docker containers, allowing for efficient use of system resources and improved performance.

In network I/O, traffic in and traffic out refer to the amount of data that is being received by a peer or orderer node (traffic in) and the amount of data that is being sent out from the node to other network participants (traffic out). The figures depicting the data on network input/output

(I/O) traffic, measured in megabytes (MB), are denoted in Fig. 5. The evaluation is performed with varying numbers of peers and transaction rates while keeping the transaction volume constant at 1,000 transactions. The resultant graph reveals a notable trend that there is a demonstrable rise in average inbound traffic as the number of peers within the network increases. High Traffic In and Traffic Out indicate significant data transfer between the client and the blockchain network. This can help assess the network's capacity to handle data volume. Comparing Traffic In and Traffic Out for different workloads can reveal which scenarios generate more data transfer. This aids in understanding the impact of various use cases on the network.

Several use cases are outlined by varying the key parameters, such as transaction rate and number of transactions, in order to perform the test on the Hyperledger Caliper. These use cases enable assessment of the system's performance and functionality under different situations and conditions, which can help identify potential bottlenecks and improve system efficiency.

3.2.4 Success rate

The success rate of a blockchain can be measured by evaluating the ratio of successfully executed transactions to the total number of transactions attempted. Successful transactions refer to those transactions that are completed without encountering any errors or exceptions during their execution.

4 Experimental results and analysis

The subsequent section demonstrates the different configurable parameters cataloged in Table 2 along with the experimental setup specified in Table 3 to conduct the evaluation. The experiment involves utilizing a personal computer equipped with advanced hardware specifications, including an AMD Ryzen 5 5500U processor with Radeon Graphics, 16GB of RAM, and a 512GB SSD, running the Ubuntu operating system version 22.04 LTS. The performance of the HLF version 2.4.9 platform is assessed through rigorous testing using the Hyperledger Caliper tool [39], including versions v0.5.0. The impact of varying the transaction rate (rateControl), varying the number of transactions, the programming language adopted to write the smart contract, and the number of organizations on the blockchain's performance. A simple money transfer chaincode that incorporates the function open() and query() is employed in the experiment. With the use of the open function, a new account is generated and initialized with the specified amount of money.

The query function retrieves the amount of money in a given account. It has been observed that the complexity of the chaincode used to execute transactions can also impact performance. More complex chaincode can require more processing power, leading to slower transaction processing times. As established earlier, this study involves varying parameters such as transaction rate, with rates ranging from 25TPS to 350TPS while keeping the number of transactions fixed at 1000. Additionally, the number of transactions is varied while keeping the transaction rate fixed to observe the significant changes in throughput and latency, the resource consumption of the various components, and identify potential areas for optimization in the system. By varying these parameters and observing the resulting changes in performance, this study aims to obtain a more exhaustive understanding of the behavior of the system under different scenarios and conditions.

The performance of a blockchain is not only affected by transaction rate and number but also by the number of peers, orderers, and organizations. In this study, the number of organizations is varied from one to three with the focus on observing the impact on the performance of the

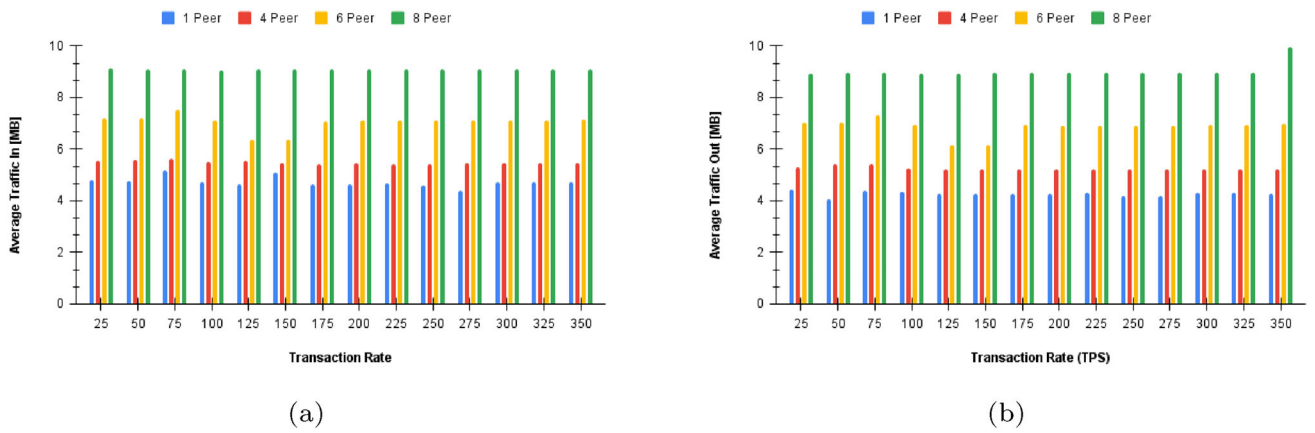

Fig. 5 Graphical representation of resource monitor of traffic in [MB] and traffic out [MB] with multiple peers

Table 3 Experimental setup and configuration for hyperledger fabric performance evaluation

Component	Description	Parameters
Platform	Hyperledger Fabric	v2.4.9
Number of Organizations	The number of independent organizations participating in the network	1, 2, 3
Database	State Database	CouchDB
Channel	Private communication pathway	Single private channel
Number of Ordering Service	The number of nodes participating in the ordering service (Solo, Raft)	1, 3, 5 orderer
Chaincode Implementation	The programming language used to develop the chaincode (smart contract)	GO, Node.js
Transaction Type	The type of transaction being executed	Open, Query
Transaction Rate	The number of transactions submitted per second to the network	25 TPS, 50 TPS, 75 TPS, 100 TPS, 125 TPS, 150 TPS, 175 TPS, 200 TPS, 225 TPS, 250 TPS, 275 TPS, 300 TPS, 325 TPS,350 TPS
Number of Transactions	The number of transactions submitted	10, 100, 1000, 10,000, 100,000

blockchain. The experiment employs a multi-round test case where the transaction rate is progressively increased in each round. Furthermore, each new round has a higher transaction rate than the previous round. We have conducted each experiment at least 20 times for each defined parameter.

4.1 Impact of transaction rate on latency and throughput

Figure 6a illustrates the throughput and average latency for 1 organization with 1 peer and single orderer over different transaction rates, and Fig. 6b illustrates the throughput and average latency for 2 organizations with 2 peers (1 peer per organization) and single orderer over different transaction rates as well.

4.1.1 Observation

As mentioned previously, the chaincode deployed in the Fabric network is related to a simple money transfer between the accounts and has the function open and query. Throughput is evaluated by varying transaction rates with each round, starting from 25 transactions per second (TPS) and increasing by 25 TPS in each subsequent round until reaching 350 TPS. From Fig. 6 (a), it can be noticed that for open( ), transaction rate ranging from 25 TPS to 150 TPS, there is a linear growth in throughput, and the throughput delivered is 25 TPS, 49.9 TPS, 74.5 TPS, 99.7 TPS, 105.7 TPS, and 119.6 TPS respectively. However, After the transaction rate of 150 TPS, throughput started to decrease as the transaction rate increased. This suggests that the system may encounter bottlenecks as the load increases beyond a certain point. Based on the result, it can

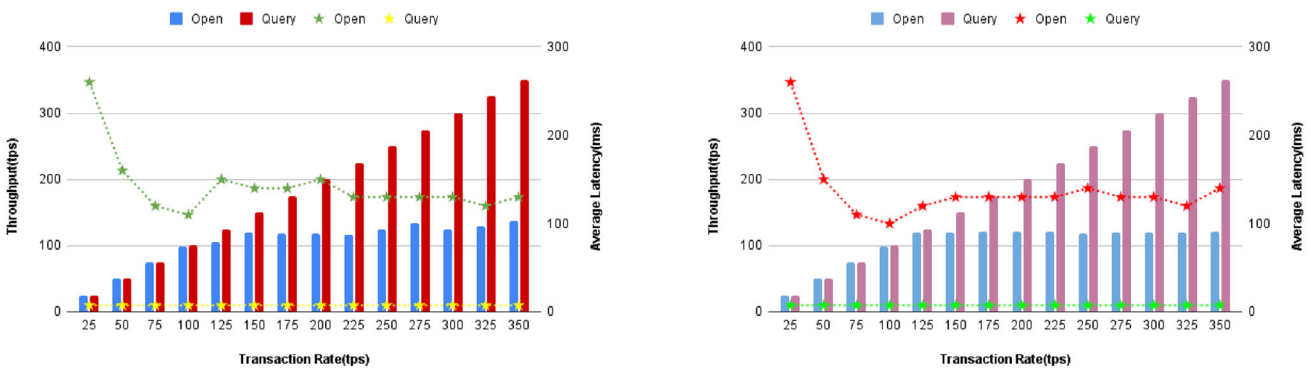

Fig. 6 Impact of transaction rate on latency and throughput (**a**) 1 organization 1 peer and (**b**) 2 organizations 2 peers

be inferred that the test environment used in the study is capable of handling open() transactions up to a rate of 150 transactions per second (TPS). At a transaction rate of 25 TPS, the average transaction latency is higher than rates ranging from 50 TPS to 350 TPS. Specifically, the average latency at a rate of 25 TPS is around 0.26 s or 260 milliseconds.

According to the results presented for our test environment, the average latency of transactions is at its minimum when the transaction rate is 100 TPS, with an average latency of 110 milliseconds or 0.11 s. After the transaction rate of 225 TPS, the average latency varies between 130 ms to 120 ms. This indicates that the system is effective when handling transactions at a 100 TPS rate and that increasing or decreasing the transaction rate may result in higher latencies and can impact performance. Likewise in Fig. 6b, for open (), it can be seen that from transaction rate 25 TPS to 200 TPS, there is an increase in throughput (TPS) as compared to (a). Moreover, the average latency is relatively low in Fig. 6b until the transaction rate of 175 TPS is reached, after which there is some variation in the average latency between 130 ms to 140 ms respectively. It has been observed that in this test environment either one or two organizations, the query type transaction can be executed at a rate of 350 transactions per second (TPS) without experiencing any significant delays.

4.2 Number of transactions' impact on latency and throughput

Figure 7 demonstrates the impact on throughput and average latency by varying the number of transactions over a fixed transaction rate. The broad array of transactions 10,100,1000,10,000,100,000 are submitted to the blockchain at the fixed rate of 200 TPS. Figure 7a illustrates the impact on throughput and latency for 1 organization with 1 peer and (b) depicts the impact for 2 organizations with 2 peers (1 peer per organization) by varying the workload.

4.2.1 Observation

Figures 7a and 6b evaluate the influence of the number of transactions on average latency and throughput. For open(), 10 transactions are sent at the rate of 200 TPS (as shown in Fig. 7a), the observed throughput is 46.5 TPS, and the average latency is high, measuring 180 ms or 0.18 s. Similarly, in Fig. 7b, throughput is observed to be 39.4 TPS, and the average latency is 210 ms or 0.21 sec. In addition, the throughput for 100, 1000, 10,000, and 100,000 transactions for 1 organization and 2 organizations are 110.7, 117.5, 134.3, 135 and 111.2, 121.8, 135.5, and 135.2 TPS, respectively. Figure 7a and b illustrate the impact on latency and throughput when 10 transactions are sent at a rate of 200 TPS in query type transaction, and the observed latency in both cases is 0.02 sec, which is slightly higher than the average latency observed for 100, 1000, 10,000, and 100,000 transactions. This indicates that the blockchain system's performance is impacted by the number of transactions being processed. It has been observed that up to 100,000 transactions are supported by this system depending on the function (open, query) with very minimal latency.

4.3 Impact of ordering service on latency and throughput

The Figures presented demonstrate the impact of ordering services on average latency and throughput. Figure 8 (a) illustrates the impact on throughput by employing the Raft ordering service in the 1 organization 1peer, while Fig. 8b illustrates the same for the 2 organizations 2 peers scenario. Graphical representations Fig. 8c–e showcase the variation in throughput and latency exerting the Solo ordering service in 1 organization 1 peer (case 1), 2 organization 2peer (case 2), and Raft ordering service in 1 organization 1peer (case 1) and 2 organization 2peer (case 2).

4.3.1 Observation

It can be observed from Fig. 8a for open() that there is a linear growth in throughput with the varying range of transaction rate from 25 TPS to 150 TPS and again shows a rise in throughput can be seen at 200 TPS. On the other hand, the observed average latency in the same scenario is higher at 25 TPS and 50 TPS as compared to the transaction rate ranging from 175 TPS to 350 TPS. In contrast to the results shown in Fig. 8a, the average latency observed for transaction rates ranging from 75 TPS to 350 TPS is between 0.12 s to 0.11 s, indicating a lower latency compared to the results obtained in (b). The (c), (d), and (e) figures describe the impact on throughput and latency by employing Solo and Raft ordering services. It can be observed that the Raft ordering service handles up to 100,000 transactions very effectively with minimum delay. The results obtained from our test environment show that the Raft ordering service performs effectively in the context of increased throughput and less latency as compared to the Solo ordering service in both cases i.e. with varying transaction rates and varying numbers of transactions.

4.4 Impact of programming language on latency and throughput

In the HLF blockchain, a chaincode is a program or a smart contract that establishes the business logic and rules governing the interactions between participants in a blockchain

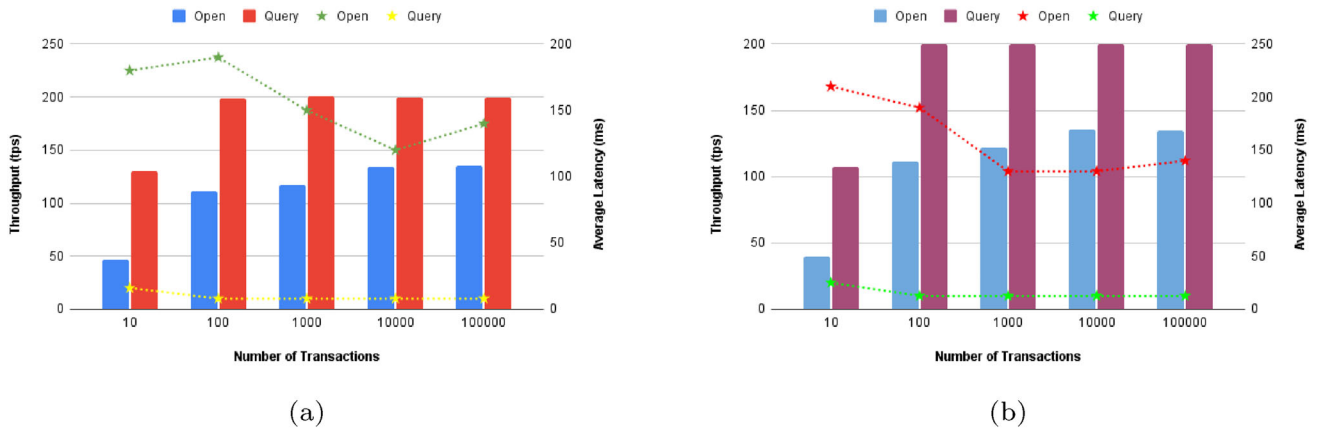

Fig. 7 Number of transactions impacting the performance from the perspective of latency and throughput (**a**) 1 organization 1 peer (**b**) 2 organization 2 peers

network. Chaincode is deployed on a specific channel of a blockchain network and is utilized to read and write the state of the ledger. Chaincode in the HLF blockchain can be written in Node.js or Go language. The chaincode employed in this study is written in Go language and Node.js and evaluated to see the impact on latency and throughput under different transaction rates (Fig. 9a, b) and the number of transactions (Fig. 9c, d).

4.4.1 Observation

Figure 9a depicts the performance of a smart contract written in the Go language while (b) shows the performance of a smart contract written in Node.js. In Fig. 9a, b, for open() type transactions, there is a linear growth in throughput as the transaction rate increases from 25 TPS up to 200 TPS implying that the system is capable of efficiently processing transactions up to a rate of 200 TPS. According to the results, the chaincode developed in the Go language outperforms the one developed in Node.js in the context of throughput and average latency, however, the difference is not very significant. The Go language-based chaincode shows slightly lower latency and higher throughput compared to the Node.js-based chaincode. Go language is considered more efficient for chaincode development in HLF due to its static typing, compiled nature, and optimized runtime performance. Node.js, on the other hand, is dynamically typed and interpreted, which may result in lower performance and scalability for complex chaincode applications.

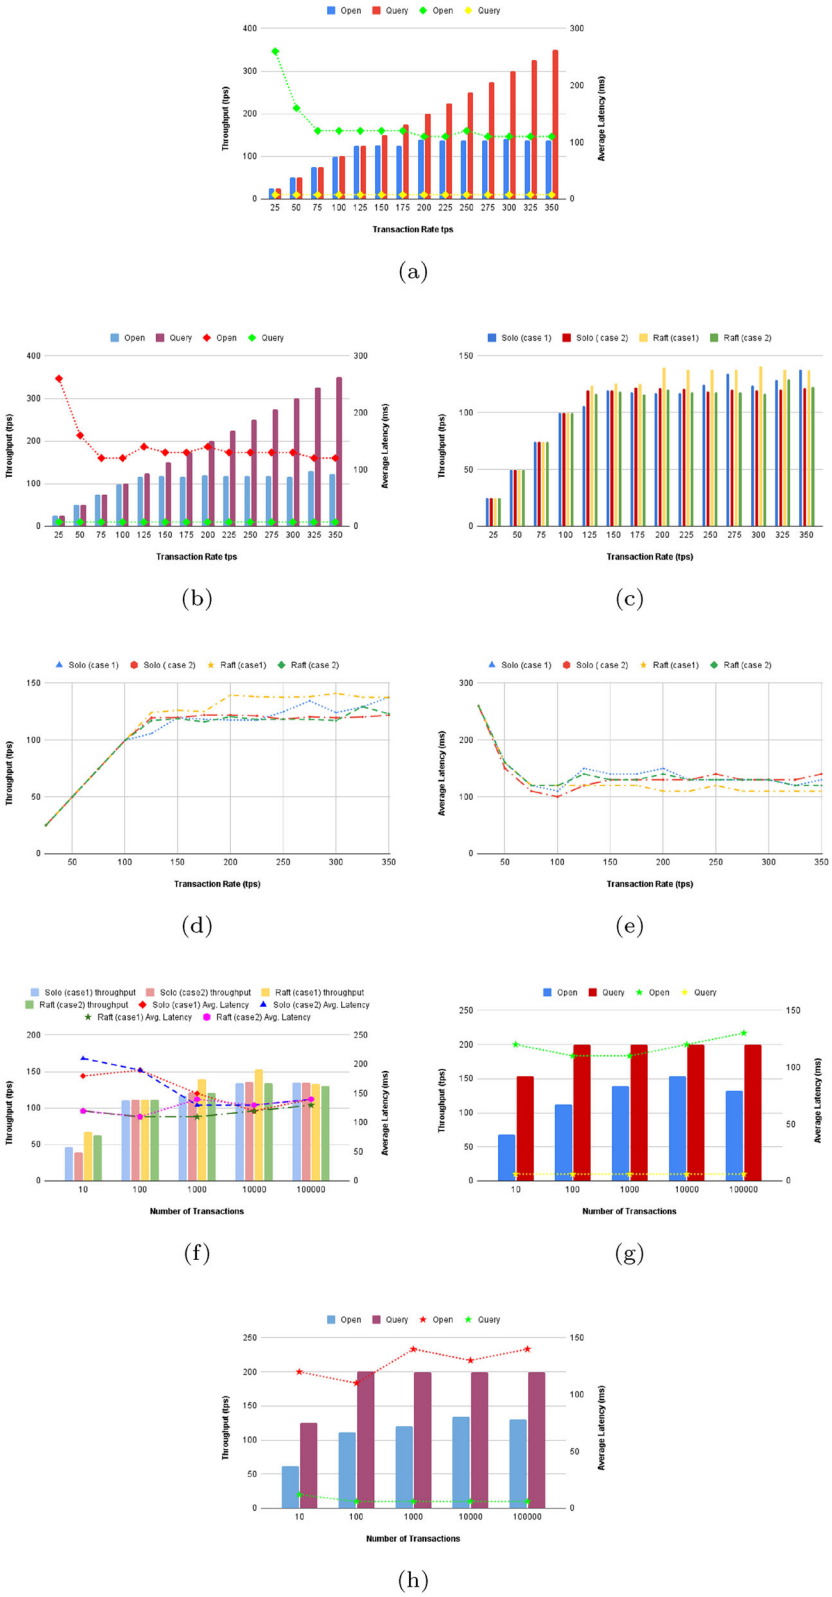
4.5 Impact of multiple organizations on Latency and Throughput

In this experiment, 3 organizations with one peer in every organization are observed in terms of throughput and latency. Figure 10a and b depict the variation in throughput and latency as the number of organizations increases. Additionally, Fig. 10c and d present the findings with respect to throughput and latency for different numbers of transactions across multiple organizations. Figure 10a and c employ Solo ordering services, while Fig. 10b and d employ Raft ordering services.

4.5.1 Observation

Graphs illustrate that the inclusion of a third organization results in linear growth in throughput for transaction rates ranging from 25 to 175 TPS and is also able to handle 100,000 transactions with a small delay. The results show that the inclusion of a third organization has led to a decrease in throughput compared to the scenarios with a single organization and two organizations. Additionally, after reaching 175 TPS, there is no significant change in the throughput observed. Figure 10a, b, and d show an increase in the average latency, indicating that the inclusion of a third organization in the network results in higher latency. It can be implied from the results that adding more organizations to a network, can potentially result in increased complexity and communication overhead, which may negatively impact the network's performance in terms of latency and throughput.

When evaluating the performance of a blockchain network using the success rate as a measure, notable findings indicate that both the open and query operations have consistently achieved a 100% success rate across all evaluation parameters. This indicates that the permissioned blockchain, under analysis, has consistently executed both open() and query() without encountering any failures or errors.Based on the observations from Fig. 11, it has been noticed that the CPU resource utilization during the execution of different workloads shows that in case 1(Using



Solo ordering service with 1 organization and 1 peer), case 2 (Using Raft ordering service with 1 organization and 1 peer), case 3(Using Solo ordering service with 2 organization with 1 peer per organization), and case 4 (using Raft ordering service with 2 organizations with 1 peer per organization), as well as case 5 (using the Go

Fig. 8 Impact of ordering service on throughput and average latency

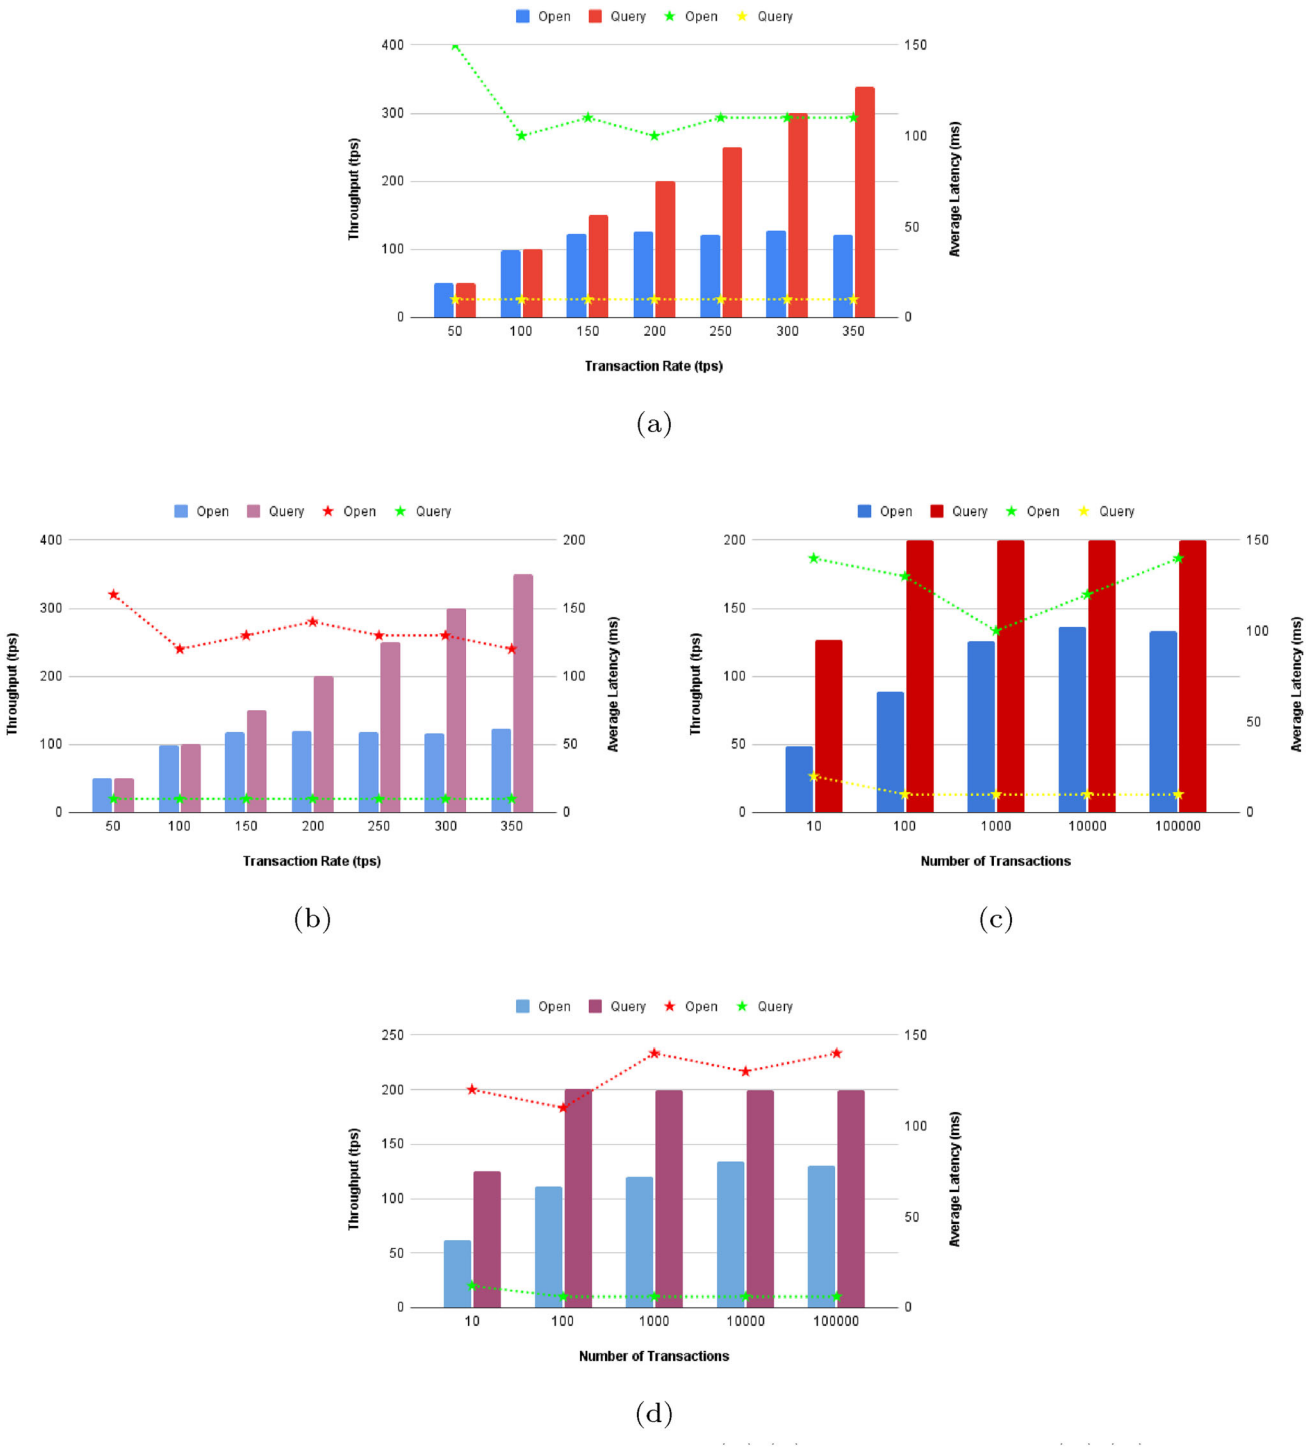


Fig. 9 Chaincode written in go language (**a**, **c**) and Node.js (**b**, **d**) to evaluate latency and throughput experienced under different transaction rate and the number of transactions

language to write chaincode), and case 6 and case 7 (using 3 organizations with 1 peer per organization), the CPU usage remains below 50%. In simpler terms, the CPU usage for these scenarios, including various configurations and setups, is relatively low and does not exceed half of the available processing power. This indicates that the executed workloads do not heavily strain the CPU resources, suggesting that the system has ample capacity to handle the workload without reaching its maximum processing capability.

HLF is a widely adopted and compelling choice for blockchain-based applications due to its modular

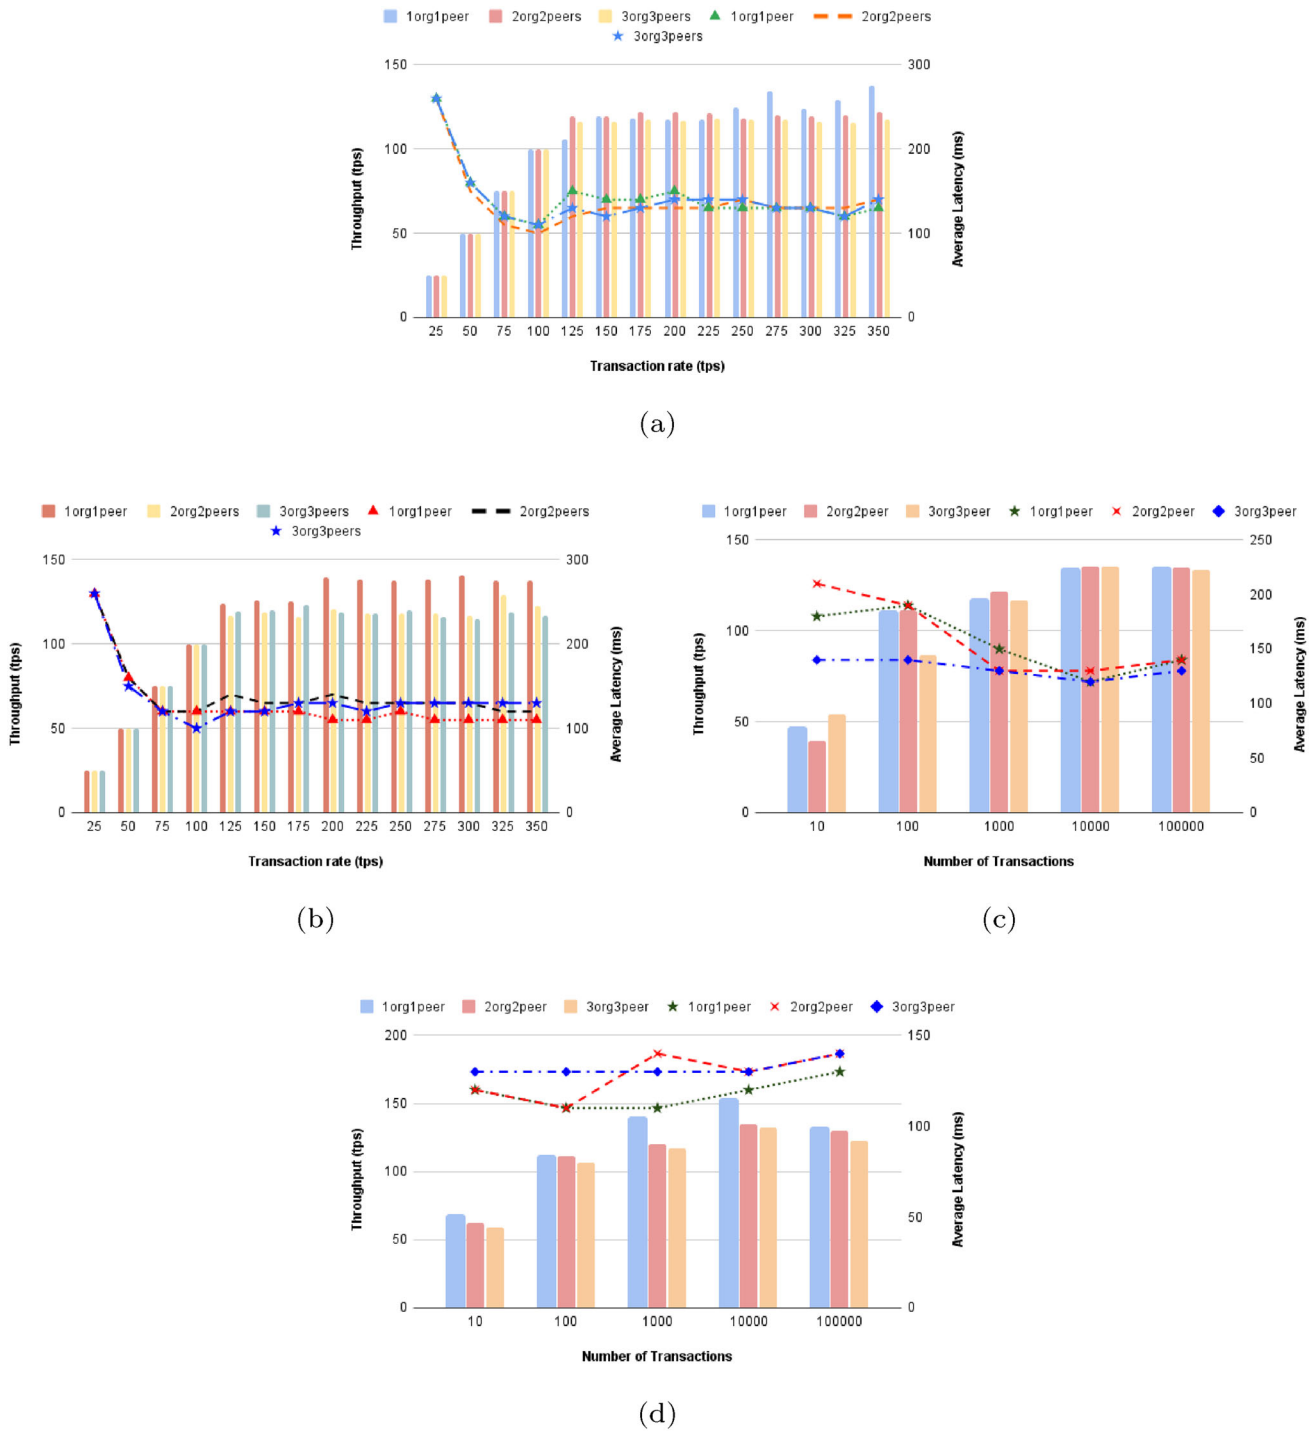

Fig. 10 Impact of the increased number of organizations on latency and throughput experienced under different transaction rates and the number of transactions

architecture, support for confidential transactions, and scalability features. HLF has its shortcomings. Hyperledger Fabric uses Optimistic Concurrency Control (OCC), which means it simulates transactions on individual peers before endorsement. This can lead to failures if multiple transactions try to modify the same data concurrently. Also, some failures that occur due to invalid signatures, mismatched world states, or policy misconfigurations can hinder successful transactions. In our study, we noticed instances of transaction failure, including occurrences such as MVCC_READ_CONFLICT, ENDORSEMENT_POLICY_FAILURE, and the timeout expired.

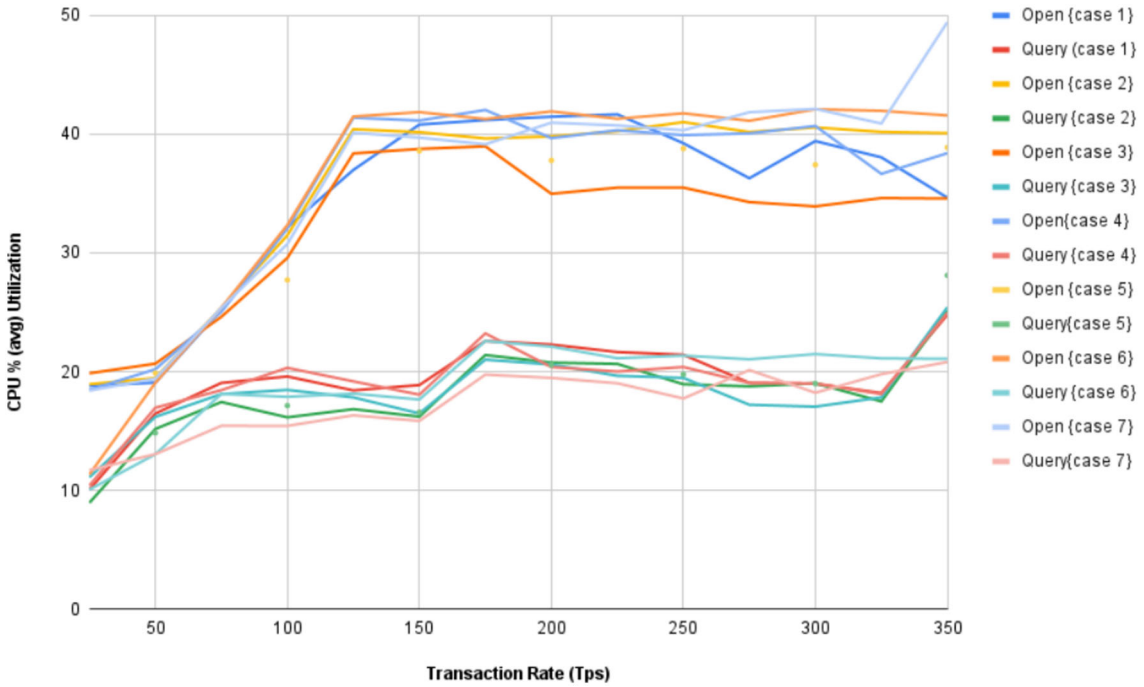

Fig. 11 CPU% average utilization in executing open() and query() in a varied number of transaction rates for different numbers of organization and ordering services

The read-write conflict arises when multiple transactions try to modify the same data concurrently. Let Txn_i and Txn_j be transactions, and their respective read sets and write sets after endorsement simulation are represented as $Read(Txn_i)$: Read a set of transaction Txn_i. $Write(Txn_i)$: Write set of transaction Txn_i. Assuming Txn_i is ordered before Txn_j within the same block (i.e., Txn_i is confirmed before Txn_j), then Txn_j is considered a conflicting transaction and will be marked invalid during validation if any of the read-write conflict or write-write conflict conditions hold. HLF utilizes the Multi-Version Concurrency Control (MVCC) mechanism to manage the consistency of records. This involves tracking changes to a record's version through a structured format consisting of key-value pairs along with corresponding version information, e.g., key: Value, version.

As shown in Fig. 12, when the first transaction reaches the validation stage, MVCC detects a mismatch. The version of the key it read earlier doesn't match the current version (due to the second transaction's modification). This mismatch triggers the MVCC_READ_CONFLICT error. In HLF, transactions require endorsement from peers before being committed. The endorsement policy defines which organizations or specific peers must endorse the transaction for it to be valid. There could be various reasons for the endorsement policy failure, such as missing endorsement, incorrect chaincode implementation, and read-write set mismatches, as concurrent writes can cause version inconsistencies leading to endorsement failure. To resolve these failures, it needs to ensure that the policy aligns with the transaction's participants, utilize Caliper's features to verify endorsement targets, and examine chaincode logs for errors.

5 Discussion

By fostering trust in a decentralized environment, blockchain technology underpins its core functionalities, including robust security, data privacy, scalability, and efficient performance. In private deployments, Hyperledger Fabric frequently surpasses Ethereum (Private Deployment) and Besu (Ethereum's Client) when it comes to

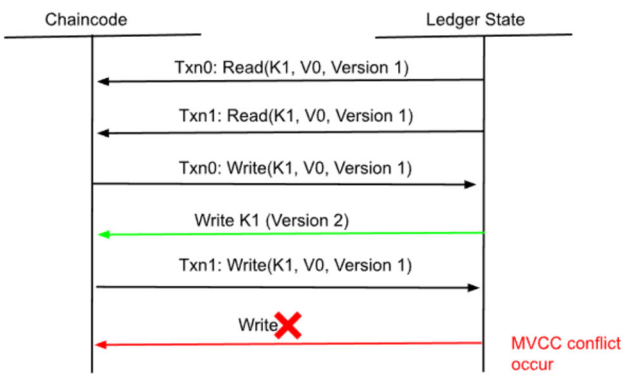

Fig. 12 An example to illustrate read-write conflict

throughput and latency, as illustrated in Fig. 13. This research is more focused on analyzing the performance characteristics of HLF under varying workloads. This section discusses the findings of this research work and delves into the reasons behind the observed behavior.

Reasons for the Observed Behaviors: Over the course of the study, we have analyzed the factors that may influence the performance of the HLF blockchain. It has been observed that the number of organizations, orderers, and peers has a substantial impact on performance and scalability. A network with too many peers and organizations can result in slower transaction processing times, whereas a network with too few peers can result in a lack of fault tolerance. The performance of the network is influenced by both the transaction rate and the number of transactions. As the transaction rate increases, there is a linear growth in throughput until a certain point. Our deployment of Hyperledger Fabric encountered a critical performance bottleneck during a recent load test. As we scaled transaction volume beyond one million, a significant number of transactions began failing with a "timeout expired while executing transaction" error. This behavior suggests that the network's capacity to process transactions was exceeded, leading to timeouts. Similarly, increasing the transactions per second (TPS) beyond a certain threshold resulted in the same error. HLF offers different ordering services, such as Solo, Kafka, and Raft, each having its own strengths and weaknesses and features depicted in Table 4. In Hyperledger Fabric (HLF), a transition from a Kafka-based ordering service to a Raft-based consensus mechanism was implemented, commencing with version 2.0. This strategic shift aimed to streamline the ordering service and lay the groundwork for the potential future integration of Byzantine Fault Tolerance (BFT) capabilities. While neither Raft nor Kafka inherently possess Byzantine fault tolerance properties, the Raft algorithm's design facilitates the inclusion of such mechanisms in future versions of HLF. This establishes the basis for potentially enhancing the consensus protocol within HLF to incorporate Byzantine fault tolerance, particularly for permissioned blockchain deployments. Our evaluation reveals that the Raft ordering service demonstrably outperformed the Solo approach in terms of performance when processing a diverse range of transaction volumes and rates.

Further considering the impact of programming language on throughput or latency, no substantial variation can be seen since both the programming languages Node.js and Go have their own set of advantages and shortcomings. However, the complexity of chaincode certainly has a great impact on the performance of the HLF blockchain, considering that the complex chaincode may necessitate more computing resources, resulting in slower transaction processing times. The hardware resources available to network nodes might also have an impact on performance. Nodes with faster CPUs, larger memory, and quicker disc I/O can process transactions more quickly and govern more concurrent requests. In our research, we observed that network bandwidth played a significant role in influencing latency. Specifically, the available network bandwidth had a direct impact on the time it took for transactions to propagate and be processed within the HLF network.

In Fig. 14, Case 1 of our study, we examined the impact of operating within a restricted network bandwidth, which resulted in higher latency compared to Case 2, where the system was evaluated under conditions of high network bandwidth. HLF relies on a substantial amount of network bandwidth to ensure efficient operation. This necessity arises from the requirement of distributing transactions to all nodes in the network and validating them.

When the network experiences congestion or has limited bandwidth availability, it can significantly impact the speed of transaction processing and introduce latency issues.

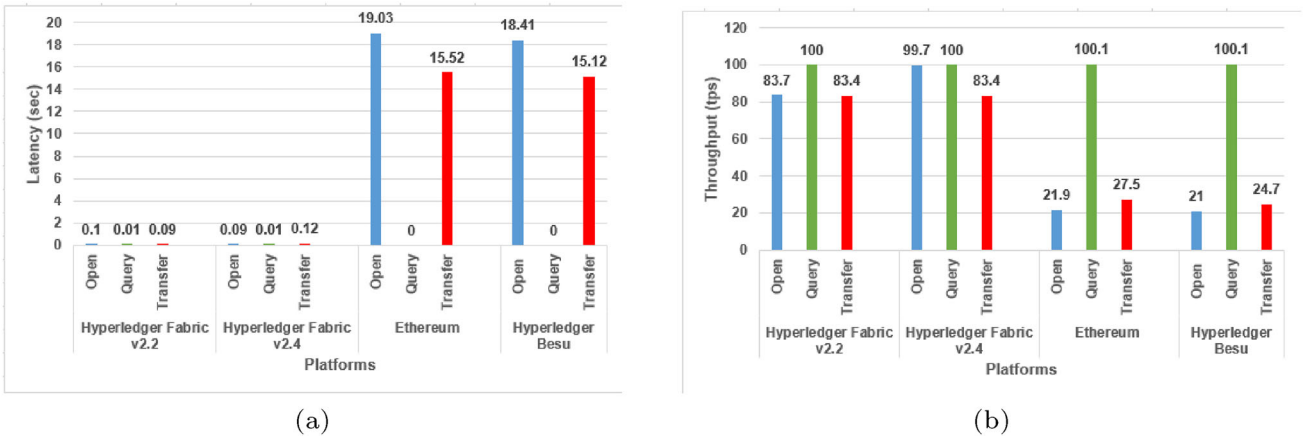

Fig. 13 Latency (average latency) and throughput measured for different platforms for 1000 TXNs transactions [10]

Table 4 Comparison of key features of various consensus mechanisms in ordering service

Features	Solo	Kafka	Raft	PBFT
Byzantine Fault Tolerance	No	No	No	Yes
Crash Fault Tolerance	No	Yes	Yes	Yes
Network Parition Tolerance	No	High	High	Medium
Configuration Complexity	Low	Medium	Low	High
Performance	Limited	High	High	Medium (Increased overhead)
Scalability	Medium	High	High	Medium

6 Conclusion and future work

We conclude that blockchain is gaining exponential popularity among tech savvies. Numerous business applications such as digital identification, secure information exchange, regulatory compliance, asset tokenization, anti-counterfeiting, contract management, and many more are incorporating the blockchain to enhance the product. Choosing the appropriate platform following the need that provides the best performance in all aspects is essential. In our study, we have investigated the impact of workload characteristics on the average latency, resource consumption, and throughput of HLF. The findings suggest that the system works effectively for average latency and throughput between the transaction rate of 150 TPS to 200 TPS and is able to handle 100,000 transactions with minimal delay.

The architecture of HLF is built upon the principles of the Deterministic Consensus Algorithm. This implies that when a new block is sent by the ordering node to any peer for validation, it is ensured to be both final and accurate. This design principle assures the consistency and reliability of the blockchain ledger, as all nodes in the network give consent to the ledger's state. During the evaluation, it was observed that the Raft ordering service outperformed the Solo ordering service, demonstrating higher throughput and lower latency. Our study will help in knowing the effect of several elements on the scalability and performance of HLF version 2.4.9. The HLF is a popular blockchain platform intended for developing enterprise-grade distributed ledger applications. In addition, an investigation of the scalability of the network elucidated that as the number of organizations in the HLF network increased, the throughput decreased and the latency increased. Our study provides statistics on the performance and scalability such as average latency, resource consumption, and throughput. In our investigation, we concluded that several other factors also have a notable influence on the performance of HLF. These factors include CPU power, disk space, the design of chaincode, and network bandwidth. To gain a deeper understanding of performance and scalability in permissioned blockchains, we will expand our future studies. This will involve incorporating factors like network latency, security, and fault tolerance. Additionally, we will evaluate various endorsement policies and consensus protocols under diverse workloads.

Abstract

Transition metal-based mixed metal oxides (MMOs) are nexus nanomaterials that garner significant interest from scientists because of their unique magnetic, electronic, optical and catalytic properties that can easily be tailored by varying their composition and structure. Although MMOs hold significant potential in multifunctional applications, but they are plagued by certain challenges such as identifying the appropriate method for synthesis, complications in controlling the surface area and the oxidation states of the constituent transition metals, while also ensuring the homogenous distribution of the constituent metal ions. Therefore, the present work aims to study the formation of homogenous and porous zinc-copper-nickel mixed metal oxide (ZnCuNi-MMO) by performing calcination of ZnCuNi-LDH at 350 °C. The obtained ZnCuNi-MMO was characterized using PXRD, SEM–EDX and BET techniques. Thereafter, ZnCuNi-MMO was applied as a heterogeneous catalyst for the hydrogenation of *p*-nitroaniline (*p*-NA) and catalytic reduction of methyl orange (MO) dye. The pollutant degradation characteristics were assessed using time-dependent UV–Visible absorption spectroscopy showing advanced efficient behavior of ZnCuNi-MMO towards the hydrogenation of *p*-NA (96.98%) and reduction of MO (95.58%). The catalyst exhibited fast reaction rates (0.402 min^{-1} for hydrogenation of *p*-NA and 0.471 min^{-1} for catalytic reduction of MO) and kinetics analysis of the experimental data was found to be coherent with the pseudo-first order model, thereby implying that the catalysis proceeded through the Langmuir–Hinshelwood mechanism. Thus the obtained experimental results highlight the utility and viability of synthesized MMO as an efficacious and sustainable catalytic material.

1 Introduction

Nitroarene compounds and azo dyes are few of the most pernicious pollutants that currently threaten the health of our ecosystem. Their uninhibited release into water bodies from textile, cosmetics, pharmaceutical, leather, and tanning industries greatly contributes to the deterioration of quality of water bodies. Further, their chemical and thermal inertness, along with the high toxicity of these pollutants necessitates the need for their elimination from water sources. A variety of processes such as adsorption, coagulation-flocculation, filtration, etc. have been developed for their elimination, but they are often found to be ineffective and lead to formation of secondary pollutants, thereby limiting their practical applications [1–4]. Furthermore, drawbacks such as particle agglomeration, membrane fouling, difficulty in flocculant removal, etc. plague traditional treatment methods and call for the development of alternate water remediation strategies [5].

Recently, catalytic degradation of pollutants has emerged as an effective, economical, and green methodology for water remediation since the catalytic reduction of azo dyes yields carbon dioxide and water as benign by-product [6]. While the catalytic treatment of nitroarene compounds such as *p*-nitroaniline yields commercially useful by-products such as *p*-phenylenediamine that can be further utilized for the fabrication of cosmetics, engineering polymers and composites [7–9]. Thus, catalysis can prove to be a beneficial strategy for pollutant sequestration. This methodology often utilizes sodium borohydride ($NaBH_4$) as a reducing agent along with a catalytic material. But on its own, $NaBH_4$ exhibits slow reaction rates for reduction reactions since the reaction is kinetically unfeasible, but in the presence of suitable catalysts, reaction rates are enhanced dramatically. For this purpose, the use of various classes of materials such as metal oxides, noble metals, and carbonaceous materials as catalysts has been previously reported [10–13]. But their commercial applications are quite limited due to the drawbacks such as high cost agglomeration tendency, material instability, and low catalytic efficiency.

In recent years, layered double hydroxides (LDHs) have emerged as new generation heterogeneous catalytic materials since they possess unique structural features and exceptional properties such as high surface area, ion exchange capacity, memory effect property, etc. [14]. They are two-dimensional layered materials consisting of positively charged layers and have anions and water molecules present in the interlayer region. Positive charge on the brucite-like layers of LDHs appears by virtue of the substitution of divalent cations by trivalent cations, thereby creating a charge deficit on the layers. This charge deficit is offset by the interlayer anions that are sandwiched in between the LDH layers along with

water molecules. Their anion and cation exchange capabilities make them extremely versatile and tailorable materials for catalytic applications [15–17]. Furthermore, the incorporation of transition metals in LDHs imparts extraordinary optical, electronic, and magnetic properties to these materials due to the synergistic interactions that arise in the lattice. However, these materials sometimes tend to become less effective as catalysts due to catalytic poisoning by organic moieties.

Therefore, in order to further enhance the tenability and utility of LDHs, an effective methodology is their conversion into mixed metal oxides (MMOs) using thermal treatment methods. MMOs synthesized using conventional methods often possess non-uniform distribution of metal cations, and possess high agglomeration tendencies. Conversely, LDH precursor-based MMOs possess enhanced surface areas and homogeneous distribution of constituent metals, leading to excellent catalytic abilities [18, 19]. Additionally, MMOs containing transition metals also exhibit a myriad of exemplary catalytic properties due to the synergistic interactions between the transition metals in the lattice. Specifically, the addition of zinc, copper and nickel in MMOs can prove to be a boon since they are cost effective and abundant in nature. Apart from this, they offer properties having electron transport and relay abilities, broad band gaps (3.3 – 4.0 eV), high mechanical and thermal stabilities, and electron defects [20–22]. Zn, Cu and Ni play a key role in reduction of organic pollutants since they possess special electronic structures, high surface areas and large number of active sites, due to which they can adsorb various molecules on their surface and activate them. Furthermore, oxidation states of Cu and Ni can be easily tailored, as result of which they are often employed for the fabrication of various homogenous (eg. organometallic complexes) and heterogeneous catalysts (eg. LDHs, Metal–organic frameworks (MOF)) by combining them with a variety of anionic, cationic and neutral ligands. Additionally, their morphologies can be easily tailored, giving rise to special microstructures and they often possess pyro- and piezo-electric properties along with special electronic, optical and magnetic properties that can prove to be beneficial for a wide array of catalytic applications [23–25]. For instance, Murugahandham et al. reported the synthesis of ZnO nanobundles and employed them for the catalytic ozonation of 2-ethyl ethoxy acetate [26]. Belay et al. synthesized zero-valent copper and copper oxides using different precursors and studied their catalytic ability for the reduction of NO_3^- to NO_2^- [27]. In another study, Bhosale et al. reported the use of NiO nanorods for the catalytic synthesis of substituted benzimidazole, benzoxazole and benzothiazole [28]. But inspite of their several favourable characteristics, the combined use of Zn, Cu and Ni in LDHs and LDH derivatives remains limited. Furthermore, although few reports describing the use of LDHs for catalytic reduction of azo dyes and *p*-nitroaniline are available in literature, but virtually no reports describe the use of LDH-derived ZnCuNi-MMOs for catalytic reduction of organic pollutants [29–31].

Therefore, the objectives of the current study include the synthesis and characterization of ZnCuNi-MMO that was synthesized in accordance with our previous report, as presented in Fig. 1 [32]. The synthesized MMO was applied as a heterogeneous catalyst for the hydrogenation of *p*-NA and reduction MO pollutants, and kinetics analysis for the catalysis reactions were carried out. It was observed that ZnCuNi-MMO exhibited excellent removal efficiencies and fast reaction rates for the hydrogenation of *p*-nitroaniline and catalytic reduction of methyl orange in short intervals of time.

2 Experimental

2.1 Synthesis of ZnCuNi-MMO

ZnCuNi-MMO was prepared by the thermal treatment of ZnCuNi-LDH precursor as per the methodology described by Pathak et al. [32]. Briefly, 4.249 mmol zinc acetate dehydrate (Merck, 98.00% purity), 0.37 mmol copper acetate monohydrate (Merck, 98.00% purity) and 0.37 mmol nickel acetate tetrahydrate (CDH chemicals, 98.00% purity) were separately dissolved in 10 mL distilled water and then mixed with each other with constant stirring. Then 5 mL of 30% H_2O_2 and 30 mL distilled water were added to the above solution and it was sonicated for 30 min. Afterwards, the reaction mixture was stirred for 24 h and subsequently, it was dried completely at 60 °C. The obtained ZnCuNi-LDH was then calcined in muffle furnace at 350 °C for 6 h to obtain black-greyish colored ZnCuNi-MMO.

2.2 Catalytic Activity of ZnCuNi-MMO

The catalytic prowess of synthesized ZnCuNi-MMO was evaluated by studying the hydrogenation of *p*-nitroaniline (*p*-NA) and reduction of methyl orange (MO) dye as model reactions in presence of sodium borohydride ($NaBH_4$).

For the hydrogenation of *p*-nitroaniline (*p*-NA), *p*-NA solution (1 mL, 1 mM) was mixed well with 1 mL of distilled water followed by the addition of freshly prepared $NaBH_4$ solution (1 mL, 100 mM). After this, the catalytic reaction was initiated by addition of with 0.001 g ZnCuNi-MMO to the reaction mixture. Progress of hydrogenation reaction was determined by recording the absorption spectrum of *p*-NA at $\lambda_{max} = 380$ nm using UV–visible spectrophotometer at 1 min intervals till solution was completely decolorized.

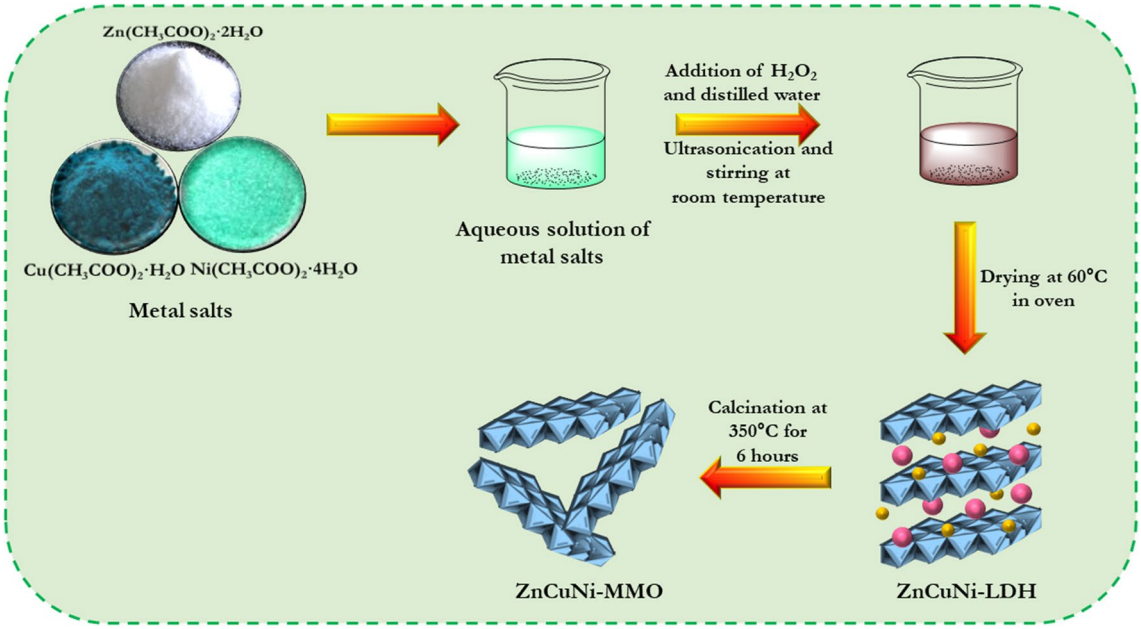

Fig. 1 Schematic representation of synthesis of ZnCuNi-MMO

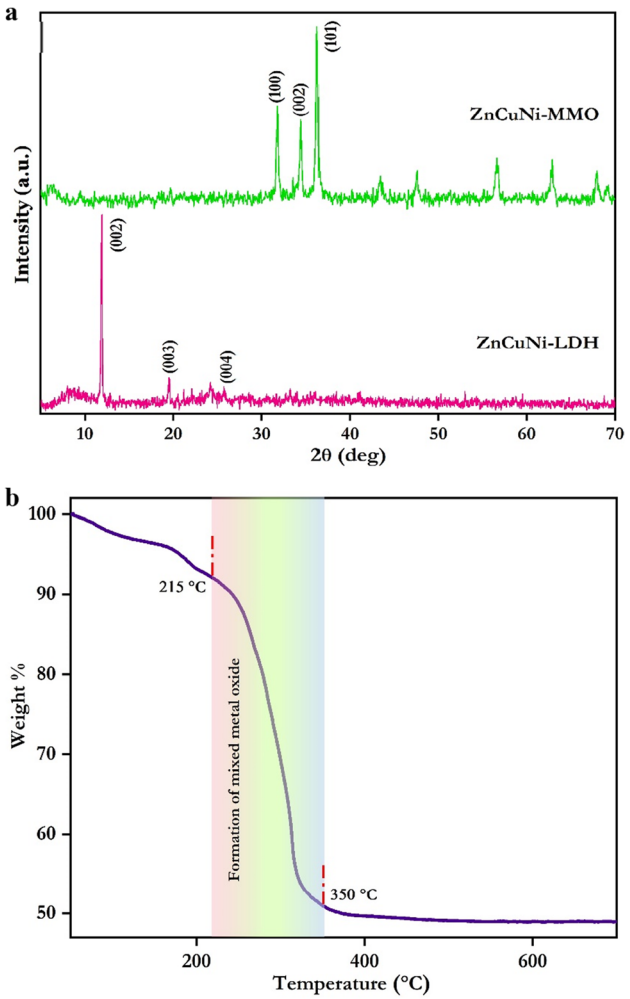

Fig. 2 **a** Comparitive plot of PXRD patterns of ZnCuNi-LDH and ZnCuNi-MMO **b** TGA thermogram of ZnCuNi-LDH

The catalytic reduction of MO dye using ZnCuNi-MMO was evaluated in a similar manner. MO solution (1 mL, 100 ppm) was mixed well with 1 mL distilled water and 1 mL of freshly prepared 100 mM $NaBH_4$ solution. Then 0.001 g MMO was added to reaction mixture and reaction progress was determined by recording absorption spectrum at $\lambda_{max} = 466$ nm at 1 min intervals till complete decolorization of solution.

The percentage degradation of *p*-NA and MO was calculated using the formula:

$$Percentage/degradation = \frac{(C_O - C_f)}{C_O} \times 100 \quad (1)$$

where C_O and C_f denote the initial and final concentrations of *p*-NA and MO.

3 Results and Discussion

3.1 Characterisation Results

The PXRD diffractogram of ZnCuNi-LDH presented in Fig. 2a was found to be consistent with the typical hydrotalcite pattern exhibiting sharp intense peaks at low *2θ* angle and low intensity peaks at higher *2θ* angle, corresponding to *(002), (003)* and *(004)* hkl planes. The appearance of these peaks corroborated the formation of highly crystalline LDH in pure phase. The basal spacing distance for *(002)* plane was found to be 7.41 Å, that was coherent with previously

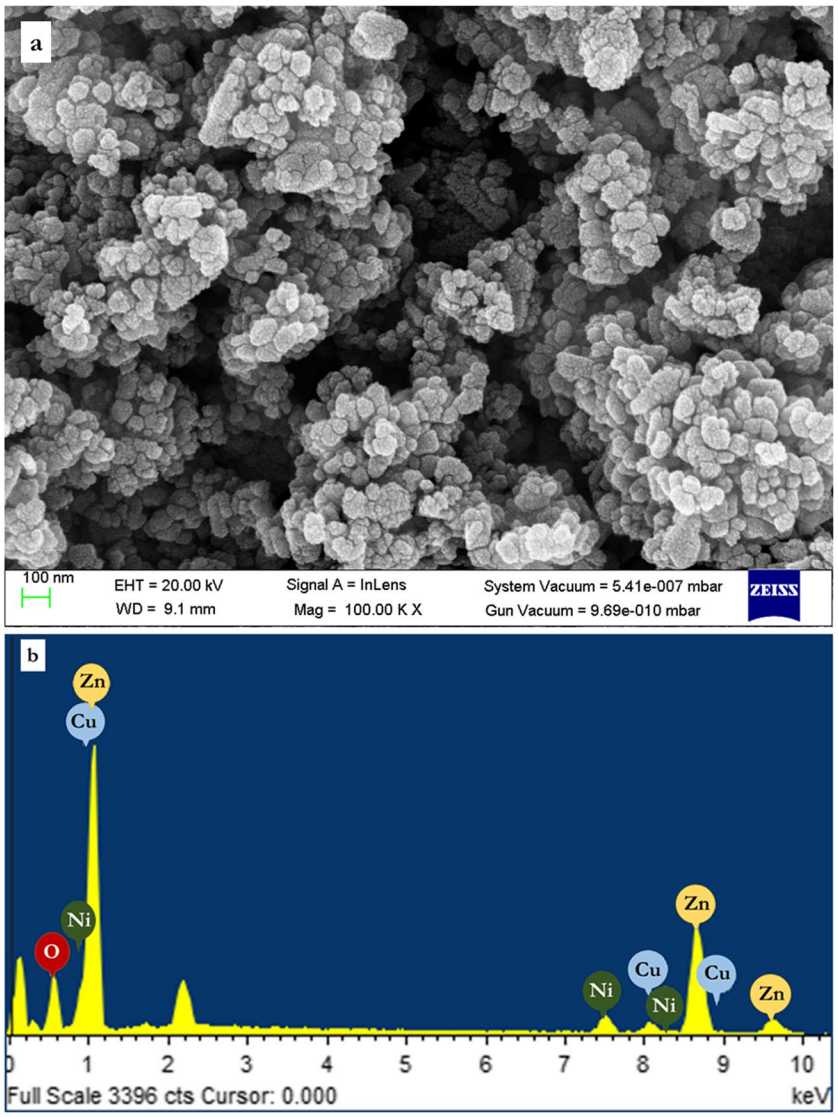

Fig. 3 **a** SEM micrograph and **b** EDX spectrum of ZnCuNi-MMO

reported values in literature [33]. The thermal stability of ZnCuNi-LDH precursor was ascertained from the TGA thermogram presented in Fig. 2b. Thermal degradation of ZnCuNi-LDH included the initial loss of physisorbed and interlayer water molecules upto 215 °C, followed by the decarboxylation, dehydroxylation and removal of interlayer acetate ions from the LDH lattice upto 350 °C leading to the breakdown of LDH layers and formation of pure phase mixed metal oxide (MMO) [34]. Based on TGA results obtained for the LDH, 350 °C was chosen as the optimal temperature for calcination of ZnCuNi-LDH to synthesize ZnCuNi-MMO.

Upon calcination, collapse of layered structure was observed, leading to the disappearance of characteristic peaks of LDH in PXRD pattern (Fig. 2a). The emergence of new peaks at 31.8°, 34.56° and 36.39° corresponding to *(100), (002)* and *(101)* hkl planes of hexagonal wurtzite structure of crystalline ZnO with space group $P6_3mc$ was observed. Thus, the PXRD results support the formation of pure and homogenous ZnCuNi-MMO upon the complete decomposition of LDH on thermal treatment [35]. The average crystallite size was calculated using the Debye–Scherrer equation and was found to be 24.89 nm.

The surface morphology and microstructure of ZnCuNi-MMO was examined using SEM technique. The SEM micrograph presented in Fig. 3a shows the absence of the plate-liked morphology responsible for layered structure of LDH and clearly indicates presence of irregular spherical aggregates, thereby confirming the formation of mixed metal oxide (MMO) [36]. Further, the presence of Zn, Cu and Ni was confirmed using EDX that clearly showed their homogeneous distribution in the lattice (Fig. 3b).

Surface area is a critical parameter that monitors the catalytic activity of a material. The specific surface area (S_{BET}) and pore structure of ZnCuNi-MMO were

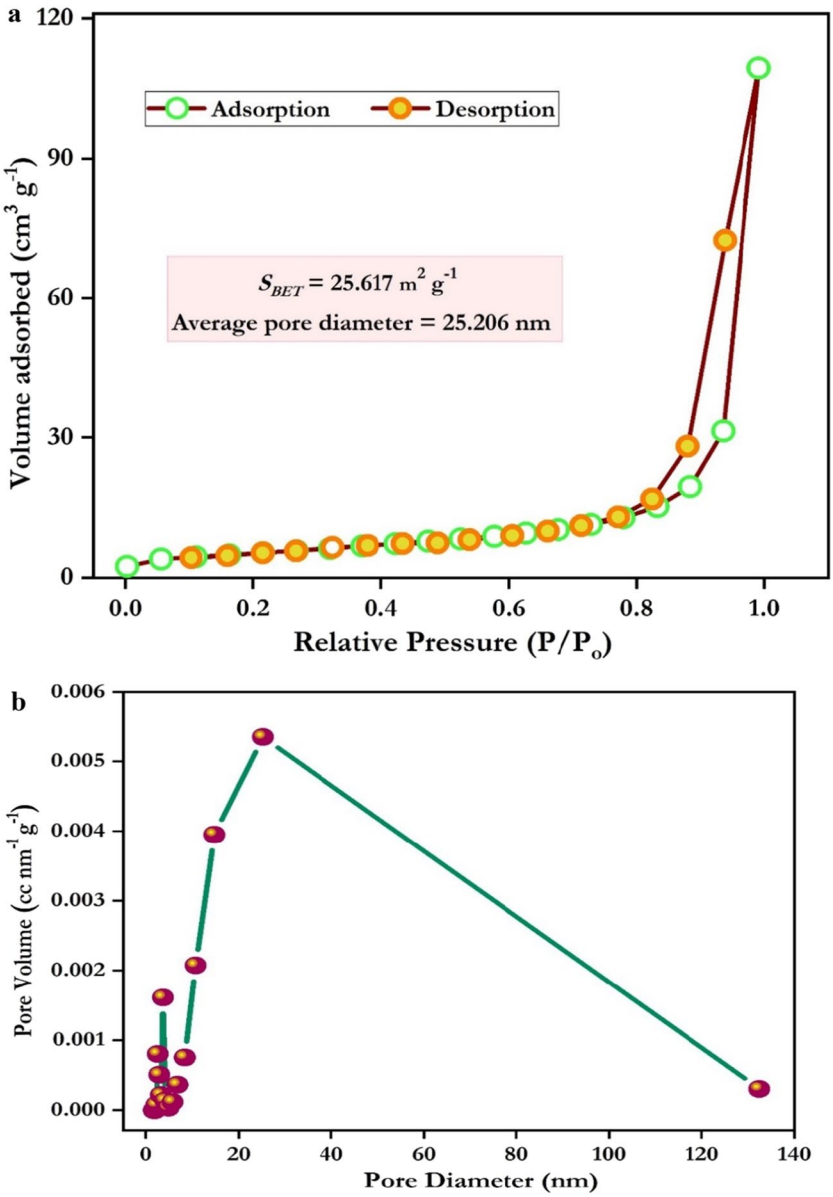

Fig. 4 **a** N_2 adsorption–desorption isotherm and **b** corresponding pore size distribution plots of ZnCuNi-MMO

investigated using N_2 adsorption–desorption study by BET analysis (Fig. 4a-b). S_{BET} was found to be 25.617 m^2g^{-1}, while the values of pore volume and average pore diameter, calculated using the BJH method, were found to be 0.174 cc g^{-1} and 25.206 nm respectively. The shape of the isotherm is similar to Type-IV, as described by IUPAC classification, and it was inferred that synthesized ZnCuNi-MMO possessed mesoporosity. The appearance of H3-type hysteresis loop indicated the existence of narrow slit-shaped pores in the mesoporous ZnCuNi-MMO aggregates [37]. The formation of pores may be a consequence of the calcination of ZnCuNi-LDH. Therefore, the textural properties described above render ZnCuNi-MMO as suitable materials for catalytic applications.

3.2 Catalytic Activity

The catalytic prowess of ZnCuNi-MMO for the $NaBH_4$-assisted hydrogenation of *p*-NA and reduction of MO was examined using time dependent UV–Visible spectrophotometry. In the catalytic experiment, the rate of reaction is assumed independent of $NaBH_4$ concentration since $NaBH_4$ (100 mM) was added in excess. Therefore, kinetics of the hydrogenation of *p*-NA and catalytic reduction of MO were calculated in accordance with the pseudo-first order model presented in Eq. (2) as follows:

$$\ln\left(\frac{C_f}{C_O}\right) = K \tag{2}$$

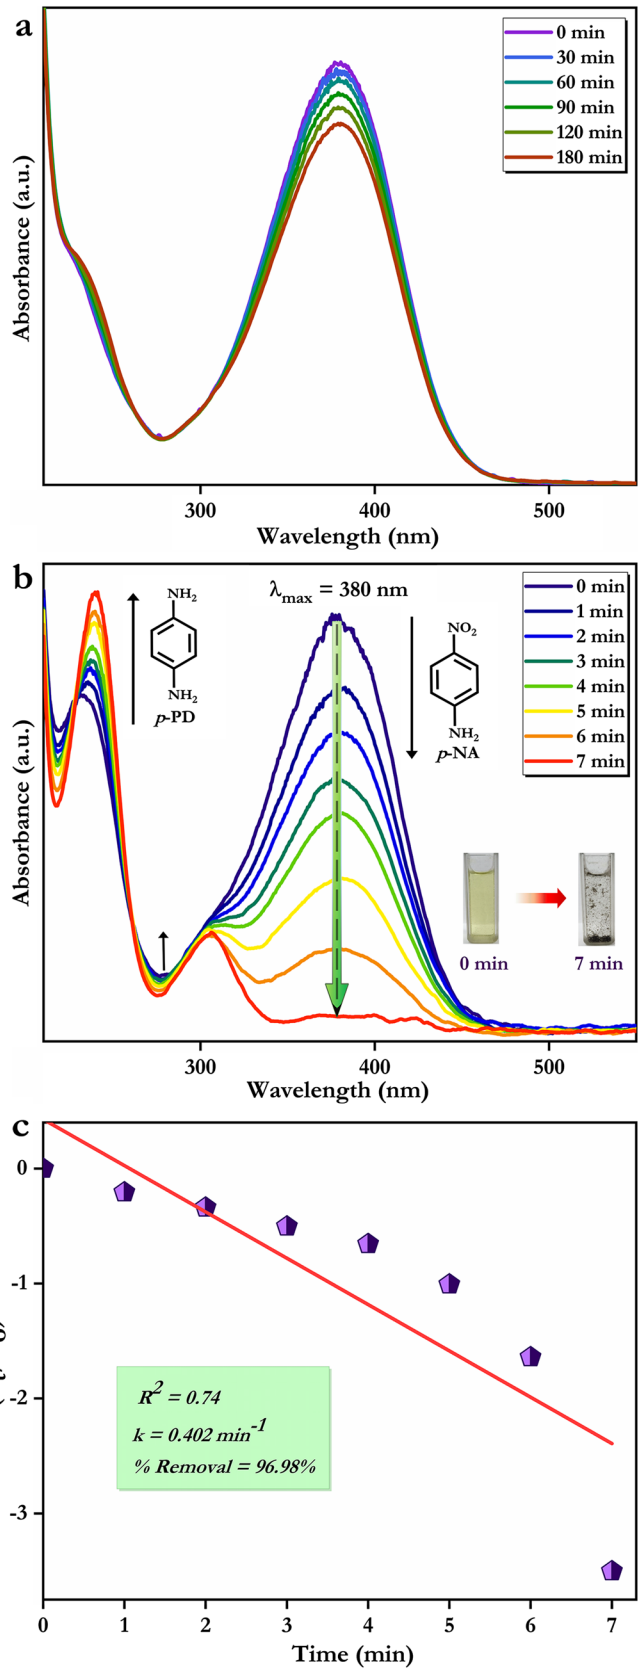

Fig. 5 **a** Time-dependent UV–Vis absorption spectrum of hydrogenation of *p*-NA using $NaBH_4$, **b** Time-dependent UV–Vis absorption spectrum and **c** linear regression of pseudo-first kinetics model for the $NaBH_4$ – assisted hydrogenation of *p*-NA using ZnCuNi-MMO

Table 1 Structures of *p*-NA and MO with the potential products formed on their catalytic treatment with $NaBH_4$ and ZnCuNi-MMO

Organic Pollutant	λ_{max} of pollutant (nm)	By-product	λ_{max} of by-product (nm)
p-Nitroaniline 	380	*p*-phenylenediamine 	240 and 304
Methyl orange 	466	Sulfanilic Acid 	250

where C_O and C_f are the initial and final concentrations of *p*-NA and MO, while K denotes rate constant.

Since the reaction solutions possess distinct colours, their reaction rate can be evaluated in terms of comparative absorptive intensity based on the Beer-Lambert law (Eq. (3))

$$A = \varepsilon Cl \tag{3}$$

$$\ln\left(\frac{C_f}{C_O}\right) = \ln\left(\frac{A_f}{A_O}\right) = kt \tag{4}$$

where A_O and A_f are the initial and final absorbance of *p*-NA and azo dyes.

3.2.1 Catalytic Hydrogenation of *p*-NA

NACs such as *p*-NA possess high toxicity and chemical inertness, thereby making them extremely harmful to plant and animal life [38]. Thus, it is extremely necessary to eliminate these pollutants from water bodies. Also, the hydrogenation product of *p*-NA i.e. *p*-phenylenediamine (*p*-PD) is an important commercial product [39–41]. Therefore, the catalytic hydrogenation of *p*-NA can serve a two-fold purpose. Thus, the hydrogenation of *p*-NA by ZnCuNi-MMO to form *p*-phenylenediamine was evaluated in the presence of excess $NaBH_4$. The time dependent UV–Visible spectrum was recorded at $\lambda_{max} = 380$ nm to monitor the hydrogenation of *p*-NA.

Initially, hydrogenation of *p*-NA was examined in the presence of $NaBH_4$ in order to determine the role of catalyst. The time dependent UV–Visible spectra of *p*-NA hydrogenation using $NaBH_4$ is presented in Fig. 5a. It was observed that when only $NaBH_4$ was added to reaction mixture, there was a very slow decrease in the absorbance of *p*-NA at $\lambda_{max} = 380$ nm leading to only 13.86% hydrogenation of *p*-NA even after 3 h. However, upon addition of ZnCuNi-MMO to the reaction mixture, it was observed that the intensity of peak at $\lambda_{max} = 380$ nm corresponding to *p*-NA began decreasing at a rapid rate and eventually disappeared after 7 min (Fig. 5b). The percentage removal efficiency, calculated using Eq. (1) was found to be 96.98%. The hydrogenation of *p*-NA due to conversion of the nitro group to amine group ($-NH_2$) was further confirmed by visual examination of the reaction mixture that showed change in colour from bright yellow to colourless. Further, appearance of new peaks at 240 nm and 304 nm confirmed the formation of *p*-phenylenediamine (*p*-PD) that is the hydrogenation product of *p*-NA (Table 1) [42]. Therefore, it was concluded that addition of ZnCuNi-MMO to the reaction mixture was essential for the efficient hydrogenation of *p*-NA. The rate of reaction was evaluated by monitoring the decrease in absorbance of *p*-NA at $\lambda_{max} = 380$ nm, and rate constant of reduction (k) was determined by linearly plotting ln (C_f/C_o) versus reaction time t (min). Therefore, k was calculated from the kinetics data using Eq. (4) by employing the pseudo first order model and was found to be 0.402 min^{-1} ($R^2 = 0.74$) (Fig. 5c).

3.2.2 Methyl Orange Reduction

Methyl orange, an anionic azo dye, is a common pH indicator and textile dyeing agent. The presence of azo (-N=N-) chromophore group is responsible for the bright orange

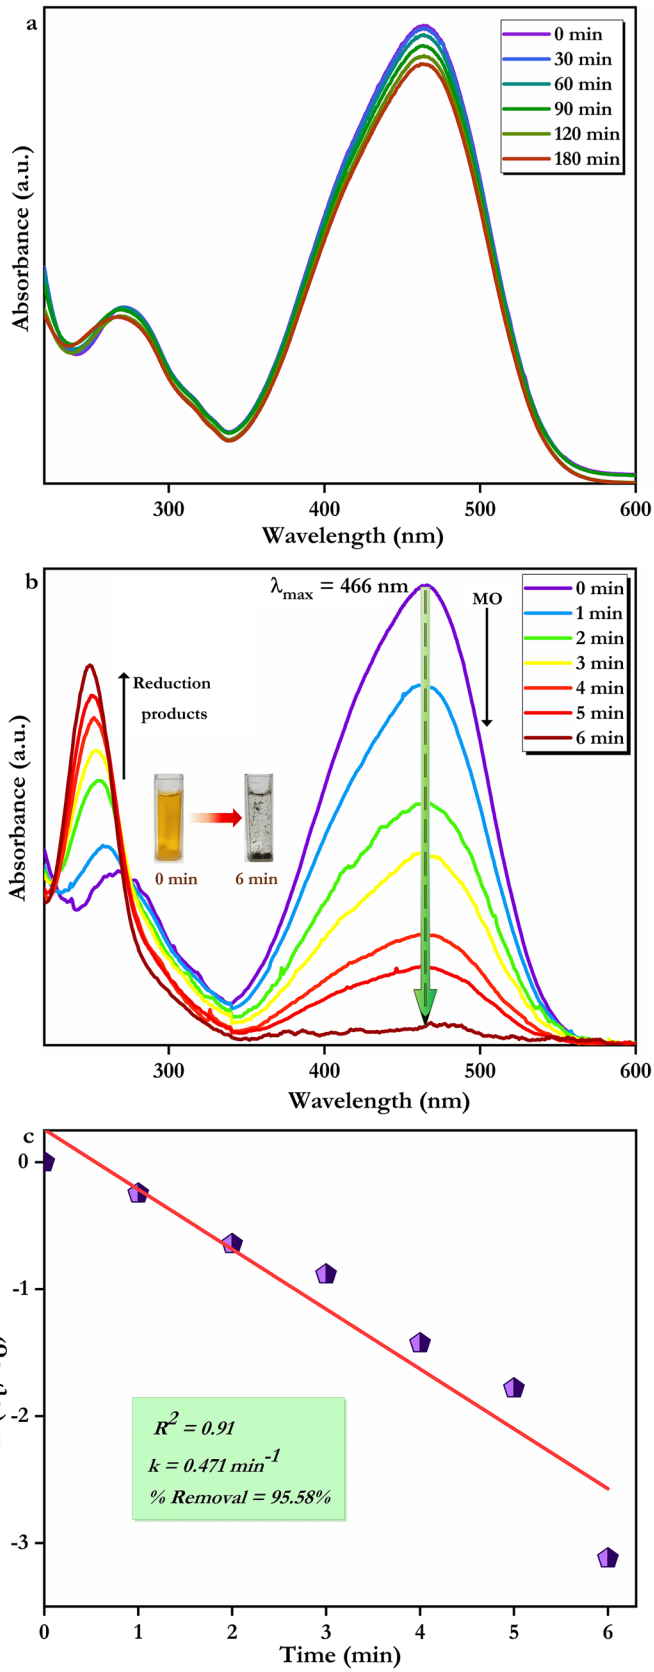

Fig. 6 **a** Time-dependent UV–Vis absorption spectrum of catalytic reduction of MO using $NaBH_4$, **b** Time-dependent UV–Vis absorption spectrum and **c** linear regression of pseudo-first kinetics model for the $NaBH_4$ – assisted catalytic reduction of MO using ZnCuNi-MMO

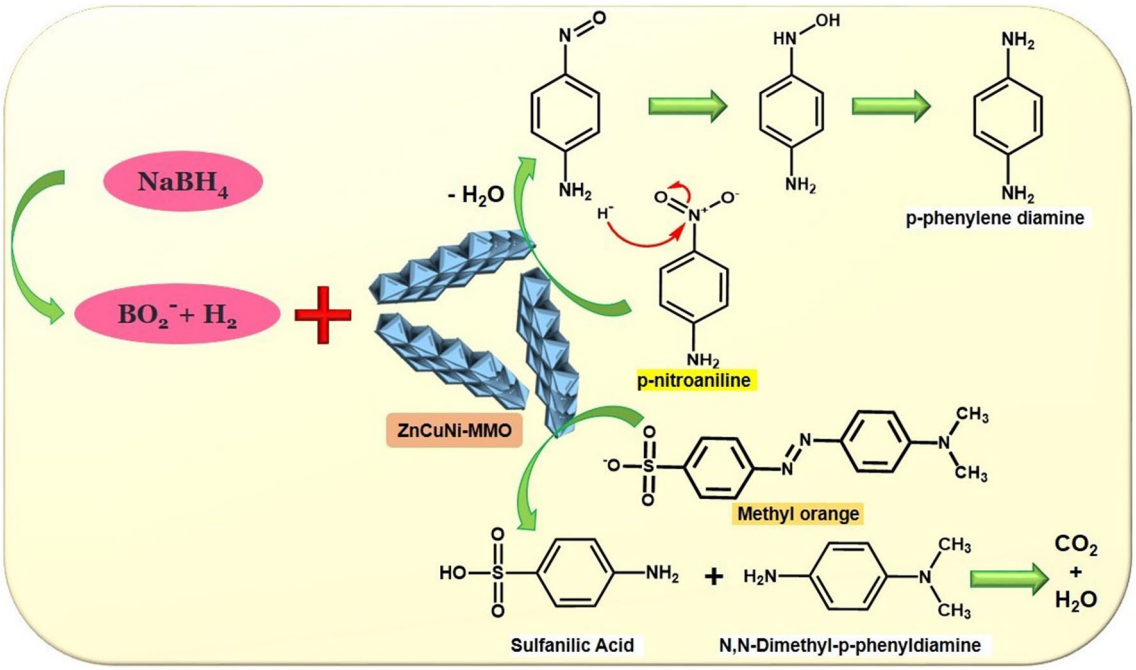

Fig. 7 Postulated mechanism for the $NaBH_4$- assisted catalytic degradation of *p*-NA and MO using ZnCuNi-MMO

color of MO dye. According to several reports, MO has been found to be toxic and excessive exposure to MO may cause skin and eye irritation, nausea, and diarrhea [43, 44]. Hence, the elimination of MO from water sources has become an issue of much concern.

Initially, catalytic reduction of MO was examined in the presence of $NaBH_4$ and time dependent UV–Visible spectrum was recorded at $\lambda_{max}=466$ nm to determine the extent of MO reduction by ZnCuNi-MMO (Fig. 6a). It was observed that addition of only $NaBH_4$ to reaction mixture leads to a very slow decrease in the absorbance of MO at $\lambda_{max}=466$ nm leading to only 8.76% reduction of MO even after 3 h. Subsequently, on addition of ZnCuNi-MMO to the reaction mixture. With addition of ZnCuNi-MMO catalyst, the intensity of peak corresponding to MO dye present at $\lambda_{max}=466$ nm began to decrease rapidly until its disappearance after 6 min corresponding to the complete decolorisation of the reaction mixture. Percentage reduction of MO, calculated using Eq. (1), was found to be 95.58%. The formation of by-products was corroborated by the emergence of a new peak at 250 nm and its intensity kept increasing with time (Fig. 6b). Therefore, it was concluded that addition of ZnCuNi-MMO to the reaction mixture was essential for the efficient reduction of MO. The rate constant *k*, calculated from Eq. (4) in accordance with pseudo first order kinetics, was evaluated to be 0.471 min^{-1} ($R^2=0.91$) (Fig. 6c). It may be worth noting that the interaction of $NaBH_4$ with MO molecules results in only partial reduction of the azo group, while the simultaneous action of $NaBH_4$ and ZnCuNi-MMO catalyst is successful in breaking the chromophore azo (-N=N-) group of MO and leads to the formation of smaller amine moieties. The appearance of absorbance peaks around 250 nm may be attributed to the possible formation of hydrazine derivatives as reduction products, potentially including sulfanilic acid (Table 1) [12]. The disappearance of peak at 466 nm and the emergence of new peak at 250 nm corroborates the reduction of MO by the catalytic action of ZnCuNi-MMO.

3.2.3 Postulated Mechanism

The catalytic experiments show that ZnCuNi-MMO can act as an excellent catalyst for the $NaBH_4$ assisted hydrogenation of *p*-NA and catalytic reduction of MO. The catalysis process is known to follow the Langmuir–Hinshelwood mechanism, which includes the adsorption of reactions on catalyst surface followed by the interaction between the adsorbed reactants to form products. The potential mechanism for the $NaBH_4$- assisted hydrogenation of *p*-NA and catalytic reduction of MO is presented in Fig. 7.

$NaBH_4$ is a good reducing agent and on addition to water, $NaBH_4$ produces nucleophilic borohydride (BH_4^-) anions. These BH_4^- anions breakdown into BO_2^- that deliver electrons to the catalyst and H_2 that get adsorbed on the MMO surface. H_2 adsorbed on ZnCuNi-MMO surface forms a metal-hydride complex that aids in the transfer of H_2 and electrons to the $–NO_2$ group. This leads to the hydrogenation of $–NO_2$ group to $–NH_2$, and results in the formation of *p*-phenylenediamine.

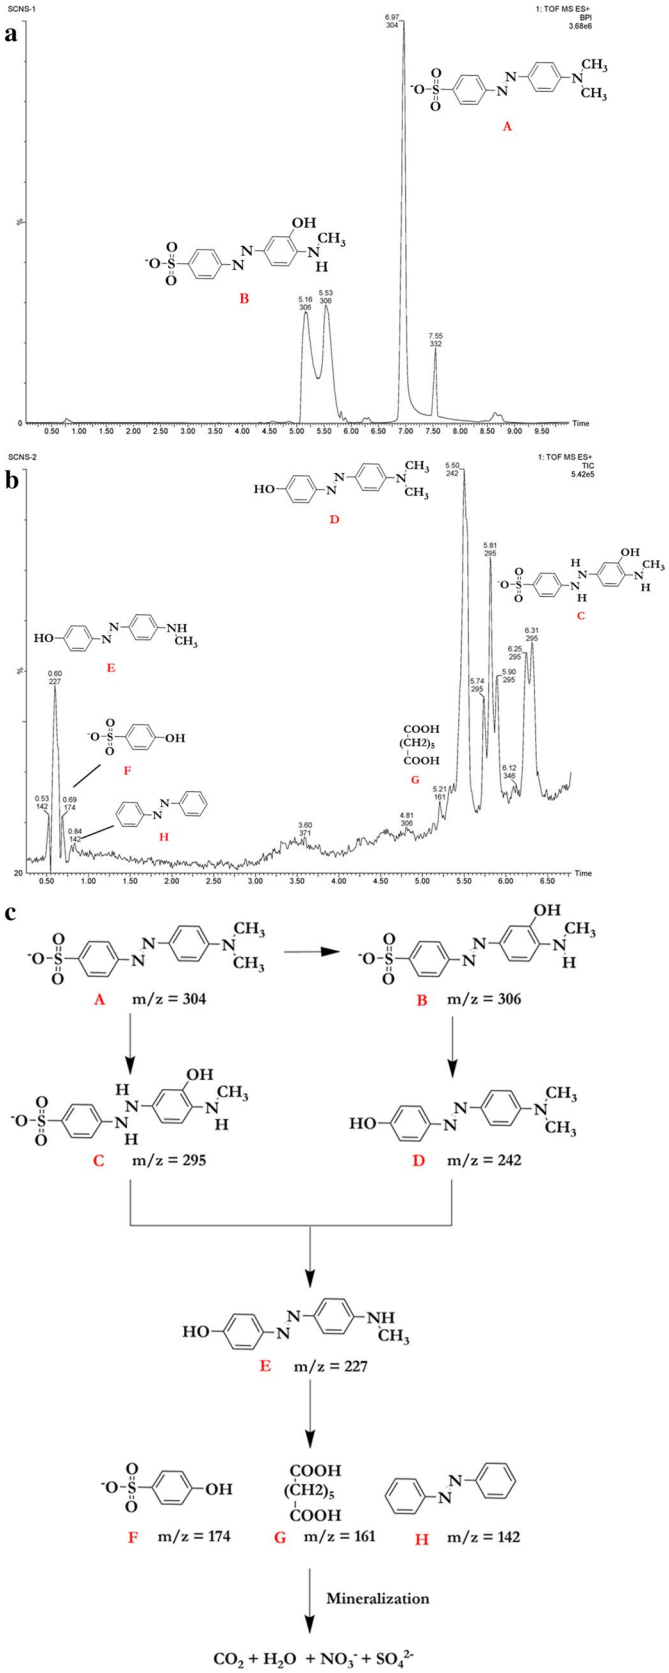

Fig. 8 LC–MS chromatograms of **a** untreated MO (0 min) and **b** by-products obtained on $NaBH_4$- assisted catalytic reduction of MO using ZnCuNi-MMO and **c** potential degradation pathway of MO

Table 2 Comparison of removal efficiencies of ZnCuNi-MMO with previously reported catalysts

Pollutant	Catalyst	Time (min)	Removal Efficiency	Reference
p-NA	Bi_2S_3	10	96%	[48]
	Au nanowire networks	17	Complete reduction	[49]
	RGO-Ni Nanocomposite	190	93%	[50]
	ZnCuNi-MMO	7	96.98%	This work
MO	Asp-Au NPs	10	> 95%	[12]
	NiFe2O4/γ-Fe2O3	36	Complete reduction	[51]
	Ag–Cu Rhizome Powder	9	96%	[52]
	ZnCuNi-MMO	6	95.58%	This work

While in case of MO, the dye molecules are adsorbed onto the ZnCuNi-MMO surface. ZnCuNi-MMO acts as an electron donor while the dye molecules act as an electron acceptor and get reduced to its hydrazine derivatives such as sulfanilic acid. Finally, the reduction products are desorbed from MMO surface, thereby regenerating it for further catalytic activity.

The products formed on the catalytic reduction of *p*-NA and MO are benign, can be easily degraded, less toxic, do not pollute, and hold commercial importance. Therefore, catalytic reduction of *p*-NA and MO using ZnCuNi-MMO in presence of $NaBH_4$ is a favourable methodology for the elimination of these pollutants from aqueous medium.

3.3 Degradation Products of Methyl Orange

The degradation products of MO dye were examined using LC–MS to gain a better understanding of the degradation process. The LC–MS chromatograms of untreated MO (0 min) and the reaction mixture after complete decolourisation of MO (6 min) in ESI + mode are presented in Fig. 8. MO ($C_{14}H_{14}N_3NaO_3S$) gets converted to $C_{14}H_{14}N_3SO_3^-$ due to the dissociation of Na^+ in water. In the LC–MS chromatogram presented in Fig. 8a, the parent molecule MO exhibits a clear signal at $m/z = 304$ (A). Additionally, the signal at $m/z = 306$ (B) may correspond to the presence of monohydroxylated MO. Further, the LC–MS chromatogram presented in Fig. 8b clearly shows the appearance of signals corresponding to by-products of MO degradation. The signals appearing at $m/z = 295$ (C), 242 (D), 227 (E), 174 (F), 161 (G) and 147 (H) correspond to the by-products (illustrated in Fig. 8c) that are formed as a result of the degradation of MO in the presence of $NaBH_4$ and ZnCuNi-MMO [45–47].

Based on the potential degradation pathway of MO presented in Fig. 8c, it may be assumed that the degradation of MO consists of processes including bond cleavage, demethylation, hydroxyl group insertion, detachment of sulfonic group, benzene ring opening and finally the mineralization of intermediates to potentially form CO_2, H_2O, NO_3^-, SO_4^{2-}, etc.

3.4 Comparison With Reported Catalysts

The comparison of the catalytic activity of ZnCuNi-MMO with previously reported catalysts towards the hydrogenation of *p*-NA and catalytic reduction of MO is presented in Table 2. The rate constants for reactions catalyzed by ZnCuNi-MMO were found to be comparable or even better than the rate constants of most reported catalysts. Therefore, it may be concluded that ZnCuNi-MMO holds the potential to be an excellent candidate for the catalytic reduction of nitroarene compounds and azo dyes. The superior catalytic activity may be attributed to the small size, high surface area and homogeneous distribution of Zn, Cu and Ni in ZnCuNi-MMO catalyst.

4 Conclusion

In summary, the current study reports the facile synthesis of homogeneous MMO having uniform distribution of Zn, Cu, and Ni by thermal treatment of ZnCuNi-LDH precursor. The high specific surface area of 25.617 m^2g^{-1} estimated using BET indicates that they may hold practical importance for catalytic applications. Keeping in view the above observations, ZnCuNi-MMO was applied as a catalyst for carrying out the hydrogenation of *p*-NA and catalytic reduction of MO dye. ZnCuNi-MMO was able to successfully hydrogenate *p*-NA to *p*-phenylenediamine, and reduce MO to its hydrazine derivatives including sulfanilic acid respectively with efficiency of more than 95% within ~ 7 min. The reaction rates, evaluated using pseudo-first order model, were found to be comparatively higher than already existing catalysts i.e. 0.402 min^{-1} (*p*-NA hydrogenation) and 0.471 min^{-1} (MO dye reduction). The catalytic action of ZnCuNi-MMO with the intermediates BO_2^- and H_2 that are produced on the hydrolysis of $NaBH_4$ enable its action as an electron relay and facilitate the formation of metal-hydride complexes that catalyze the hydrogenation of *p*-NA and reduction of MO. Further, LC–MS technique was employed to identify potential products formed on the catalytic reduction of MO, that are generally considered to be benign and less toxic, and

the degradation pathway for MO was elucidated. Therefore, these favourable attributes of ZnCuNi-MMO indicate their multifarious applicability for the degradation of nitroarene compounds and organic dyes in water remediation, and they may be considered as potential candidates for other catalytic applications.
